For most substances, the critical point is at a very high temperature and pressure (Table 11.7). Water, for instance, has a critical temperature of 374 °C and a critical pressure of 217.7 atm.

Much has been written about CO_2, particularly its role as a greenhouse gas, but, as a supercritical fluid, it is useful as a solvent in our "green chemistry" revolution. Not only is CO_2 widely available, essentially nontoxic, nonflammable, and inexpensive, but it is relatively easy to reach its critical temperature and critical pressure. One use of supercritical CO_2 is to extract caffeine from coffee. Coffee beans are first treated with steam to bring the caffeine to the surface. The beans are then immersed in supercritical CO_2, which selectively dissolves the caffeine but leaves the compounds that give flavor to coffee. The solution of caffeine in supercritical CO_2 is poured off, and the CO_2 is evaporated, trapped, and reused. Similarly, supercritical CO_2 is used to extract the essential oils in hops to add to beer, and it is used to extract valuable chemicals from algae.

Surface Tension, Capillary Action, and Viscosity

Molecules in the interior of a liquid interact with molecules all around them (Figure 11.16). In contrast, molecules on the surface of a liquid are affected only by those molecules located at or below the surface layer. This leads to a net inward force of attraction on the surface molecules, contracting the surface area and making the liquid behave as though it had a skin. The toughness of this skin is measured by its **surface tension**—the energy required to break through the surface or to disrupt a liquid drop and spread the material out as a film. Surface tension causes water drops to be spheres and not little cubes, for example, because a sphere has a smaller surface area than any other shape of the same volume (page 490).

Capillary action and the observation of a curved **meniscus** when liquids are in various containers are other consequences of intermolecular forces. When a piece of paper is partly immersed in water, the water rises in the paper because polar water molecules are attracted to the C—OH bonds present in the cellulose molecules in the paper (Figure 11.17, *left*).

In Figure 11.17 (*right*) we observe the different behavior of water and mercury in glass tubes. Polar water molecules are attracted to the Si—OH bonds on the

SI_photo/Shutterstock.com

Spherical water droplets. Forces acting on molecules at the surface of a liquid are different than those acting on a molecule in the interior of a liquid. This causes water droplets to be spheres and not little cubes.

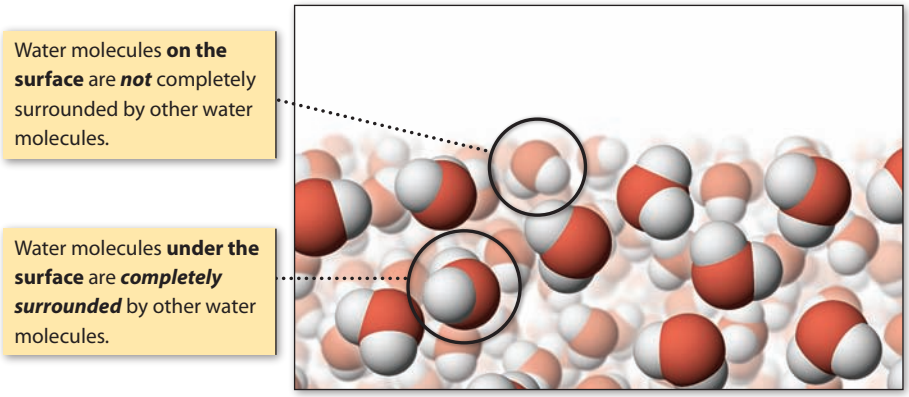

Figure 11.16 Intermolecular forces in a liquid and surface tension.

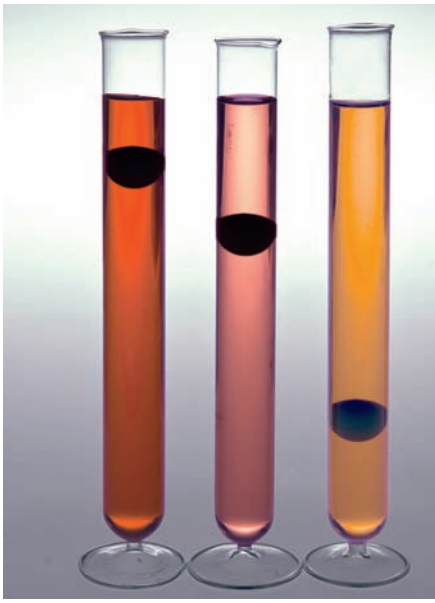
Capillary Action
A piece of paper is partly immersed in water. Polar water molecules are attracted to the C–OH groups in the cellulose of the paper and water moves up the paper.

Meniscus
Water in glass tubes (*right*) is attracted to the polar –OH groups on the surface of glass and so water forms a downward facing or concave meniscus. Mercury, however, is not attracted to the glass surface, and so forms a convex meniscus (*left*).



© Cengage Learning/Charles D. Winters

Figure 11.17
Intermolecular forces: capillary action (left) and the formation of a meniscus (right).

surface of glass by **adhesive forces**. These forces are strong enough that they can compete with the **cohesive forces** between the water molecules themselves. Thus, some water molecules can adhere to the walls; other water molecules are attracted to them by cohesive forces and build a "bridge" back into the liquid. The adhesive forces between the water and the glass are great enough that the water level rises along the edges. The rise will continue until the attractive forces—adhesion between water and glass, cohesion between water molecules—are balanced by the force of gravity pulling down on the water column. These forces lead to the characteristic concave, or downward-curving, **meniscus** seen with water in a glass tube (Figure 11.17).

In some liquids, cohesive forces (high surface tension) are greater than adhesive forces with glass. Mercury is one example. Mercury does not climb the walls of a glass capillary. In fact, when it is in a glass tube, mercury will form a convex, or upward-curving, meniscus (Figure 11.17).

One other important property of liquids in which intermolecular forces play a role is **viscosity**, the resistance of liquids to flow (Figure 11.18). When you turn over a glassful of water, it empties quickly. In contrast, it takes much more time to empty a glassful of olive oil or honey. Olive oil consists of molecules with long chains of carbon atoms, and it is about 70 times more viscous than ethanol, a small molecule with only two carbons and one oxygen. Longer chains have greater intermolecular forces because there are more atoms to attract one another, with each atom contributing to the total force. Honey (a concentrated aqueous solution of sugar molecules), however, is also a viscous liquid, even though the size of the molecules is fairly small. In this case, the sugar molecules have numerous —OH groups, and these lead to greater forces of attraction due to hydrogen bonding.

© Cengage Learning/Charles D. Winters

Figure 11.18 Viscosity. One way to measure viscosity is to compare the rate at which a heavy object drops in a liquid. Here you see the difference in viscosity of various motor oils. The oils become less viscous from left to right.

APPLYING CHEMICAL PRINCIPLES

11.1 Chromatography

Separation of mixtures into pure components is important in both the synthesis and the analysis of chemical compounds. A variety of methods are used for separations, including distillation, precipitation, and filtration. However, the most common means of separation of mixtures is chromatography, and the photo here shows a student using an instrument called a high performance liquid chromatograph.

Chromatography is a general term for a collection of related separation methods. It entails using a mobile phase (commonly a liquid or gas) to move a sample (that is, the components in a mixture) through an immiscible stationary phase (usually a liquid or solid). The mobile and stationary phases are chosen so that the components in the mixture distribute themselves to varying degrees between the two phases. The rate at which components in a mixture move through the stationary phase depends on their intermolecular interactions with the mobile and stationary phases. Components that interact weakly with the stationary phase move more quickly through the stationary phase than the components that interact more strongly with that phase.

© Cengage Learning/Charles D. Winters

A student uses a high-performance liquid chromatograph (HPLC) for an analysis.

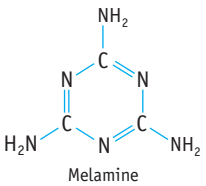
In one common form of chromatography, called partition chromatography, both the mobile and stationary phases are liquids. For example, a polar mobile phase (such as a mixture of methanol and water) is passed through a very thin column containing a nonpolar stationary phase. A common stationary phase is nonpolar octadecane ($C_{18}H_{38}$). The linear, 18-carbon chain (referred to as C-18) is usually bonded to a solid support, such as small silica particles, to immobilize it inside the column. As the mixture passes through the C-18 column, the components continuously move back and forth between the two liquid phases, with the less polar components spending more time in the nonpolar phase than the more polar components. In an ideal separation, the components that emerge from the column (that is, the eluents) are completely separated.

Questions:

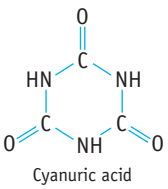
1. Assume that a mixture of the three molecules below are separated on a C-18 column using a methanol/water mixture as the mobile phase.
   a. Which of the three molecules is most attracted to the mobile phase? What are the forces that attract the molecule to the water/methanol phase?
   b. Which molecule is most attracted to the stationary phase? What are the forces that attract the molecule to the nonpolar phase?
   c. In what order will the three molecules exit (or "elute from") the column?

1-pentanol

ethyl propyl ether



1,5-pentanediol



2. In gas chromatography the mobile phase is an inert gas such as N_2 or He. A mixture's components must be volatile if they are to move in the mobile phase. As with liquid chromatography, the separation is based upon forces of attraction of the various sample components with the mobile and the stationary phases; greater attractive forces between a compound and the column will result in a longer elution time. Assume that you want to separate a group of hydrocarbons, such as pentane (C_5H_{12}), hexane (C_6H_{14}), heptane (C_7H_{16}), and octane (C_8H_{18}) using a column with a nonpolar stationary phase. Predict the order of elution of these species from the column and explain your answer.

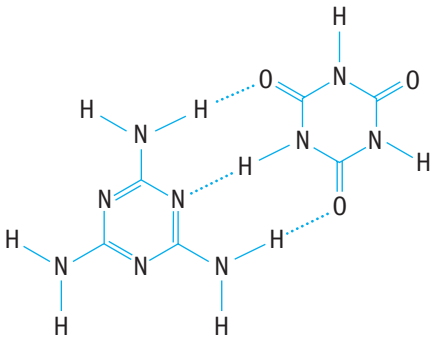
11.2 A Pet Food Catastrophe

In early 2007 pet owners all over the United States reported pets becoming seriously ill or dying. Dogs and cats developed symptoms of kidney failure, which included loss of appetite, vomiting, extreme thirst, and lethargy. Round, greenish-brown kidney stones were also found to be clogging the kidneys of stricken pets. This was mysterious at first, but, within two months, chemists and toxicologists traced the ailments to two compounds in the pet food: melamine and cyanuric acid.

Melamine

Cyanuric acid

Melamine is used to make plastics and fertilizers. It is not approved for food use. Cyanuric acid is used to stabilize chlorine in swimming pools and to sanitize food processing equipment. The acid is sometimes formed as a by-product in the manufacture of melamine, so melamine samples can be contaminated with cyanuric acid.



Eric Isselee/Shutterstock.com

But why was melamine in pet food in the first place? A U.S. manufacturer of pet food, which also supplied other companies that in turn distributed the food under their brand names, had purchased wheat gluten from a supplier in China. Wheat gluten is a concentrated vegetable protein used as a thickener and binder in pet food. The speculation is that the Chinese supplier had added melamine to the wheat gluten to raise the apparent nitrogen content. When products are tested for protein content, any nitrogen found is assumed to come from protein. Adding melamine is an inexpensive way to deceive the buyer into thinking that the product contains a higher percentage of protein.

Melamine and cyanuric acid by themselves are not toxic, but when the compounds are present together they are. The reason is hydrogen bonding! Mixing melamine and cyanuric acid in water produces insoluble crystals of melamine cyanurate.

The structure shows only the hydrogen bonding between two molecules. However, additional hydrogen bonding to other molecules is possible, and the result is further aggregation of cyanuric acid and melamine to form an insoluble material.

The behavior of the hydrogen-bonded complex depends on pH. In the stomach, a very acidic medium with a low pH, hydrogen bonding does not occur between these compounds, and the compounds are soluble. The body seeks to get rid of these chemicals through the kidneys, however, and there the compounds encounter a near neutral pH. Hydrogen bonding can then occur, and the molecules aggregate to form solid melamine cyanurate.

Questions:

1. Calculate the weight percent of nitrogen in melamine and cyanuric acid and compare this value to the average percent of nitrogen in protein (14%).
2. An infant formula was also found to have been contaminated with 0.14 ppm melamine. (The abbreviation ppm stands for parts per million. This means, for example, there is 1 g of a substance per million grams of the product.) What mass of melamine is there in a package of infant formula with a mass of 454 g (one pound)?

CHAPTER GOALS REVISITED

The goals of this chapter are keyed to specific Study Questions to help you organize your review.

11.1 States of Matter and Intermolecular Forces

- Know what types of intermolecular forces exist and what molecular propertes they can influence. 1, 2.

11.2 Interactions Between Ions and Molecules with a Permanent Dipole

- Know what determines the strength of the interaction between ions and molecules with permanent dipoles and the effect of that interaction. 9, 10, 31.

11.3 Interactons Between Molecules with a Permanent Dipole

- Recognize that two polar molecules can interact through dipole–dipole forces. 3, 4, 29, 43.
- Understand how hydrogen bonding can occur and can affect the properties of water. 7, 29, 47.

11.4 Intermolecular Forces Involving Nonpolar Molecules

- Identify instances where a dipole can be induced by interaction with a polar molecule, Debye forces. 2.
- Identify instances where molecules interact by induced dipole–induced dipole forces (London dispersion forces). 3, 5, 30.

11.5 A Summary of van der Waals Intermolecular Forces

- Describe the various kinds of intermolecular forces in liquids and solids. **3–10, 29, 30.**

11.6 Properties of Liquids

- Define the equilibrium vapor pressure of a liquid, and explain the relationship between the vapor pressure and boiling point of a liquid. **17, 19, 33.**
- Describe how intermolecular interactions affect the energy necessary to break through the surface of a liquid (surface tension), capillary action, and the resistance to flow, or viscosity, of liquids. **25–28.**
- Describe the phenomena of the critical temperature, T_c, and critical pressure, P_c, of a substance. **23, 24, 53.**
- Calculate enthalpy changes for changes of state. **11, 12.**
- Represent the connection between vapor pressure and temperature graphically. **19, 21, 33.**
- Use the Clausius–Clapeyron equation to relate vapor pressure and enthalpy of vaporization. **21, 22, 39.**

KEY EQUATIONS

Equation 11.1 (page 512) The Clausius–Clapeyron equation relates the equilibrium vapor pressure, P, of a volatile liquid to the molar enthalpy of vaporization ($\Delta_{vap}H°$) at a given temperature, T. (R is the universal constant, 0.008314462 kJ/K · mol.)

$$\ln P = -(\Delta_{vap}H°/RT) + C$$

Equation 11.2 (page 512) This modification of the Clausius–Clapeyron equation allows you to calculate $\Delta_{vap}H°$ if you know the vapor pressures at two different temperatures.

$$\ln \frac{P_2}{P_1} = -\frac{\Delta_{vap}H°}{R}\left[\frac{1}{T_2} - \frac{1}{T_1}\right]$$

STUDY QUESTIONS

▲ denotes challenging questions. **Blue-numbered questions** have answers in Appendix N and fully worked solutions in the *Student Solutions Manual*.

Practicing Skills

Intermolecular Forces

(See Sections 11.1–11.5 and Examples 11.1–11.4.)

1. What intermolecular force(s) must be overcome to perform the following?
   (a) melt ice
   (b) sublime solid I_2
   (c) convert liquid NH_3 to NH_3 vapor

2. Intermolecular forces: What type of forces must be overcome between I_2 molecules when solid I_2 dissolves in methanol, CH_3OH? What type of forces must be disrupted between CH_3OH molecules when I_2 dissolves? What type of forces exist between I_2 and CH_3OH molecules in solution?

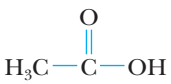
Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

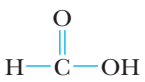


3. What type of intermolecular forces must be overcome in converting each of the following from a liquid to a gas?
   (a) liquid O_2
   (b) mercury
   (c) CH_3I (methyl iodide)
   (d) CH_3CH_2OH (ethanol)

4. What type of intermolecular forces must be overcome in converting each of the following from a liquid to a gas?
   (a) CO_2
   (b) NH_3
   (c) $CHCl_3$
   (d) CCl_4

5. Considering intermolecular forces in the pure substance, which of these substances exists as a gas at 25 °C and 1 atm?
   (a) Ne
   (b) CH_4
   (c) CO
   (d) CCl_4

6. Considering intermolecular forces in the pure substance, which of these substances exists as a gas at 25 °C and 1 atm?
   (a) $CH_3CH_2CH_2CH_3$ (butane)
   (b) CH_3OH (methanol)
   (c) Ar



7. Which of the following compounds would be expected to form intermolecular hydrogen bonds in the liquid state?
   (a) CH_3OCH_3 (dimethyl ether)
   (b) CH_4
   (c) HF
   (d) CH_3CO_2H (acetic acid)

acetic acid

   (e) Br_2
   (f) CH_3OH (methanol)

8. Which of the following compounds would be expected to form intermolecular hydrogen bonds in the liquid state?
   (a) H_2Se
   (b) HCO_2H (formic acid)

formic acid

   (c) HI
   (d) acetone, $(CH_3)_2CO$

acetone

9. In each pair of ionic compounds, which is more likely to have the more negative enthalpy of hydration? Briefly explain your reasoning in each case.
   (a) LiCl or CsCl
   (b) $NaNO_3$ or $Mg(NO_3)_2$
   (c) RbCl or $NiCl_2$

10. When salts of Mg^{2+}, Na^+, and Cs^+ are placed in water, the ions are hydrated. Which of these three cations is most strongly hydrated? Which one is least strongly hydrated?

Liquids

(See Section 11.6 and Examples 11.5 and 11.6.)

11. Ethanol, CH_3CH_2OH, has a vapor pressure of 59 mm Hg at 25 °C. What quantity of energy as heat is required to evaporate 125 mL of the alcohol at 25 °C? The enthalpy of vaporization of the alcohol at 25 °C is 42.32 kJ/mol. The density of the liquid is 0.7849 g/mL.

12. The enthalpy of vaporization of liquid mercury is 59.11 kJ/mol. What quantity of energy as heat is required to vaporize 0.500 mL of mercury at 357 °C, its normal boiling point? The density of mercury is 13.6 g/mL.

13. Answer the following questions using Figure 11.12:
   (a) What is the approximate equilibrium vapor pressure of water at 60 °C? Compare your answer with the data in Appendix G.
   (b) At what temperature does water have an equilibrium vapor pressure of 600 mm Hg?
   (c) Compare the equilibrium vapor pressures of water and ethanol at 70 °C. Which is higher?

14. Answer the following questions using Figure 11.12:
   (a) What is the equilibrium vapor pressure of diethyl ether at room temperature (approximately 20 °C)?
   (b) Place the three compounds in Figure 11.12 in order of increasing intermolecular forces.
   (c) If the pressure in a flask is 400 mm Hg and if the temperature is 40 °C, which of the three compounds (diethyl ether, ethanol, and water) are liquids, and which are gases?

15. Assume you seal 1.0 g of diethyl ether (Figure 11.12) in an evacuated 100.-mL flask. If the flask is held at 30 °C, what is the approximate gas pressure in the flask? If the flask is placed in an ice bath, does additional liquid ether evaporate, or does some ether condense to a liquid?

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

16. Refer to Figure 11.12 to answer these questions:

(a) You heat some water to 60 °C in a lightweight plastic bottle and seal the top very tightly so gas cannot enter or leave the carton. What happens when the water cools?

(b) If you put a few drops of liquid diethyl ether on your hand, does it evaporate completely or remain a liquid?

17. Which member of each of the following pairs of compounds has the higher boiling point?

(a) O_2 or N_2 (c) HF or HI

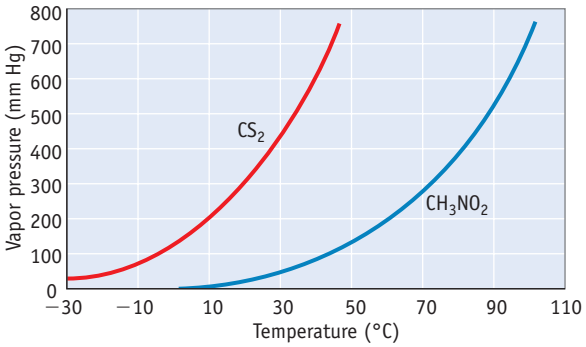
(b) SO_2 or CO_2 (d) SiH_4 or GeH_4

18. Place the following four compounds in order of increasing boiling point:

(a) C_5H_{12} (c) C_2H_6

(b) CCl_4 (d) Ne

19. Vapor pressure curves for CS_2 (carbon disulfide) and CH_3NO_2 (nitromethane) are drawn here.



(a) What are the approximate vapor pressures of CS_2 and CH_3NO_2 at 40 °C?

(b) What type(s) of intermolecular forces exist in the liquid phase of each compound?

(c) What is the normal boiling point of CS_2? Of CH_3NO_2?

(d) At what temperature does CS_2 have a vapor pressure of 600 mm Hg?

(e) At what temperature does CH_3NO_2 have a vapor pressure of 600 mm Hg?

20. You are comparing three different substances, A, B, and C, all liquids and having similar molar masses. The vapor pressure at 25 °C for substance A is less than the vapor pressure for B at this temperature. Substance C has the highest boiling point of the three substances. List the three substances A, B, or C in order of the strength of intermolecular forces, from least to greatest.

21. Equilibrium vapor pressures of benzene, C_6H_6, at various temperatures are given in the table.

Temperature (°C)	Vapor Pressure (mm Hg)
7.6	40.
26.1	100.
60.6	400.
80.1	760.

(a) What is the normal boiling point of benzene?

(b) Plot these data so that you have a graph resembling the one in Figure 11.12. At what temperature does the liquid have an equilibrium vapor pressure of 250 mm Hg? At what temperature is the vapor pressure 650 mm Hg?

(c) Calculate the molar enthalpy of vaporization for benzene using the Clausius–Clapeyron equation.

22. Vapor pressure data are given here for octane, C_8H_{18}.

Temperature (°C)	Vapor Pressure (mm Hg)
25	13.6
50.	45.3
75	127.2
100.	310.8

Use the Clausius–Clapeyron equation to calculate the molar enthalpy of vaporization of octane and its normal boiling point.

23. Can carbon monoxide (T_c = 132.9 K; P_c = 34.5 atm) be liquefied at or above room temperature? Explain briefly.

24. Methane (CH_4) cannot be liquefied at room temperature, no matter how high the pressure. Propane (C_3H_8), another simple hydrocarbon, has a critical pressure of 42 atm and a critical temperature of 96.7 °C. Can this compound be liquefied at room temperature?

25. What is surface tension? Give an example illustrating the phenomenon of surface tension. Explain why surface tension is the consequence of intermolecular forces.

26. What factors affect the viscosity of a substance? Which of the following substances, water (H_2O), ethanol (CH_3CH_2OH), ethylene glycol ($HOCH_2CH_2OH$), and glycerol ($HOCH_2CH(OH)CH_2OH$), is expected to have the highest viscosity? Should viscosity of a substance be affected by temperature? Explain your answers.

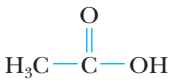
Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.



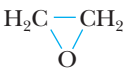
27. If a piece of filter paper (an absorbent paper used in laboratories) is suspended above a beaker of water and just touching the surface, water will slowly move up the paper. What is the name given to this phenomenon, and how is this behavior explained?

28. When water is placed in a buret it forms a concave meniscus at the surface. In contrast, mercury (in a manometer for example) forms a convex meniscus (Figure 11.17). Explain why this phenomenon occurs, and why the two liquids give different results. Predict the meniscus shape if the buret is filled with ethylene glycol ($HOCH_2CH_2OH$).

General Questions

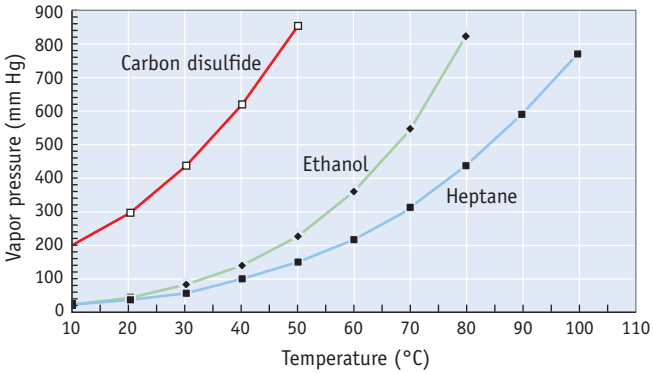
These questions are not designated as to type or location in the chapter. They may combine several concepts.

29. What types of intermolecular forces are important in the liquid phase of (a) CCl_4, (b) CH_3Cl, and (c) CH_3CO_2H (acetic acid)?



acetic acid

30. What types of intermolecular forces are important in the liquid phase of (a) C_2H_6 and (b) $(CH_3)_2CHOH$?



31. Which of the following salts, Li_2SO_4 or Cs_2SO_4, is expected to have the more exothermic enthalpy of hydration?

32. Select the substance in each of the following pairs that should have the higher boiling point:
    (a) Br_2 or ICl
    (b) neon or krypton
    (c) CH_3CH_2OH (ethanol) or C_2H_4O (ethylene oxide, structure below)

ethylene oxide

33. Use the vapor pressure curves illustrated here to answer the questions that follow.

(a) What is the vapor pressure of ethanol, C_2H_5OH, at 60 °C?
(b) Considering only carbon disulfide (CS_2) and ethanol, which has the stronger intermolecular forces in the liquid state?
(c) At what temperature does heptane (C_7H_{16}) have a vapor pressure of 500 mm Hg?
(d) What are the approximate normal boiling points of each of the three substances?
(e) At a pressure of 400 mm Hg and a temperature of 70 °C, is each substance a liquid, a gas, or a mixture of liquid and gas?

34. Which of the following ionic compounds will have the most negative enthalpy of hydration?
    (a) $Fe(NO_3)_2$ (c) NaCl
    (b) $CoCl_2$ (d) $Al(NO_3)_3$

35. Rank the following compounds in order of increasing molar enthalpy of vaporization: CH_3OH, C_2H_6, HCl.

36. Rank the following molecules in order of increasing boiling point: $CH_3CH_2CH_2CH_2CH_3$, CH_3F, CH_3Cl.

37. Mercury and many of its compounds are dangerous poisons if breathed, swallowed, or even absorbed through the skin. The liquid metal has a vapor pressure of 0.00169 mm Hg at 24 °C. If the air in a small room is saturated with mercury vapor, how many atoms of mercury vapor occur per cubic meter?

38. ▲ The following data are the equilibrium vapor pressure of limonene, $C_{10}H_{16}$, at various temperatures. (Limonene is used as a scent in commercial products.)

Temperature (°C)	Vapor Pressure (mm Hg)
14.0	1.0
53.8	10.
84.3	40.
108.3	100.
151.4	400.

(a) Plot these data as ln P versus $1/T$ so that you have a graph resembling the one in Figure 11.13.
(b) At what temperature does the liquid have an equilibrium vapor pressure of 250 mm Hg? At what temperature is it 650 mm Hg?
(c) What is the normal boiling point of limonene?
(d) Calculate the molar enthalpy of vaporization for limonene using the Clausius–Clapeyron equation.

In the Laboratory

39. You are going to prepare a silicone polymer, and one of the starting materials is dichlorodimethylsilane, $SiCl_2(CH_3)_2$. You need its normal boiling point and to measure equilibrium vapor pressures at various temperatures.

Temperature (°C)	Vapor Pressure (mm Hg)
−0.4	40.
+17.5	100.
51.9	400.
70.3	760.

(a) What is the normal boiling point of dichlorodimethylsilane?

(b) Plot these data as ln P versus $1/T$ so that you have a plot resembling the one in Figure 11.13. At what temperature does the liquid have an equilibrium vapor pressure of 250 mm Hg? At what temperature is it 650 mm Hg?

(c) Calculate the molar enthalpy of vaporization for dichlorodimethylsilane using the Clausius–Clapeyron equation.

40. A "hand boiler" can be purchased in toy stores or at science supply companies. If you cup your hand around the bottom bulb, the volatile liquid in the boiler boils, and the liquid moves to the upper chamber.

(a) Using your knowledge of kinetic molecular theory and intermolecular forces, explain how the hand boiler works.

Photos: © Cengage Learning/Charles D. Winters

(b) Which of the following liquids would be best to use in the hand boiler? Explain.

Compound	Normal Boiling Point
Ethanol	78.4 °C
Chloroform	61.3 °C
CCl_3F	23.7 °C

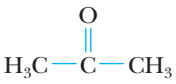
41. ▲ The photos below illustrate an experiment you can do yourself. Place 10 mL of water in an empty soda can, and heat the water to boiling. Using tongs or pliers, turn the can over in a pan of cold water, making sure the opening in the can is below the water level in the pan.

(a)

(b)

Photos: © Cengage Learning/Charles D. Winters

(a) Describe what happens, and explain it in terms of the subject of this chapter.



(b) Prepare a molecular level sketch of the situation inside the can before heating and after heating (but prior to inverting the can).

42. If you place 1.0 L of ethanol (C_2H_5OH) in a small laboratory that is 3.0 m long, 2.5 m wide, and 2.5 m high, will all the alcohol evaporate? If some liquid remains, how much will there be? The vapor pressure of ethanol at 25 °C is 59 mm Hg, and the density of the liquid at this temperature is 0.785 g/cm^3.

Summary and Conceptual Questions

The following questions may use concepts from this and previous chapters.

43. Acetone, CH_3COCH_3, is a common laboratory solvent. It is usually contaminated with water, however. Why does acetone absorb water so readily? Draw molecular structures showing how water and acetone can interact. What intermolecular force(s) is(are) involved in the interaction?

44. Cooking oil floats on top of water. From this observation, what conclusions can you draw regarding the polarity or hydrogen-bonding ability of molecules found in cooking oil?

45. Liquid ethylene glycol, $HOCH_2CH_2OH$, is one of the main ingredients in commercial antifreeze. Would you predict its viscosity to be greater or less than that of ethanol, CH_3CH_2OH?

46. Liquid methanol, CH_3OH, is placed in a glass tube. Is the meniscus of the liquid concave or convex? Explain briefly.

Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

47. Account for these facts:

(a) Although ethanol (C_2H_5OH) (bp, 80 °C) has a higher molar mass than water (bp, 100 °C), the alcohol has a lower boiling point.

(b) Mixing 50 mL of ethanol with 50 mL of water produces a solution with a volume slightly less than 100 mL.

48. Rationalize the observation that $CH_3CH_2CH_2OH$, 1-propanol, has a boiling point of 97.2 °C, whereas a compound with the same empirical formula, methyl ethyl ether ($CH_3CH_2OCH_3$), boils at 7.4 °C.

49. Cite two pieces of evidence to support the statement that water molecules in the liquid state exert considerable attractive force on one another.

50. During thunderstorms in the Midwest, very large hailstones can fall from the sky. (Some are the size of golf balls!) To preserve some of these stones, we put them in the freezer compartment of a frost-free refrigerator. Our friend, who is a chemistry student, tells us to use an older model that is not frost-free. Why?

51. Refer to Figure 11.8 to answer the following questions:

(a) Of the three hydrogen halides (HX), which has the largest total intermolecular force?

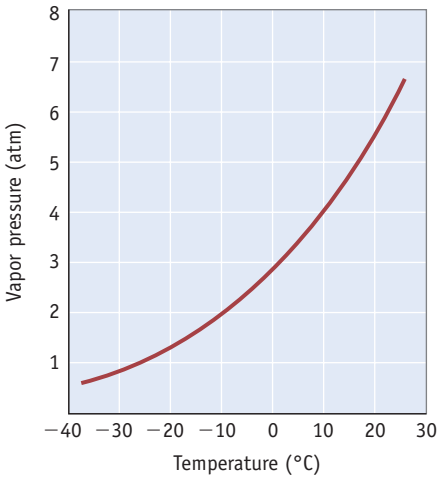
(b) Why are the dispersion forces greater for HI than for HCl?

(c) Why are the dipole–dipole forces greater for HCl than for HI?

(d) Of the seven molecules in Figure 11.8, which involves the largest dispersion forces? Explain why this is reasonable.

52. At the Fred Hutchison Cancer Research Center in Seattle it was discovered that mice can be put into a state of suspended animation by applying a low dose of hydrogen sulfide, H_2S. The breathing rate of the mice fell from 120 to 10 breaths per minute and their temperature fell to just 2 °C above ambient temperature. Six hours later the mice were revived and seemed to show no negative effects.

(a) Hydrogen sulfide is a gas at room temperature and normal atmospheric pressure whereas water is a liquid with a low vapor pressure under the same conditions. Explain this observation.



(b) The H_2S gas delivered to the mice had a concentration of 80 ppm. (A concentration of 1 ppm is 1 part per million, or one molecule in every 1 million molecules.) If you deliver 1.0 L of gas (a mixture of O_2, N_2, and H_2S) at a total pressure of 725 mm Hg at a temperature of 22 °C, what is the partial pressure of the H_2S gas?

(c) Hydrogen sulfide can be converted to sulfuric acid. If 5.2 L of H_2S gas at 130 mm Hg pressure and 25 °C is allowed to react with O_2 gas, how many liters of O_2 gas, also at 130 mm Hg pressure and 25 °C, are required for complete reaction? Assume the following reaction occurs.

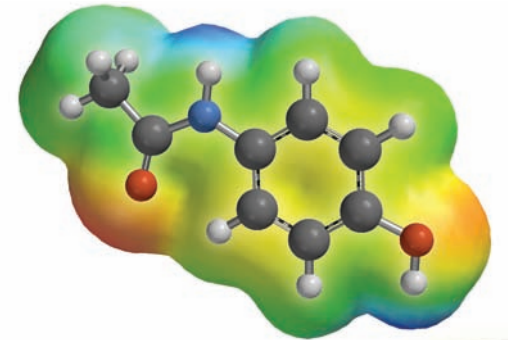
$$H_2S(g) + 2\ O_2(g) \rightarrow H_2SO_4(\ell)$$

53. A fluorocarbon, CF_4, has a critical temperature of −45.7 °C and a critical pressure of 37 atm. Are there any conditions under which this compound can be a liquid at room temperature? Explain briefly.

54. ▲ The figure below is a plot of vapor pressure versus temperature for dichlorodifluoromethane, CCl_2F_2. The enthalpy of vaporization of the liquid is 165 kJ/g, and the specific heat capacity of the liquid is about 1.0 J/g · K.

(a) What is the approximate normal boiling point of CCl_2F_2?

(b) A steel cylinder containing 25 kg of CCl_2F_2 in the form of liquid and vapor is set outdoors on a warm day (25 °C). What is the approximate pressure of the vapor in the cylinder?



(c) The cylinder valve is opened, and CCl_2F_2 vapor gushes out of the cylinder in a rapid flow. Soon, however, the flow becomes much slower, and the outside of the cylinder is coated with ice frost. When the valve is closed and the cylinder is reweighed, it is found that 20 kg of CCl_2F_2 is still in the cylinder. Why is the flow fast at first? Why does it slow down long before the cylinder is empty? Why does the outside become icy?

(d) Which of the following procedures would be effective in emptying the cylinder rapidly (and safely)? (1) Turn the cylinder upside down, and open the valve. (2) Cool the cylinder to −78 °C in dry ice, and open the valve. (3) Knock off the top of the cylinder, valve and all, with a hammer.

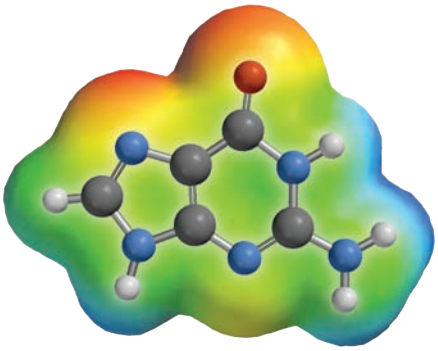
55. Acetaminophen is used in analgesics. A model of the molecule is shown here with its electrostatic potential surface. Where are the most likely sites for hydrogen bonding?



Acetaminophen

56. Shown here are models of two bases in DNA with the electrostatic potential surfaces: cytosine and guanine. What sites in these molecules are involved in hydrogen bonding with each other? Draw molecular structures showing how cytosine can hydrogen-bond with guanine.

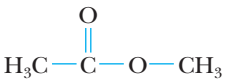
Cytosine

Guanine

57. List four properties of liquids that are directly determined by intermolecular forces.

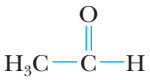
58. List the following ions in order of hydration energies: Na^+, K^+, Mg^{2+}, Ca^{2+}. Explain how you determined this order.

59. Compare the boiling points of the various isomeric hydrocarbons shown in the table below. Notice the relationship between boiling point and structure; branched-chain hydrocarbons have lower boiling points than the unbranched isomer. Speculate on possible reasons for this trend. Why might the intermolecular forces be slightly different in these compounds?



Compound	Boiling Point (°C)
Hexane	68.9
3-Methylpentane	63.2
2-Methylpentane	60.3
2,3-Dimethylbutane	58.0
2,2-Dimethylbutane	49.7

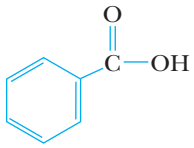
60. An 8.82-g sample of Br_2 is placed in an evacuated 1.00 L flask and heated to 58.8 °C, the normal boiling point of bromine. Describe the contents of the flask under these conditions.



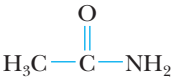
61. Polarizability is defined as the extent to which the electron cloud surrounding an atom or molecule can be distorted by an external charge. Rank the halogens (F_2, Cl_2, Br_2, I_2) and the noble gases (He, Ne, Ar, Kr, Xe) in order of polarizability (from least polarizable to most polarizable). What characteristics of these substances could be used to determine this ranked order?

62. In which of the following organic molecules might we expect hydrogen bonding to occur?

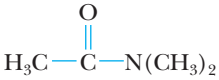
(a) methyl acetate, $CH_3CO_2CH_3$



(b) acetaldehyde (ethanal), CH_3CHO



(c) acetone (2-propanone) (see Question 8)



(d) benzoic acid ($C_6H_5CO_2H$)

(e) acetamide (CH_3CONH_2 an amide formed from acetic acid and ammonia)

(f) N,N-dimethylacetamide [$CH_3CON(CH_3)_2$, an amide formed from acetic acid and dimethylamine]

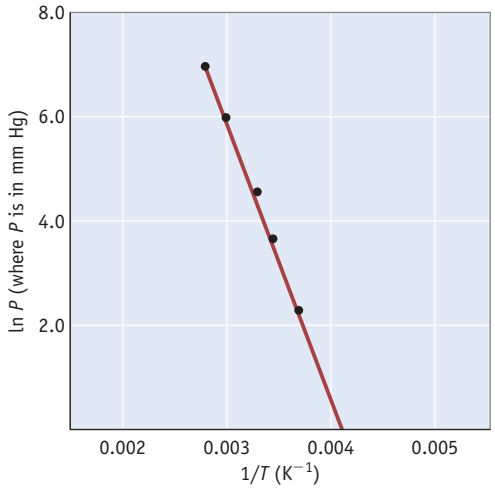
63. A pressure cooker (a kitchen appliance) is a pot on which the top seals tightly, allowing pressure to build up inside. You put water in the pot and heat it to boiling. At the higher pressure, water boils at a higher temperature, and this allows food to cook at a faster rate. Most pressure cookers have a setting of 15 psi, which means that the pressure in the pot is 15 psi above atmospheric pressure (1 atm = 14.70 psi). Use the Clausius–Clapeyron equation to calculate the temperature at which water boils in the pressure cooker.



64. Vapor pressures of $NH_3(\ell)$ at several temperatures are given in the table below. Use this information to calculate the enthalpy of vaporization of ammonia.

Temperature (°C)	Vapor Pressure (atm)
−68.4	0.132
−45.4	0.526
−33.6	1.000
−18.7	2.00
4.7	5.00
25.7	10.00
50.1	20.00

65. Chemists sometimes carry out reactions in liquid ammonia as a solvent. With adequate safety protection these reactions can be done at temperatures above ammonia's boiling point in a sealed, thick-walled glass tube. If the reaction is being carried out at 20 °C, what is the pressure of ammonia inside the tube? (Use data from the previous question to answer this question.)

66. The data in the following table were used to create the graph shown below (P = vapor pressure of ethanol (CH_3CH_2OH) expressed in mm Hg, T = kelvin temperature).

ln P	$1/T$ (K^{-1})
2.30	0.00369
3.69	0.00342
4.61	0.00325
5.99	0.00297
6.63	0.00285

(a) Derive an equation for the straight line in this graph.

(b) Describe in words how to use the graph to determine the enthalpy of vaporization of ethanol.

(c) Calculate the vapor pressure of ethanol at 0.00 °C and at 100 °C.

67. Water (10.0 g) is placed in a thick-walled glass tube whose internal volume is 50.0 cm^3. Then all the air is removed, the tube is sealed, and then the tube and contents are heated to 100 °C.

(a) Describe the appearance of the system at 100 °C.

(b) What is the pressure inside the tube?

(c) At this temperature, liquid water has a density of 0.958 g/cm^3. Calculate the volume of liquid water in the tube.

(d) Some of the water is in the vapor state. Determine the mass of water in the gaseous state.

68. Acetone is a common solvent. (See Study Question 8 for the structure of acetone.)

(a) Allyl alcohol, $CH_2{=}CH{-}CH_2OH$, is an isomer of acetone. Acetone has a vapor pressure of 100 mm Hg at +7.7 °C. Predict whether the vapor pressure of allyl alcohol is higher or lower than 100 mm Hg at this temperature? Explain.

(b) Use the Clausius–Clapeyron equation to calculate the enthalpy of vaporization of acetone from the following data.

Temperature (°C)	Vapor Pressure (mm Hg)
−9.4	40.
+7.7	100.
39.5	400.
56.5	760.

(c) Fluorination of acetone, C_3H_6O (substitution of fluorine for H) produces a gaseous compound with the formula $C_3H_{6-x}F_xO$. To identify this compound its molar mass was determined by measuring the gas density. The following data were obtained: Mass of gas, 1.53 g; volume of flask = 264 mL; pressure exerted by gas, 722 mm Hg; temperature, 22 °C. Calculate the molar mass from this information, then identify the molecular formula.

CHAPTER OUTLINE

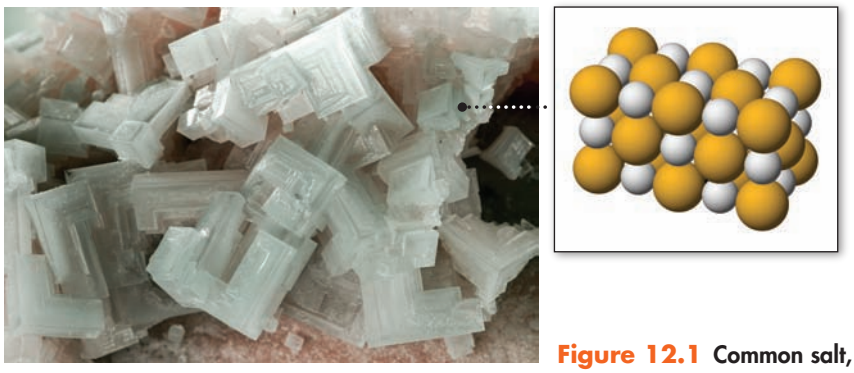
12.1 Crystal Lattices and Unit Cells

12.2 Structures and Formulas of Ionic Solids

12.3 Bonding in Ionic Compounds: Lattice Energy

12.4 Bonding in Metals and Semiconductors

12.5 Other Types of Solid Materials



12.6 Phase Changes

12.1 Crystal Lattices and Unit Cells

Goals for Section 12.1

- Define the unit cell for a crystalline compound.
- Understand the relationship of unit cell structure, atom radius, and cell dimensions.

In both gases and liquids, molecules move continually and randomly, and they rotate and vibrate as well. An orderly arrangement of molecules in the gaseous or liquid state is not possible. In solids, however, the molecules, atoms, or ions cannot change their relative positions (although they vibrate and occasionally rotate). Thus, a regular, repeating pattern of atoms or molecules within the structure—a long-range order—is possible and is indeed a characteristic of most solids. The beautiful, external (macroscopic) regularity of many crystalline compounds (such as those of salt, Figure 12.1) is a consequence of their internal order.

Figure 12.1 **Common salt, NaCl.**

◀ **The Lesedi La Rona diamond.** Diamonds are the hardest material known and so are used industrially to cut and polish other, softer materials. This diamond, which measures 1,111 carats (or 222.2 g), is one of the largest ever found. It was discovered in 2015 in the southern African country of Botswana, and given the name "Lesedi La Rona," which means "Our Light" in Tswana, the language of Botswana. It was offered for sale at an auction in 2016, where the bidding started at 50 million dollars. It did not sell.

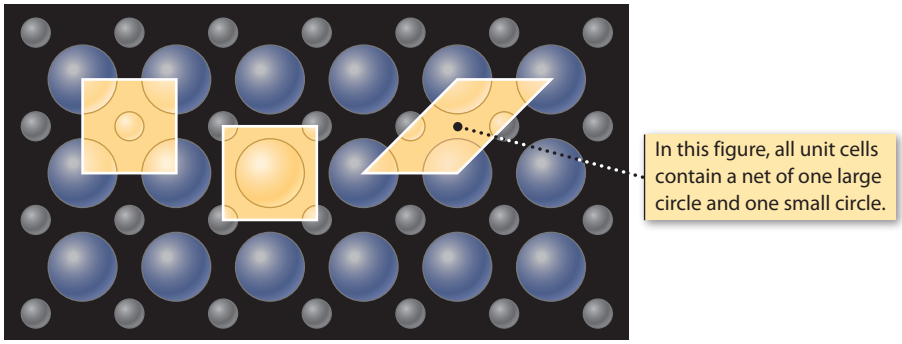

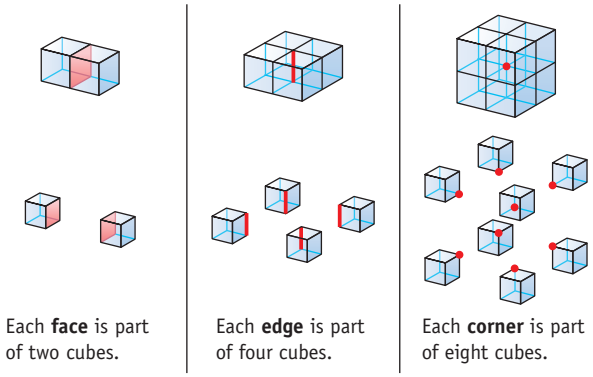

Figure 12.2 Unit cells for a flat, two-dimensional solid made from circular "atoms."
A lattice can be represented as being built from repeating unit cells. This two-dimensional lattice can be built by translating the unit cells throughout the plane of the figure. Each unit cell must move by the length of one side of the cell. Be sure to notice that several unit cells are possible, with two of the most obvious being squares.

Structures of solids can be described as three-dimensional lattices of atoms, ions, or molecules. For a crystalline solid, we can identify the **unit cell**, the smallest repeating unit that has all of the symmetry characteristics of the arrangement of atoms, ions, or molecules in the solid.

To understand unit cells, consider first a two-dimensional lattice model, the repeating pattern of circles in Figure 12.2. The yellow square at the left is a unit cell because the overall pattern can be created from a group of these cells by joining them edge to edge. It is also a requirement that unit cells reflect the stoichiometry of the solid. Here, the square unit cell at the left contains one smaller circle and one fourth of each of the four larger circles, giving a total of one small and one large circle per two-dimensional unit cell.

You may recognize that it is possible to draw other unit cells for this two-dimensional lattice. One option is the square in the middle of Figure 12.2 that fully encloses a single large circle and parts of small circles that add up to one net small circle. Yet another possible unit cell is the parallelogram at the right. Other unit cells can be drawn, but it is conventional to draw unit cells in which atoms or ions are placed at the **lattice points**; that is, at the corners of the square, cube, or other geometric object that constitutes the unit cell.

The three-dimensional lattices of solids can be built by assembling three-dimensional unit cells much like building blocks. The assemblage of these three-dimensional unit cells defines the **crystal lattice**.

Assembling a crystal lattice from cubic unit cells

To construct crystal lattices, nature can use any of seven three-dimensional unit cells (Figure 12.3). They differ from one another in that their sides have different relative lengths and their edges meet at different angles. The simplest of the

Types of cells. There are seven basic unit cells. All except the hexagonal unit cell are parallelepipeds (a solid with six faces, each of which is a parallelogram). In a cube, all angles (*a*-*o*-*c*, *a*-*o*-*b*, and *c*-*o*-*b*; where *o* is the origin) are 90°, and all sides are equal. In other cells, the angles and sides may be the same or different.

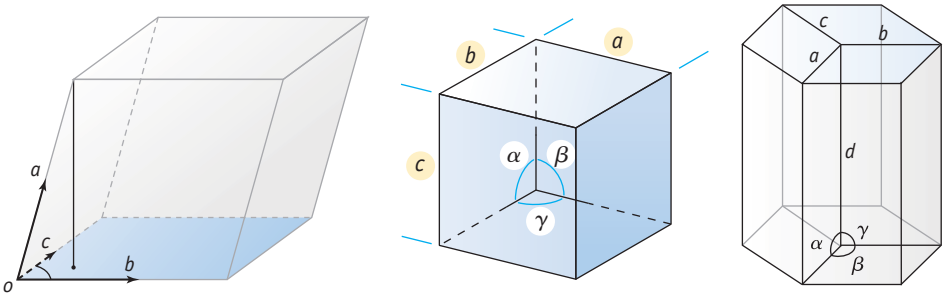

Figure 12.3 Unit cells.

seven crystal lattices is the **cubic unit cell**, a cell with edges of equal length that meet at 90° angles. We shall look in detail at only this structure because cubic unit cells are the simplest unit cells to understand and because they are commonly encountered.

Cubic Unit Cells

Within the cubic class, three cell symmetries occur: **primitive cubic (pc)**, **body-centered cubic (bcc)**, and **face-centered cubic (fcc)** (Figure 12.4). All three have identical atoms, molecules, or ions at the corners of the cubic unit cell. The bcc and fcc arrangements, however, differ from the primitive cube in that they have additional particles at other locations. The bcc structure is called *body-centered* because it has an additional particle, of the same type as those at the corners, at the center of the cube. The fcc arrangement is called *face-centered* because it has a particle, of the same type as the corner atoms, in the center of each of the six faces of the cube. Examples of each

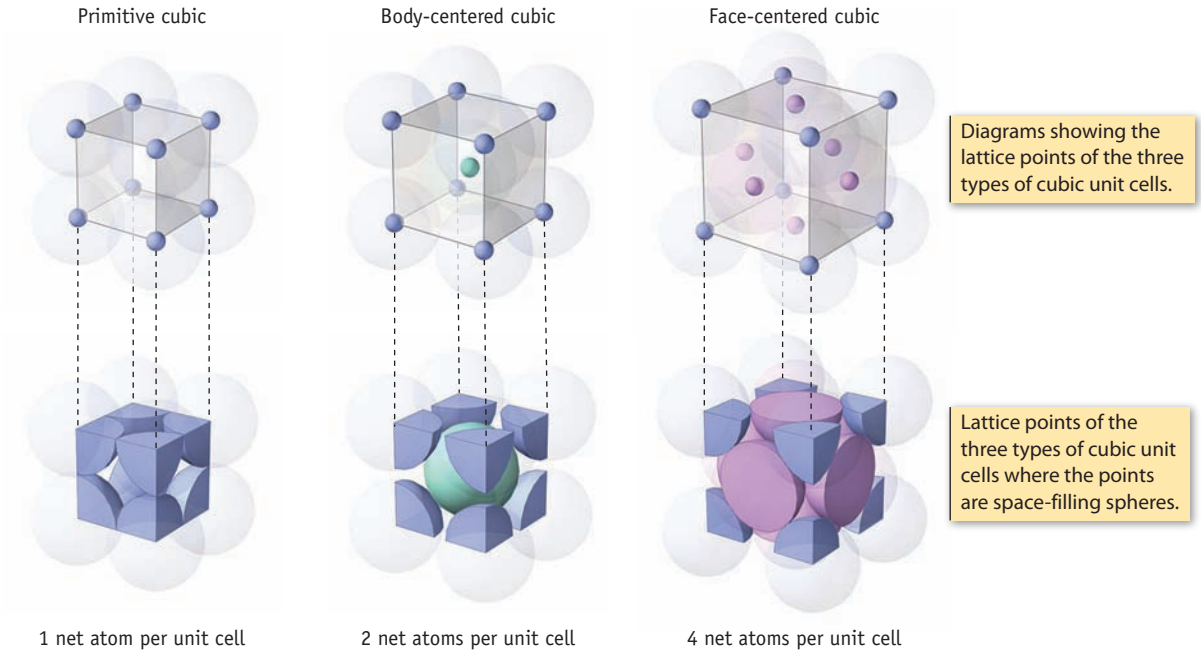

Figure 12.4 The three cubic unit cells. Because eight unit cells in a crystal lattice share a corner atom, only $\frac{1}{8}$ of each corner atom lies within a given unit cell; the remaining $\frac{7}{8}$ lies in seven other unit cells that touch that corner. Because each face of an fcc unit cell is shared with another unit cell, one half of each atom in the face of a face-centered cube lies in a given unit cell, and the other half lies in the adjoining cell. (See also Figure 12.6.)

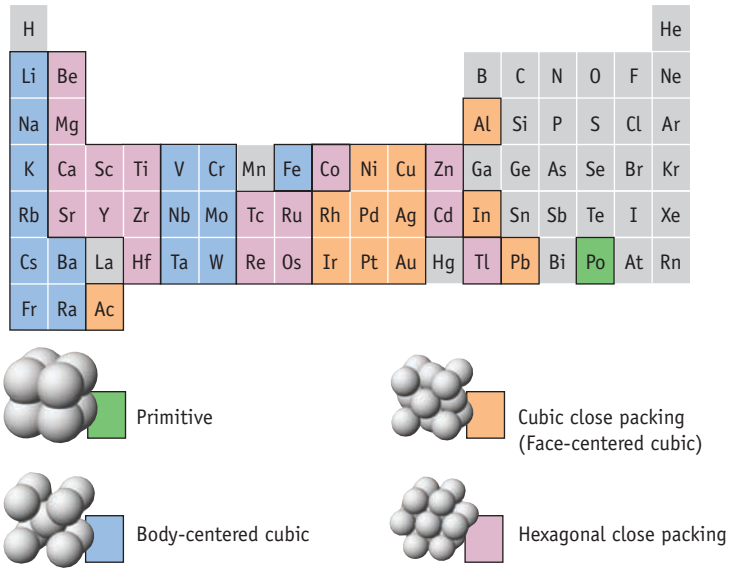

Figure 12.5 Metals use four different unit cells. Three are based on the cube, and the fourth is the hexagonal unit cell (*A Closer Look: Packing Oranges, Marbles, and Atoms*). (Many metals can crystallize in more than one structure. Mn, for example, can be bcc or fcc.)

structure are found among the crystal lattices of the metals (Figure 12.5). The alkali metals, for example, are body-centered cubic, whereas nickel, copper, and aluminum are face-centered cubic. Only one metal, polonium, has a primitive cubic lattice.

When the cubes pack together to make a three-dimensional crystal of a metal, the atom at each corner is shared among eight cubes (Figures 12.4 and 12.6, *left*). Therefore, only one eighth of each corner atom is actually within a given unit cell. Furthermore, because a cube has eight corners, and because one eighth of the atom at each corner "belongs to" a particular unit cell, the corner atoms contribute a net of one atom to a given unit cell. Thus, *the primitive cubic arrangement has one net atom within the unit cell.*

$$(8 \text{ corners of a cube})(\tfrac{1}{8} \text{ of each corner atom within a unit cell}) = 1 \text{ net atom per unit cell for the primitive cubic unit cell}$$

A body-centered cube has an additional atom wholly within the unit cell at the cube's center in addition to those at the cube corners. Therefore, *the body-centered cubic arrangement has a net of two atoms within the unit cell.*

In a face-centered cubic arrangement, there is an atom on each of the six faces of the cube in addition to those at the cube corners. One half of each atom on a face belongs to a given unit cell (Figure 12.6, *right*). Three net atoms are therefore contributed by the atoms on the faces of the cube:

$$(6 \text{ faces of a cube})(\tfrac{1}{2} \text{ of an atom within a unit cell}) = 3 \text{ net face-centered atoms within a face-centered cubic unit cell}$$

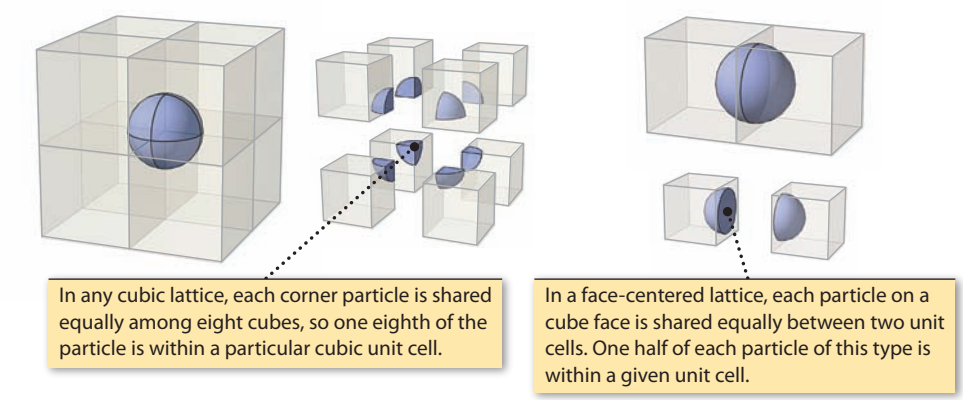

Figure 12.6 Atom sharing at cube corners and faces.

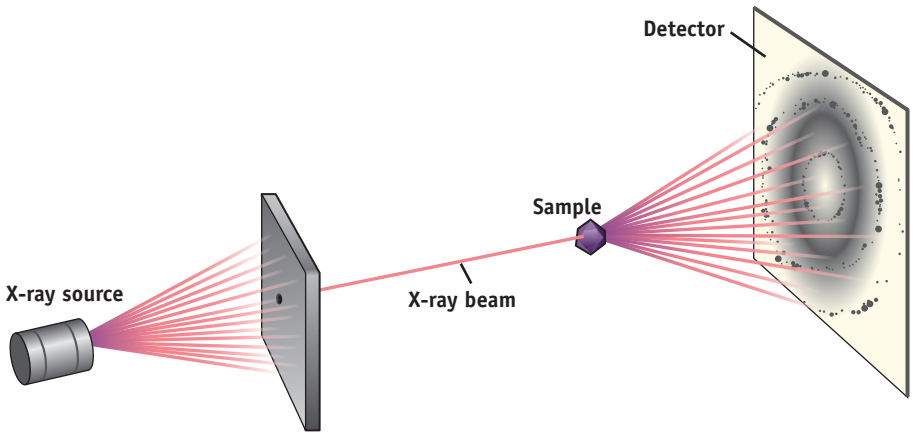

Figure 12.7 X-ray crystallography. In the x-ray diffraction experiment, a beam of x-rays is directed at a crystalline solid. The photons of the x-ray beam are scattered by the atoms of the solid. The pattern of scattered x-rays is recorded and related to the locations of the atoms or ions in the crystal.

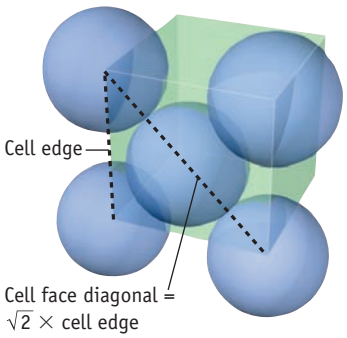
Thus, *the face-centered cubic arrangement has a net of four atoms within the unit cell,* one contributed by the corner atoms and three contributed by the atoms centered in the six faces.



An experimental technique, x-ray crystallography, can be used to determine the structure of a crystalline substance (Figure 12.7). Once the structure is known, the information can be combined with other experimental information to calculate such useful parameters as the radius of an atom or ion (Example 12.1).

EXAMPLE 12.1

Determining an Atom Radius from Lattice Dimensions

Problem Aluminum has a density of 2.699 g/cm^3, and the atoms are packed in a face-centered cubic crystal lattice. What is the radius of an aluminum atom (in picometers)?

What Do You Know? You know aluminum atoms are packed in a face-centered cubic unit cell, and, if you look carefully at such a cell, you would recognize the atoms in a fcc cell do not touch along the cell edges but do so in the faces (as illustrated below).

One face of a face-centered cubic unit cell.

This is important because, from geometry, you know the length of a cell edge and the cell diagonal distance are related by the Pythagorean theorem. That is, the diagonal distance is equal to the square root of 2 times the length of the cell edge.

Strategy Map 12.1

PROBLEM

What is the **radius** of **Al** in solid Al?

DATA/INFORMATION

- Al unit cell is **FCC** with $d = 2.699\ g/cm^3$
- Need Al ***atomic weight***
- Need ***Avogadro's number***

STEP 1. Calculate **mass** of unit cell (= 4 Al atoms).

Mass of Al atom, **mass** of unit cell

STEP 2. Calculate **volume** of unit cell from mass and density.

Volume of unit cell

STEP 3. Calculate **length** of unit cell ***edge*** from cell volume.

Length of unit cell edge

STEP 4. Relate **atom radius** to **unit cell edge length**.

Radius of atom

Strategy If you know the cell edge length, you can calculate the diagonal distance across a face, and the illustration above shows the atom radius is one fourth of this distance. So, the problem is to find the length of the cell edge. This dimension is the cube root of the cell volume, and you can find the volume from the density and mass of the unit cell. The density is given, and the mass of the cell is 4 times the mass of an atom. As described in Chapter 2, the mass of an Al atom can be found from its atomic mass and Avogadro's number. Therefore, you should proceed as follows:

1. Find the mass of a unit cell from the mass of an Al atom and knowing that there are 4 atoms in the fcc unit cell.
2. Determine the volume of the unit cell using the cell mass and the density of aluminum.
3. Find the length of a side of the unit cell from its volume.
4. Calculate the atom radius from the edge dimension.

SOLUTION

1. *Calculate the mass of the unit cell.*

$$\text{Mass of 1 Al atom} = \left(\frac{26.98\ \text{g}}{1\ \text{mol}}\right)\left(\frac{1\ \text{mol}}{6.022 \times 10^{23}\ \text{atoms}}\right) = 4.4802 \times 10^{-23}\ \text{g/atom}$$

$$\text{Mass of unit cell} = \left(\frac{4.4802 \times 10^{-23}\ \text{g}}{1\ \text{Al atom}}\right)\left(\frac{4\ \text{Al atoms}}{1\ \text{unit cell}}\right) = 1.7921 \times 10^{-22}\ \text{g/unit cell}$$

2. *Calculate the volume of the unit cell from the unit cell mass and density.*

$$\text{Volume of unit cell} = \left(\frac{1.7921 \times 10^{-22}\ \text{g}}{\text{unit cell}}\right)\left(\frac{1\ \text{cm}^3}{2.699\ \text{g}}\right) = 6.6399 \times 10^{-23}\ \text{cm}^3/\text{unit cell}$$

3. *Calculate the length of a unit cell edge.* The length of the unit cell edge is the cube root of the cell volume.

$$\text{Length of unit cell edge} = \sqrt[3]{6.6399 \times 10^{-23}\ \text{cm}^3} = 4.0494 \times 10^{-8}\ \text{cm}$$

4. *Calculate the atom radius.* As illustrated in the model above, the diagonal distance across the face of the cell is equal to four times the Al atom radius.

$$\text{Cell face diagonal} = 4 \times (\text{Al atom radius})$$

The cell diagonal is the hypotenuse of a right isosceles triangle, so, using the Pythagorean theorem,

$$(\text{Diagonal distance})^2 = 2 \times (\text{edge})^2$$

Taking the square root of both sides, we have

$$\begin{aligned}\text{Diagonal distance} &= \sqrt{2} \times (\text{cell edge}) \\ &= \sqrt{2} \times (4.0494 \times 10^{-8}\ \text{cm}) = 5.7267 \times 10^{-8}\ \text{cm}\end{aligned}$$

We divide the diagonal distance by 4 to obtain the Al atom radius in cm.

$$\text{Al atom radius} = \frac{5.7267 \times 10^{-8}\ \text{cm}}{4} = 1.4317 \times 10^{-8}\ \text{cm}$$

Atomic dimensions are often expressed in picometers, so we convert the radius to that unit.

$$1.4317 \times 10^{-8}\ \text{cm}\left(\frac{1\ \text{m}}{100\ \text{cm}}\right)\left(\frac{1\ \text{pm}}{1 \times 10^{-12}\ \text{m}}\right) = 143.2\ \text{pm}$$

Think about Your Answer This calculation illustrates one method by which the atomic radii of metals (given in Figure 7.11) were determined.

(a) *Determining an Atom Radius from Lattice Dimensions:* Gold has a face-centered unit cell, and its density is 19.32 g/cm^3. Calculate the radius of a gold atom.

(b) *The Structure of Solid Iron:* Iron has a density of 7.8740 g/cm^3, and the radius of an iron atom is 126 pm. Verify that solid iron has a body-centered cubic unit cell. (Be sure to note that the atoms in a body-centered cubic unit cell touch along the diagonal across the cell. They do not touch along the edges of the cell.) (*Hint:* The diagonal distance across the unit cell = edge $\times \sqrt{3}$.)

A CLOSER LOOK

Packing Oranges, Marbles, and Atoms

Have you ever tried to stack some oranges into a pile that doesn't fall over and that takes up as little space as possible? How did you do it? Clearly, the pyramid arrangement below on the right works, whereas the cubic one on the left is much less efficient.

Photos: © Cengage Learning/Charles D. Winters

Only 52% of the space is filled in the cubic packing arrangement. If you could stack oranges as a body-centered cube, that would be slightly better; 68% of the space is used. However, the best method is the pyramid stack, which is really a face-centered cubic arrangement. Oranges, marbles, or atoms packed this way occupy 74% of the available space.

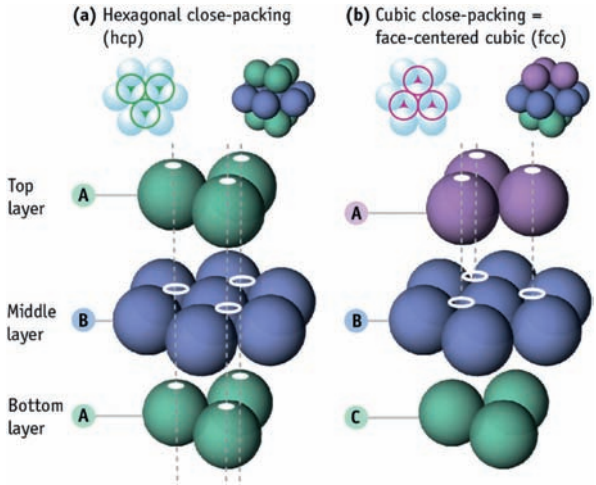
To fill three-dimensional space, the most efficient way to pack spherical objects like atoms or ions is to begin with a hexagonal arrangement of spheres, as in this arrangement of marbles.

© Cengage Learning/ Charles D. Winters

Succeeding layers of atoms (or ions) are then stacked one on top of the other in two different ways. Depending on the stacking pattern (Figure A), you will get either a **cubic close-packed (ccp)** or **hexagonal close-packed (hcp)** arrangement.

In the hcp arrangement, additional layers of particles are placed above and below a given layer, fitting into the same depressions on either side of the middle layer. In a three-dimensional crystal, the layers repeat their pattern in the manner ABABAB. . . . Atoms in each A layer are directly above the ones in another A layer; the same holds true for the B layers.

In the ccp arrangement, the atoms of the "top" layer (A) rest in depressions in the middle layer (B), and those of the "bottom" layer (C) are oriented opposite to those in the top layer. In a crystal, the pattern is repeated ABCABCABC. . . . By turning the whole crystal, you can see that the ccp arrangement is the face-centered cubic structure (Figure B).



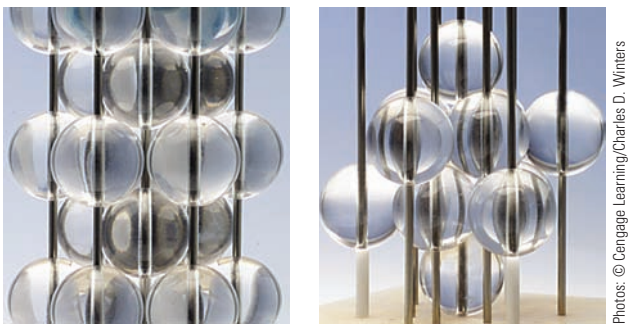


Figure A Efficient packing. The most efficient ways to pack atoms (or ions) in crystalline materials are hexagonal close-packing (hcp) and cubic close packing (ccp).

12.2 Structures and Formulas of Ionic Solids

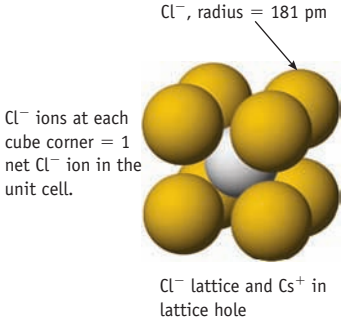
Goals for Section 12.2

- Understand the relationship of unit cell structure and formula for ionic compounds.
- Relate unit cell dimensions, ionic radii, and solid density.

The lattices of many ionic compounds are built by taking a primitive or face-centered cubic lattice of ions of one type and placing ions of opposite charge in the holes within the lattice. This produces a three-dimensional lattice of regularly placed ions of both kinds. The smallest repeating unit in these structures is, by definition, the unit cell for the ionic compound, and the contents of the cell reflects its formula.

The choice of the lattice and the number and location of the occupied holes in the lattice are the keys to understanding the relationship between the lattice structure and the formula of a salt.

Generally, ionic lattices are assembled by placing the larger ions at the lattice points and placing the smaller ions in the holes in the lattice. Consider, for example, the ionic compound cesium chloride, CsCl (Figure 12.8). The compound has a primitive cubic unit cell of chloride ions (one net Cl^-ion, Figure 12.6), and a cesium ion fits into a hole in the center of the cube.



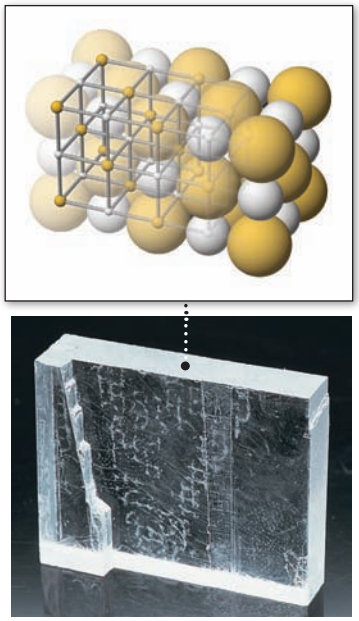


Figure 12.8 Cesium chloride (CsCl) unit cell. The unit cell of CsCl is a primitive cubic unit cell of Cl^- ions with a Cs^+ ion in the center of the unit cell.

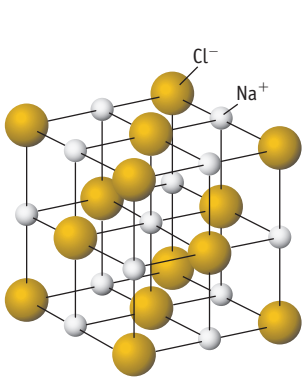

Next, look at the structure for NaCl. An extended view of the lattice and one unit cell are illustrated in Figures 12.9a and 12.9b, respectively. The Cl^- ions are arranged in a face-centered cubic unit cell, and the Na^+ ions are arranged in a regular manner between these ions. Notice that each Na^+ ion is surrounded by six Cl^- ions in an octahedral geometry. Thus, the Na^+ ions are said to be in **octahedral holes** (Figure 12.9c).

For NaCl a face-centered cubic lattice of Cl^- ions has a net of four Cl^- ions within the unit cell. There is one Na^+ ion in the center of the unit cell, contained totally within the unit cell. In addition, there are 12 Na^+ ions along the edges of the unit cell. Each of these Na^+ ions is shared among four unit cells, so each contributes

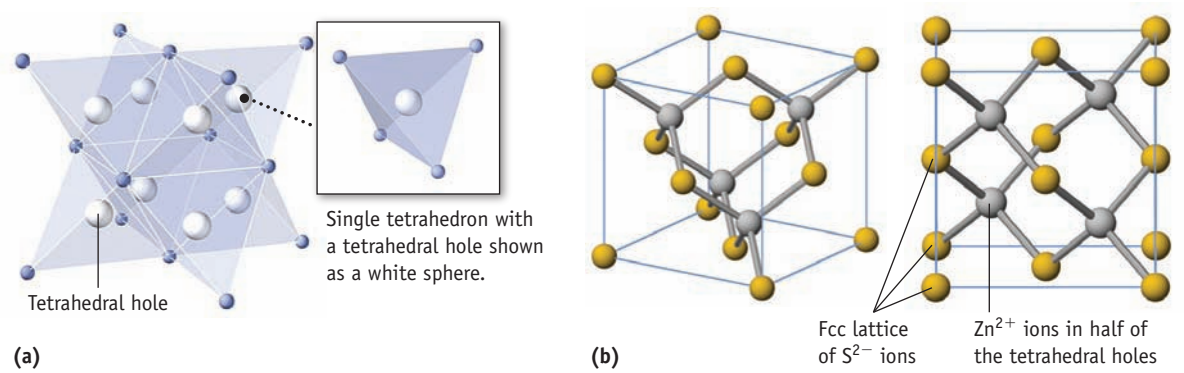

Figure 12.10 Tetrahedral holes and two views of the ZnS (zinc blende) unit cell. **(a)** The tetrahedral holes in a face-centered cubic lattice. **(b)** This unit cell is an example of a face-centered cubic lattice of ions of one type with ions of the opposite type in one half of the tetrahedral holes.

one fourth of an Na^+ ion to the unit cell, giving three additional Na^+ ions within the unit cell.

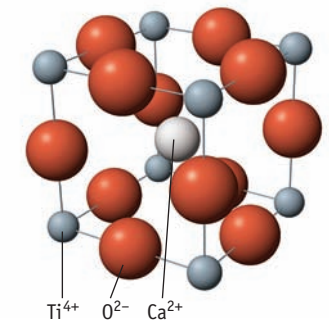
(1 Na^+ ion in the center of the unit cell) + ($\frac{1}{4}$ of a Na^+ ion in each edge $\times$ 12 edges) = net of 4 Na^+ ions in NaCl unit cell

This accounts for the fact that a unit cell of NaCl has a 1:1 ratio of Na^+ and Cl^- ions, as the formula requires.

Another common unit cell also has ions of one type in a face-centered cubic unit cell. However, ions of the other type are located in **tetrahedral holes**, wherein each ion is surrounded by four oppositely charged ions. As illustrated in Figure 12.10a, there are eight tetrahedral holes in a face-centered cubic unit cell. In ZnS (commonly called *zinc blende*), the sulfide ions (S^{2-}) form a face-centered cubic unit cell. The zinc ions (Zn^{2+}) occupy one half of the tetrahedral holes, and each Zn^{2+} ion is surrounded by four S^{2-} ions. The unit cell has four S^{2-} ions (making up the fcc lattice) and four Zn^{2+} ions contained wholly within the unit cell (in tetrahedral holes). This 1:1 ratio of ions matches the ratio in the formula.

In summary, compounds with the formula MX commonly form one of three possible crystal structures:

1. M^{n+} ions occupying the cubic hole in a primitive cubic X^{n-} lattice. Example: CsCl.
2. M^{n+} ions in all the octahedral holes in a face-centered cubic X^{n-} lattice. Example: NaCl.
3. M^{n+} ions occupying half of the tetrahedral holes in a face-centered cubic lattice of X^{n-} ions. Example: ZnS.



Chemists and geologists in particular have observed that the sodium chloride or "rock salt" structure is adopted by many ionic compounds: all the alkali metal halides (except CsCl, CsBr, and CsI), all the oxides and sulfides of the alkaline earth metals (such as CaO), and all the oxides of formula MO of the transition metals of the fourth period (for example, NiO).

EXAMPLE 12.2

Ionic Structure and Formula of Perovskite

Problem One unit cell of the common mineral perovskite is illustrated in the margin. This compound is composed of calcium and titanium cations and oxide anions. Based on the unit cell, what is the formula of perovskite?

What Do You Know? The cell is composed of the ions Ca^{2+}, Ti^{4+}, and O^{2-}. The Ca^{2+} ion is wholly within the cell, the Ti^{4+} ions are at the corners of the cell, and the O^{2-} ions are in the cell edges.

The unit cell of the mineral perovskite.

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Strategy Based on the locations of the ions, decide on the net number of ions of each kind within the cell.

SOLUTION

Number of Ca^{2+} ions:

One ion is in the cube center = 1 net Ca^{2+} ion

Number of Ti^{4+} ions:

(8 Ti^{4+} ions at cube corners) × ($\frac{1}{8}$ of each ion inside unit cell) = 1 net Ti^{4+} ion

Number of O^{2-} ions:

(12 O^{2-} ions in cube edges) × ($\frac{1}{4}$ of each ion inside unit cell) = 3 net O^{2-} ions

Thus, the formula of perovskite is $CaTiO_3$.

Think about Your Answer $CaTiO_3$ is a reasonable formula. One Ca^{2+} ion and three O^{2-} ions would require a titanium ion with a 4+ charge, a reasonable value because titanium is in Group 4B of the periodic table.

Check Your Understanding

If an ionic solid has an fcc lattice of anions (X) and *all* of the tetrahedral holes are occupied by metal cations (M), is the formula of the compound MX, MX_2, or M_2X?

EXAMPLE 12.3

The Relation of the Density of an Ionic Compound and Its Unit Cell Dimensions

Problem Magnesium oxide has a face-centered cubic unit cell of oxide ions with magnesium ions in octahedral holes. If the radius of Mg^{2+} is 79 pm and the density of MgO is 3.56 g/cm^3, what is the radius of an oxide ion?

What Do You Know? This is similar to Example 12.1 in that you want to find the size of one ion or atom in the cell. You are given the density of the compound and the fact that the unit cell is face-centered cubic. In addition, you know the radius of a Mg^{2+} ion.

Strategy Our strategy can be outlined as follows:

1. Calculate the mass of a unit cell:
   a) Use the atomic masses of Mg and O and Avogadro's number to calculate the mass of one formula unit of MgO.
   b) The unit cell is face-centered cubic. Because the lattice points are O^{2-} ions, this tells you there are 4 O^{2-} ions within the cell. There are Mg^{2+} ions in the octahedral holes, so you know there are also 4 Mg^{2+} ions within the cell. The mass of the unit cell is thus equal to that of 4 MgO units.
2. Calculate the volume of the unit cell from the unit cell mass and known density of MgO.
3. Calculate the length of one edge from the cell volume (length = volume$^{1/3}$).
4. Calculate the radius of the oxide ion.

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

SOLUTION

1. *Calculate the mass of the unit cell.* An ionic compound of formula MX (here MgO) and based on a face-centered cubic lattice of O^{2-} ions with Mg^{2+} ions in the octahedral holes has 4 MgO units per unit cell.

$$\text{Unit cell mass} = \left(\frac{40.304\ \text{g}}{1\ \text{mol MgO}}\right)\left(\frac{1\ \text{mol MgO}}{6.022 \times 10^{23}\ \text{units of MgO}}\right)\left(\frac{4\ \text{MgO units}}{1\ \text{unit cell}}\right)$$

$$= 2.6771 \times 10^{-22}\ \text{g/unit cell}$$

2. *Calculate the volume of the unit cell from the unit cell mass and density.*

$$\text{Unit cell volume} = \left(\frac{2.6671 \times 10^{-22}\ \text{g}}{\text{unit cell}}\right)\left(\frac{1\ \text{cm}^3}{3.56\ \text{g}}\right) = 7.520 \times 10^{-23}\ \text{cm}^3\text{/unit cell}$$

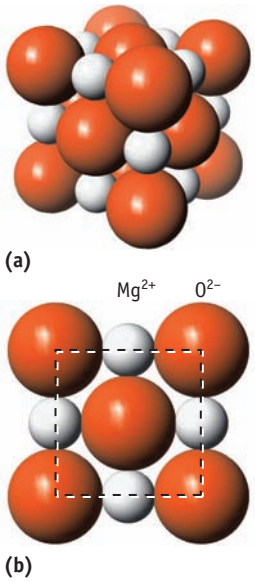
3. *Calculate the edge dimension of the unit cell in pm.*

$$\text{Unit cell edge} = \sqrt[3]{7.520 \times 10^{-23}\ \text{cm}^3} = 4.221 \times 10^{-8}\ \text{cm}$$

$$\text{Unit cell edge} = 4.221 \times 10^{-8}\ \text{cm}\left(\frac{1\ \text{m}}{100\ \text{cm}}\right)\left(\frac{1 \times 10^{12}\ \text{pm}}{1\ \text{m}}\right) = 422.1\ \text{pm}$$

4. *Calculate the oxide ion radius.*

One face of the MgO unit cell is shown in the margin. The O^{2-} ions define the lattice, and the Mg^{2+} and O^{2-} ions along the cell edge just touch one another. This means that one edge of the cell is equal to one O^{2-} radius (x) plus twice the Mg^{2+} radius plus one more O^{2-} radius.



$$\text{MgO unit cell edge} = x\ \text{pm} + 2(79\ \text{pm}) + x\ \text{pm} = 422.1\ \text{pm}$$

$$x = \text{oxide ion radius} = 132\ \text{pm}$$

Think about Your Answer Chemists often check the chemical literature to judge the reasonableness of an answer. The calculated result here is very close to the value in Figure 7.11 (140 pm).

Check Your Understanding

Potassium chloride has the same unit cell as NaCl. Using the ion sizes in Figure 7.11, calculate the density of KCl.

Magnesium oxide. (a) A unit cell of MgO showing oxide ions in a face-centered cubic lattice with Mg^{2+} ions in the octahedral holes. **(b)** One face of the cell.

12.3 Bonding in Ionic Compounds: Lattice Energy

Goal for Section 12.3

- Calculate the lattice enthalpy of an ionic solid and relate the magnitude of the lattice enthalpy to ion size and charge.

Ionic compounds typically have high melting points, an indication of the strength of the bonding in the ionic crystal lattice. A measure of that is the lattice energy.

Ionic compounds have positive and negative ions arranged in a three-dimensional lattice in which there are extensive attractions between ions of opposite charge and repulsions between ions of like charge. Each of these interactions is governed by an equation related to Coulomb's law (Equation 2.3). For example, $U_{\text{ion pair}}$, the energy of attractive interactions between a pair of ions, is given by

$$U_{\text{ion pair}} = C \times \frac{(n^+e)(n^-e)}{d}$$

Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

C is a constant that depends on the unit cell structure, d is the distance between the ion centers, and e is the charge on an electron. The term n^+e represents the charge on the cation in the ion pair, and the term n^-e is the charge on the negative ion. The important thing to notice about this equation is that *the energy depends directly on the charges on the ions and inversely on the distance between them*.

Because n^+e and n^-e have different signs, the energy calculated by this equation will have a negative value. That is, the energy of the system is *lowered* based on the attractive forces between the two particles. A similar equation (using n^+e and n^+e, or n^-e and n^-e) can be used to calculate the energy associated with the repulsion of two particles having similar charges. In this case the net energy is *higher* due to the repulsion of the two particles.

We can use information on the charges of the ions and their location in the lattice to calculate the energy of the system. Taking NaCl as an example (Figure 12.9), focus on the Na^+ ion in the center of the unit cell. We see it is surrounded by, and attracted to, six Cl^- ions. Just a bit farther away from the Na^+ ion, however, there are 12 Na^+ ions along the edges of the cubes, and there is a force of repulsion between the center Na^+ and these ions. And if we still focus on the Na^+ ion in the "center" of the unit cell, we see there are eight more Cl^- ions at the corners of the cube, and these are attracted to the center Na^+ ion. Taking into account *all* of the interactions between the ions in a lattice, it is possible to calculate the **lattice energy, $\Delta_{lattice}U$**, the energy of formation of one mole of a solid crystalline ionic compound when ions in the gas phase combine (Table 12.1). For sodium chloride, this reaction is

$$Na^+(g) + Cl^-(g) \rightarrow NaCl(s)$$

When dealing with ionic compounds chemists often use **lattice enthalpy, $\Delta_{lattice}H$**. The same trends are seen in both lattice energy and enthalpy, and, because we are dealing with a condensed phase, the numerical values are nearly the same.

We shall focus here on the dependence of lattice enthalpy on ion charges and sizes. As given by Coulomb's law, the higher the ion charges, the greater the attraction between oppositely charged ions, so $\Delta_{lattice}H$ has a larger negative value for more highly charged ions. This is illustrated by the lattice enthalpies of MgO and NaF. The value of $\Delta_{lattice}H$ for MgO (-4050 kJ/mol) is about four times more negative than the value for NaF (-926 kJ/mol) because the charges on the Mg^{2+} and O^{2-} ions $[(2+) \times (2-)]$ are twice as large as those on Na^+ and F^- ions.

Because the attraction between ions is inversely proportional to the distance between them, the effect of ion size on lattice enthalpy is also predictable: A lattice built from smaller ions generally leads to a more negative value for the lattice enthalpy (Table 12.1 and Figure 12.11). For alkali metal halides, for example, the lattice enthalpy for lithium compounds is more negative than that for potassium compounds because the Li^+ ion is much smaller than the K^+ cation. Similarly, lattice enthalpies of fluorides are more negative than those for iodides with the same cation.

TABLE 12.1

Lattice Energies of Some Ionic Compounds

Compound	$\Delta_{lattice}U$ (kJ/mol)
LiF	−1037

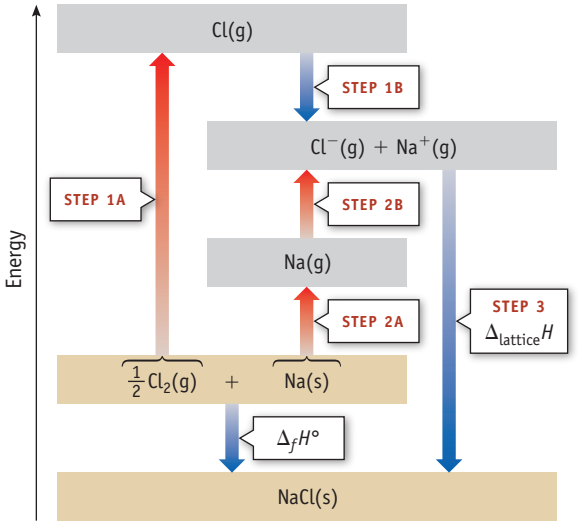

Figure 12.12 Born–Haber cycle for the formation of NaCl(s) from the elements. The calculation in the text uses enthalpy values, and the value obtained is the lattice enthalpy, $\Delta_{lattice}H$. The difference between $\Delta_{lattice}U$ and $\Delta_{lattice}H$ is generally small and can be corrected for, if desired. (Note that the energy diagram is not to scale.)

Calculation of lattice energies by this procedure (a Born–Haber cycle) is named for Max Born (1882–1970) and Fritz Haber (1868–1934), German scientists who played prominent roles in thermodynamic research.

Calculating a Lattice Enthalpy from Thermodynamic Data

Lattice enthalpies can be calculated from other thermodynamic data using a **Born–Haber cycle**, an application of Hess's law (Section 5.7). The energy level diagram in Figure 12.12 shows the enthalpy terms involved in this calculation. Recall that the enthalpy change involved along one path from reactants to products is the same as the sum of enthalpy changes along another path. Let us use as an example the calculation of the lattice enthalpy for NaCl(s), for which the enthalpy of formation is known.

$$Na(s) + 1/2\ Cl_2(g) \rightarrow NaCl(s) \qquad \Delta_f H^\circ\ [NaCl(s)] = -411.12\ kJ/mol$$

The pathway illustrated in Figure 12.12 for sodium chloride involves five steps. In Step 1A Cl_2 molecules are converted to Cl atoms, and in Step 2A solid sodium is vaporized to Na atoms in the gas phase. In Step 1B the Cl atoms form $Cl^-(g)$ ions, and in Step 2B the Na atoms form $Na^+(g)$ ions. With the ions having been formed, they combine to form solid NaCl. The enthalpy of each of these steps is known, except for Step 3, $\Delta_{lattice}H$, the objective of the calculation.

Step 1A	$1/2\ Cl_2(g) \rightarrow Cl(g)$	$\Delta H^\circ_{1A} = +121.3$ kJ/mol (Enthalpy of dissociation, Appendix L)
Step 2A	$Na(s) \rightarrow Na(g)$	$\Delta H^\circ_{2A} = +107.3$ kJ/mol (Enthalpy of formation, Appendix L)
Step 1B	$Cl(g) + e^- \rightarrow Cl^-(g)$	$\Delta H^\circ_{1B} = -349$ kJ/mol (Electron attachment enthalpy, Appendix F)
Step 2B	$Na(g) \rightarrow Na^+(g) + e^-$	$\Delta H^\circ_{2B} = +496$ kJ/mol) (Enthalpy of ionization, Appendix F)
Step 3	$Na^+(g) + Cl^-(g) \rightarrow NaCl(s)$	$\Delta_{lattice}H = ?$
	$Na(s) + 1/2\ Cl_2(g) \rightarrow NaCl(s)$	$\Delta_f H^\circ[NaCl(s)] = -411.12$ kJ/mol (Enthalpy of formation, Appendix L)

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Notice that the chemical equations along one pathway—Steps 1A, 1B, 2A, 2B, and 3—add up to the equation for formation of NaCl(s) from the elements, and the enthalpy changes for those steps add up to the enthalpy of formation of NaCl(s).

$$\Delta_f H^\circ\ [\mathrm{NaCl(s)}] = \Delta H_{\text{Step 1A}} + \Delta H_{\text{Step 1B}} + \Delta H_{\text{Step 2A}} + \Delta H_{\text{Step 2B}} + \Delta H_{\text{Step 3}}$$

Using the known enthalpy change values for each step, the value for $\Delta H_{\text{Step 3}}$ ($\Delta_{\text{lattice}} H$) is found to be −787 kJ/mol, in good agreement with the value in Table 12.1.

12.4 Bonding in Metals and Semiconductors

Goals for Section 12.4

- Understand the electron sea and band theories of metals and how these theories are used to explain the properties of metals.
- Understand the nature of semiconductors.

Bonding in Metals: The Electron Sea Model

We have described the solid-state structures of metals as regular lattices of atoms. The fact that most metals have high melting and boiling points tells us that the forces of attraction between atoms in the lattice, that is, the bonding between metal atoms, must be very strong.

The classical picture of bonding in metals is the *electron sea model*. This is a qualitative model in which metal ions formed by the loss of one or more valence electrons are arranged in their lattice positions. The electrons from ionization of the metal atoms make up an "electron sea" surrounding the metal ions (Figure 12.13). The "bond" between particles in this model is associated with the coulombic forces of attraction between the electrons and the positively charged metal ions.

The significant feature of this model is that the electrons are not associated with the individual metal ions and are free to move throughout the lattice. In other types of bonding, the bonding electrons are more localized. In covalent bonds, bonding electrons are placed between atoms. In ionic bonding, the electrons are firmly attached in the individual ions. With both ionic and covalent bonding, a significant expenditure of energy would accompany changes in the electronic structure. The high electrical conductivity of metals arises because the electrons are free to move throughout the lattice under the influence of an applied electric potential; there is no large energy barrier to the movement of the electrons.

Thermal conductivity is also a direct consequence of electron mobility, which allows rapid dispersion of heat within a sample of metal. Malleability and ductility (characteristics in which metals can be pounded into sheets or drawn into wires) are facilitated because moving metal ions in the lattice in these processes doesn't require breaking chemical bonds.

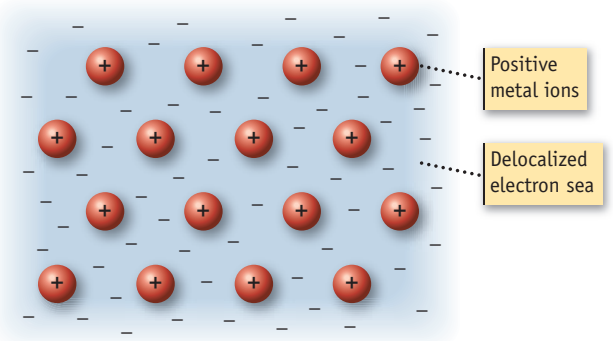

Figure 12.13 Electron Sea Model for Metal Bonding. Coulombic forces of attraction exist between metal ions and delocalized electrons.

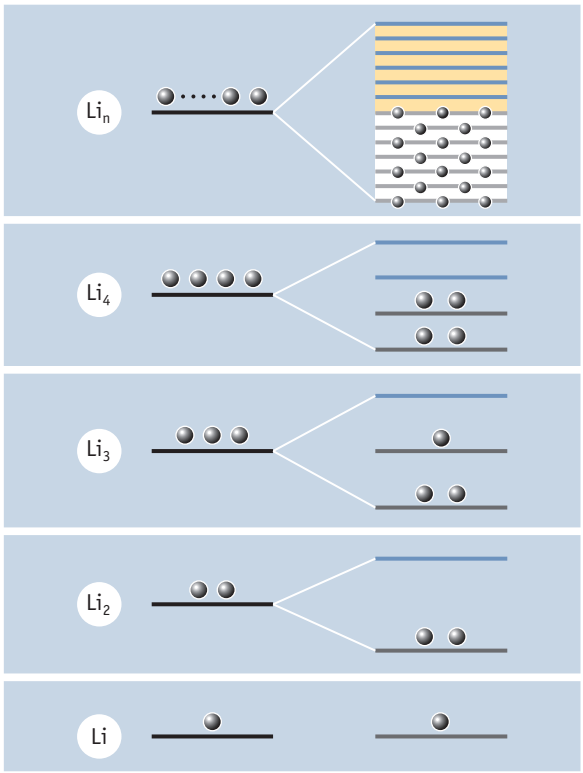

Figure 12.14 Bands of molecular orbitals in a lithium crystal. Here, the 2*s* valence orbitals of Li atoms are combined to form molecular orbitals. As more atoms with the same valence orbitals are added, the number of molecular orbitals grows until the orbitals are so close in energy that they merge into a band of molecular orbitals. If 1 mol of Li atoms, each with its 2*s* valence orbital, is combined, 6×10^{23} molecular orbitals are formed. However, only 1 mol of electrons, or 3×10^{23} electron pairs, is available, so only half of these molecular orbitals are filled. (See Section 9.2 for the discussion of molecular orbital theory.)

Bonding in Metals: Band Theory

Molecular orbital theory (Chapter 9) was used to rationalize covalent bonding in molecules, and the **band theory** model of metallic bonding is an extension of MO theory. Band theory simply views a metal as a "supermolecule" with an enormous number of atoms.

Even a tiny piece of metal contains a very large number of atoms and an even larger number of valence orbitals. In 1 mol of lithium atoms, for example, there are 6×10^{23} atoms. Considering only the 2*s* valence orbitals of lithium, there are 6×10^{23} atomic orbitals, from which 6×10^{23} molecular orbitals can be created. (Recall that the total number of molecular orbitals is equal to the total number of atomic orbitals contributed by the combining atoms; Section 9.2.) The molecular orbitals that we envision in lithium, or for any metal, will span all the atoms in the crystalline solid. A mole of lithium has 1 mol of valence electrons, and these electrons occupy the lower-energy bonding orbitals. The bonding is described as *delocalized* because the electrons are associated with all the atoms in the crystal and not with a specific bond between two atoms.

An energy level diagram for a metal shows the bonding and antibonding molecular orbitals blending together into a band of molecular orbitals (Figure 12.14), with the individual MOs being so close together in energy that they are not distinguishable. Each molecular orbital can accommodate two electrons of opposite spin.

In metals, there are not enough electrons to fill all of the molecular orbitals. In 1 mol of Al atoms, for example, 18×10^{23} 3*s* and 3*p* electrons, or 9×10^{23} electron pairs, are sufficient to fill only a portion of the 24×10^{23} molecular orbitals created by the 3*s* and 3*p* orbitals of the Al atoms. Many more orbitals are available than electron pairs to occupy them.

At 0 K, the electrons in any metal will all be in orbitals with the lowest possible energy, resulting in the lowest possible energy for the system. The highest filled level at 0 K is called the **Fermi level** (Figure 12.15).

In metals at temperatures above 0 K, thermal energy will cause some electrons to occupy orbitals above the Fermi level. Even a small input of energy (for example, raising the temperature a few degrees above 0 K) will cause electrons to move from filled orbitals to higher-energy orbitals. For each electron promoted, two singly occupied levels result: a negative electron in an orbital above the Fermi level and a positive "hole"—from the absence of an electron—in an orbital below the Fermi level.

The positive holes and negative electrons in a piece of metal account for its electrical conductivity. Electrical conductivity arises from the movement of electrons and holes in singly occupied states in the presence of an applied electric field. When an electric field is applied to the metal, negative electrons move toward the positive side, and the positive "holes" move to the negative side. (Positive holes "move" because an electron from an adjacent atom can move into the hole, thereby creating a new "hole.")

Figure 12.16 Electronic devices all made from semiconductors. (top) Computer chips. (left) LED lights. (right) Transistors.

The band of energy levels in a metal is essentially continuous, that is, the energy gaps between levels are extremely small. A consequence of this is that a metal can absorb energy of nearly any wavelength, causing an electron to move to a higher energy state. The now-excited system can immediately emit a photon of the same energy as the electron returns to the original energy level. This rapid and efficient absorption *and* reemission of light are the reason polished metal surfaces are reflective and appear lustrous (shiny).

Semiconductors

Semiconducting materials are at the heart of solid-state electronic devices such as computer chips and light-emitting diodes (LEDs) (Figure 12.16). Semiconductors do not conduct electricity easily but can be encouraged to do so by the input of energy. This property allows devices made from semiconductors to essentially have "on" and "off" states, which form the basis of the binary logic used in computers. We can understand how semiconductors function by looking at their electronic structure, following the band theory approach used for metals.

Figure 12.17 The structure of diamond, an insulator. The structures of silicon and germanium, semiconductors, are similar in that each atom is bound tetrahedrally to four others.

Bonding in Semiconductors: The Band Gap

The Group 4A elements carbon (an insulator, in the diamond form), silicon, and germanium (semiconductors) have similar structures. Each atom is surrounded by four other atoms at the corners of a tetrahedron (Figure 12.17). Typically, we would represent the bonding in these elements using a localized bond model. However, the band model for bonding can also be used to explain the conductivity of these elements. In the band model, the valence orbitals (the *ns* and *np* orbitals) of each atom are combined to form molecular orbitals that are delocalized over the solid. However, unlike metals where there is one continuous band of molecular orbitals, in semiconductors there are two distinct bands, a lower-energy *valence band* and a higher-energy *conduction band*, separated by a *band gap* [Figure 12.15, *right*, and Figure 12.18]. In the Group 4A elements, the orbitals of the valence band are completely filled and the conduction band is empty. The band gap is an energy barrier to the promotion of electrons from the valence band to the higher-energy conduction band.

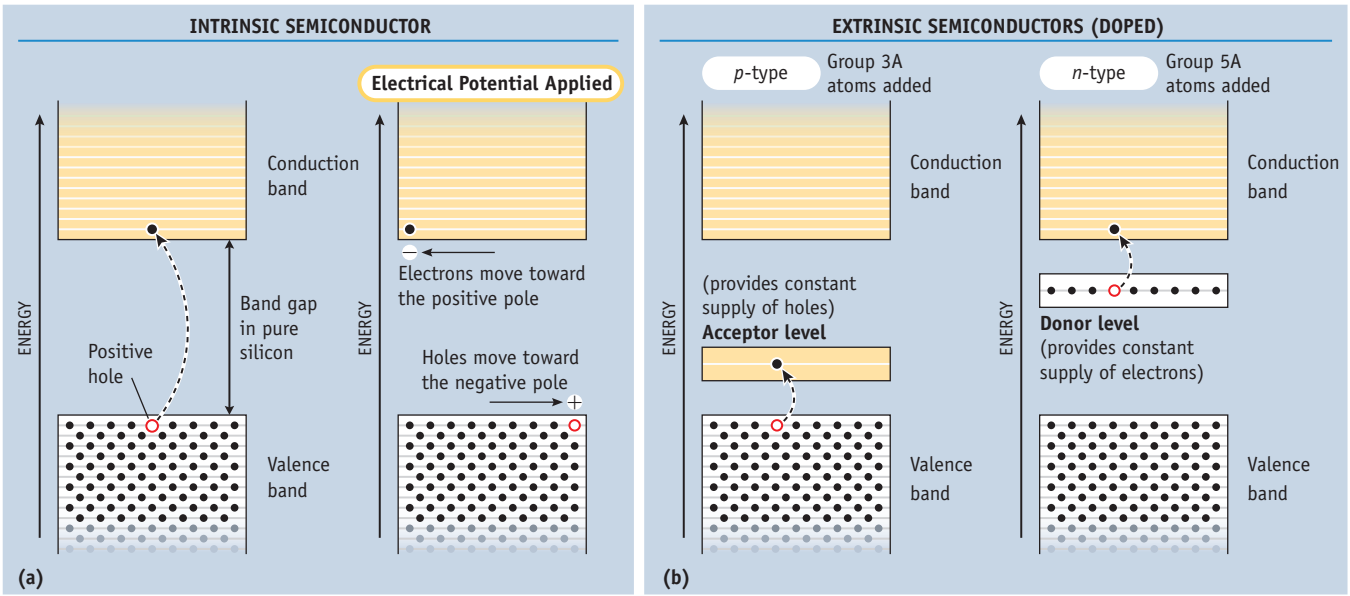

Figure 12.18 Intrinsic (a) and extrinsic (b) semiconductors.

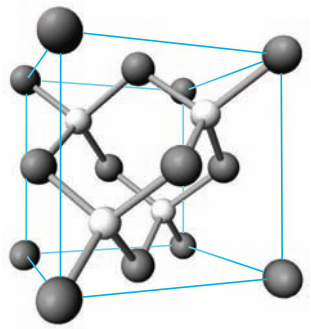
The band gap in diamond is 580 kJ/mol—so large that electrons are trapped in the filled valence band and cannot make the transition to the conduction band, even at elevated temperatures. Thus, it is not possible to create positive "holes," and diamond is an insulator, a nonconductor.

Silicon and germanium have much smaller band gaps, 106 kJ/mol for silicon and 68 kJ/mol for germanium. As a result they are semiconductors. These elements can conduct a small current because thermal energy is sufficient to promote a few electrons from the valence band across the band gap to the conduction band (Figure 12.18). Conduction then occurs when the electrons in the conduction band migrate in one direction and the positive holes in the valence band migrate in the opposite direction under an applied electric potential.



Pure silicon and germanium are called **intrinsic semiconductors**, with the name referring to the fact that this is an intrinsic or naturally occurring property of the pure material (Figure 12.18a). In intrinsic semiconductors, the number of electrons in the conduction band is determined by the temperature and the magnitude of the band gap. The smaller the band gap, the smaller the energy required to promote a significant number of electrons. As the temperature increases, more electrons are promoted into the conduction band, and a higher conductivity results.

There are also **extrinsic semiconductors**. The conductivity of these materials is controlled by adding small numbers of different atoms (typically about 1 atom per 10^6 other atoms) called *dopants* (Figure 12.18b). This means the characteristics of semiconductors can be changed by altering their chemical makeup.

Suppose a few silicon atoms in the silicon lattice are replaced by aluminum atoms (or atoms of some other Group 3A element). Aluminum has only three valence electrons, whereas silicon has four. Four Si-Al bonds are created per aluminum atom in the lattice, but these bonds must be deficient in electrons. According to band theory, the Si-Al bonds form a discrete but empty band at an energy level higher than the valence band but lower than the conduction band. This level is referred to as an *acceptor level* because it can accept electrons from the valence band. The gap between the valence band and the acceptor level is usually quite small, so electrons can be promoted readily to the acceptor level. The positive holes created in the valence band are able to move under the influence of an electric potential, so current results from the hole mobility. Because *positive* holes are created in an aluminum-doped semiconductor, this is called a **p-type semiconductor** (Figure 12.18b, *left*).

Gallium arsenide, GaAs. The unit cell of GaAs has As atoms in an fcc lattice with Ga atoms in tetrahedral holes. It is an important semiconductor used in infrared emitting diodes, laser diodes, and solar cells.

Now suppose phosphorus atoms (or atoms of some other Group 5A element such as arsenic) are incorporated into the silicon lattice instead of aluminum atoms. This material is also a semiconductor, but it now has extra electrons because each phosphorus atom has one more valence electron than the silicon atom it replaces in the lattice. Semiconductors doped in this manner have a discrete, partially filled donor level that resides just below the conduction band. Electrons can be promoted to the conduction band from this donor band, and electrons in the conduction band carry the charge. Such a material, consisting of *negative* charge carriers, is called an ***n*-type semiconductor** (Figure 12.18b, *right*).

One group of materials that have desirable semiconducting properties is the III-V semiconductors, so called because they are formed by combining elements from Group 3A (such as Ga and In) with elements from Group 5A (such as As or Sb).

Gallium arsenide, GaAs, is a common semiconducting material that has electrical conductivity properties that are sometimes preferable to those of pure silicon or germanium. The crystal structure of GaAs is similar to that of diamond and silicon; each Ga atom is tetrahedrally coordinated to four As atoms, and vice versa.

It is also possible for Group 2B and 6A elements to form semiconducting compounds such as cadmium sulfide, CdS. The farther apart the elements are found in the periodic table, however, the more ionic the bonding becomes. As the ionic character of the bonding increases, the band gap will increase, and the material will become a weaker semiconductor. Thus, the band gap in CdS is 232 kJ/mol, compared to a band gap in GaAs of 140 kJ/mol.

These materials can also be modified by substituting other atoms into the structure. For example, in one widely used semiconductor, aluminum atoms are substituted for gallium atoms in GaAs, giving materials with a range of compositions ($Ga_{1-x}Al_xAs$). The importance of this modification is that the band gap depends on the relative proportions of the elements, so it is possible to control the size of the band gap by adjusting the composition. As Al atoms are substituted for Ga atoms, for example, the band gap energy increases.

12.5 Other Types of Solid Materials

Goal for Section 12.5

- Characterize the different types of solids.

So far, we have described the structures of metals and simple ionic solids. Now we turn briefly to the other categories of solids: molecular solids, network solids, amorphous solids, and alloys (Table 12.2).

Molecular Solids

Compounds such as H_2O and CO_2 exist as solids under appropriate conditions. In these cases, it is molecules, rather than atoms or ions, that pack in a regular fashion in a three-dimensional lattice. You have already seen an example of a molecular solid: ice (Figure 11.5).

The way molecules are arranged in a crystalline lattice depends on the shape of the molecules and the types of intermolecular forces. Molecules tend to pack in the most efficient manner and to align in ways that maximize intermolecular forces of attraction. Thus, the water structure was established to gain the maximum intermolecular attraction through hydrogen bonding.

Most of the information on molecular geometries, bond lengths, and bond angles discussed in Chapter 8 came from studies of the structures of molecular solids.

TABLE 12.2 Structures and Properties of Various Types of Solid Substances

Type	Examples	Structural Units	Forces Holding Units Together	Typical Properties
Ionic	NaCl, K_2SO_4, $CaCl_2$, $(NH_4)_3PO_4$	Positive and negative ions; no discrete molecules	Ionic; attractions among charges on positive and negative ions	Hard; brittle; high melting point; poor electric conductivity as solid, good as liquid; often water-soluble
Metallic	Iron, silver, copper, other metals	Metal atoms (positive metal ions with delocalized electrons)	Metallic; electrostatic attraction among metal ions and electrons	Malleable; ductile; good electric conductivity in solid and liquid; good heat conductivity; wide range of hardness and melting points
Molecular	H_2, O_2, I_2, H_2O, CO_2, CH_4, CH_3OH, CH_3CO_2H	Molecules	London dispersion forces, dipole–dipole forces, hydrogen bonds	Low to moderate melting points and boiling points; soft; poor electric conductivity in solid and liquid
Network	Graphite, diamond, quartz, feldspars, mica	Atoms held in an extended two- or three-dimensional network	Covalent; directional electron-pair bonds	Wide range of hardness and melting points (three-dimensional bonding > two-dimensional bonding); poor electric conductivity, with some exceptions
Amorphous	Glass, polyethylene, nylon	Covalently bonded networks with no long-range regularity	Covalent; directional electron-pair bonds	Noncrystalline; wide temperature range for melting; poor electric conductivity, with some exceptions
Alloy	Sterling silver, bronze, brass	Lattice of metal atoms with other metal atoms in the lattice (interstitial or substitutional)	Metallic	Wide range of physical and electrical properties. Can be homogeneous or heterogeneous mixtures or intermetallic compounds.

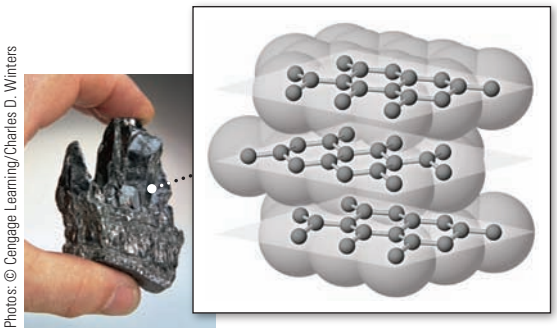
Network Solids

Network solids are composed entirely of a three-dimensional array of covalently bonded atoms. Common examples include allotropes of carbon: graphite, graphene, and diamond. Elemental silicon is also a network solid with a diamond-like structure.

Graphite consists of carbon atoms bonded together in flat sheets that cling only weakly to one another (Figure 12.19). Within the layers, each carbon atom is surrounded by three other carbon atoms in a trigonal–planar arrangement. The layers can slip easily over one another, which explains why graphite is soft, a good lubricant, and used in pencil lead. (Pencil "lead" is not the element lead but rather a composite of clay and graphite.)

As described in more detail in *Applying Chemical Principles 12.2 Nanotubes and Graphene, The Hottest New Network Solids* (page 554) the past two decades have seen the discovery of materials such as carbon nanotubes and graphene. Both are the subject of extensive research and development and both have commercial potential.

Diamond, which has a relatively low density (d = 3.51 g/cm^3), is the hardest material and the best conductor of heat known. It is transparent to visible light, as well as to infrared and ultraviolet radiation. In addition to its use in jewelry, diamond is used in abrasives and in diamond-coated cutting tools. In the structure of diamond (Figure 12.17), each carbon atom is bonded to four other carbon atoms at the corners of a tetrahedron, and this pattern extends throughout the solid.



Silicates, compounds composed of silicon and oxygen, are also network solids and make up an enormous class of chemical compounds. You know them in the form of sand, quartz, talc, and mica, or as a major constituent of rocks such as granite. The beautiful mineral jade is based on a network of SiO_4 tetrahedra, and quartz is also a network solid (Figure 12.19) consisting of tetrahedral silicon atoms covalently bonded to oxygen atoms in a giant three-dimensional lattice.

Jade, a network solid. This jade, from New Zealand, consists of chains and sheets of linked SiO_4^{4-} tetrahedra along with ions such as Fe^{2+}. This particular sample is the nephrite form of jade, with the formula $Ca_2(MgFe)_5(SiO_4)_2(OH)_2$.

Graphite, layers of six-member rings of carbon atoms.

Silicon dioxide, SiO_2. Common quartz is a network of linked SiO_4 tetrahedra.

Figure 12.19 Network solids: graphite and quartz are among many examples.

Most network solids are hard and rigid and are characterized by high melting and boiling points. These characteristics reflect the fact that a great deal of energy must be provided to break the covalent bonds in the lattice. For example, silicon dioxide melts at temperatures higher than 1700 °C.

Amorphous Solids

A characteristic property of pure crystalline solids—whether metals, ionic solids, or molecular solids—is that they melt at a specific temperature. For example, water in the form of ice melts at 0 °C, aspirin at 135 °C, lead at 327.5 °C, and NaCl at 801 °C. Because pure solids have specific and reproducible values, their melting points are often used to identify chemical compounds.

Another property of crystalline solids is that they form well-defined crystals, with smooth, flat faces. When a sharp force is applied to a crystal, it will most often cleave to give smaller pieces with smooth, flat faces. The resulting solid particles are smaller versions of the original crystal (Figure 12.20a).

Many common solids, including ones that we encounter every day, do not have these properties, however. These are *amorphous solids*, solids that do not have a regular structure. Glass is a good example. When glass is heated, it softens over a wide

Figure 12.20 Crystalline and amorphous solids.

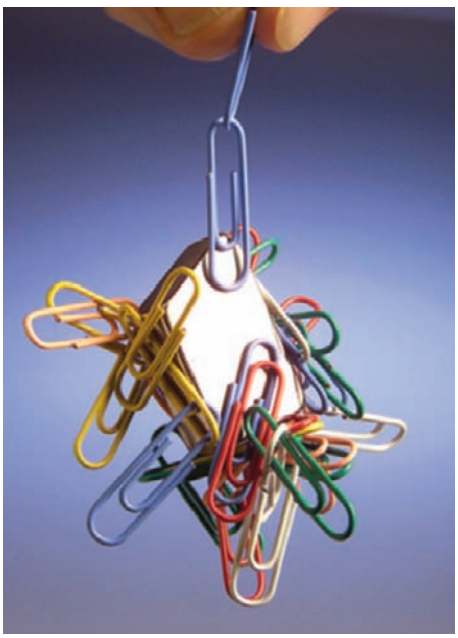
temperature range, a property useful for artisans and craftsmen who can create beautiful and functional products for our enjoyment and use. Glass also possesses a property that we would rather it not have: When glass breaks, it leaves randomly shaped pieces (Figure 12.20b). Other amorphous solids that behave similarly include common polymers such as polyethylene terephthalate (PET), nylon, and other plastics.

Alloys: Mixtures of Metals

Pure metals often do not have the ideal properties needed for many typical uses. Mixing one or more elements with metals to form alloys is done with the aim of improving the properties of the metal but still retaining the characteristics of a metal. There are many familiar examples in everyday life: bronze, brass, stainless steel, and pewter, to name a few.

Alloys are among the earliest materials made by humans. The Bronze Age, dating back to around 3300 BC, is well established in history, and the use of this alloy of copper (88%) and tin (12%) for tools and decorations is well known. Bronze was favored over copper because it was harder and stronger than pure copper. Gold amalgams (liquid mixtures of mercury and gold) have been used for centuries to gild the surface of an object. The object's surface was first coated with a gold amalgam; when heated, the mercury vaporized and left a surface coating of gold (Figure 12.21a).



In fact, most "metals" we use are alloys. Iron in its various forms is an alloy of this element with small amounts of carbon and other elements. Stainless steel, made from iron, chromium, and several other elements, is much more corrosion resistant than iron, and aluminum used in the aerospace industry contains about 5% magnesium to improve its hardness.

Some magnets now widely used in hard disc drives and small motors are an alloy based on neodymium, with a composition $Nd_2Fe_{14}B$. You may have seen them in toy stores or novelty shops (Figure 12.21b).

John C. Kotz

(a) The dome of Saint Issac's Cathedral in St. Petersburg (Russia) was coated with gold by making an amalgam of gold (with mercury). The mercury was then evaporated, leaving the gold. It is said that the fumes from the mercury resulted in the death of 60 workers.

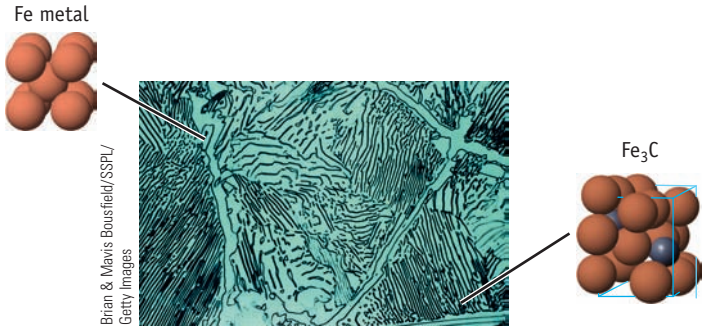
Figure 12.22
Homogeneous alloys.

Substitutional alloy
14-karat gold

(a) The solute atoms can substitute for one of the lattice atoms.

Interstitial alloy
Steel

(b) The solute atoms may be interstitial atoms, fitting into holes in the crystal lattice.



Sterling silver, commonly used in jewelry and which one might mistakenly think of as pure silver, is an alloy composed of 92.5% Ag and 7.5% Cu. Pure silver is soft and easily damaged, and the addition of copper makes the metal more rigid. You can confirm that an article of jewelry is sterling silver by looking for the stamp that says either "sterling" or "925," which means 92.5% silver.

Gold used in jewelry is rarely pure (24 karat) gold. More often, you will find 18 K, 14 K, or 9 K stamped in a gold object, referring to alloys that are 18/24, 14/24, or 9/24 gold. The 18 K "yellow" gold is 75% gold, and the remaining 25% is copper and silver. As with sterling silver, the added metals lead to a harder and more rigid material (and one that is less costly).

There are three general classes of alloys: homogeneous alloys (substitutional or interstitial alloys), heterogeneous alloys, and intermetallic compounds. In solid solutions (homogeneous alloys), the element in larger amount is usually considered the "solvent" and the other the "solute." As with solutions in liquids, the solute atoms in a solid are dispersed throughout the solvent such that the bulk structure is homogeneous. Unlike liquid solutions, however, there are limitations based on the sizes of solvent and solute atoms. For a solid solution to form, the solute atoms must be incorporated in such a way that the original crystal structure of the solvent metal is preserved. This can be achieved in two ways (Figure 12.22). In interstitial alloys, the solute atoms occupy the interstices, the small holes in the crystal lattice between solvent atoms. The solute atoms must be substantially smaller than the metal atoms making up the lattice to fit into these positions. In substitutional alloys, the solute atoms replace solvent atoms in the original crystal structure. For this to occur, the solute and solvent atoms must be similar in size.

If the size constraints are not met, then a mixture of the two component elements will likely be a heterogeneous alloy. If such a mixture is viewed under a microscope, regions of different composition and crystal structure are seen (Figure 12.23).

Figure 12.23 Heterogeneous alloy. The alloy pearlite consists of regions of body-centered cubic iron and other regions of cementite, Fe_3C.

Intermetallic alloys are actually compounds rather than mixtures (Figure 12.24). They have a definite stoichiometry and formula, and the atoms are ordered rather than random. This ordering often leads to alloys having higher melting points and better structural stability.

Examples of intermetallic compounds include Ni_3Al, Nb_3Sn, $SmCo_5$, Mg_2Pb, and $AuCu_3$. In general, intermetallic compounds are likely to form if there is a substantial difference in the electronegativity of the two elements. In Mg_2Pb, for example, the electronegativities of Mg and Pb are 1.3 and 2.3, respectively.

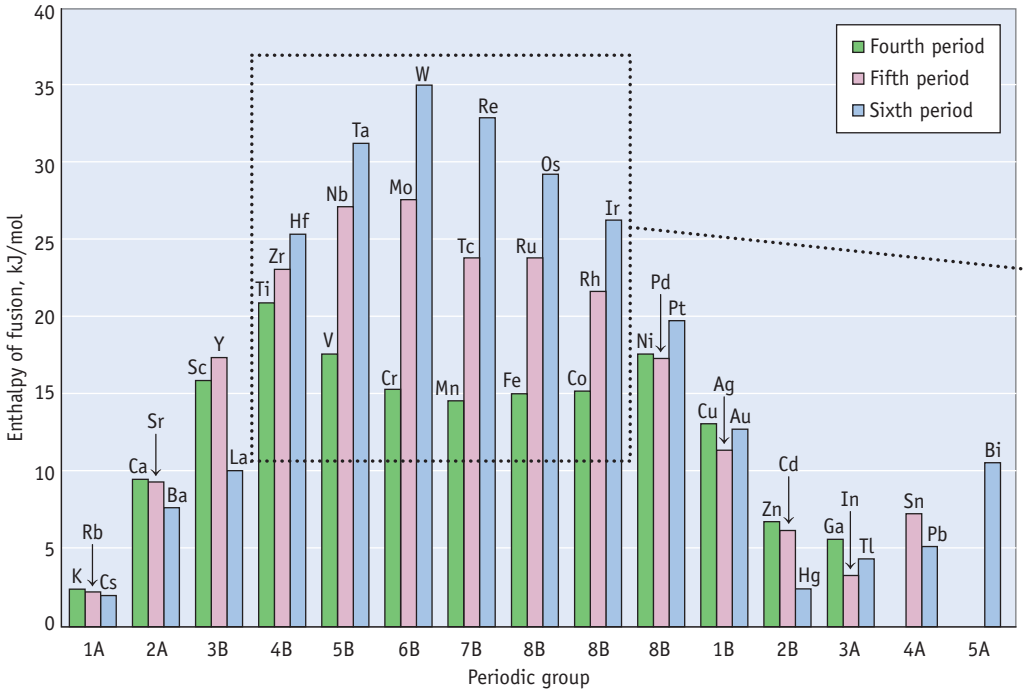
Ni_3Al

Figure 12.24 An intermetallic alloy. This alloy is a major component of jet engines owing to its low density and strength at high temperatures.

12.6 Phase Changes

Goals for Section 12.6

- Identify the significant points and regions of phase diagrams and use the diagrams to evaluate the vapor pressure of a liquid and the relative densities of liquid and solid phases.
- Sketch a phase diagram from information about a substance.
- Relate the processes of melting and sublimation and the associated enthalpy changes.



Melting: Conversion of Solid into Liquid

The melting point of a solid is the temperature at which the lattice collapses and the solid is converted into a liquid. Like any phase change, melting involves an energy change, called the *enthalpy of fusion* (given in kilojoules per mole) (see Chapter 5).

Energy absorbed as heat on melting = enthalpy of fusion = $\Delta_{fusion}H$ (kJ/mol)

Energy evolved as heat on freezing = enthalpy of crystallization = $-\Delta_{fusion}H$ (kJ/mol)

Enthalpies of fusion have a very wide range of values (Table 12.3). A low melting temperature will certainly mean a low value for the enthalpy of fusion, whereas high melting points are associated with high enthalpies of fusion. Figure 12.25

Enthalpies of fusion increase significantly for group 4B–8B metals on descending the periodic table. These elements have especially high melting points.

Figure 12.25 Enthalpy of fusion of fourth-, fifth-, and sixth-period metals. Enthalpies of fusion range from 2–5 kJ/mol for Group 1A elements to 35.2 kJ/mol for tungsten.

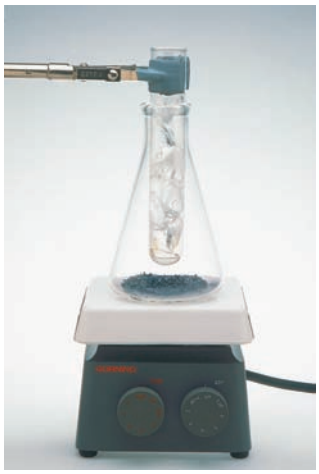
TABLE 12.3 Melting Points and Enthalpies of Fusion of Some Elements and Compounds

Element or Compound	Melting Point (°C)	Enthalpy of Fusion (kJ/mol)	Type of Interparticle Forces
Metals			
Hg	−39	2.29	Metal bonding.
Na	98	2.60	
Al	660	10.7	
Ti	1668	20.9	
W	3422	35.2	
Molecular Solids: Nonpolar Molecules			
O_2	−219	0.440	London dispersion forces (which increase with size and molar mass).
F_2	−220	0.510	
Cl_2	−102	6.41	
Br_2	−7.2	10.8	
Molecular Solids: Polar Molecules			
HCl	−114	1.99	All three HX molecules have dipole–dipole forces as well as London dispersion forces (which increase with size and molar mass).
HBr	−87	2.41	
HI	−51	2.87	
H_2O	0	6.01	Hydrogen bonding, London dispersion forces.
Ionic Solids			
NaF	996	33.4	All ionic solids have extended ion–ion interactions. Note the general trend is the same as for lattice energies (see Section 12.3 and Figure 12.11).
NaCl	801	28.2	
NaBr	747	26.1	
NaI	660	23.6	

shows the enthalpies of fusion for the metals of the fourth through the sixth periods. Here we see that transition metals have high enthalpies of fusion, with many of those in the sixth period being extraordinarily high. Tungsten, which has the second highest melting point of all the known elements (carbon has the highest melting point), also has the highest enthalpy of fusion among the transition metals. This is the reason tungsten has been used since 1908 for the filaments in incandescent lightbulbs.

Table 12.3 presents some data for several basic types of substances: metals, polar and nonpolar molecules, and ionic solids. In general, nonpolar molecular solids have low melting points. Melting points increase within a series of related molecules, however, as the size and molar mass increase. This happens because London dispersion forces are generally larger when the molar mass is larger. Thus, increasing amounts of energy are required to break down the intermolecular forces in the solid.

The ionic compounds in Table 12.3 have higher melting points and higher enthalpies of fusion than the molecular solids. This property is due to the strong ion–ion forces present in ionic solids, forces that are reflected in large negative lattice energies. Because ion–ion forces depend on ion size (as well as ion charge), there is a good correlation between lattice energy and the position of the metal or halogen in the periodic table. For example, the data in Table 12.3 show a decrease in melting point and enthalpy of fusion for sodium salts as the halide ion increases in size. This parallels the decrease in lattice energy seen with increasing ion size (Figure 12.11).



© Cengage Learning/Charles D. Winters

Molten ionic compounds conduct electricity. Ionic solids generally have high lattice energies and require energy to disrupt the lattice. However, once molten the ions are mobile, and the liquid will conduct electricity.

Iodine sublimes when heated.

If an ice-filled test tube is inserted into the flask, crystals of iodine are deposited from the vapor on the cold surface.

Figure 12.26 Sublimation. Sublimation is the conversion of a solid directly to its vapor. Here, iodine (I_2) sublimes when warmed.

Sublimation: Conversion of Solid into Vapor

Molecules can escape directly from the solid to the gas phase by sublimation (Figure 12.26).

$$\text{Solid} \rightarrow \text{gas} \qquad \text{Energy required as heat} = \Delta_{\text{sublimation}}H$$

Sublimation, like fusion and evaporation, is an endothermic process. The energy required as heat is called the **enthalpy of sublimation**. Water, which has a molar enthalpy of sublimation of 46.7 kJ/mol, can be converted from solid ice to water vapor quite readily. A good example of this phenomenon is the sublimation of frost from grass and trees as night turns to day on a cold winter morning.

Phase Diagrams

Depending on the conditions of temperature and pressure, a substance can exist as a gas, a liquid, or a solid. In addition, under certain specific conditions, two (or even three) states can coexist in equilibrium. This information is summarized in a **phase diagram**.

Water

Figure 12.27 illustrates the phase diagram for water. The lines in a phase diagram identify the temperatures and pressures at which two phases exist at equilibrium. Conversely, all points that do not fall on the lines in the figure represent conditions under which there is only one stable state. Line *A*–*B* in Figure 12.27 represents conditions for solid–vapor equilibrium, and line *A*–*C* for liquid–solid equilibrium. The line from point *A* to point *D*, representing the temperatures and pressures at which the liquid and vapor phases are in equilibrium, is the same curve plotted for water vapor pressure in Figure 11.12. Recall that the normal boiling point, 100 °C in the case of water, is the temperature at which the equilibrium vapor pressure is 760 mm Hg.

Point *A*, appropriately called the **triple point**, indicates the conditions under which all three phases coexist in equilibrium. For water, the triple point is at $P = 4.588$ mm Hg (611.7 Pa) and $T = 273.16$ K.

The line *A*–*C* shows the conditions of pressure and temperature at which solid–liquid equilibrium exists. (Because no vapor pressure is involved here, the pressure referred to is the external pressure on the liquid.) For water, this line has a *negative slope* of about −0.01 °C for each one-atmosphere increase in pressure. That is, the higher the external pressure, the lower the melting point.

Perhaps the most interesting feature of the water phase diagram is the negative slope of the solid–liquid equilibrium line. Very few other substances in the universe have this property! The negative slope of this equilibrium line can be explained

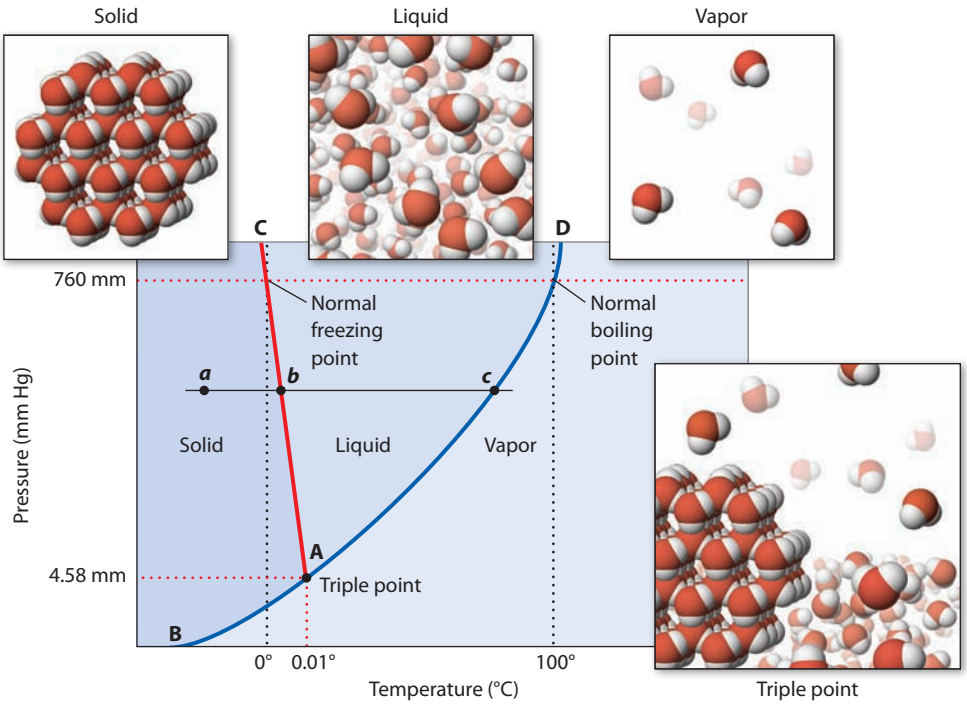

Figure 12.27 Phase diagram for water. The scale is intentionally exaggerated to be able to show the triple point and the negative slope of the line representing the liquid–solid equilibrium. (Points *a*, *b*, and *c* are discussed in the text.)

from our knowledge of the structure of water and ice. When the pressure on an object increases, common sense tells us that the volume of the object will become smaller, giving the substance a higher density. Because ice is less dense than liquid water (due to the open lattice structure of ice, Figure 11.5), ice and water in equilibrium respond to increased pressure (at constant T) by melting ice to form more water because the same mass of liquid water requires less volume.

Phase Diagrams and Thermodynamics

Phase Change and Thermodynamics The connection between the phase changes of water and thermodynamics is also illustrated in Figure 5.7.

Let us explore the water phase diagram further by correlating phase changes with thermodynamic data. Suppose we begin with ice at −10 °C and under a pressure of 500 mm Hg (point *a* on Figure 12.27). As ice is heated (at constant P), it absorbs about 2.1 J/g · K in warming from −10 °C (point *a*) to a temperature between 0 °C and 0.01 °C (point *b*). At this point, the solid is in equilibrium with liquid water. Solid-liquid equilibrium is maintained until 333 J/g has been transferred to the sample and it has become liquid water at this temperature. If the liquid, still under a pressure of 500 mm Hg, absorbs 4.184 J/g · K, it warms to point *c*. The temperature at point *c* is about 89 °C, and equilibrium is established between liquid water and water vapor. The equilibrium vapor pressure of the liquid water is 500 mm Hg. If about 2300 J/g is transferred to the liquid–vapor sample, the equilibrium vapor pressure remains 500 mm Hg until the liquid is completely converted to vapor at 89 °C.

Carbon Dioxide

The features of the phase diagram for CO_2 (Figure 12.28) are generally the same as those for water but with the important difference that the CO_2 solid–liquid equilibrium line has a positive slope. Once again, increasing pressure on the solid in equilibrium with the liquid will shift the equilibrium to the more dense phase, but for CO_2 this will be the solid. Because solid CO_2 is denser than the liquid, the newly formed solid CO_2 sinks to the bottom in a container of liquid CO_2.

Another feature of the CO_2 phase diagram is the triple point that occurs at a pressure of 5.10 atm (517 kPa) and 216.6 K (−56.6 °C). Carbon dioxide cannot be a liquid at pressures less than 5.10 atm.

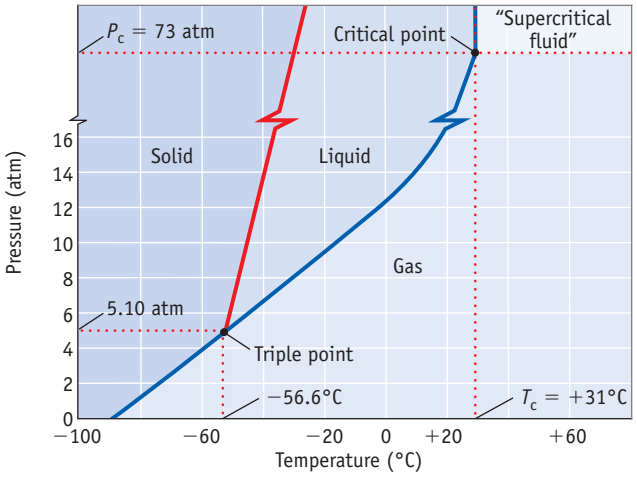

Figure 12.28 The phase diagram of CO_2. Notice in particular the positive slope of the solid–liquid equilibrium line. (For more on the critical point, see Section 11.6.)

At pressures around normal atmospheric pressure, CO_2 will be either a solid or a gas, depending on the temperature. At a pressure of 1 atm, solid CO_2 is in equilibrium with the gas at a temperature of 194.6 K (= −78.5 °C). As a result, as solid CO_2 warms above this temperature, it sublimes rather than melts. Carbon dioxide is called *dry ice* for this reason; it looks like water ice, but it does not melt.

From the CO_2 phase diagram, we can also learn that CO_2 gas can be converted to a liquid at room temperature (20–25 °C) by exerting a moderate pressure on the gas. In fact, CO_2 is regularly shipped in tanks as a liquid to laboratories and industrial companies.

Finally, the critical pressure and temperature for CO_2 are 73 atm and 31 °C, respectively. Because the critical temperature and pressure are easily attained in the laboratory, it is possible to observe the transformation to supercritical CO_2 (Figure 11.15, page 513).

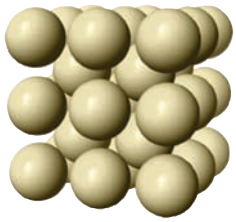
APPLYING CHEMICAL PRINCIPLES

12.1 Lithium and "Green Cars"

You are well aware of the use of metals in our economy: copper in electric wiring; aluminum in airplanes and soft drink cans; lead and zinc in batteries; and iron in cars, buses, and bridges. You may be less aware of metals such as the platinum group metals (platinum, palladium, rhodium, iridium, and ruthenium) in the catalytic converter in your car and lanthanides used in ultrastrong magnets. And that lithium is used in the batteries in your laptop.

Much of the world's lithium comes from northern Chile and southern Bolivia. There, groundwater with high concentrations of Group 1A salts is pumped into ponds. The solution slowly evaporates in the intense sunlight of the high Andes plateau, and, after about a year, the highly concentrated solution is finally taken to a chemical plant where it is evaporated to give white, powdered lithium carbonate. It is estimated that Bolivia alone has a reserve of about 73 million metric tons of Li_2CO_3. To produce lithium metal, the carbonate is converted to LiCl, which is then electrolyzed to produce the metal.

Fortunately lithium is quite abundant on the Earth. We say "fortunately" because lithium compounds have a wide range



Ksenia Ragozina/Shutterstock.com

Lithium and lithium salts. The high plateau in Bolivia where ground water contains high concentrations of Group 1A salts, among them lithium carbonate. The water is left in the Sun to deposit the salts by evaporation.

A view of the solid-state structure of lithium.

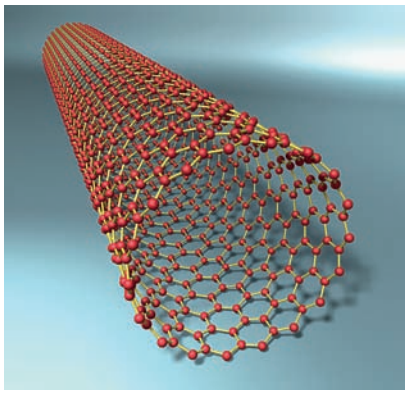
of uses: in ceramics and glass, in reagents for the production of pharmaceuticals, and in lubricating greases. However, there is one emerging use of lithium that may exceed all the others in the future: batteries for electric and hybrid cars and for aircraft.

Lithium batteries have been much in the news. In particular, Tesla, a builder of electric vehicles that use lithium batteries, is building an enormous factory to produce these batteries, not only for vehicles but also for home electric storage. It is clear that lithium-based batteries will become more important and that availability of lithium will be critical.

Questions:

1. What mass of lithium can be obtained from 73 million metric tons of lithium carbonate? (1 metric ton = 1000 kg.)
2. Describe the unit cell of lithium (see Figure).
3. The lithium unit cell is a cube with sides of 351 pm. Use this information, and a knowledge of unit cells, to calculate the density of lithium metal.
4. In the process of making lithium metal, Li_2CO_3 is converted to LiCl. Suggest a way to do this.

12.2 Nanotubes and Graphene—The Hottest New Network Solids



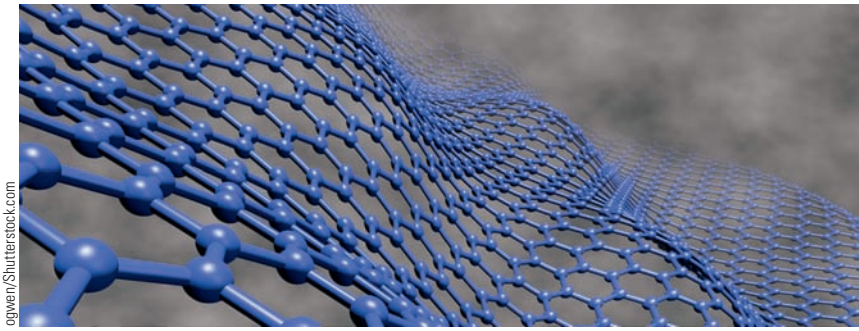
One of the most interesting developments in chemistry in the last 20 years has been the discovery of new forms of carbon. First, there were buckyballs and then carbon nanotubes.

Common graphite, from which your pencil lead is made, consists of six-member rings of carbon atoms connected in sheets, and the sheets stack one on top of another like cards in a deck (Figure 12.19). But if carbon compounds are heated under the right conditions, the carbon atoms assemble into sheets, and the sheets close on themselves to form tubes. These are called **nanotubes** because the tubes are only a nanometer or so in diameter. Sometimes they are single tubes, and other times they are tubes within tubes. Carbon nanotubes are at least 100 times stronger than steel but only one sixth as dense, and they conduct heat and electricity far better than copper. Thus, there has been enormous interest in their commercial applications, but it has also been difficult to make them with consistent properties.

Now there is also **graphene**, a single sheet of six-member rings of carbon atoms. Researchers in England, Andre Geim and Kostya Novoselov, discovered graphene in a simple way: Put a flake of graphite on Scotch tape, fold the tape over, and then pull it apart. The graphite layers come apart, and, if you do it enough times, only one layer—one C atom thick!—is left on the tape. Chemists and physicists soon found that the material is extremely strong and that it is a better conductor of electrons than any other material at room temperature. Several thousand research papers were soon published about graphene, and Geim and Novoselov received the 2010 Nobel Prize in Physics for their discovery.

The sticky tape method is clearly not suitable for producing large quantities of graphene, so now it is made by high-temperature vapor deposition, in which carbon atoms in the gas phase are deposited on a surface, or by using chemical methods to pry open graphite layers.

Potential uses of graphene seem almost endless in areas such as medicine (drug delivery), electronics (transistors), energy (solar cells and batteries), environmental (water filtration), and chemical (catalyst).



Digital Art/Corbis/Getty Images

Carbon nanotube. These tubes are assembled from six-member rings of carbon atoms and are typically about 1 nm in diameter.

Questions:

1. Based on a C–C distance of 139 pm, what is the side-to-side dimension of a planar, C_6 ring?
2. If a graphene sheet has a width of 1.0 micrometer, how many C_6 rings are joined across the sheet?
3. Estimate the thickness of a sheet of graphene (in pm). How did you determine this value?

ogwen/Shutterstock.com

Graphene is a single sheet of six-member carbon rings. This latest material in the world of carbon chemistry is a better conductor of electrons than any other material. http://www.graphene.manchester.ac.uk

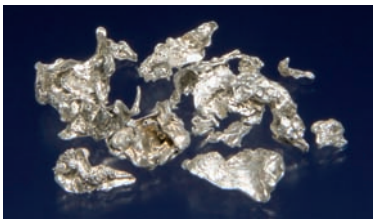
12.3 Tin Disease



Organ pipes in northern European cathedrals have been made of tin for several hundred years. It is believed that the metal improves both the tone and appearance of the pipes. Now organ pipes are made of a tin-lead alloy, in part because many old organ pipes have crumbled over time due to "tin disease." Gray splotches appear on the normally shiny metal, and over time the metal crumbles to a gray powder, which chemical analysis shows is pure tin.

What is the cause of "tin disease"? Two allotropes of tin exist at atmospheric pressure. The metallic form, known as white tin (or β-tin), is stable at temperatures above 13 °C (Figure 1). This metallic form of tin has a tetragonal crystal structure (Figure 2). Below 13 °C, the metal undergoes a phase transition to a cubic crystal structure that is similar to diamond (Figure 12.17). The transition occurs slowly, with a rate that depends on the purity of the tin and the temperature, but the final product is gray tin or α-tin.

The tetragonal structure of white tin has atoms at each corner as well as an atom in four of its six faces and an atom at the center of the lattice (Figure 2). The cubic crystal lattice structure of gray tin has an atom on each of the six faces and four atoms within the unit cell (in addition to atoms at the corners) as in the diamond structure.

The low-temperature transformation of white tin to gray tin has been used to explain two famous disasters in history, one apparently true, the other false.

Early in the 20th century, there was great interest in reaching the South Pole, and many tried. The British explorer Robert Scott mounted a large expedition and reached the Pole in January 1912 with a party of five. It was an enormous accomplishment, but he learned to his great disappointment that the Norwegian Roald Amundsen had beaten him by five weeks. Having reached their goal, the Scott party started the 800-mile journey back across the polar ice to the Ross Sea. Along the journey to the Pole they had left food and fuel for use on their return trip. Both fuel and food were packed in tin cans with tin-soldered joints. Unfortunately, in the extremely low temperature, the tin in the joints turned into gray tin, flaked off, and the fuel leaked out. The fuel was gone, and all in Scott's party perished.

© Cengage Learning/ Charles D. Winters

Figure 1 A sample of white tin. This common element has a density of 7.31 g/cm^3 and a melting point of 232 °C.

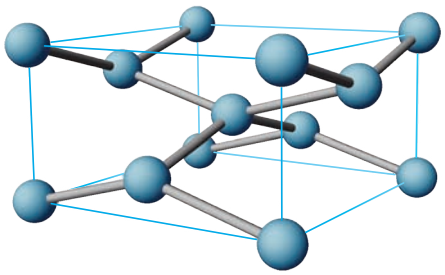


Figure 2 A tetragonal unit cell of white tin (β-tin). The tetragonal unit cell has 90° angles at each corner. Two of the three sides are equal in length (583 pm) while the third side is shorter (318 pm). (Note that the lines connecting atoms are not bonds. They are meant only to show the spatial relationship of the atoms.)

Another story of tin disease is a myth: the legend of crumbling buttons on the overcoats of French soldiers in 1812. In the winter of 1812, Napoleon's army fought and lost a brutal campaign in Russia. The shiny tin buttons used by the French soldiers are said to have crumbled in the cold Russian climate so they could not keep their clothing around them in the frigid weather. The problem with this story is that the uniform buttons at the time were made of bone.

Questions:

1. How many tin atoms are contained in the tetragonal crystal lattice unit cell of β-tin? How many tin atoms are contained in the cubic crystal lattice unit cell of α-tin?
2. Using the dimensions of the unit cell (Figure 2) and the molar mass of tin, calculate the density of white tin (in g/cm^3).
3. The density of gray tin is 5.769 g/cm^3. Determine the dimensions (in pm) of the cubic crystal lattice.
4. Determine the percentage of space occupied by tin atoms in both the tetragonal and cubic crystal lattices. The atomic radius of tin is 141 pm.

CHAPTER GOALS REVISITED

The goals for this chapter are keyed to specific Study Questions to help you organize your review.

12.1 Crystal Lattices and Unit Cells

- Define the unit cell for a crystalline compound. 1–4, 42a,b.
- Understand the relationship of unit cell structure, atom radius, and cell dimensions. 3, 9, 10, 42, 43, 45.

12.2 Structures and Formulas of Ionic Solids

- Understand the relationship of unit cell structure and formula for ionic compounds. 5–8.
- Relate unit cell dimensions, ionic radii, and solid density. 4, 11.

12.3 Bonding in Ionic Solids: Lattice Energy

- Calculate the lattice enthalpy of an ionic solid and relate the magnitude of the lattice enthalpy to ion size and charge. 13, 14, 54, 64.

12.4 Bonding in Metals and Semiconductors

- Understand the electron sea and band theories of metals and how these theories are used to explain the properties of metals. 21, 22.
- Understand the nature of semiconductors. 23–26, 55–59.

12.5 Other Types of Solid Materials

- Characterize the different types of solids. 27–30.

12.6 Phase Changes

- Identify the significant points and regions of phase diagrams and use the diagrams to evaluate the vapor pressure of a liquid and the relative densities of liquid and solid phases. 37, 38.
- Sketch a phase diagram from information about a substance. 41.
- Relate the processes of melting and sublimation and the associated enthalpy changes. 35, 36.

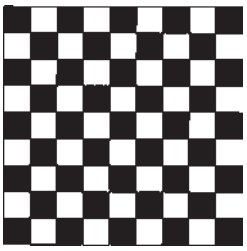
▲ denotes challenging questions. **Blue-numbered questions** have answers in Appendix N and fully worked solutions in the *Student Solutions Manual*.

Practicing Skills

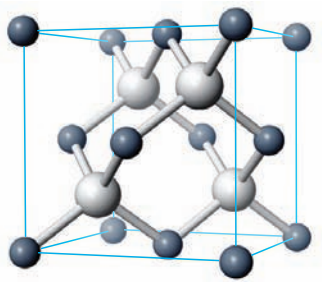


Metallic and Ionic Solids

(See Sections 12.1 and 12.2 and Examples 12.1–12.3.)

1. Outline a two-dimensional unit cell for the pattern shown here. If the black squares are labeled A and the white squares are B, what is the simplest formula for a "compound" based on this pattern?

2. Outline a two-dimensional unit cell for the pattern shown here. If the black squares are labeled A and the white squares are B, what is the simplest formula for a "compound" based on this pattern?

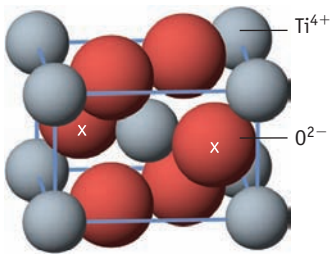


3. A portion of the crystalline lattice for potassium is illustrated below.
   (a) In what type of unit cell are the K atoms arranged?

A portion of the solid-state structure of potassium.

   (b) If one edge of the potassium unit cell is 533 pm, what is the density of potassium?

4. The unit cell of silicon carbide, SiC, is illustrated below.
   (a) In what type of unit cell are the (dark gray) C atoms arranged?
   (b) If one edge of the silicon carbide unit cell is 436.0 pm, what is the calculated density of this compound?

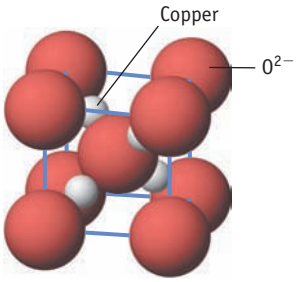


A portion of the solid-state structure of silicon carbide.

5. One way of viewing the unit cell of perovskite was illustrated in Example 12.2. Another way is shown here. Prove that this view also leads to a formula of $CaTiO_3$.

Perovskite unit cell

6. Rutile, TiO_2, crystallizes in a structure characteristic of many other ionic compounds. How many formula units of TiO_2 are in the unit cell illustrated here? (The oxide ions marked by an *x* are wholly within the cell; the others are in the cell faces.)



Unit cell for rutile

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

7. Cuprite is a semiconductor. Oxide ions are at the cube corners and in the cube center. Copper ions are wholly within the unit cell.
   (a) What is the formula of cuprite?
   (b) What is the oxidation number of copper?

Unit cell for cuprite

8. The mineral fluorite, which is composed of calcium ions and fluoride ions, has the unit cell shown here.
   (a) What type of unit cell is described by the Ca^{2+} ions?
   (b) Where are the F^- ions located, in octahedral holes or tetrahedral holes?
   (c) Based on this unit cell, what is the formula of fluorite?

Unit cell of fluorite

9. Calcium metal crystallizes in a face-centered cubic unit cell. The density of the solid is 1.54 g/cm^3. What is the radius of a calcium atom?

10. The density of copper metal is 8.95 g/cm^3. If the radius of a copper atom is 127.8 pm, is the copper unit cell primitive, body-centered cubic, or face-centered cubic?

11. Potassium iodide has a face-centered cubic unit cell of iodide ions with potassium ions in octahedral holes. The density of KI is 3.12 g/cm^3. What is the length of one side of the unit cell? (Ion sizes are found in Figure 7.11.)

12. ▲ A unit cell of cesium chloride is illustrated in Figure 12.8. The density of the solid is 3.99 g/cm^3, and the radius of the Cl^- ion is 181 pm. Calculate the radius of the Cs^+ ion in the center of the cell. (Assume that the Cs^+ ion touches all of the corner Cl^- ions.)

Ionic Bonding and Lattice Energy

(See Section 12.3.)

13. Predict the trend in lattice energy, from least negative to most negative, for the following compounds based on the ion charges and ionic radii: LiI, LiF, CaO, RbI.

14. Examine the trends in lattice energy in Table 12.1. The value of the lattice energy becomes somewhat more negative on going from NaI to NaBr to NaCl, and all are in the range from −700 to −800 kJ/mol. Suggest a reason for the observation that the lattice energy of NaF ($\Delta_{lattice}U$ = −926 kJ/mol) is much more negative than those of the other sodium halides.

15. To melt an ionic solid, energy must be supplied to disrupt the forces between ions so the regular array of ions collapses. Predict (and explain) how the melting point is expected to vary as a function of the distance between cation and anion.

16. Which compound in each of the following pairs should have the higher melting point? Explain briefly.
   (a) NaCl or RbCl
   (b) BaO or MgO
   (c) NaCl or MgS

17. Calculate the molar enthalpy of formation, $\Delta_f H°$, of solid lithium fluoride from the lattice energy (Table 12.1) and other thermochemical data. The enthalpy of formation of Li(g), $\Delta_f H°$ [Li(g)] = 159.37 kJ/mol. Other required data can be found in Appendices F and L.

18. Calculate the lattice enthalpy for RbCl. In addition to data in Appendices F and L, you will need the following information:

$$\Delta_f H°\ [Rb(g)] = 80.9\ kJ/mol$$

$$\Delta_f H°\ [RbCl(s)] = -435.4\ kJ/mol$$

Metals and Semiconductors

(See Section 12.4.)

19. Considering only the molecular orbitals formed by combinations of the 2*s* atomic orbitals, how many molecular orbitals can be formed by 1000 Li atoms? In the lowest energy state, how many of these orbitals will be populated by pairs of electrons and how many will be empty?

20. How many molecular orbitals will be formed by combination of the 3*s* and 3*p* atomic orbitals in 1.0 mol of Mg atoms? At 0 K, what fraction of these orbitals will be occupied by electron pairs?

21. Conduction of an electric current is a general property associated with metals. How does the band theory for metallic bonding explain conductivity?

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

22. Most metals are shiny, that is, they reflect light. How does the band theory for metals explain this characteristic?

23. Elemental silicon and carbon (in the diamond allotropic form) have the same solid-state structure. However, diamond is an insulator and silicon is a semiconductor. Explain why there is a difference.

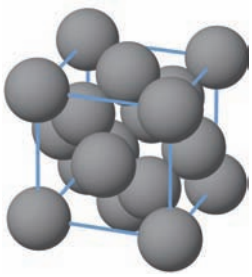
24. List the Group 4A elements in order of the size of the band gap.

25. Define the terms intrinsic semiconductor and extrinsic semiconductor. Give an example of each.

26. Is aluminum-doped silicon a *p*-type or an *n*-type semiconductor? Explain how conductivity occurs in this semiconductor.

Other Types of Solids

(See Section 12.5.)



27. Which of the following allotropes of carbon is not a network solid?

(a) graphite
(b) diamond
(c) buckyballs (C_{60})
(d) graphene

28. A soft, white waxy solid melts over a temperature range from 120 °C to 130 °C. It doesn't dissolve in water and it doesn't conduct electricity. These properties are consistent with its identity as

(a) a network solid
(b) an ionic solid
(c) an amorphous solid
(d) a metallic solid

29. A diamond unit cell is shown here.

Unit cell of diamond

(a) How many carbon atoms are in one unit cell?

(b) The unit cell can be considered as a cubic unit cell of C atoms with other C atoms in holes in the lattice. What type of unit cell is this (pc, bcc, fcc)? In what holes are other C atoms located, octahedral or tetrahedral holes?

30. The structure of graphite is given in Figure 12.19.

(a) What type of intermolecular forces exist between the layers of six-member carbon rings?

(b) Account for the lubricating ability of graphite. That is, why does graphite feel slippery? Why does pencil lead (which is really graphite in clay) leave black marks on paper?

31. We have identified six types of solids (metallic, ionic, molecular, network, amorphous, alloys). What particles make up each of these solids and what are the forces of attraction between these particles?

32. List the general properties of each type of solid.

33. Classify each of the following materials as falling into one of the categories listed in Table 12.2. What particles make up these solids and what are the forces of attraction between particles? Give one physical property of each.

(a) gallium arsenide
(b) polystyrene
(c) silicon carbide
(d) perovskite, $CaTiO_3$

34. Classify each of the following materials as falling into one of the categories listed in Table 12.2. What particles make up these solids, and what are the forces of attraction between particles? Give one physical property of each.

(a) Si doped with P
(b) graphite
(c) benzoic acid, $C_6H_5CO_2H$
(d) Na_2SO_4

Phase Changes

(See Section 12.6.)

35. Benzene, C_6H_6, is an organic liquid that freezes at 5.5 °C (Figure 11.1) to form beautiful, feather-like crystals. How much energy is evolved as heat when 15.5 g of benzene freezes at 5.5 °C? (The enthalpy of fusion of benzene is 9.95 kJ/mol.) If the 15.5-g sample is remelted, again at 5.5 °C, what quantity of energy is required to convert it to a liquid?

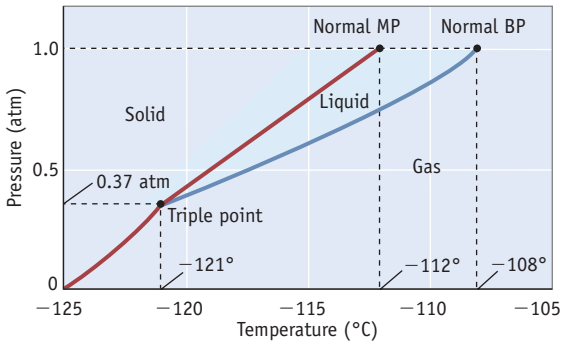
36. The specific heat capacity of silver is 0.235 J/g · K. Its melting point is 962 °C, and its enthalpy of fusion is 11.3 kJ/mol. What quantity of energy, in joules, is required to change 5.00 g of silver from a solid at 25 °C to a liquid at 962 °C?

Phase Diagrams and Phase Changes

(See Section 12.6.)

37. Consider the phase diagram of CO_2 in Figure 12.28.

(a) Is the density of liquid CO_2 greater or less than that of solid CO_2?



(b) In what phase do you find CO_2 at 5 atm and 0 °C?

(c) Can CO_2 be liquefied at 45 °C?

38. Use the phase diagram given here to answer the following questions:

(a) In what phase is the substance found at room temperature and 1.0 atm pressure?

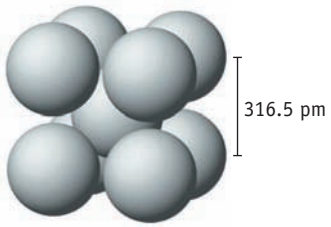
(b) If the pressure exerted on a sample is 0.75 atm and the temperature is −114 °C, in what phase does the substance exist?

(c) If you measure the vapor pressure of a liquid sample and find it to be 380 mm Hg, what is the temperature of the liquid phase?

(d) What is the vapor pressure of the solid at −122 °C?

(e) Which is the denser phase—solid or liquid? Explain briefly.

39. Liquid ammonia, $NH_3(\ell)$, was once used in home refrigerators as the heat transfer fluid. The specific heat capacity of the liquid is 4.7 J/g · K and that of the vapor is 2.2 J/g · K. The enthalpy of vaporization is 23.33 kJ/mol at the boiling point. If you heat 12 kg of liquid ammonia from −50.0 °C to its boiling point of −33.3 °C, allow it to evaporate, and then continue warming to 0.0 °C, how much energy must you supply?



40. If your air conditioner is more than several years old, it may use the chlorofluorocarbon CCl_2F_2 as the heat transfer fluid. The normal boiling point of CCl_2F_2 is −29.8 °C, and the enthalpy of vaporization is 20.11 kJ/mol. The gas and the liquid have molar heat capacities of 117.2 J/mol · K and 72.3 J/mol · K, respectively. How much energy is evolved as heat when 20.0 g of CCl_2F_2 is cooled from +40 °C to −40 °C?

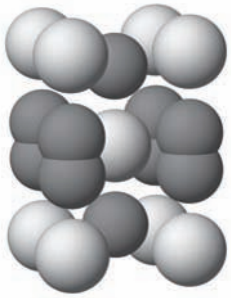
General Questions

These questions are not designated as to type or location in the chapter. They may combine several concepts.

41. Sketch a phase diagram for O_2 from the following information: normal boiling point, 90.18 K; normal melting point, 54.8 K; and triple point, 54.34 K at a pressure of 2 mm Hg. Very roughly estimate the vapor pressure of liquid O_2 at −196 °C, the lowest temperature easily reached in the laboratory. Is the density of liquid O_2 greater or less than that of solid O_2?

42. ▲ Tungsten crystallizes in the unit cell shown here.

Unit cell for tungsten



(a) What type of unit cell is this?

(b) How many tungsten atoms occur per unit cell?

(c) If the edge of the unit cell is 316.5 pm, what is the radius of a tungsten atom? (*Hint:* The W atoms touch each other along the diagonal line from one corner of the unit cell to the opposite corner of the unit cell.)

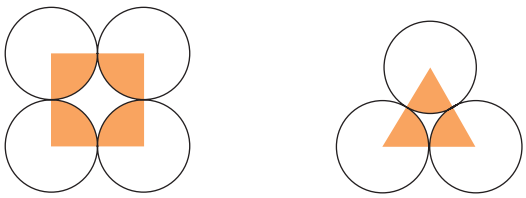
43. Silver crystallizes in a face-centered cubic unit cell. Each side of the unit cell has a length of 409 pm. What is the radius of a silver atom?

44. ▲ The unit cell shown here is for calcium carbide. How many calcium atoms and how many carbon atoms are in each unit cell? What is the formula of calcium carbide? (Calcium ions are silver in color and carbon atoms are gray.)

Unit cell for calcium carbide

45. The very dense metal iridium has a face-centered cubic unit cell and a density of 22.56 g/cm^3. Use this information to calculate the radius of an atom of the element.

46. Vanadium metal has a density of 6.11 g/cm^3. Assuming the vanadium atomic radius is 132 pm, is the vanadium unit cell primitive cubic, body-centered cubic, or face-centered cubic?



47. ▲ Calcium fluoride is the well-known mineral fluorite. Each unit cell contains four Ca^{2+} ions and eight F^- ions. The F^- ions fill all the tetrahedral holes in a face-centered cubic lattice of Ca^{2+} ions. The edge of the CaF_2 unit cell is 5.46295×10^{-8} cm in length. The density of the solid is 3.1805 g/cm^3. Use this information to calculate Avogadro's number.

48. ▲ Iron has a body-centered cubic unit cell with a cell dimension of 286.65 pm. The density of iron is 7.874 g/cm^3. Use this information to calculate Avogadro's number.

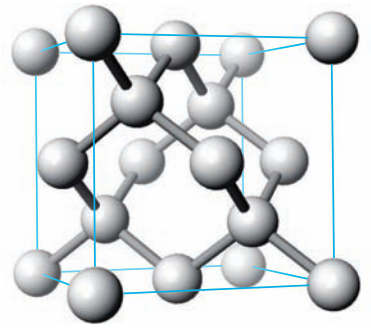
49. ▲ You can get some idea of how efficiently spherical atoms or ions are packed in a three-dimensional solid by seeing how well circular atoms pack in two dimensions. Using the drawings shown here, prove that B is a more efficient way to pack circular atoms than A. The unit cell of A contains portions of four circles and one hole. In B, packing coverage can be calculated by looking at a triangle that contains portions of three circles and one hole. Show that A fills about 80% of the available space, whereas B fills closer to 90% of the available space.



50. Consider the three types of cubic units cells.

(a) ▲ Assuming that the spherical atoms or ions in a primitive cubic unit cell just touch along the cube's edges, calculate the percentage of occupied space within the unit cell. (Recall that the volume of a sphere is $(4/3)\pi r^3$, where r is the radius of the sphere.)

(b) Compare the percentage of occupied space in the primitive cell (pc) with the bcc and fcc unit cells. Based on this, will a metal in these three forms have the same or different densities? If different, in which is it most dense? In which is it least dense?

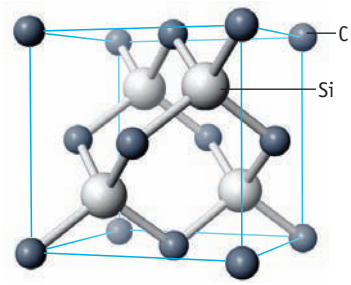
51. The solid-state structure of silicon is shown below.

Unit cell for silicon

(a) Describe this crystal as pc, bcc, or fcc.

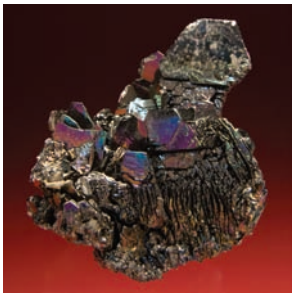
(b) What type of holes are occupied in the lattice?

(c) How many Si atoms are there per unit cell?



(d) Calculate the density of silicon in g/cm^3 (given that the cube edge has a length of 543.1 pm).

(e) ▲ Estimate the radius of the silicon atom. (*Note:* The Si atoms on the edges do not touch one another.)



52. The solid-state structure of silicon carbide is shown below.

(a) How many atoms of each type are contained within the unit cell? What is the formulas of silicon carbide?

(b) ▲ Knowing that the Si—C bond length is 188.8 pm (and the Si—C—Si bond angle is 109.5°), calculate the density of SiC.

Unit cell of SiC

53. Spinels are solids with the general formula AB_2O_4 (where A^{2+} and B^{3+} are metal cations of the same or different metals). The best-known example is common magnetite, Fe_3O_4 [which you can formulate as $(Fe^{2+})(Fe^{3+})_2O_4$]. Another example is the mineral often referred to as *spinel*, $MgAl_2O_4$.

© Cengage Learning/Charles D. Winters

A crystal of the spinel $MgAl_2O_4$

The oxide ions of spinels form a face-centered cubic lattice. In a *normal spinel*, cations occupy $^1/_8$ of the tetrahedral sites and $^1/_2$ of the octahedral sites.

(a) In $MgAl_2O_4$, in what types of holes are the magnesium and aluminum ions found?

(b) The mineral chromite has the formula $FeCr_2O_4$. What ions are involved, and in what types of holes are they found?

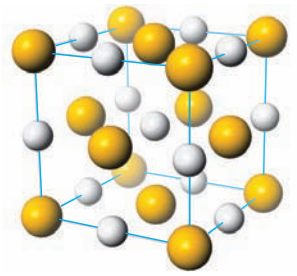
54. Using the thermochemical data below and an estimated value of −2481 kJ/mol for the lattice energy for Na_2O, calculate the value for the *second* electron affinity of oxygen [$O^-(g) + e^- \rightarrow O^{2-}(g)$].

Quantity	Numerical Value (kJ/mol)
Enthalpy of atomization of Na	107.3
Ionization energy of Na	495.9
Enthalpy of formation of solid Na_2O	−418.0
Enthalpy of formation of O(g) from O_2	249.1
First electron attachment enthalpy of O	−141.0

55. The band gap in gallium arsenide is 140 kJ/mol. What is the maximum wavelength of light needed to excite an electron to move from the valence band to the conduction band?

56. The conductivity of an intrinsic semiconductor increases with increasing temperature. How can this be rationalized?

57. Which will show the highest conductivity at 298 K, silicon or germanium?



58. Identify the following as either *p*- or *n*-type semiconductors.
   (a) germanium doped with arsenic
   (b) silicon doped with phosphorus
   (c) germanium doped with indium
   (d) germanium doped with antimony

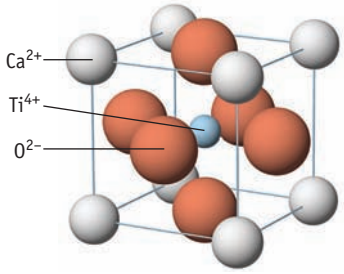
59. Diamond-based semiconductors are currently of enormous interest in the research community. Although diamond itself is an insulator, the addition of a dopant will narrow the band gap. One semiconductor system has diamond with boron as a dopant. Is this a *p*- or an *n*-type semiconductor?

60. Molecular solids, network solids, and amorphous solids all contain atoms that are joined together by covalent bonds. However, these classes of compounds are very different in overall structure, and this leads to different physical properties associated with each group. Describe how the overall structures of these classes of solids differ from each other.

In the Laboratory

61. Like ZnS, lead(II) sulfide, PbS (commonly called *galena*), has a 1:1 empirical formula with a 2+ cation combined with the sulfide anion.

Unit cell of PbS



© Cengage Learning/Charles D. Winters

Sample of galena

Does PbS have the same solid structure as ZnS? If different, how are they different? How is the unit cell of PbS related to its formula?

62. $CaTiO_3$, a perovskite, has the structure below.
   (a) If the density of the solid is 4.10 g/cm^3, what is the length of a side of the unit cell?
   (b) Calculate the radius of the Ti^{4+} ion in the center of the unit cell. How well does your calculation agree with a literature value of 75 pm?

Unit cell of the perovskite $CaTiO_3$

63. Potassium bromide has the same lattice structure as NaCl. Given the ionic radii of K^+ (133 pm) and Br^- (196 pm), calculate the density of KBr.

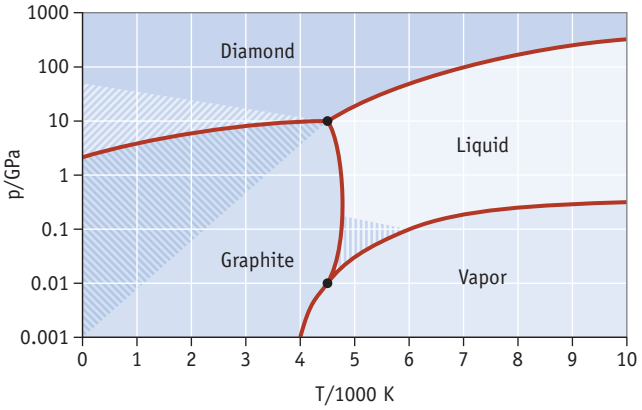
64. Calculate the lattice energy of $CaCl_2$ using a Born-Haber cycle and data from Appendices F and L and Table 7.5.

Summary and Conceptual Questions

The following questions may use concepts from this and previous chapters.

65. ▲ Boron phosphide, BP, is a semiconductor and a hard, abrasion-resistant material. It is made by reacting boron tribromide and phosphorus tribromide in a hydrogen atmosphere at high temperature (>750 °C).
    (a) Write a balanced chemical equation for the synthesis of BP. (*Hint:* Hydrogen is a reducing agent.)
    (b) Boron phosphide crystallizes in a zinc-blend structure, formed from boron atoms in a face-centered cubic lattice and phosphorus atoms in tetrahedral holes. How many tetrahedral holes are filled with P atoms in each unit cell?
    (c) The length of a unit cell of BP is 478 pm. What is the density of the solid in g/cm^3?
    (d) Calculate the closest distance between a B and a P atom in the unit cell. (Assume the B atoms do not touch along the cell edge. The B atoms in the faces touch the B atoms at the corners of the unit cell.)

66. ▲ Why is it not possible for a salt with the formula M_3X (Na_3PO_4, for example) to have a face-centered cubic lattice of X anions with M cations in octahedral holes?



67. ▲ Two identical swimming pools are filled with uniform spheres of ice packed as closely as possible. The spheres in the first pool are the size of grains of sand; those in the second pool are the size of oranges. The ice in both pools melts. In which pool, if either, will the water level be higher? (Ignore any differences in filling space at the planes next to the walls and bottom.)

68. Spinels are described in Study Question 53. Consider two normal spinels, $CoAl_2O_4$ and $SnCo_2O_4$. What metal ions are involved in each? What are their electron configurations? Are the metal ions paramagnetic, and if so how many unpaired electrons are involved?

69. Outline a procedure to calculate the percent of space occupied by the atoms in an fcc arrangement.

70. The sample of nephrite jade shown on page 545 has the formula $Ca_2(Mg, Fe)_5(Si_4O_{11})_2(OH)_2$. (Iron in this formula is in the +2 oxidation state.)
    (a) What is the charge on the $(Si_4O_{11})^{n-}$ ion in this compound?
    (b) What is the oxidation state of Si in this compound?
    (c) What is the percent of iron in a sample of jade that has the formula $Ca_2(Mg_{0.35}Fe_{0.65})_5(Si_4O_{11})_2(OH)_2$?
    (d) The iron ions in the formula for nephrite have the same degree of paramagnetism as seen for $Fe^{2+}(g)$. How many unpaired electrons per iron ion does this represent?

71. Phase diagrams for materials that have allotropes can be more complicated than those shown in the chapter. Use the phase diagram for carbon given here to answer the following questions.

    (a) How many triple points are present and what phases are in equilibrium for each?
    (b) Is there a single point where all four phases are in equilibrium?
    (c) Which is more stable at high pressures, diamond or graphite?
    (d) Which is the stable phase of carbon at room temperature and 1 atmosphere pressure?

72. Prepare a graph of lattice enthalpy for lithium, sodium, and potassium halides (Table 12.1) vs. the sum of the ionic radii for the component ions (Figure 7.11). Evaluate the results and comment on the relationship between these quantities.

CHAPTER OUTLINE

13.1 Units of Concentration

13.2 The Solution Process

13.3 Factors Affecting Solubility: Pressure and Temperature

13.4 Colligative Properties

13.5 Colloids

13.1 Units of Concentration

Goals for Section 13.1

- Calculate and use the concentration units: molality, mole fraction, weight percent, and parts per million (ppm).
- Recognize the difference between molarity and molality.

Our attention in this chapter focuses on the properties of solutions. Experience tells us that adding a solute to a pure liquid will change the properties of the liquid. Indeed, that is the reason some solutions are made. For instance, adding antifreeze to the water in your car's radiator prevents the coolant from boiling in the summer and freezing in the winter. Freezing and boiling point, osmotic pressure, and changes in solvent vapor pressure for solutions are examples of properties discussed in this chapter. These properties, called **colligative properties**, depend on the number of solute particles per solvent molecule and not on the identity of the solute.

Solutions A solution is a homogeneous mixture of two or more substances in a single phase. By convention, the component present in largest amount is identified as the solvent and the other components as the solutes (Section 1.3).

To analyze the colligative properties of solutions, we need ways of defining solute concentrations that reflect the number of molecules or ions of solute per molecule of solvent. Four concentration units described here have this characteristic: molality, mole fraction, weight percent, and parts per million (ppm).

The **molality**, m, of a solution is defined as the amount of solute (mol) per kilogram of solvent.

$$\text{Concentration } (c, \text{mol/kg}) = \text{molality of solute} = \frac{\text{amount of solute (mol)}}{\text{mass of solvent (kg)}} \qquad (13.1)$$

To prepare a 1.00 molal solution, for example, you would add 1.00 mol of solute to 1.00 kg of water.

Molarity is a concentration unit defined earlier and used in stoichiometry calculations (Section 4.5). This unit is not useful when dealing with most colligative properties because, when preparing a solution of given molarity, the amount of solvent is not known.

◀ **Scuba diving: The solubility of gases in your bodily fluids is important to consider when diving.**

Figure 13.1 **Preparing 0.100 molal and 0.100 molar solutions.**

The difference between *molality* (m) and *molarity* (M) is illustrated in Figure 13.1. The flask on the right contains a 0.100 M aqueous solution of potassium chromate. It was made by adding enough water to 0.100 mol of K_2CrO_4 to make 1.000 L of solution. If 1.00 L (1.00 kg) of water is added to 0.100 mol of K_2CrO_4 to make a 0.100 molal solution, the volume of solution is greater than 1.000 L, as you see in the left side of the photograph.

Mole Fraction and Gases We previously introduced the use of mole fractions when discussing mixtures of gases in Section 10.5.

The **mole fraction**, X, of a solution component is defined as the amount of that component (n_A) divided by the total amount of all of the components of the mixture ($n_A + n_B + n_C + \ldots$). Mathematically it is represented as

$$\text{Mole fraction of A } (X_A) = \frac{n_A}{n_A + n_B + n_C + \ldots} \tag{13.2}$$

Consider a solution that contains 1.00 mol (46.1 g) of ethanol, C_2H_5OH, in 9.00 mol (162 g) of water. The mole fraction of alcohol is 0.100, and that of water is 0.900.

$$X_{\text{ethanol}} = \frac{1.00 \text{ mol ethanol}}{1.00 \text{ mol ethanol} + 9.00 \text{ mol water}} = 0.100$$

$$X_{\text{water}} = \frac{9.00 \text{ mol water}}{1.00 \text{ mol ethanol} + 9.00 \text{ mol water}} = 0.900$$

Notice that the sum of the mole fractions of the components in the solution equals 1.000, a relationship that must be true, based on how mole fraction is defined.

Weight percent is the mass of one component divided by the total mass of the mixture, multiplied by 100%:

$$\text{Weight \% A} = \frac{\text{mass of A}}{\text{mass of A} + \text{mass of B} + \text{mass of C} + \ldots} \times 100\% \tag{13.3}$$

© Cengage Learning/Charles D. Winters

Figure 13.2 **Weight percent.** The composition of many common products is often given in terms of weight percent.

The alcohol–water mixture has 46.1 g of ethanol and 162 g of water, so the total mass of solution is 208 g, and the weight % of alcohol is

$$\text{Weight \% ethanol} = \frac{46.1 \text{ g ethanol}}{46.1 \text{ g ethanol} + 162 \text{ g water}} \times 100\% = 22.2\%$$

Weight percent is a common unit in consumer products (Figure 13.2). Vinegar, for example, is an aqueous solution containing approximately 5% acetic acid and

95% water. The label on a common household bleach lists its active ingredient as 6.00% sodium hypochlorite (NaOCl) and 94.00% inert ingredients.

The unit **ppm (parts per million)** also refers to relative quantities of solute and solvent by mass; 1.0 ppm represents a solution containing 1.0 g of a substance in a sample with a total mass of 1.0 million g (equivalent to 1 mg in 1000 g). This unit is typically used to identify concentrations of solutes in very dilute solutions. It is useful in chemistry (especially in environmental chemistry) and in disciplines such as biology, geology, and oceanography.

ppb and ppt The units ppb (parts per billion) and ppt (parts per trillion) are related to ppm. Sophisticated analytic techniques are now available that can detect trace impurities in solution at the ppb and ppt range.

EXAMPLE 13.1

Calculating Mole Fraction, Molality, and Weight Percent

Problem Suppose you add 1.2 kg of ethylene glycol, $HOCH_2CH_2OH$, as an antifreeze to 4.0 kg of water in the radiator of your car. What are the mole fraction, molality, and weight percent of the ethylene glycol?

What Do You Know? You know the identity and masses of solute and solvent.

Strategy The amount of solute and solvent can be calculated using the mass and molar mass of each material. The masses and amounts of solute and solvent can then be combined to calculate the concentration in each of the desired concentration units using Equations 13.1–13.3.

SOLUTION The 1.2 kg of ethylene glycol (molar mass = 62.1 g/mol) is equivalent to 19.3 mol, and 4.0 kg of water represents 222 mol.

Mole fraction:

$$X_{\text{glycol}} = \frac{19.3 \text{ mol ethylene glycol}}{19.3 \text{ mol ethylene glycol} + 222 \text{ mol water}} = 0.080$$

Molality:

$$c_{\text{glycol}} = \frac{19.3 \text{ mol ethylene glycol}}{4.0 \text{ kg water}} = 4.8 \text{ mol/kg} = 4.8\ m$$

Weight percent:

$$\text{Weight \%} = \frac{1.2 \times 10^3 \text{ g ethylene glycol}}{1.2 \times 10^3 \text{g ethylene glycol} + 4.0 \times 10^3 \text{ g water}} \times 100\% = 23\%$$

Think about Your Answer Although the numerical values are very different, the information contained in these values is similar; each relates the relative numbers of solvent and solute particles.

Check Your Understanding

(a) If you dissolve 10.0 g (about one heaping teaspoonful) of sugar (sucrose, $C_{12}H_{22}O_{11}$) in a cup of water (250. g), what are the mole fraction, molality, and weight percent of sugar?

(b) Seawater has a sodium ion concentration of 1.08×10^4 ppm. If the sodium is present in the form of dissolved sodium chloride, what mass of NaCl is in each liter of seawater? Seawater is denser than pure water because of dissolved salts. Its density is 1.05 g/mL.

© Cengage Learning/Charles D. Winters

Commercial antifreeze. This solution contains ethylene glycol, $HOCH_2CH_2OH$, an organic alcohol that is readily soluble in water. Regulations specify that the weight percent of ethylene glycol in ethylene glycol–based antifreeze must be at least 75%. (The remainder of the solution can be other glycols and water.)

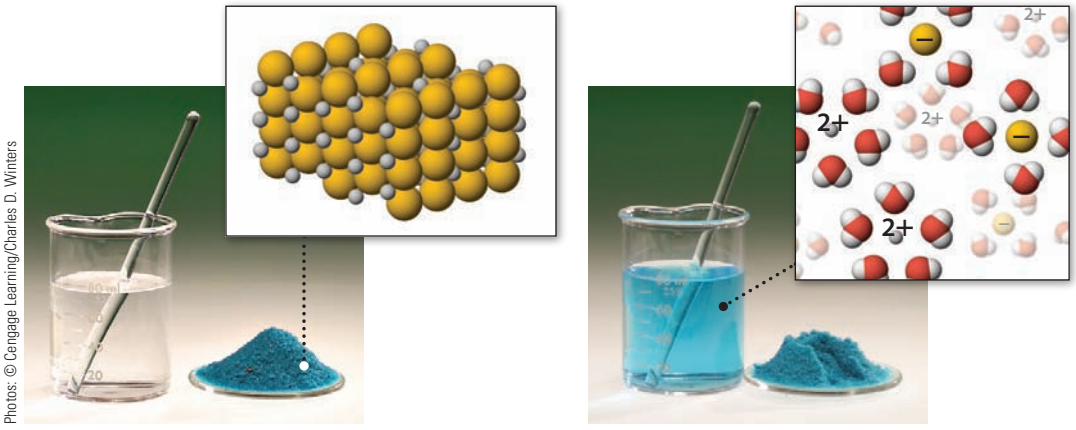
13.2 The Solution Process

Goals for Section 13.2

- Understand the process of dissolving a solute in a solvent and recognize the terminology used (saturated, unsaturated, supersaturated, solubility, miscible).
- Understand the thermodynamics associated with the solution process and calculate the enthalpy of solution from thermodynamic data.

Unsaturated The term unsaturated is used when referring to solutions with solute concentrations that are less than that of a saturated solution.



If solid $CuCl_2$ is added to a beaker of water, the salt will begin to dissolve (Figure 13.3). The amount of solid diminishes, and the concentrations of $Cu^{2+}(aq)$ and $Cl^-(aq)$ in the solution increase. If we continue to add $CuCl_2$, however, we will eventually reach a point when no additional $CuCl_2$ seems to dissolve. The concentrations of $Cu^{2+}(aq)$ and $Cl^-(aq)$ will not increase further, and any additional solid $CuCl_2$ added after this point will remain as a solid at the bottom of the beaker. We say that such a solution is **saturated**.

Although no change is observed on the macroscopic level when a solution is saturated, it is a different matter on the particulate level. The process of dissolving continues, with Cu^{2+} and Cl^- ions leaving the solid state and entering solution. However, at the same time solid $CuCl_2(s)$ is being formed from $Cu^{2+}(aq)$ and $Cl^-(aq)$. The rates at which $CuCl_2$ is dissolving and reprecipitating are equal in a saturated solution, so that no net change in the concentration of ions is observed on the macroscopic level.

This process is another example of a dynamic equilibrium (Section 3.3), and we can describe what happens in terms of an equation with substances linked by a set of double arrows ($\rightleftharpoons$):

$$CuCl_2(s) \rightleftharpoons Cu^{2+}(aq) + 2\ Cl^-(aq)$$

A saturated solution gives us a way to define precisely the solubility of a solid in a liquid. **Solubility** is the concentration of solute in a saturated solution in equilibrium with undissolved solute. The solubility of $CuCl_2$, for example, is 70.6 g in 100 mL of water at 0 °C. If we add 100.0 g of $CuCl_2$ to 100 mL of water at 0 °C, we can expect 70.6 g to dissolve, and 29.4 g of solid to remain.

Photos: © Cengage Learning/Charles D. Winters

(a) Copper(II) chloride, the solute, is added to water, the solvent.

(b) Interactions between water molecules and Cu^{2+} and Cl^- ions allow the solid to dissolve. The ions are now sheathed with water molecules.

Figure 13.3 Making a solution of copper(II) chloride (the solute) in water (the solvent). When ionic compounds dissolve in water, each ion is surrounded by water molecules. The number of water molecules depends on ion size and charge.

A CLOSER LOOK

Supersaturated Solutions

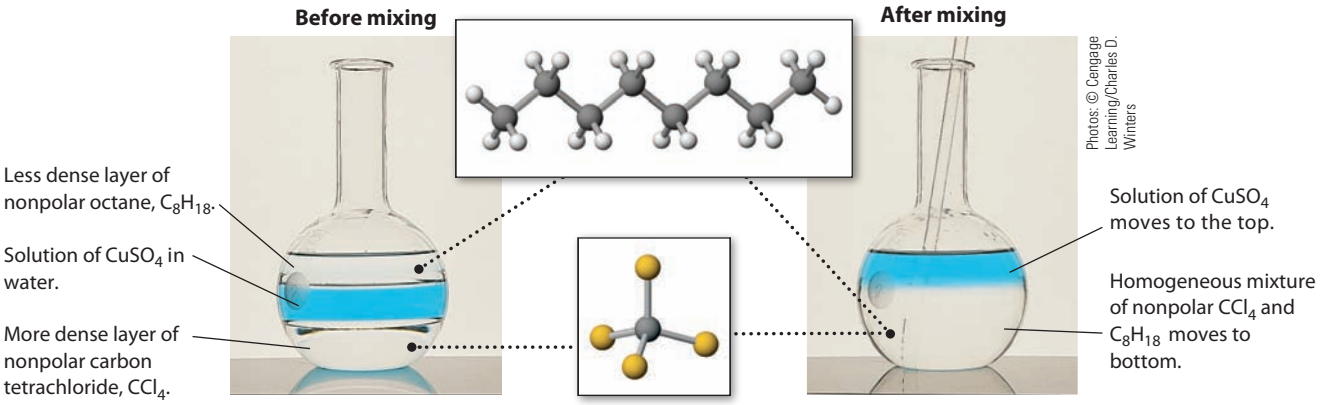
Although it may seem a contradiction, it is possible for a solution to hold more dissolved solute than the amount in a saturated solution. Such solutions are referred to as **supersaturated**. Supersaturated solutions are unstable, and the excess solid eventually crystallizes from the solution until the equilibrium concentration of the solute is reached.

The solubility of substances often decreases if the temperature is lowered. Supersaturated solutions are usually made by preparing a saturated solution at an elevated temperature and then carefully cooling it. If the rate of crystallization is slow, the solid may not precipitate when the solubility is exceeded. The result is a solution that has more solute than the amount defined by equilibrium conditions.

When disturbed in some manner, a supersaturated solution moves toward equilibrium by precipitating solute. This change can occur rapidly, often with the evolution of thermal energy. In fact, supersaturated solutions are used in "heat packs" to apply heat to injured muscles. When crystallization of sodium acetate ($NaCH_3CO_2$) from a supersaturated solution in a heat pack is initiated, the temperature of the heat pack rises to about 50 °C and crystals of solid sodium acetate are detected inside the bag.

© Cengage Learning/Charles D. Winters

Supersaturated solutions. When a supersaturated solution is disturbed, the dissolved salt (here sodium acetate, $NaCH_3CO_2$) rapidly crystallizes.



© Cengage Learning/Charles D. Winters

Heat of crystallization. A heat pack relies on the heat evolved by the crystallization of sodium acetate.

Liquids Dissolving in Liquids

If two liquids can be mixed in any proportion to form a homogeneous mixture they are said to be **miscible**. In contrast, **immiscible** liquids do not fully mix in all proportions; they exist in contact with each other as separate layers (Figure 13.4). Ethanol (C_2H_5OH) and water, both polar compounds, are miscible, as are the nonpolar liquids octane (C_8H_{18}) and carbon tetrachloride (CCl_4). Many similar observations like these have led to a rule of thumb: *Like dissolves like.* Nonpolar liquids frequently are miscible, as are polar liquids.

(a) Before mixing. The colorless, denser bottom layer is nonpolar carbon tetrachloride, CCl_4. The blue middle layer is a solution of $CuSO_4$ in water, and the colorless, less dense top layer is nonpolar octane, C_8H_{18}. This mixture was prepared by carefully layering one liquid on top of another, without mixing.

(b) After mixing. After stirring the mixture, the two nonpolar liquids form a homogeneous mixture. The mixture of CCl_4 and C_8H_{18} has a greater density than water.

Figure 13.4
Miscibility.

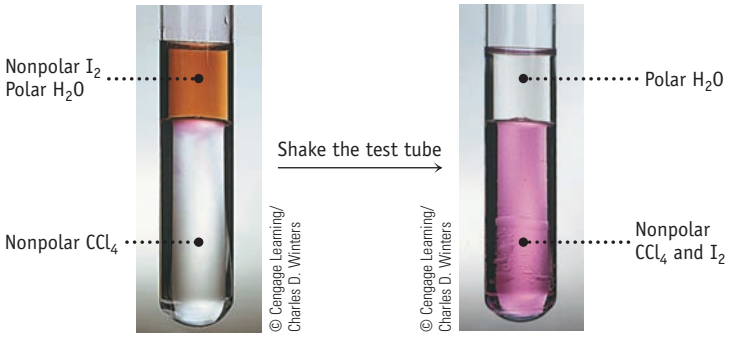

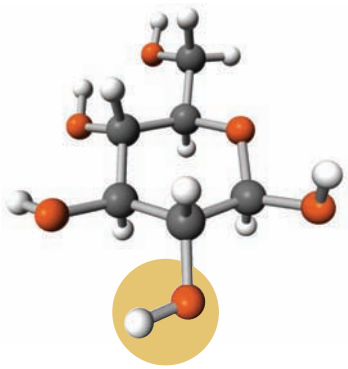

Figure 13.5 Solubility of nonpolar iodine in polar water and nonpolar carbon tetrachloride. When a solution of nonpolar I_2 in water (the brown layer on top in the left test tube) is shaken with nonpolar CCl_4 (the colorless bottom layer in the left test tube), the I_2 transfers preferentially to the nonpolar solvent. Evidence for this is the purple color of the bottom CCl_4 layer in the test tube on the right.

Like dissolves like. Glucose has five —OH groups on each molecule, groups that allow it to form hydrogen bonds with water molecules. As a result, glucose dissolves readily in water.

On the other hand, nonpolar solvents such as C_8H_{18} and CCl_4 are not miscible with water. As a general rule, polar solvents are likely not to be miscible with nonpolar solvents.

Solids Dissolving in Liquids

The "like dissolves like" guideline also holds for molecular solids dissolving in liquids. Nonpolar solids such as naphthalene, $C_{10}H_8$, dissolve readily in nonpolar solvents such as benzene, C_6H_6, and hexane, C_6H_{14}. Iodine, I_2, a nonpolar inorganic solid, dissolves in water to some extent, but, given a choice, it dissolves to a larger extent in a nonpolar liquid such as CCl_4 (Figure 13.5). Polar solids are often soluble in polar liquids such as water. Sucrose (sugar), a polar molecular solid with multiple —OH groups, is readily soluble in water, a fact well known because of its use to sweeten beverages.

As was seen with nonpolar liquids, most nonpolar solids are likely to be insoluble or have low solubilities in polar solvents such as water. The reverse is also true; polar solutes, sugar for example, are likely to have low solubility in nonpolar solvents such as gasoline.

Ionic compounds can be considered extreme examples of polar compounds, and they do not dissolve in nonpolar solvents. Sodium chloride, for example, does not dissolve in liquids such as hexane or CCl_4. However, the solubility of ionic compounds in the polar solvent water is not as easily predicted. Recall the solubility guidelines (Figure 3.10), which predict that some ionic compounds are soluble in water while others are not.

Network solids, including graphite, diamond, and quartz sand (SiO_2), do not dissolve in water. (Where would all the beaches be if sand dissolved in water?) The covalent chemical bonding in network solids is simply too strong to be broken; the lattice remains intact when in contact with water.

Enthalpy of Solution

What is the basis for the "like dissolves like" guideline? There are two factors that determine whether any process will occur. One factor is the enthalpy change for the process, here the *enthalpy of solution*. The second factor is the *entropy* change for the process. Entropy is a thermodynamic function that is a measure of the dispersal of the energy of the particles in the mixture relative to the pure liquids (Figure 13.6). The greater the energy dispersal, the greater is the entropy, and the more favorable the process. We discuss entropy more fully in Chapter 18, but here we only point out that in evaluating solutions, the entropy effect is often dominant. The enthalpy of solution, which can be interpreted readily based on attractive forces between particles, is an important factor in determining solubility, but less so than entropy.

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

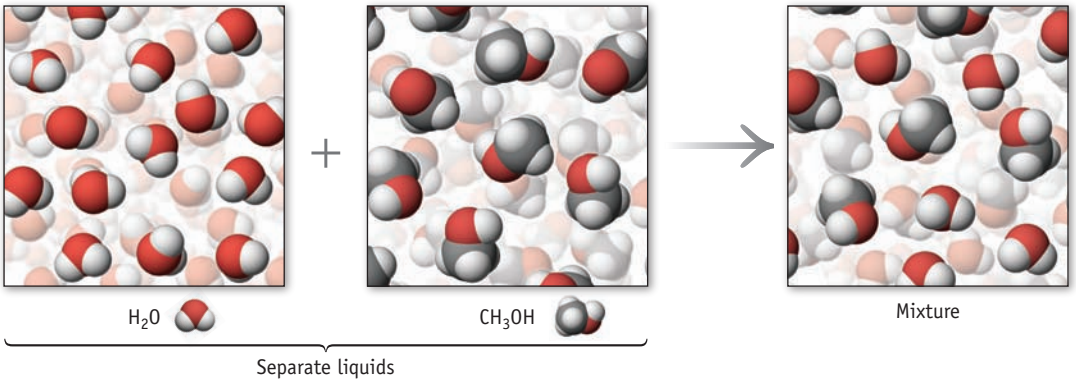

Figure 13.6 Driving the solution process—entropy. When two similar liquids—here water and methanol—are mixed, the molecules intermingle, and the energy of the system is more dispersed than in the two, separate pure liquids. A measure of this energy dispersal is entropy, a thermodynamic function described in more detail in Chapter 18.

It is possible to assess the enthalpy change that occurs when a solution forms by evaluating the intermolecular forces between particles. In pure water and pure methanol (CH_3OH), the major force between molecules is hydrogen bonding involving —OH groups. When the two liquids are mixed, hydrogen bonding between methanol and water molecules also occurs. Because solute-solvent and solute-solute forces of attraction are of similar magnitude, we can predict that the enthalpy change for the solution process will be small.

Similarly, the enthalpy change when dissolving a nonpolar solute in a nonpolar solvent is expected to be near zero. Molecules of pure octane or pure CCl_4, both of which are nonpolar, are held together in the liquid phase by London dispersion forces (Section 11.4). When these nonpolar liquids are mixed, the energy associated with the forces of attraction between solute and solvent is similar to the forces of attraction between octane and CCl_4 molecules in the pure liquids. As with solutions of polar solutes in polar solvents, little or no energy change occurs; the solution process is expected to be nearly energy neutral.

For ionic compounds dissolving in water, a favorable enthalpy change (a negative $\Delta_{soln}H$) generally leads to a compound being soluble. For example, sodium hydroxide is very soluble, dissolving in water with significant heat evolution (Figure 13.7a). An unfavorable enthalpy factor, however, does not guarantee that an ionic compound will not dissolve. Sodium chloride is quite soluble in water despite the fact that the solution process is slightly endothermic. And, ammonium nitrate is quite soluble in water in a process that is also endothermic, evidenced by the fact that the solution becomes noticeably colder (Figure 13.7b). In these cases, we must conclude that entropy is the driving force in the solution process.

Entropy and the Solution Process
It is generally accepted that entropy is a more important contributor to the solution process. (See Chapter 18 and T. P. Silverstein: "The real reason why oil and water don't mix." *Journal of Chemical Education*, Vol. 75, pp. 116–118, 1998.)

To further understand the energetics of the solution process, we will use the process of dissolving KF in water to illustrate what occurs. The energy level diagram in Figure 13.8 will help you follow the changes. Solid potassium fluoride has an ionic crystal lattice with alternating K^+ and F^- ions held in place by attractive forces due to their opposite charges. In water, these ions are separated from each other and *hydrated*; that is, they are surrounded by water molecules. Ion–dipole forces of attraction bind water molecules strongly to each ion. The energy change occurring on going from the reactant, KF(s), to the products, K^+(aq) and F^-(aq), is the sum of the energies of two individual steps:

1. Energy must be supplied to separate the ions in the lattice against their attractive forces. This is the reverse of the process defining the lattice enthalpy of an ionic compound (Section 12.3), and its value will be equal to $-\Delta_{lattice}H$. Separating the ions from one another is highly endothermic because the attractive forces between ions are strong.

(a) Dissolving NaOH in water is a strongly exothermic process.

(b) A "cold pack" contains solid ammonium nitrate, NH_4NO_3, and a package of water. When the water and NH_4NO_3 are mixed and the salt dissolves, the temperature of the system drops, owing to the endothermic enthalpy of solution of ammonium nitrate ($\Delta_{soln}H° = +25.7$ kJ/mol).

Photos: © Cengage Learning/Charles D. Winters

Figure 13.7 Dissolving ionic solids and enthalpy of solution.

2. Energy is evolved when the individual ions dissolve in water, where each ion becomes surrounded by water molecules. Strong forces of attraction (ion–dipole forces) are involved (Section 11.2). This process, referred to as **hydration** when water is the solvent, is strongly exothermic.

We can represent the process of dissolving KF in terms of these chemical equations:

Step 1: $KF(s) \longrightarrow K^+(g) + F^-(g)$ $\quad -\Delta_{lattice}H$

Step 2: $K^+(g) + F^-(g) \longrightarrow K^+(aq) + F^-(aq)$ $\quad \Delta_{hydration}H$

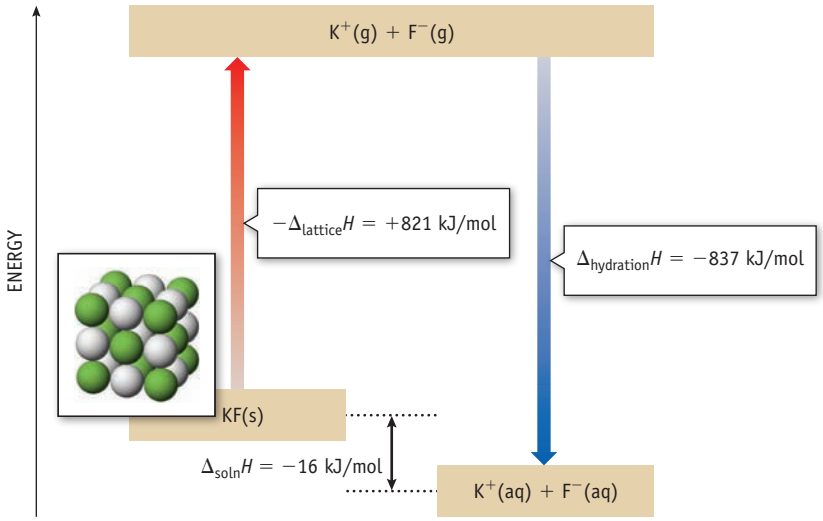

Figure 13.8 Model for energy changes on dissolving KF. An estimate of the magnitude of the energy change on dissolving an ionic compound in water is achieved by imagining it as occurring in two steps at the particulate level. Here, KF is first separated into cations and anions in the gas phase with an expenditure of 821 kJ per mol of KF. These ions are then hydrated, with $\Delta_{hydration}H$ estimated to be −837 kJ. The net energy change is −16 kJ, a slightly exothermic enthalpy of solution.

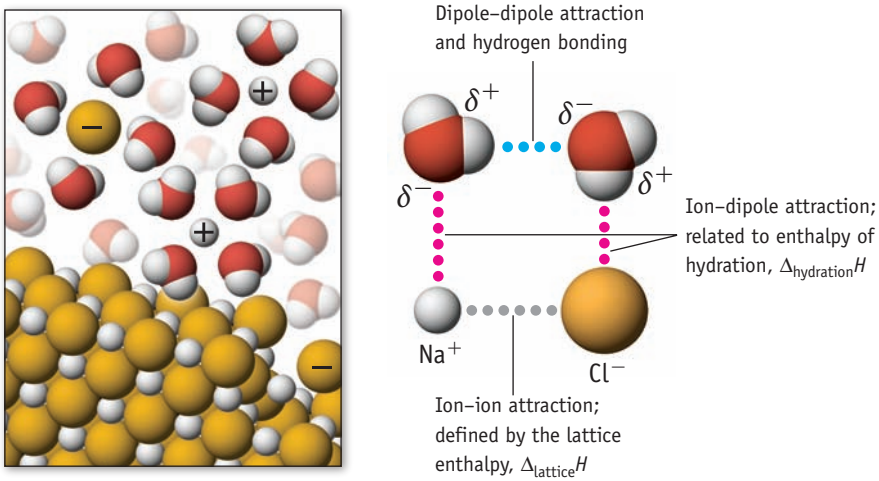

Figure 13.9 Dissolving an ionic solid in water. This process is a balance of forces. There are intermolecular forces between water molecules, and ion–ion forces are at work in the ionic crystal lattice. To dissolve, the ion–dipole forces between water and the ions (as measured by $\Delta_{hydration}H$) must overcome the ion–ion forces (as measured by $\Delta_{lattice}H$) and the intermolecular forces in water.

The enthalpy of the overall reaction, called the **enthalpy of solution** ($\Delta_{soln}H$), is the sum of the two enthalpy changes.

$$\text{Overall:} \quad KF(s) \longrightarrow K^+(aq) + F^-(aq) \qquad \Delta_{soln}H = -\Delta_{lattice}H + \Delta_{hydration}H$$

We can use this equation to calculate $\Delta_{hydration}H$. From the lattice energy for KF (−821 kJ/mol, calculated using a Born-Haber cycle; Section 12.3), and the value of $\Delta_{soln}H$ (−16.4 kJ/mol, from calorimetry) we can determine $\Delta_{hydration}H$ to be −837 kJ/mol.

As a general rule, to be water-soluble an ionic compound will have an enthalpy of solution that is exothermic or only slightly endothermic (Figure 13.9). In the latter instance, it is assumed that the enthalpy-disfavored solution process will be balanced by a favorable entropy of solution. If the enthalpy of solution is very endothermic (because of a low hydration energy) then the compound is unlikely to be soluble. Similarly, we can conclude that nonpolar solvents would not solvate ions strongly, and that the solution process would thus be energetically unfavorable. We therefore predict that an ionic compound, such as copper(II) sulfate, is not very soluble in nonpolar solvents such as carbon tetrachloride and octane (Figure 13.4).

It is also important to recognize that the enthalpy of solution is the difference between two very large numbers. Small variations in either lattice energy or hydration enthalpies can determine whether the solution process is endo- or exothermic.

TABLE 13.1

Data for Calculating Enthalpy of Solution

Compound	$\Delta_f H°$(s) (kJ/mol)	$\Delta_f H°$ (aq, 1 *m*) (kJ/mol)
LiF	−616.9	−611.1
NaF	−573.6	−572.8
KF	−568.6	−585.0
RbF	−557.7	−583.8
LiCl	−408.7	−445.6
NaCl	−411.1	−407.3
KCl	−436.7	−419.5
RbCl	−435.4	−418.3
NaOH	−425.9	−469.2
NH_4NO_3	−365.6	−339.9

Enthalpy of Solution: Thermodynamic Data

Tables of thermodynamic values often include values for the enthalpies of formation of aqueous solutions of salts. For example, $\Delta_f H°$ for NaCl(aq) (−407.3 kJ/mol, Table 13.1 and Appendix L) refers to the formation of a 1 *m* solution of NaCl from the elements. It may be considered to involve the enthalpy changes for two steps: (1) the formation of NaCl(s) from the elements Na(s) and Cl_2(g) in their standard states ($\Delta_f H°$), and (2) the formation of a 1 *m* solution by dissolving solid NaCl in water ($\Delta_{soln}H°$):

Formation of NaCl(s):	$Na(s) + \frac{1}{2}\,Cl_2(g) \longrightarrow NaCl(s)$	$\Delta_f H° = -411.1$ kJ/mol
Dissolving NaCl(s):	$NaCl(s) \longrightarrow NaCl(aq, 1\ m)$	$\Delta_{soln}H° = +3.8$ kJ/mol
Net process:	$Na(s) + \frac{1}{2}\,Cl_2(g) \longrightarrow NaCl(aq, 1\ m)$	$\Delta_f H° = -407.3$ kJ/mol

By combining the enthalpies of formation of a solid and of its aqueous solution, we can calculate the enthalpy of solution, as outlined in Example 13.2.

EXAMPLE 13.2

Calculating an Enthalpy of Solution

Problem Determine the enthalpy of solution for NH_4NO_3, the compound used in cold packs.

What Do You Know? The solution process for NH_4NO_3 is represented by the equation

$$NH_4NO_3(s) \longrightarrow NH_4NO_3(aq)$$

The enthalpies of formation of NH_4NO_3 in the solid state (−365.6 kJ/mol) and in solution (−339.9 kJ/mol) are given in Table 13.1.

Strategy Equation 5.6 (Section 5.7) states that the enthalpy change for a process is the difference between the enthalpy of formation, $\Delta_f H$, of the final state (here the compound in solution) and the initial state (the solid).

SOLUTION The enthalpy change for this process is calculated using Equation 5.6 as follows:

$$\begin{aligned}\Delta_{soln}H^\circ &= \Sigma[n\Delta_f H^\circ(\text{product})] - \Sigma[n\Delta_f H^\circ(\text{reactant})] \\ &= \Delta_f H^\circ\left[NH_4NO_3(aq)\right] - \Delta_f H^\circ\left[NH_4NO_3(s)\right] \text{ (where } n = 1 \text{ for both)} \\ &= -339.9 \text{ kJ} - (-365.6 \text{ kJ}) = +25.7 \text{ kJ}\end{aligned}$$

Think about Your Answer The process is endothermic, as indicated by the fact that $\Delta_{soln}H^\circ$ has a positive value and as verified by the experiment in Figure 13.7b.

Check Your Understanding

Use the data in Table 13.1 to calculate the enthalpy of solution for NaOH.

13.3 Factors Affecting Solubility: Pressure and Temperature

Goals for Section 13.3

- Describe the effects of pressure and temperature on the solubility of a solute.
- Use Henry's law to calculate the solubility of a gas in a solvent.
- Apply Le Chatelier's principle to predict the change in solubility of gases with temperature changes.

Pressure and temperature are two external factors that influence solubility. Both affect the solubility of gases in liquids, whereas only temperature is a factor in the solubility of solids in liquids.

Dissolving Gases in Liquids: Henry's Law

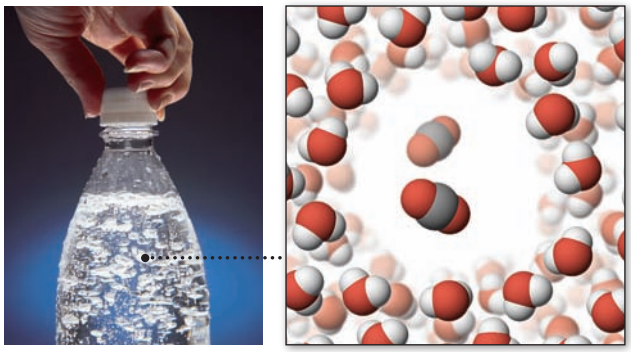
The solubility of a gas in a liquid is directly proportional to the gas pressure. This is a statement of **Henry's law**,

$$S_g = k_H P_g \tag{13.4}$$

where S_g is the gas solubility (in mol/kg), P_g is the partial pressure of the gaseous solute, and k_H is Henry's law constant (Table 13.2), a constant characteristic of the solute and solvent.

Carbonated soft drinks illustrate how Henry's law works. These beverages are packed under pressure in a chamber filled with carbon dioxide gas, some of which

TABLE 13.2



Henry's Law Constants for Gases in Water (25 °C)*

Gas	k_H (mol/kg·bar)
He	3.8×10^{-4}
H_2	7.8×10^{-4}
N_2	6.0×10^{-4}
O_2	1.3×10^{-3}
CO_2	0.034
CH_4	1.4×10^{-3}
C_2H_6	1.9×10^{-3}

*From http://webbook.nist.gov/chemistry/. *Note:* 1 bar = 0.9869 atm.

Figure 13.10 Gas solubility and pressure. Carbonated beverages are bottled under high CO_2 pressure. When the bottle is opened, the pressure is released, and bubbles of CO_2 form within the liquid and rise to the surface. After some time, an equilibrium between dissolved CO_2 and atmospheric CO_2 is reached. The beverage tastes flat when most of its dissolved CO_2 is lost.

dissolves in the beverage. When the can or bottle is opened, the partial pressure of CO_2 above the solution drops, causing the solubility of CO_2 to drop. Gas bubbles out of the solution (Figure 13.10).

We can better understand the effect of pressure on solubility by examining the system at the particulate level. The solubility of a gas is defined as the concentration of the dissolved gas in equilibrium with the substance in the gaseous state. At equilibrium, the rate at which solute gas molecules escape the solution and enter the gaseous state equals the rate at which gas molecules re-enter the solution. An increase in pressure results in more molecules of gas striking the surface of the liquid and entering the solution in a given time. The solution eventually reaches a new equilibrium when the concentration of gas dissolved in the solvent is high enough that the rate of gas molecules escaping the solution again equals the rate of gas molecules entering the solution.

Limitations of Henry's Law Henry's law holds quantitatively only for gases that do not interact chemically with the solvent. It does not accurately predict the solubility of NH_3 in water, for example, because this compound reacts with water to give small concentrations of NH_4^+ and OH^-.

EXAMPLE 13.3

Using Henry's Law

Problem What is the concentration of O_2 in a freshwater stream in equilibrium with air at 25 °C and at a pressure of 1.0 bar? Express the answer in grams of O_2 per kg of water.

What Do You Know? You know the total air pressure and temperature, and you can look up the Henry's law constant (1.3×10^{-3} mol/kg · bar). (Note that 1 bar is approximately 1 atm; Section 10.1.)

Strategy You first must find the partial pressure of O_2 from its mole fraction in air (0.21) and the specified atmospheric pressure (1.0 bar). Then use Henry's law to calculate its molar solubility.

SOLUTION

(a) The mole fraction of O_2 in air is 0.21, and, because the total pressure is 1.0 bar, the partial pressure of O_2 is 0.21 bar.

(b) Using the O_2 partial pressure for P_g in Henry's law, we have:

$$\text{Solubility of } O_2 = k_H P_g = \left(\frac{1.3 \times 10^{-3} \text{ mol}}{\text{kg} \cdot \text{bar}}\right)(0.21 \text{ bar}) = 2.73 \times 10^{-4} \text{ mol/kg}$$

(c) Calculate the concentration in g/kg from the concentration in mol/kg and the molar mass of O_2:

$$\text{Solubility of } O_2 = \left(\frac{2.73 \times 10^{-4} \text{ mol}}{\text{kg}}\right)\left(\frac{32.0 \text{ g}}{\text{mol}}\right) = 0.0087 \text{ g/kg}$$

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Think about Your Answer The concentration of O_2 is 8.7 ppm (8.7 mg/1000 g). This concentration is quite low, but it is sufficient to provide the oxygen required by aquatic life.

Check Your Understanding

What is the concentration of CO_2 in water at 25 °C when the partial pressure is 0.33 bar? (Although CO_2 reacts with water to give traces of H_3O^+ and HCO_3^-, the reaction occurs to such a small extent that Henry's law is obeyed at low CO_2 partial pressures.)

Temperature Effects on Solubility: Le Chatelier's Principle

The solubility of all gases in water decreases with increasing temperature. You may realize this from everyday observations such as the appearance of bubbles of air as water is heated below the boiling point.

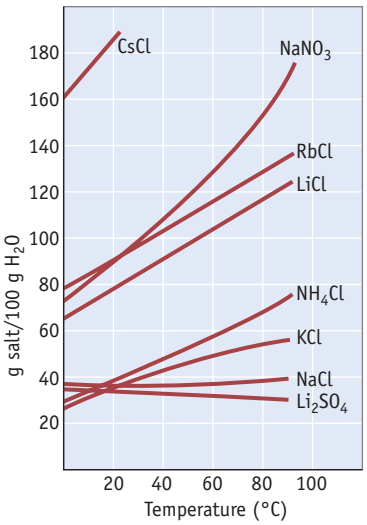
It is possible to predict the effect of temperature on the solubility of a gas from the enthalpy of solution. When gases dissolve in water they usually do so in an exothermic process

$$\text{Gas} + \text{liquid solvent} \underset{}{\overset{\Delta_{soln}H < 0}{\rightleftharpoons}} \text{saturated solution} + \text{energy}$$

The reverse process, loss of dissolved gas molecules from a solution, requires energy as heat. At equilibrium, the rates of the two processes are the same.

To account for the effect of temperature on solubility, we turn to **Le Chatelier's principle**, which states that a change in any of the factors determining an equilibrium causes the system to adjust by shifting in the direction that reduces or counteracts the effect of the change. If a solution of a gas in a liquid is heated, for example, the equilibrium will shift to absorb some of the added energy. That is, the reaction

$$\text{Gas} + \text{liquid solvent} \underset{\text{Add energy. Equilibrium shifts left.}}{\overset{\text{Exothermic process; } \Delta_{soln}H \text{ is negative.}}{\rightleftharpoons}} \text{saturated solution} + \text{energy}$$



shifts to the left if the temperature is raised because energy is absorbed in the process that produces free gas molecules and pure solvent. This shift corresponds to less gas dissolved and a lower solubility at higher temperature—the observed result.

The solubility of solids in water is also affected by temperature, but, unlike the situation involving solutions of gases, no general pattern of behavior is observed. In Figure 13.11, the solubilities of several salts are plotted versus temperature. The solubility of many salts increases with increasing temperature, but there are notable exceptions. Predictions based on whether the enthalpy of solution is positive or negative work most of the time, but exceptions do occur.

Chemists take advantage of the variation of solubility with temperature to purify compounds. An impure sample of a compound that is more soluble at higher temperatures is dissolved by heating the solution. The solution is then cooled to decrease the solubility (Figure 13.11c). When the limit of solubility is reached at the lower temperature, crystals of the pure compound form. If the process is done slowly and carefully, it is sometimes possible to obtain very large crystals.

13.4 Colligative Properties

Goals for Section 13.4

- Using Raoult's law, calculate the effect of dissolved solutes on solvent vapor pressure ($P_{solvent}$).
- Calculate the effect on boiling point and freezing point of a solvent caused by a solute.
- Calculate the osmotic pressure (Π) for solutions.
- Use colligative properties to determine the molar mass of a solute.
- Use the van't Hoff factor in colligative property calculations involving ionic solutes.

Changes in Vapor Pressure: Raoult's Law

When a non-volatile solute dissolves in a liquid, the vapor pressure of the solvent is lowered. Experiments show that the vapor pressure of the solvent over the solution, $P_{solvent}$, is proportional to the mole fraction (X) of the solvent. We can write an equation, called **Raoult's law**, that expresses this relationship:

$$P_{solvent} = X_{solvent}\, P°_{solvent} \qquad (13.5)$$

Raoult's law tells us that the vapor pressure of solvent over a solution ($P_{solvent}$) is some fraction of the pure solvent equilibrium vapor pressure ($P°_{solvent}$). For example, if 95% of the molecules in a solution are solvent molecules ($X_{solvent} = 0.95$), then the vapor pressure of the solvent ($P_{solvent}$) is 95% of $P°_{solvent}$.

An **ideal solution** is defined as one that obeys Raoult's law precisely. However, just as no gas is truly ideal, no solution is truly ideal. Nonetheless, Raoult's law is a good approximation of solution behavior in most instances, especially at low solute concentration.

Equilibrium Vapor Pressure Recall the equilibrium vapor pressure of a liquid is defined as the pressure of the vapor when the liquid and the vapor are in equilibrium (Section 11.6).

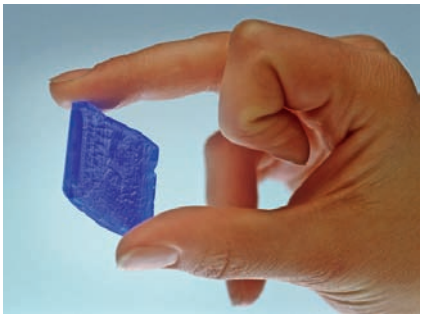
A CLOSER LOOK

Growing Crystals



The very large crystal you see in the photo was grown at the Lawrence Livermore Laboratory in California. It weighs 318 kg and measures $66 \times 53 \times 58$ cm. The crystal was grown by suspending a thumbnail-sized seed crystal in a 6-foot tank of saturated KH_2PO_4. The temperature of the solution was gradually reduced from 65 °C over a period of about 50 days. The large crystals are sliced into thin plates, which are used to convert light from a laser from infrared to ultraviolet.

You can grow crystals from chemicals you can find in the supermarket. Alum (potassium aluminum sulfate) is a particularly good choice. Heat about 100 mL of water and then add the alum until no more will dissolve. Allow the mixture to cool undisturbed overnight. The next day small "seed" crystals will have formed. Remove one small crystal that appears well formed, and then pour the saturated solution into another clean jar. Carefully tie a thread or a piece of nylon fishing line around the seed crystal and suspend it in the saturated solution. (Don't let it touch the sides or the bottom.) Cover the jar lightly and put it aside in a place where it can sit undisturbed for a few days or weeks, and a well-formed crystal will form.

A copper(II) sulfate crystal grown by a student.

For Raoult's law to apply, the forces of attraction between solute and solvent molecules must be the same as those between solvent molecules in the pure solvent. This is frequently the case when molecules with similar structures are involved. Thus, solutions of one hydrocarbon in another (hexane, C_6H_{14}, dissolved in octane, C_8H_{18}, for example) follow Raoult's law quite closely. However, with other solutions deviations from Raoult's law are observed. If solvent–solute interactions are stronger than solvent–solvent interactions, the measured vapor pressure will be lower than the value calculated by Raoult's law. If the solvent–solute interactions are weaker than solvent–solvent interactions, the vapor pressure will be higher.

Raoult's law can be modified to give another useful equation that allows us to calculate the *lowering* of the vapor pressure of the *solvent*, $\Delta P_{\text{solvent}}$, as a function of the mole fraction of the *solute*.

$$\Delta P_{\text{solvent}} = P_{\text{solvent}} - P°_{\text{solvent}}$$

Substituting Raoult's law for P_{solvent}, we have

$$\Delta P_{\text{solvent}} = (X_{\text{solvent}}\, P°_{\text{solvent}}) - P°_{\text{solvent}} = -(1 - X_{\text{solvent}})P°_{\text{solvent}}$$

In a solution that has only the volatile solvent and one nonvolatile solute, the sum of the mole fraction of solvent and solute must be 1:

$$X_{\text{solvent}} + X_{\text{solute}} = 1$$

Therefore, $1 - X_{\text{solvent}} = X_{\text{solute}}$, and the equation for $\Delta P_{\text{solvent}}$ can be rewritten as

$$\Delta P_{\text{solvent}} = -X_{\text{solute}}\, P°_{\text{solvent}} \qquad (13.6)$$

Thus, the *decrease* in the vapor pressure of the solvent is proportional to the mole fraction (the relative number of particles) of solute.

EXAMPLE 13.4

Using Raoult's Law

Problem You dissolve 651 g of ethylene glycol, $HOCH_2CH_2OH$, in 1.50 kg of water. What is the vapor pressure of the water over the solution at 90 °C? Assume ideal behavior for the solution.

What Do You Know? This is a Raoult's law problem where you want to know $P_{solvent}$. To calculate $P_{solvent}$ you need the mole fraction of solvent and the vapor pressure of the pure solvent. You can calculate the mole fraction of solute from the masses of solute and solvent and the molar masses of these species. The vapor pressure of pure water at 90 °C (= 525.8 mm Hg) is found in Appendix G.

Strategy First calculate the mole fraction of the solvent (water) and then combine that with the vapor pressure of pure solvent at the specified temperature using Raoult's law (Equation 13.5).

SOLUTION

(a) Calculate the amounts of water and ethylene glycol and, from these, the mole fraction of water.

$$\text{Amount of water} = 1.50 \times 10^3 \text{ g} \left(\frac{1 \text{ mol}}{18.02 \text{ g}} \right) = 83.24 \text{ mol water}$$

$$\text{Amount of ethylene glycol} = 651 \text{ g} \left(\frac{1 \text{ mol}}{62.07 \text{ g}} \right) = 10.49 \text{ mol glycol}$$

$$X_{water} = \frac{83.24 \text{ mol water}}{83.24 \text{ mol water} + 10.49 \text{ mol glycol}} = 0.8881$$

(b) Next apply Raoult's law.

$$P_{water} = X_{water} P°_{water} = (0.8881)(525.8 \text{ mm Hg}) = 467 \text{ mm Hg}$$

Think about Your Answer Although a substantial mass of ethylene glycol was added to the water, the decrease in the vapor pressure of the solvent was only 59 mm Hg, or about 11%:

$$\Delta P_{water} = P_{water} - P°_{water} = 467 \text{ mm Hg} - 525.8 \text{ mm Hg} = -59 \text{ mm Hg}$$

Ethylene glycol is ideal for use as antifreeze. It dissolves easily in water, is noncorrosive, and is relatively inexpensive. Because of its high boiling point, it will not evaporate readily. It is, however, toxic to animals, so it is being replaced by less toxic propylene glycol.

Check Your Understanding

Assume you dissolve 10.0 g of sucrose ($C_{12}H_{22}O_{11}$) in 225 mL (225 g) of water and warm the water to 60 °C. What is the vapor pressure of the water over this solution? (Appendix G lists $P°(H_2O)$ at various temperatures.)

Boiling Point Elevation

Suppose you have a solution of a nonvolatile solute in the volatile solvent benzene. If the solute concentration is 0.200 mol in 100. g of benzene (C_6H_6) (= 2.00 mol/kg), this means that $X_{benzene} = 0.865$. Using $X_{benzene}$ and applying Raoult's law, we can calculate that the vapor pressure of the solvent at 60 °C will drop from 400. mm Hg for the pure solvent to 346 mm Hg for the solution:

$$P_{benzene} = X_{benzene} P°_{benzene} = (0.865)(400. \text{ mm Hg}) = 346 \text{ mm Hg}$$

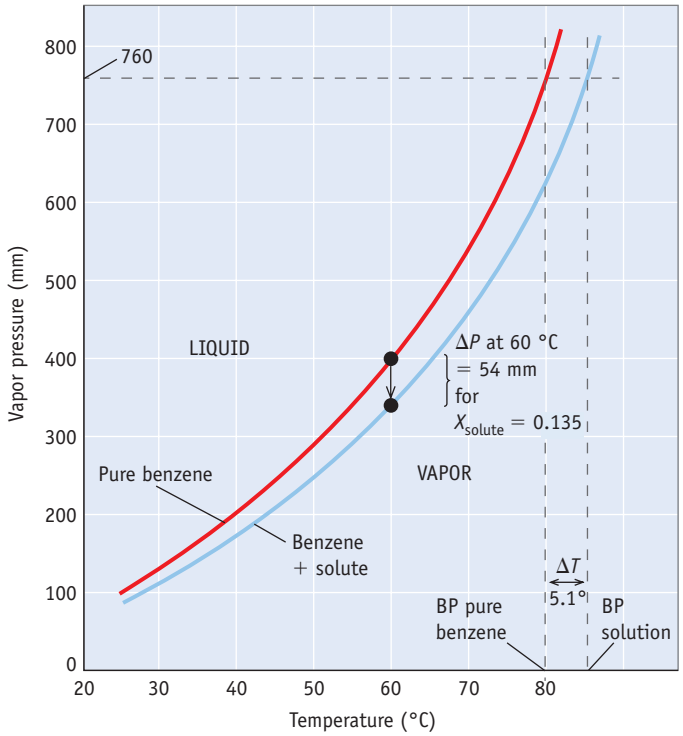

Figure 13.12 Lowering the vapor pressure of benzene by addition of a nonvolatile solute. The curve drawn in red represents the vapor pressure of pure benzene, and the curve in blue represents the vapor pressure of a solution containing 0.200 mol of a solute dissolved in 0.100 kg of solvent (2.00 *m*). This graph was created by doing a series of calculations such as the one shown in the text. As an alternative, the graph could be created by measuring various vapor pressures for the solution in a laboratory experiment.

This point is marked on the vapor pressure graph in Figure 13.12. Additional points calculated in the same way for other temperatures define the vapor pressure curve for the solution (the lower curve in Figure 13.12).

An important observation we can make in Figure 13.12 is that the vapor pressure lowering caused by the nonvolatile solute leads to an increase in the boiling point. The normal boiling point of a liquid is the temperature at which its vapor pressure is equal to 1 atm or 760 mm Hg (Section 11.6). In Figure 13.12, we see that the normal boiling point of pure benzene (at 760 mm Hg) is about 80 °C. Tracing the vapor pressure curve for the solution, it is apparent that the vapor pressure reaches 760 mm Hg at a temperature about 5 °C higher than this value.

An important question is how the boiling point of the solution varies with solute concentration. In fact, a simple relationship exists: the boiling point elevation, ΔT_{bp}, is directly proportional to the molality of the solute.

$$\text{Elevation in boiling point} = \Delta T_{bp} = K_{bp} \cdot m_{solute} \qquad (13.7)$$

In this equation, K_{bp} is a proportionality constant called the **molal boiling point elevation constant**. It has the units of degrees/molal (°C/*m*). Values for K_{bp} are determined experimentally, and different solvents have different values (Table 13.3). Formally, the value of K_{bp} corresponds to the elevation in boiling point for a 1 *m* solution.

TABLE 13.3 Some Boiling Point Elevation and Freezing Point Depression Constants

Solvent	Normal Boiling Point (°C) Pure Solvent	K_{bp} (°C/*m*)	Normal Freezing Point (°C) Pure Solvent	K_{fp} (°C/*m*)
Water	100.00	+0.5121	0.0	−1.86
Benzene (C_6H_6)	80.10	+2.53	5.50	−5.12
Camphor ($C_{10}H_{16}O$)	207.4	+5.611	179.75	−39.7
Chloroform ($CHCl_3$)	61.70	+3.63	—	—

EXAMPLE 13.5

Boiling Point Elevation

Problem Eugenol, a compound found in nutmeg and cloves, has the formula $C_{10}H_{12}O_2$. What is the boiling point of a solution containing 0.144 g of this compound dissolved in 10.0 g of benzene?

What Do You Know? You know the identity and mass of both the solute and the solvent. You will need to look up the boiling point for pure benzene and the value of K_{bp}.

Strategy

- Calculate the solution concentration (molality, *m*, in mol/kg) from the amount of eugenol and the mass of solvent (kg).
- Calculate the change in boiling point using Equation 13.7 (with a value of K_{bp} from Table 13.3).
- Add the change to the boiling temperature of pure benzene to obtain the new boiling point.

SOLUTION

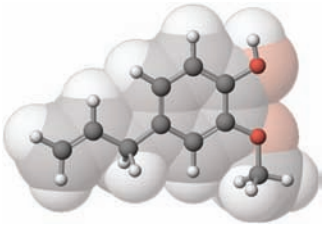
(a) Solution concentration

$$0.144 \text{ g eugenol} \left(\frac{1 \text{ mol eugenol}}{164.2 \text{ g}} \right) = 8.770 \times 10^{-4} \text{ mol eugenol}$$

$$c_{\text{eugenol}} = \frac{8.770 \times 10^{-4} \text{ mol eugenol}}{0.0100 \text{ kg benzene}} = 8.770 \times 10^{-2}\ m$$

(b) Boiling point elevation

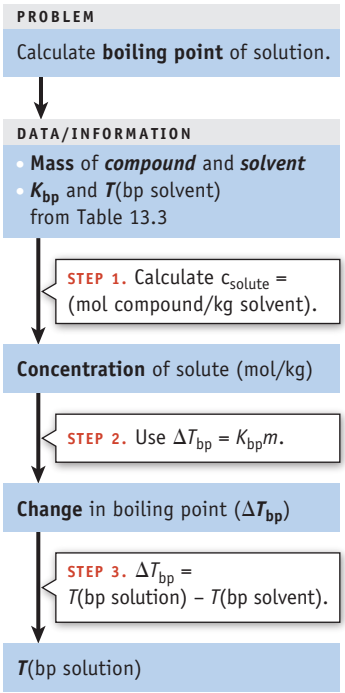
$$\Delta T_{bp} = (2.53\ ^\circ\text{C}/m)(0.08770\ m) = 0.222\ ^\circ\text{C}$$



Because the boiling point rises relative to that of the pure solvent, the boiling point of the solution is

$$80.10\ ^\circ\text{C} + 0.222\ ^\circ\text{C} = 80.32\ ^\circ\text{C}$$

Think about Your Answer Boiling point elevation is proportional to the solute concentration so sizable increases in boiling point are possible at high concentrations.



Check Your Understanding

What quantity of ethylene glycol, $HOCH_2CH_2OH$, must be added to 125 g of water to raise the boiling point by 1.0 °C? Express the answer in grams.

Eugenol, $C_{10}H_{12}O_2$, is an important component in oil of cloves, a commonly used spice.

Strategy Map 13.5

The elevation of the boiling point of a solvent on adding a solute has many practical consequences. One of them is the protection your car's engine receives in summer using "all-season" antifreeze. The main ingredient of commercial antifreeze is ethylene glycol, $HOCH_2CH_2OH$. The car's radiator and cooling system are sealed to keep the coolant under pressure, ensuring that it will not vaporize at normal engine temperatures. When the air temperature is high in the summer, however, the radiator could "boil over" if it were not protected with "antifreeze." By adding this nonvolatile liquid, the solution in the radiator has a higher boiling point than that of pure water.

Why Is the Boiling Point of a Solution Elevated and Its Freezing Point Depressed? The answer to this question is related to entropy, a thermodynamic function discussed in Chapter 18. You can consult a website that has a discussion of entropy (entropysite.oxy.edu) or the specific site at which colligative properties are discussed: http://entropysite.oxy.edu/entropy_is_simple/index.html.

Freezing Point Depression

Another consequence of dissolving a solute in a solvent is that the freezing point of the solution is lower than that of the pure solvent (Figure 13.13). For an ideal

A CLOSER LOOK

Hardening of Trees

Hope Jahren is a botanist of considerable note. She has written a delightful book, *Lab Girl* (Alfred Knopf, New York, 2016), a book partly about her life and her career in teaching and research in universities, but also about her passion for understanding the biology of trees. In one chapter, she describes the reason trees do not freeze in the winter, a topic directly related to the subject of this chapter.

"In order to prepare for their long winter journey, trees undergo a process known as 'hardening.' First the permeability of the cell walls increases drastically, allowing pure water to flow out while concentrating the sugars, proteins, and acids left behind. These chemicals act as a potent antifreeze, such that the cell can now dip well below freezing and the fluid inside of it will still persist in a syrupy liquid form. The spaces between the cells are now filled with an ultrapure distillate of cell water, so pure that there are no stray atoms upon which an ice crystal could nucleate and grow. Ice is a three-dimensional crystal of molecules, and freezing requires a nucleation spot—some chemical aberration upon which the pattern may start to build. Pure water devoid of any such site may be 'supercooled' to forty degrees below zero and still remain an ice-free liquid. It is in this 'hardened' state, with some cells packed full of chemicals and others sectioned off for purity, that a tree embarks on its winter journey, standing unmoved through the frost, sleet, and blizzards of the season. These trees do not grow during the winter; they merely stand and ride planet Earth to the other side of the sun, where the North Pole will finally be tilted toward the heat source and the tree will experience summer."

"The vast majority of northern trees prepare well for their wintertime journey, and death due to frost damage is extremely rare. A chilly autumn brings on the same hardening as a balmy one, because trees do not take their cue from the changing temperature. It is the gradual shortening of the days, sensed as a steady decrease of light during the twenty-four-hour cycle, that triggers hardening. Unlike the overall character of winter, which may be mild one winter and punishing the next, the pattern of how light changes through the autumn is exactly the same every year."

(a) Adding antifreeze to water prevents the water from freezing. Here, a jar of pure water *(left)* and a jar of water to which automobile antifreeze had been added *(right)* were kept overnight in the freezing compartment of a home refrigerator.

(b) When a solution freezes, it is pure solvent that solidifies. Here, water containing a purple dye was frozen slowly. Pure ice formed along the walls of the tube, and the dye stayed in solution. The dye concentration increased as more and more solvent was frozen out, and the resulting solution had a lower and lower freezing point. Eventually, the system contained pure, colorless ice along the walls of the tube and a concentrated solution of dye in the center of the tube.

solution, the depression of the freezing point is given by an equation similar to that for the elevation of the boiling point:

$$\text{Freezing point depression} = \Delta T_{fp} = K_{fp} \cdot m_{solute} \qquad (13.8)$$

where K_{fp} is the **molal freezing point depression constant** in degrees Celsius per molal (°C/m). Values of K_{fp} for a few common solvents are given in Table 13.3. The values are negative quantities, so the result of the calculation is a negative value for ΔT_{fp}, signifying a decrease in temperature.

The practical aspects of freezing point changes from pure solvent to solution are similar to those for boiling point elevation. The very name of the liquid you add to the radiator in your car, antifreeze, indicates its purpose (Figure 13.13a). The label on the container of antifreeze tells you, for example, to add 6 qt (5.7 L) of antifreeze to a 12-qt (11.4-L) cooling system to lower the freezing point to −34 °C and to raise the boiling point to +109 °C.

EXAMPLE 13.6

Freezing Point Depression

Problem What mass of ethylene glycol, $HOCH_2CH_2OH$, must be added to 5.50 kg of water to lower the freezing point of the water from 0.0 °C to −10.0 °C?

What Do You Know? In some ways this is the reverse of Example 13.5. Here you know the change in freezing point, but wish to know how much solute is needed to produce that value of ΔT.

Strategy The solution concentration (molality, m) can be calculated from ΔT_{fp} and K_{fp} (Table 13.3) using Equation 13.8. Combine the concentration with the mass of solvent to obtain the amount of solute and then its mass.

SOLUTION

(a) Calculate the solute concentration in a solution with a freezing point depression of −10.0 °C.

$$\text{Solute concentration } (m) = \frac{\Delta T_{fp}}{K_{fp}} = \frac{-10.0\ °C}{-1.86\ °C/m} = 5.376\ m$$

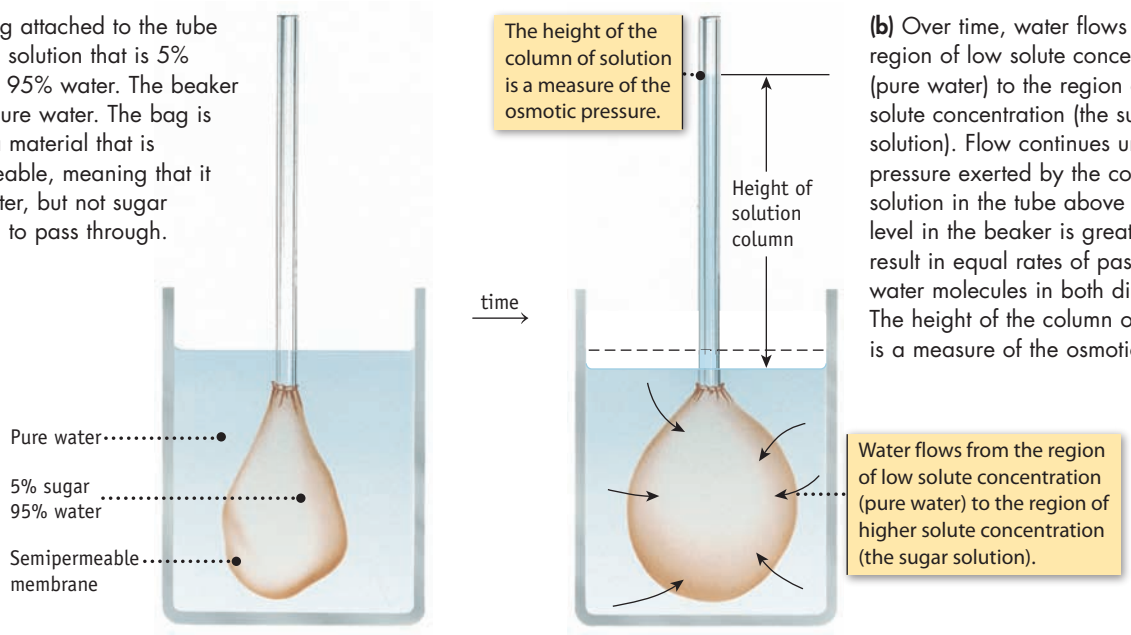
(b) Calculate the amount of solute from the concentration and solvent mass.

$$\left(\frac{5.376\ \text{mol glycol}}{1.00\ \text{kg water}}\right)(5.50\ \text{kg water}) = 29.57\ \text{mol glycol}$$

(c) Calculate the mass of the solute, ethylene glycol.

$$29.57\ \text{mol glycol}\left(\frac{62.07\ \text{g}}{1\ \text{mol}}\right) = 1840\ \text{g glycol}$$

Think about Your Answer The value of K_{fp} tells us that the freezing point of water is lower by 1.86 °C for a 1 molal solution. In this particular problem, the freezing point depression was −10.0 °C, so a molality around 5 m is reasonable. The density of ethylene glycol is 1.11 kg/L, so the volume of glycol to be added is (1.84 kg)(1 L/1.11 kg) = 1.65 L.



Check Your Understanding

In the northern United States, summer cottages are usually closed up for the winter. When doing so, the owners "winterize" the plumbing by putting antifreeze in the toilet tanks, for example. Will adding 525 g of $HOCH_2CH_2OH$ to 3.00 kg of water ensure that the water will not freeze at −25 °C?

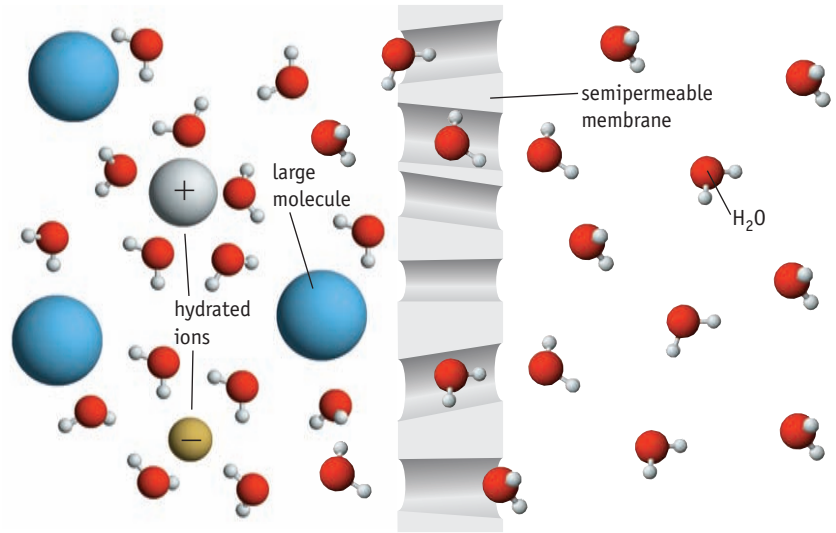
(a) The bag attached to the tube contains a solution that is 5% sugar and 95% water. The beaker contains pure water. The bag is made of a material that is semipermeable, meaning that it allows water, but not sugar molecules, to pass through.



(b) Over time, water flows from the region of low solute concentration (pure water) to the region of higher solute concentration (the sugar solution). Flow continues until the pressure exerted by the column of solution in the tube above the water level in the beaker is great enough to result in equal rates of passage of water molecules in both directions. The height of the column of solution is a measure of the osmotic pressure.

Figure 13.14 **The process of osmosis.**

Osmotic Pressure

Osmosis is the movement of solvent molecules through a semipermeable membrane from a region of lower solute concentration to a region of higher solute concentration. This movement can be demonstrated with a simple experiment. The beaker in Figure 13.14 contains pure water, and the bag and tube hold a concentrated sugar solution. The liquids are separated by a semipermeable membrane, a thin sheet of material (such as a vegetable tissue or cellophane) through which only certain types of molecules can pass. Here, water molecules can pass through the membrane, but larger sugar molecules (or hydrated ions) cannot (Figure 13.15). When the experiment is begun, the liquid levels in the beaker and the tube are the same. Over time, however, the level of the sugar solution inside the tube rises, the level of pure water in the beaker falls, and the sugar solution becomes more dilute. Eventually, no further net change occurs; equilibrium is reached.

Figure 13.15 **Osmosis at the particulate level.** Osmotic flow through a membrane that is selectively permeable (semipermeable) to water. Dissolved substances such as hydrated ions or large sugar molecules cannot diffuse through the membrane.

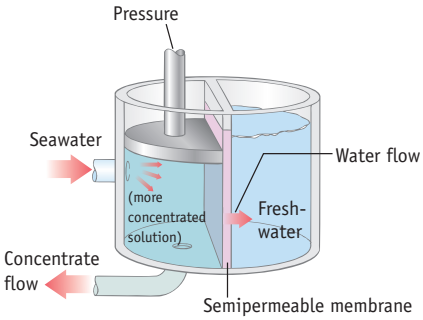
A CLOSER LOOK

Reverse Osmosis for Pure Water

Finding sources of freshwater for humans and agriculture has been a constant battle for centuries, and, if we continue using Earth's water at the present rate, those problems may increase. Although Earth has abundant water, 97% of it is too salty to drink or to use on crops. A large portion of the remaining 3% is locked in the form of ice in the polar regions and is not easily obtained.

One of the oldest ways to obtain freshwater from seawater is by evaporation. This is, however, very energy-intensive, and the salt and other materials left behind may not be useful.



Reverse osmosis is another method of obtaining freshwater from seawater or groundwater. In this technique a pressure greater than the osmotic pressure of the impure water is applied to force water through a semipermeable membrane from a region of high solute concentration to one of lower solute concentration, that is, in the reverse direction that the water would move by osmosis.

Although reverse osmosis has been known for over 200 years, only in the last few decades has it been exploited. Now some municipalities obtain drinking water this way, and pharmaceutical companies use it to obtain highly purified water. More than 15,000 reverse osmosis plants are in operation or in the planning stage worldwide.

Andy Sotiriou/Photodisc/Getty Images

A reverse osmosis plant.

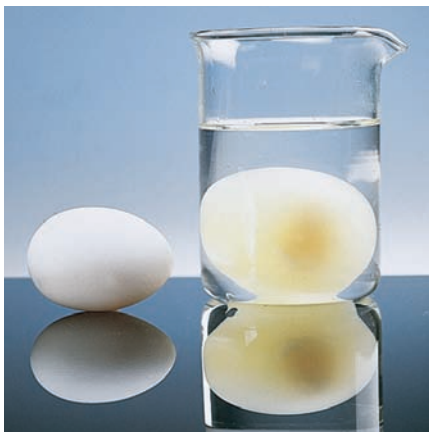
Reverse osmosis. Drinking water can be produced from seawater by reverse osmosis. The osmotic pressure of seawater is approximately 27 atm. To obtain freshwater at a reasonable rate, reverse osmosis requires a pressure of about 50 atm. For comparison, bicycle tires usually have an air pressure of 2–3 atm.

From a molecular point of view, the semipermeable membrane does not present a barrier to the movement of water molecules, so they move through the membrane in both directions. Over time, more water molecules pass through the membrane from the pure water side to the solution side than in the opposite direction. The net effect is that water molecules move from regions of low solute concentration to regions of high solute concentration.

Why does the system eventually reach equilibrium? Clearly, the solution in the tube in Figure 13.14 can never reach zero sugar or salt concentration, which would be required to equalize the concentrations of solute on both sides of the membrane. The answer lies in the fact that the solution moves higher and higher in the tube as water moves into the sugar solution. Eventually, the pressure exerted by this column of solution counterbalances the pressure exerted by the water moving through the membrane from the pure water side, and no further *net* movement of water occurs. An equilibrium of forces is achieved. The pressure created by the column of solution for the system at equilibrium is a measure of the **osmotic pressure**, Π. That is, the osmotic pressure is the difference between the height of the solution in the tube and the level of pure water in the beaker.

From experimental measurements on dilute solutions, it is known that osmotic pressure and concentration (c) are related by the equation

$$\Pi = cRT \tag{13.9}$$



In this equation, c is the molar concentration (in moles per liter); R is the gas constant; and T is the absolute temperature (in kelvins). Using a value for the gas law constant of 0.082057 L·atm/K·mol allows calculation of the osmotic pressure Π in atmospheres. This equation is analogous to the ideal gas law ($PV = nRT$), with Π taking the place of P and c being equivalent to n/V.

(a) A fresh egg is placed in dilute acetic acid. The acid reacts with the $CaCO_3$ of the shell but leaves the egg membrane intact.

(b) If the egg, with its shell removed, is placed in pure water, the egg swells.

(c) If the egg, with its shell removed, is placed in a concentrated sugar solution, the egg shrivels.

Photos: © Cengage Learning/Charles D. Winters

Figure 13.16 An experiment to observe osmosis. You can try this experiment in your kitchen. In the first step, use vinegar as a source of acetic acid.

Even solutions with low solute concentrations have a significant osmotic pressure. For example, the osmotic pressure of a 1.00×10^{-3} M solution at 298 K is 18.6 mm Hg. Low pressures such as this are easily and accurately measured, so concentrations of very dilute solutions can be determined by this technique. (Compare this to the effect of a solute on freezing point, for example. A dilute aqueous solution of similar concentration, 1.00×10^{-3} mol/kg solvent, would be expected to lower the freezing point by about 0.002 °C, too small to measure accurately.) For this reason determining a molar mass by measuring the osmotic pressure of a solution is a particularly useful technique when dealing with compounds having a very high molar mass such as polymers and large biomolecules.

Other examples of osmosis are shown in Figure 13.16. In this case, the egg's membrane serves as the semipermeable membrane. Osmosis occurs in one direction if the concentration of solute is greater inside the egg than in the exterior solution and occurs in the other direction if the concentration of the solution is less inside the egg than in the exterior solution. In both cases, solvent flows from the region of low solute concentration to the region of high solute concentration.

EXAMPLE 13.7

Determining the Osmotic Pressure of a Solution of a Polymer

Problem Polyvinyl alcohol is a water-soluble polymer with an average molar mass of 28,000 g/mol. You dissolve 1.844 g of this polymer in water to give 150. mL of solution. What is the osmotic pressure, measured at 27 °C?

What Do You Know? Osmotic pressure is calculated using Equation 13.9, $\Pi = cRT$. You are given the mass and molar mass of the polymer and the temperature and will need the gas law constant.

Strategy Calculate the concentration of the polymer, c, in mol/L. The temperature must be expressed in kelvins. Substitute these values into Equation 13.9 to solve for the osmotic pressure.

SOLUTION

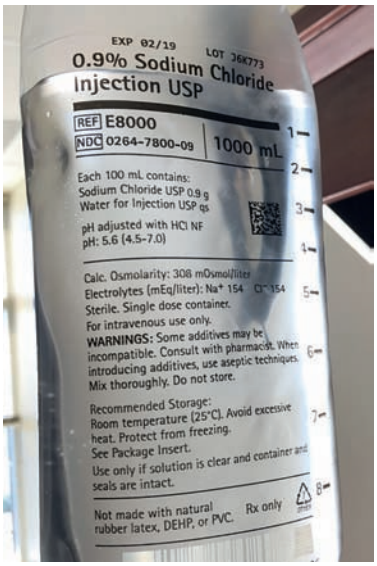
$$c = 1.844\ \text{g}(1\ \text{mol}/28{,}000\ \text{g})/(0.150\ \text{L}) = 4.39 \times 10^{-4}\ \text{mol/L}$$

$$\Pi = cRT$$

$$\Pi = (4.39 \times 10^{-4}\ \text{mol/L})(0.08206\ \text{L} \cdot \text{atm/mol} \cdot \text{K})(300\ \text{K})$$

$$\Pi = 0.011\ \text{atm}\ (= 8.2\ \text{mm Hg})$$

Think about Your Answer If the osmotic pressure is measured in a device similar to that shown in Figure 13.14, the height of the column of aqueous solution supported would be about 110 mm (8.2 mm × 13.5 mm H_2O/mm Hg = 110 mm). This would be easily measurable in the laboratory.



Check Your Understanding

Bradykinin is a small peptide (9 amino acids; 1060 g/mol) that lowers blood pressure by causing blood vessels to dilate. What is the osmotic pressure of a solution of this protein at 20 °C if 0.033 g of the peptide is dissolved in water to give 50.0 mL of solution?

A CLOSER LOOK

Osmosis and Medicine

Osmosis is of practical significance in medicine. Patients who become dehydrated through illness often need to be given water and nutrients intravenously. Water cannot simply be dripped into a patient's vein, however. Rather, the intravenous solution must have the same overall solute concentration as the patient's blood: the solution must be isoosmotic or **isotonic** (Figure B, middle). If pure water was used, the inside of a blood cell would have a higher solute concentration (lower water concentration), and water would flow into the cell. This **hypotonic** situation would cause the red blood cells to burst (lyse) (Figure B, right). The opposite situation, **hypertonicity**, occurs if the intravenous solution is more concentrated than the contents of the blood cell (Figure B, left). In this case, the cell would lose water and shrivel up (crenate). To combat this, a dehydrated patient is rehydrated in the hospital with a sterile saline solution that is 0.16 M NaCl, a solution that is isotonic with the cells of the body.

John C. Kotz

Figure A An isotonic saline solution. This solution has the same molality as body fluids.

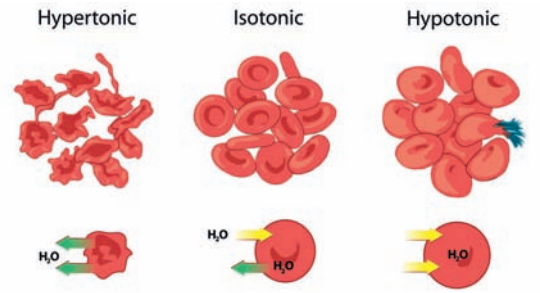


Figure B Osmosis and living cells. *(middle)* A cell placed in an isotonic solution. The net movement of water into and out of the cell is zero because the concentration of solutes inside and outside the cell is the same. *(left)* In a hypertonic solution, the concentration of solutes outside the cell is greater than that inside. There is a net flow of water out of the cell, causing the cell to dehydrate, shrink, and perhaps die. *(right)* In a hypotonic solution, the concentration of solutes outside the cell is less than that inside. There is a net flow of water into the cell, causing the cell to swell and perhaps to burst (or lyse).

Colligative Properties and Molar Mass Determination

Earlier in this book you learned how to calculate a molecular formula from an empirical formula when given the molar mass. But how do you know the molar mass of an unknown compound? An experiment must be carried out to find this crucial piece of information, and one way to do so is to use a colligative property of a solution of the compound. The strategy map used with Example 13.8 presents the basic approach to be used.

Strategy Map 13.8

EXAMPLE 13.8

Determining Molar Mass from Boiling Point Elevation

Problem A solution prepared from 1.25 g of oil of wintergreen (methyl salicylate) in 99.0 g of benzene has a boiling point of 80.31 °C. Determine the molar mass of methyl salicylate.

What Do You Know? The molar mass of a compound is the quotient of the mass of a sample (g) and the amount (mol) represented by that sample. Here you know the mass of the sample (1.25 g), so you need to find the amount (moles) that corresponds to this mass.

Strategy

- Determine ΔT_{bp} from the given boiling point of the solution. (The boiling point of pure benzene and K_{bp} for benzene are given in Table 13.3.) Use the equation $\Delta T_{bp} = K_{bp} \cdot m$ to calculate the solution concentration in units of mol/kg.
- Knowing the mass of solvent, calculate the amount of solute (mol).
- Combine the mass and amount of solute to give the molar mass [molar mass = mass (g)/amount (mol)].

SOLUTION

(a) Use the boiling point elevation to calculate the solution concentration:

$$\text{Boiling point elevation } (\Delta T_{bp}) = 80.31\ ^\circ\text{C} - 80.10\ ^\circ\text{C} = 0.21\ ^\circ\text{C}$$

$$c_{solute} = \frac{\Delta T_{bp}}{K_{bp}} = \frac{0.21\ ^\circ\text{C}}{2.53\ ^\circ\text{C}/m} = 0.0830\ m$$

(b) Calculate the amount of solute in the solution from the solution concentration:

$$\text{Amount of solute} = \left(\frac{0.0830\ \text{mol}}{1.00\ \text{kg}}\right)(0.0990\ \text{kg solvent}) = 0.00822\ \text{mol solute}$$

(c) Combine the amount of solute with its mass to obtain its molar mass.

$$\frac{1.25\ \text{g}}{0.00822\ \text{mol}} = 150\ \text{g/mol}$$

Think about Your Answer Methyl salicylate has the formula $C_8H_8O_3$ and a molar mass of 152.14 g/mol. Given that ΔT has only two significant figures, the calculated value is acceptably close to the actual value.

Check Your Understanding

An aluminum-containing compound has the empirical formula $(C_2H_5)_2AlF$. Find the molecular formula if 0.448 g of the compound dissolved in 23.46 g of benzene has a freezing point of 5.265 °C.

EXAMPLE 13.9

Osmotic Pressure and Molar Mass

Problem Beta-carotene is the most important of the A vitamins. Calculate the molar mass of β-carotene if 10.0 mL of a solution in chloroform containing 7.68 mg of β-carotene has an osmotic pressure of 26.57 mm Hg at 25.0 °C.

What Do You Know? The molar mass of a compound is the quotient of the mass of a sample and the amount represented by that sample. Here you know the mass of the sample (7.68 mg), so you need to find the amount (moles) equivalent to this mass.

Strategy

- Use Equation 13.9 to calculate the solution concentration from the osmotic pressure.
- Use the volume and concentration of the solution to calculate the amount of solute.
- Find the molar mass of the solute from its mass and amount.

SOLUTION

(a) Calculate the concentration of β-carotene from Π, R, and T.

$$\text{Concentration (mol/L)} = \frac{\Pi}{RT} = \frac{(26.57 \text{ mm Hg})\left(\frac{1 \text{ atm}}{760 \text{ mm Hg}}\right)}{(0.082057 \text{ L} \cdot \text{atm/K} \cdot \text{mol})(298.2 \text{ K})}$$

$$= 1.4287 \times 10^{-3} \text{ mol/L}$$

(b) Calculate the amount of β-carotene dissolved in 10.0 mL of solvent.

$$(1.4287 \times 10^{-3} \text{ mol/L})(0.0100 \text{ L}) = 1.429 \times 10^{-5} \text{ mol}$$

(c) Combine the amount of solute with its mass to calculate its molar mass:

$$\frac{7.68 \times 10^{-3} \text{ g}}{1.429 \times 10^{-5} \text{ mol}} = 538 \text{ g/mol}$$

Think about Your Answer Beta-carotene is a hydrocarbon with the formula $C_{40}H_{56}$ (molar mass = 536.8 g/mol).

Check Your Understanding

A 1.40-g sample of polyethylene, a common plastic, is dissolved in enough organic solvent to give 100.0 mL of solution. What is the average molar mass of the polymer if the measured osmotic pressure of the solution is 1.86 mm Hg at 25 °C?

Colligative Properties of Solutions Containing Ions

In the northern United States and Canada, it is common practice to scatter salt on snowy or icy roads or sidewalks in the winter. When the Sun shines on the snow or patch of ice, a small amount melts, and some salt dissolves in the water. As a result of the dissolved solute, the freezing point of the solution is lower than 0 °C. The solution "eats" its way through the ice, breaking it up, and the icy patch is no longer dangerous for drivers or walkers.

Salt (NaCl) is the most common substance used on roads because it is inexpensive and dissolves readily in water. Its relatively low molar mass means that the effect per gram is large. In addition, salt is especially effective because it is an electrolyte. That is, it dissolves to give ions in solution:

$$NaCl(s) \longrightarrow Na^+(aq) + Cl^-(aq)$$

Recall that *colligative properties depend not on what is dissolved but on the number of particles of solute per solvent particle.* When 1 mol of NaCl dissolves, 2 mol of ions form, which means that the effect on the freezing point of water should be twice as large as that expected for a mole of sugar. A 0.100 *m* solution of NaCl really contains two solutes, 0.100 *m* Na^+ and 0.100 *m* Cl^-. What we should use to estimate the freezing point depression is the *total* molality of solute particles:

$$m_{total} = m(Na^+) + m(Cl^-) = (0.100 + 0.100)\ mol/kg = 0.200\ mol/kg$$

$$\Delta T_{fp} = (-1.86\ °C/m)(0.200\ m) = -0.372\ °C$$

To estimate the freezing point depression for an ionic compound, first find the molality of solute from the mass and molar mass of the compound and the mass of the solvent. Then, multiply the molality by the number of ions in the formula: two for NaCl, three for Na_2SO_4, four for $LaCl_3$, five for $Al_2(SO_4)_3$, and so on.

Table 13.4 shows that as the concentration of NaCl decreases, ΔT_{fp} for NaCl approaches but does not quite reach a value that is two times larger than the value determined assuming no dissociation. Likewise, ΔT_{fp} for Na_2SO_4 approaches but does not reach a value that is three times larger. The ratio of the experimentally observed value of ΔT_{fp} to the value calculated assuming no dissociation is called the **van't Hoff factor** after Jacobus Henrikus van't Hoff (1852–1911), who studied this phenomenon. The van't Hoff factor is represented by *i*.

$$i = \frac{\Delta T_{fp},\ \text{measured}}{\Delta T_{fp},\ \text{calculated}} = \frac{\Delta T_{fp},\ \text{measured}}{K_{fp} \bullet m}$$

or

$$\Delta T_{fp}\ \text{measured} = K_{fp} \bullet m \bullet i \qquad (13.10)$$

van't Hoff factors can be used in calculations of any colligative property. Vapor pressure lowering, boiling point elevation, freezing point depression, and osmotic pressure are all larger for electrolytes than for nonelectrolytes of the same molality.

The van't Hoff factor approaches a whole number (2, 3, and so on) only with very dilute solutions. In more concentrated solutions, the experimental freezing point depressions indicate that there are fewer ions in solution than expected. This behavior, which is typical of all ionic compounds, is a consequence of the strong attractions between ions. The result is as if some of the positive and negative ions are paired, decreasing the total molality of particles. Indeed, in more concentrated solutions, and especially in solvents less polar than water, ions are extensively associated in ion pairs and in even larger clusters.

TABLE 13.4 Freezing Point Depressions of Some Ionic Solutions

Mass %	*m* (mol/kg)	ΔT_{fp} (measured, °C)	ΔT_{fp} (calculated, °C)	$\frac{\Delta T_{fp}, \text{measured}}{\Delta T_{fp}, \text{calculated}}$
NaCl				
0.00700	0.0120	−0.0433	−0.0223	1.94
0.500	0.0860	−0.299	−0.160	1.87
1.00	0.173	−0.593	−0.322	1.84
2.00	0.349	−1.186	−0.649	1.83
Na_2SO_4				
0.00700	0.00493	−0.0257	−0.00917	2.80
0.500	0.0354	−0.165	−0.0658	2.51

EXAMPLE 13.10

Freezing Point and Ionic Solutions

Problem A 0.0200 *m* aqueous solution of an ionic compound, $Co(NH_3)_4Cl_3$, freezes at −0.0640 °C. How many ions does each formula unit of $Co(NH_3)_4Cl_3$ produce on being dissolved in water?

What Do You Know? You know the freezing point depression (−0.0640 °C), the solution concentration, and K_{fp}.

Strategy The van't Hoff factor, *i*, is the ratio of the measured ΔT_{fp} to the calculated freezing point depression. First, calculate ΔT_{fp} expected for a solution in which no ions are produced. Compare this value with the actual value of ΔT_{fp}. The ratio (= *i*) will reflect the number of ions produced.

SOLUTION

(a) Calculate the freezing-point depression expected for a 0.0200 *m* solution assuming that the salt does not dissociate into ions.

$$\Delta T_{fp} \text{ calculated} = K_{fp}m = (-1.86\ °C)(0.0200\ m) = -0.0372\ °C$$

(b) Compare the calculated freezing point depression with the measured depression. This gives the van't Hoff factor:

$$i = \frac{\Delta T_{fp},\ \text{measured}}{\Delta T_{fp},\ \text{calculated}} = \frac{-0.0640\ °C}{-0.0372\ °C} = 1.72$$

The *i* value is much greater than 1 and is approaching 2. Therefore, we assume each formula unit of $Co(NH_3)_4Cl_3$ produces 2 moles of ions in solution.

Think about Your Answer We find *i* is approaching 2, meaning that the complex dissociates into two ions: $[Co(NH_3)_4Cl_2]^+$ and Cl^-. As you will see in Chapter 22, the cation is a Co^{3+} ion surrounded octahedrally by 4 NH_3 molecules and two Cl^- ions.

Check Your Understanding

Calculate the freezing point of 525 g of water that contains 25.0 g of NaCl. Assume *i*, the van't Hoff factor, is 1.85 for NaCl.

13.5 Colloids

Goal for Section 13.5

- Recognize the properties and importance of colloids.

Earlier in this chapter, we defined a solution broadly as a homogeneous mixture of two or more substances in a single phase. To this definition we should add that, in a true solution, no settling of the solute should be observed and the solute particles should be in the form of ions or relatively small molecules. Thus, NaCl and sugar form true solutions in water. You are also familiar with suspensions, which result, for example, if a handful of fine sand is added to water and shaken vigorously. Sand particles are still visible and gradually settle to the bottom of the beaker or bottle.

Colloidal dispersions, also called **colloids**, represent a state intermediate between a solution and a suspension (Figure 13.17). Colloids include many of the foods you eat and the materials around you; among them are JELL-O®, milk, fog, and porcelain (Table 13.5).

© Cengage Learning/Charles D. Winters

Figure 13.17 Gold colloid. A water-soluble salt of $[AuCl_4]^-$ is reduced to give colloidal gold metal. The colloidal gold gives the dispersion its red color (when the particles have a length or diameter of less than 100 nm). (Similarly, colloidal gold is used to give a beautiful red color to glass.) Since the days of alchemy, some have claimed that drinking a colloidal gold solution was good for the mind.

TABLE 13.5 Types of Colloids

Type	Dispersing Medium	Dispersed Phase	Examples
Aerosol	Gas	Liquid	Fog, clouds, aerosol sprays
Aerosol	Gas	Solid	Smoke, airborne viruses, automobile exhaust
Foam	Liquid	Gas	Shaving cream, whipped cream
Foam	Solid	Gas	Styrofoam, marshmallow
Emulsion	Liquid	Liquid	Mayonnaise, milk, face cream
Gel	Solid	Liquid	Jelly, JELL-O®, cheese, butter
Sol	Liquid	Solid	Gold in water, milk of magnesia, mud
Solid sol	Solid	Solid	Milkglass

Around 1860, the British chemist Thomas Graham (1805–1869) found that substances such as starch, gelatin, glue, and albumin from eggs diffused only very slowly when placed in water, compared with sugar or salt. In addition, the former substances differed significantly in their ability to diffuse through a thin membrane: Sugar molecules can diffuse through many membranes, but the very large molecules that make up starch, gelatin, glue, and albumin do not. Moreover, Graham found that he could not crystallize these substances, whereas he could crystallize sugar, salt, and other materials that form true solutions. Graham coined the word "colloid" (from the Greek, meaning "glue") to describe this class of substances that are distinctly different from true solutions and suspensions.

We now know that it is possible to crystallize some colloidal substances, albeit with difficulty, so there really is no sharp dividing line between these classes based on this property. Colloids do, however, have several distinguishing characteristics. First, many of the substances that form colloids have high molar masses; this is true of proteins such as hemoglobin that have molar masses in the thousands. Second, the particles of a colloid are relatively large (several hundred nanometers in diameter). As a consequence, they exhibit the **Tyndall effect**; they scatter visible light when dispersed in a solvent, making the mixture appear cloudy (Figure 13.18). Third, even though colloidal particles are large, they are not so large that they settle out.

Dust in the air scatters the light coming through the trees in a forest along the Oregon coast.

A narrow beam of light from a laser is passed through an NaCl solution *(left)* and then a colloidal mixture of gelatin and water *(right)*.

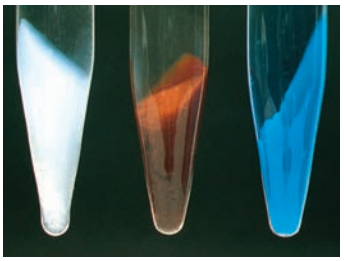
Graham also gave us the words **sol** for a colloidal dispersion of a solid substance in a fluid medium and **gel** for a colloidal dispersion that has a structure that prevents it from being mobile. JELL-O® is a sol when the solid is first mixed with boiling water, but it becomes a gel when cooled. Other examples of gels are the gelatinous precipitates of $Al(OH)_3$, $Fe(OH)_3$, and $Cu(OH)_2$ (Figure 13.19).

Because of the small size of the particles in a colloidal dispersion, they can have a very high surface area. For example, if you have one millionth of a mole of colloidal particles, each assumed to be a sphere with a diameter of 1000 nm, the total surface area of the particles would be on the order of 2 million cm^2. It is not surprising, therefore, that many of the properties of colloids depend on the properties of surfaces.



© Cengage Learning/Charles D. Winters

Figure 13.19 Gelatinous precipitates. *(left)* $Al(OH)_3$, *(center)* $Fe(OH)_3$, and *(right)* $Cu(OH)_2$.

Types of Colloids

Colloids are classified according to the state of the dispersed phase and the dispersing medium. Table 13.5 lists several types of colloids and gives examples of each.

Colloids with water as the dispersing medium can be classified as **hydrophobic** (from the Greek, meaning "water-fearing") or **hydrophilic** ("water-loving"). A *hydrophobic colloid* is one in which only weak attractive forces exist between the water and the surfaces of the colloidal particles. Examples include dispersions of metals (see Figure 13.17) and of nearly insoluble salts in water. When compounds like AgCl precipitate, the result is often a colloidal dispersion. The precipitation reaction occurs too rapidly for ions to gather from long distances and make large crystals, so the ions aggregate to form small particles that remain suspended in the liquid.

Why don't the particles come together (coagulate) and form larger particles? The answer is that the colloidal particles carry electric charges. To see how this happens, suppose AgCl ion pairs come together to form a tiny particle. If Ag^+ ions are still present in substantial concentration in the solution, these positive ions could be attracted to negative Cl^- ions on the surface of the particle. Thus the original clump of AgCl ion pairs becomes positively charged, allowing it to attract a secondary layer of anions. The particles, now surrounded by layers of ions, repel one another and are prevented from coming together to form a precipitate (Figure 13.20).

Soil particles are often carried by water in rivers and streams as hydrophobic colloids. When river water carrying large amounts of colloidal particles meets seawater with its high concentration of salts, the particles coagulate to form the silt seen at the mouth of the river (Figure 13.21). Municipal water treatment plants often add

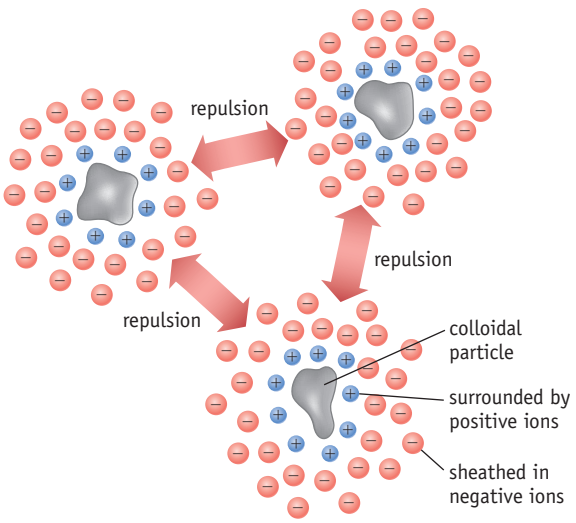


Figure 13.20 Hydrophobic colloids. A hydrophobic colloid is stabilized by positive ions adsorbed onto each particle and a secondary layer of negative ions. Because the particles bear similar charges, they repel one another, and precipitation is prevented.

NASA Earth Observatory image by Robert Simmon, using Landsat 5 data from the U.S. Geological Survey Global Visualization Viewer

Figure 13.21 Formation of silt. Silt forms at a river delta as colloidal soil particles come in contact with saltwater in the ocean. Here, the Connecticut River empties into the Long Island Sound. The high concentration of ions in seawater causes the colloidal soil particles to coagulate.

salts such as $Al_2(SO_4)_3$ to clarify water. In aqueous solution, aluminum ions exist as $[Al(H_2O)_6]^{3+}$ cations, which neutralize the charge on the hydrophobic colloidal soil particles, causing these particles to aggregate and settle out.

Hydrophilic colloids are strongly attracted to water molecules. They often have groups such as —OH and $—NH_2$ on their surfaces. These groups form strong hydrogen bonds to water, thereby stabilizing the colloid. Proteins and starch are important examples of hydrophilic colloids, and homogenized milk is the most familiar example.

Emulsions are colloidal dispersions of one liquid in another, such as oil or fat in water. Familiar examples include salad dressing, mayonnaise, and milk. If vegetable oil and vinegar are mixed to make a salad dressing, the mixture quickly separates into two layers because the nonpolar oil molecules do not interact with the polar water and acetic acid (CH_3CO_2H) molecules. So why are milk and mayonnaise apparently homogeneous mixtures that do not separate into layers? The answer is that they contain an **emulsifying agent** such as soap or a protein. Lecithin, found in egg yolks, can act as an emulsifying agent, so mixing egg yolks with oil and vinegar stabilizes the colloidal dispersion known as mayonnaise. To understand this process further, let us look into the functioning of soaps and detergents, substances known as surfactants.

Surfactants

Soaps and detergents are emulsifying agents. Soap is made by heating a fat with sodium or potassium hydroxide, which produces anions of long chain carboxylic acids, sometimes referred to as fatty acids. An example is sodium stearate.

sodium stearate, a soap

Soaps and Surfactants Sodium soaps are solid at room temperature, whereas potassium soaps are usually liquids. About 30 million tons of household and toilet soap, and synthetic and soap-based laundry detergents, are produced annually worldwide.

The fatty acid anion has a split personality: It has a nonpolar, hydrophobic hydrocarbon tail that is soluble in other similar hydrocarbons and a polar, hydrophilic head that is soluble in water.

Oil cannot be readily washed away from dishes or clothing with water because oil is nonpolar and thus insoluble in water. Instead, we add soap to the water to clean away the oil. The nonpolar molecules of the oil interact with the nonpolar hydrocarbon tails of the soap molecules, leaving the polar heads of the soap to interact with surrounding water molecules. The oil and water then mix (Figure 13.22), and the oil can then be washed away.

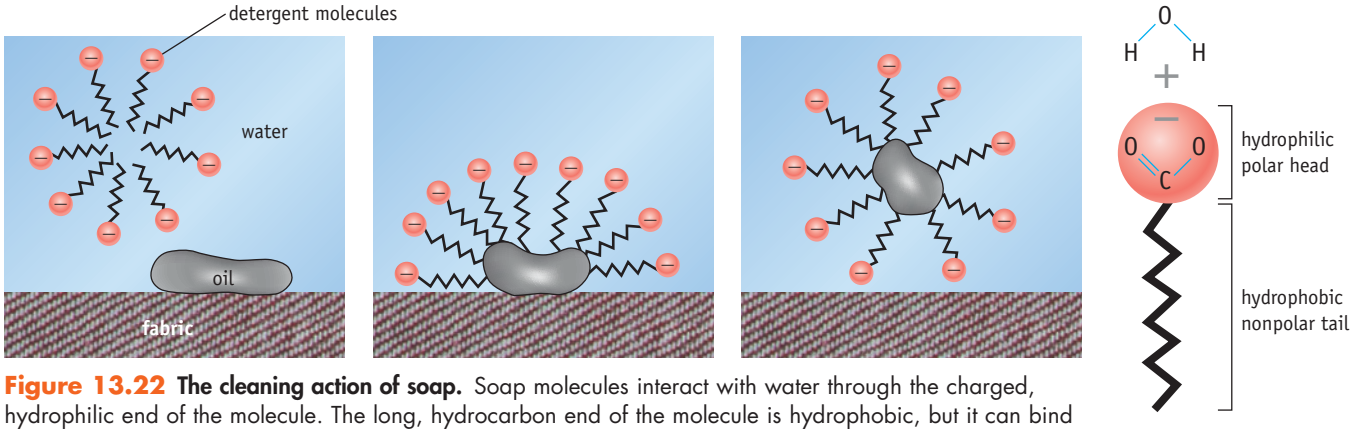

Figure 13.22 The cleaning action of soap. Soap molecules interact with water through the charged, hydrophilic end of the molecule. The long, hydrocarbon end of the molecule is hydrophobic, but it can bind through dispersion forces with hydrocarbons and other nonpolar substances.

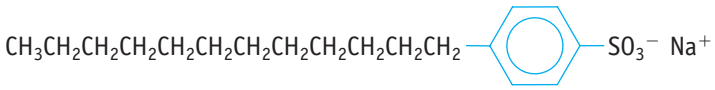
Sulfur (density = 2.1 g/cm^3) is carefully placed on the surface of water (density, 1.0 g/cm^3). The surface tension of the water keeps the denser sulfur afloat.

add surfactant →



Several drops of detergent are then placed on the surface of the water. The surface tension of the water is reduced, and the sulfur sinks to the bottom of the beaker.

© Cengage Learning/Charles D. Winters

Figure 13.23 Effect of a detergent on the surface tension of water.

Substances such as soaps that affect the properties of surfaces, and therefore affect the interaction between two phases, are called surface-active agents, or **surfactants**, for short. A surfactant used for cleaning is called a **detergent**. One function of a surfactant is to lower the surface tension of water, which enhances the cleansing action of the detergent (Figure 13.23).

Many detergents used in the home and industry are synthetic. One example is sodium laurylbenzenesulfonate, a biodegradable compound.

sodium laurylbenzenesulfonate

In general, synthetic detergents use the sulfonate group, —SO_3^-, as the polar head instead of the carboxylate group, —CO_2^-. The carboxylate anions form an insoluble precipitate with any Ca^{2+} or Mg^{2+} ions present in water. Because hard water is characterized by high concentrations of these ions, using soaps containing carboxylates produces bathtub rings and telltale gray clothing. The synthetic sulfonate detergents have the advantage that they do not form such precipitates because their calcium salts are more soluble in water.

APPLYING CHEMICAL PRINCIPLES

13.1 Distillation

Distillation is a means of separating components of a mixture based upon differences in volatility. Because petroleum consists of a large number of compounds of widely varying volatility, distillation is a key process used to produce gasoline and related products (Figure A). How does this process work?

If a mixture is composed of one volatile component and one or more nonvolatile components, a complete separation of the volatile component is possible. But, when two or more components in a mixture have nonzero vapor pressures at the mixture's boiling point, the result of a simple distillation is an incomplete separation.

Fractional distillation uses repetitive evaporation–condensation cycles to improve the separation of volatile compounds. When a mixture is boiled, the vapor above the liquid

Figure A **Equipment used for fractional distillation of petroleum in an oil refinery.**

SpaceKris/Shutterstock.com

has a higher concentration of the more volatile components than the liquid. If this vapor is condensed, then boiled again, the resulting vapor is further enriched in more volatile material.

The temperature–composition diagram for a hexane–heptane mixture is shown in Figure B. The lower curved line indicates the boiling point of the mixture as a function of the mole fraction of the more volatile component, hexane. The upper curve indicates the mole fraction of hexane in the vapor phase above the boiling solution. The blue line represents the change in composition of the mixture in the course of the fractional distillation of a mixture with an initial hexane mole fraction of 0.20. The solution may be heated until it reaches its boiling point of 90 °C. At this temperature, the mole fraction of hexane in the vapor phase can be determined by drawing a horizontal line at 90 °C that intersects the top curve. This indicates that the vapor phase has a mole fraction of hexane of 0.38 at this temperature.

The efficiency of a fractional distillation column is expressed in terms of *theoretical plates*. Each evaporation–condensation cycle requires one theoretical plate. The greater the number of theoretical plates, the better the separation for most mixtures.

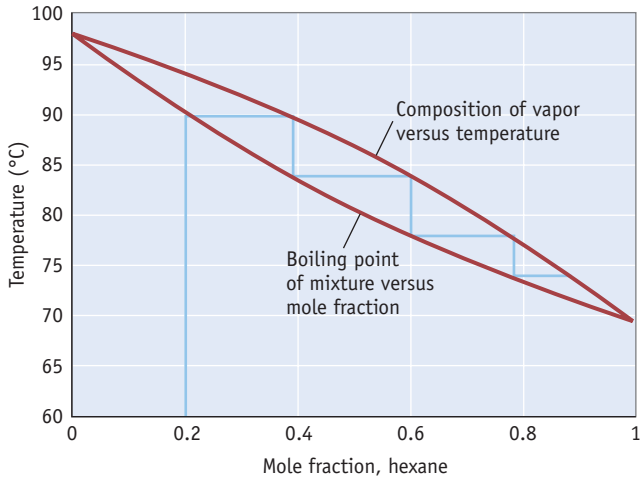

Figure B **A temperature–composition diagram for hexane (C_6H_{14})-heptane (C_7H_{16}) mixtures.**

Questions:

1. The blue line on the diagram illustrates the effect of using fractional distillation to separate a mixture of hexane (C_6H_{14}) and heptane (C_7H_{16}). If one starts a fractional distillation with a 0.20 mole fraction of hexane, what is the approximate mole fraction of hexane in the vapor phase after two evaporation–condensation cycles?
2. How many theoretical plates are required to produce a solution with a mole fraction of hexane greater than 0.90?
3. What is the mass percent of hexane in a mixture with heptane if the mole fraction of hexane is 0.20?
4. The vapor pressure of pure heptane is 361.5 mm Hg at 75.0 °C and its normal boiling point is 98.4 °C. Use the Clausius–Clapeyron equation (page 512) to determine the enthalpy of vaporization of heptane.

13.2 Henry's Law and Exploding Lakes

On Thursday, August 21, 1986, people and animals around Lake Nyos in Cameroon, a small nation on the west coast of Africa, suddenly collapsed and died. More than 1700 people and hundreds of animals were dead, but there was no apparent cause. What had brought on this disaster?

Some weeks later, the mystery was solved. Lake Nyos and nearby Lake Monoun are crater lakes, which formed when cooled volcanic craters filled with water. Importantly, Lake Nyos contains an enormous amount of dissolved carbon dioxide, which was generated as a result of volcanic activity deep in the Earth. Under the high pressure at the bottom of the lake, a very large amount of CO_2 dissolved in the water.

But on that evening in 1986, something—perhaps a small earthquake or an underwater landslide—disturbed the lake. The CO_2-saturated water at the bottom of the lake was carried to the surface, where, under lower pressure, the gas was much less soluble. About one cubic kilometer of carbon dioxide was released into the atmosphere. A geyser of water and CO_2 shot up about 260 feet; then, because this gas is more dense than air, it hugged the ground and began to

Fabian Plock/Shutterstock.com

Lake Nyos in Cameroon (western Africa), the site of a natural disaster. In 1986, a huge bubble of CO_2 escaped from the lake and asphyxiated more than 1700 people.

move with the prevailing breeze at about 45 miles per hour. When it reached villages 12 miles away, vital oxygen was displaced. The result was that both people and animals were asphyxiated.

The explosive release of CO_2 that occurred in Lake Nyos is much like what occurs when you shake a bottle of carbonated soft drink. Carbonated sodas are bottled under a high pressure of CO_2. Some of the gas dissolves in the soda, but some also remains in the small space above the liquid (called the *headspace*). The pressure of the CO_2 in the headspace is between 2 and 4 atm. When the bottle cap is removed, the CO_2 in the headspace escapes rapidly. Some of the dissolved CO_2 also comes out of solution, and you see bubbles of gas rising to the surface. If the bottle remains open, this continues until equilibrium is established with CO_2 in the atmosphere (where the partial pressure of CO_2 is 3.75×10^{-4} atm),

$$CO_2(\text{solution}) \rightleftharpoons CO_2(g)$$

and the soda goes "flat." If the newly opened soda bottle is undisturbed, however, the loss of CO_2 from solution is rather slow because bubble formation is not rapid, and your soda keeps its fizz.

Questions:

1. If the headspace of a soda is 25 mL and the pressure of CO_2 in the space is 4.0 atm (≈4.0 bar) at 25 °C, what amount of CO_2 is contained in the headspace?
2. If the CO_2 in the headspace escapes into the atmosphere where the partial pressure of CO_2 is 3.7×10^{-4} atm, what volume would the CO_2 occupy (at 25 °C)? By what amount did the CO_2 expand when it was released?
3. What is the solubility of CO_2 in water at 25 °C when the pressure of the gas is 3.7×10^{-4} bar?
4. After opening a 1.0 L soda, what mass of the dissolved CO_2 is released to the atmosphere in order to reach equilibrium? Assume that the CO_2 dissolved in the soda in the sealed bottle was in equilibrium with the CO_2 in the headspace at 4.0 bar pressure.

13.3 Narcosis and the Bends

If you have ever been scuba diving, you have heard about narcosis, also called "nitrogen narcosis," the "martini effect," or "rapture of the deep." And you probably discussed the "bends" with your diving instructor. Both of these effects are caused by gases dissolving in your blood as you breathe O_2 and N_2 from the scuba tank under pressure.

When you dive, the pressure of the air you breathe must be balanced against the external pressure of the water against your body. The pressure on your body when you are under water is normal atmospheric pressure plus the pressure of water, or about 1 atm for every 10 m of depth. To counter this, modern dive regulators automatically supply the breathing mixture at higher and higher pressures as you descend.

But here is the problem: as the gas pressure increases, the partial pressures of O_2 and N_2 increase, causing more gas to dissolve in your blood. These gases also dissolve in nerve cells in the brain and alter nerve transmission, and they have a narcotic effect. The effect is comparable to drinking a martini on an empty stomach or inhaling laughing gas (nitrous oxide, N_2O) at the dentist; it makes you slightly giddy. In severe cases, it can impair your judgment and even cause you to take the regulator out of your mouth and hand it to a fish! Some people can go as deep as 30–40 m with no problem, but others experience narcosis at shallower depths.

Another problem with breathing air at depths is oxygen toxicity. Our bodies are accustomed to a partial pressure of O_2 of 0.21 atm. At a depth of 30 m, using compressed air, the partial pressure of O_2 is about one atmosphere, which means it is comparable to breathing 100% oxygen at sea level. These higher partial pressures can harm the lungs and cause central nervous system damage.

If you ascend too rapidly from a dive, you can experience the "bends," a painful and potentially lethal condition in which nitrogen gas bubbles form in the blood as the solubility of nitrogen decreases with decreasing pressure. To diminish

Rich Carey/Shutterstock.com

the likelihood of getting the "bends," divers can use a gas mixture called "nitrox." This mixture is usually about 32–36% O_2 with correspondingly less N_2. With the lower N_2 pressure, less N_2 is dissolved in the blood. Use of nitrox allows a diver to ascend more rapidly because less time is needed to expel N_2 from the blood. And, because of the higher O_2 content of this gas mixture, nitrox has an added advantage of allowing more extended dive times.

For deep dives (about 100 m) different gas mixtures are used. A common mixture (Trimix) contains about 10% O_2, 70% He, and 20% N_2; other mixtures contain only oxygen and helium (Heliox). The lower percentage of O_2 lowers the danger of O_2 toxicity. Helium is substituted for N_2 because it is less soluble in blood and tissue, but it introduces an interesting side effect. If there is a voice link to the surface, the diver's speech sounds like Donald Duck! Speech is altered because the velocity of sound in helium is different from that in air.

Questions:

1. Calculate the external pressure experienced by a diver at a depth of 10.0 m. If a scuba diver is using compressed air at this depth, what are the partial pressures of oxygen and nitrogen? (Assume the density of water is 1.00 g/mL.)
2. At a depth of 20 meters the pressure is about 3.0 atm. Calculate the solubility of O_2 in water under 3.0 atm pressure. Then, calculate the mass of oxygen that will dissolve in 1.0 L of water under this pressure.
3. A 1.0 L sample of water is shaken in air to allow it to become saturated with both N_2 and O_2. What is the total amount of dissolved gases? If the solution was now heated and the dissolved gases expelled from solution and collected, what is the mole fraction of oxygen in the gas mixture?

CHAPTER GOALS REVISITED

The goals for this chapter are keyed to specific Study Questions to help you organize your review.

13.1 Units of Concentration

- Calculate and use the concentration units: molality, mole fraction, weight percent and parts per million (ppm). **1, 3, 5, 7, 11, 12.**
- Recognize the difference between molarity and molality. **9, 10.**

13.2 The Solution Process

- Understand the process of dissolving a solute in a solvent and recognize the terminology used (saturated, unsaturated, supersaturated, solubility, miscible). **13, 14, 17, 18, 96, 97.**
- Understand the thermodynamics associated with the solution process and calculate the enthalpy of solution from thermodynamic data. **15, 16, 73.**

13.3 Factors Affecting Solubility: Pressure and Temperature

- Describe the effects of pressure and temperature on the solubility of a solute. **17, 18.**
- Use Henry's law to calculate the solubility of a gas in a solvent. **19–22, 83, 84.**
- Apply Le Chatelier's principle to predict the change in solubility of gases with temperature changes. **23, 24.**

13.4 Colligative Properties

- Using Raoult's law, calculate the effect of dissolved solutes on solvent vapor pressure ($P_{solvent}$). **25–28, 75, 76.**
- Calculate the effect on boiling point and freezing point of a solvent caused by a solute. **29–36.**
- Calculate the osmotic pressure (Π) for solutions. **37–40, 80, 108.**
- Use colligative properties to determine the molar mass of a solute. **41–46, 66, 67.**
- Use the van't Hoff factor in colligative property calculations involving ionic solutes. **47–50, 63, 77, 95.**

13.5 Colloids

- Recognize the properties and importance of colloids. **51, 52, 85, 99.**

KEY EQUATIONS

Equation 13.1 (page 565) Molality is defined as the amount of solute per kilogram of solvent.

$$\text{Concentration } (c,\ \text{mol/kg}) = \text{molality of solute} = \frac{\text{amount of solute (mol)}}{\text{mass of solvent (kg)}}$$

Equation 13.2 (page 566) The mole fraction, X, of a solution component is defined as the number of moles of a given component of a mixture (n_A, mol) divided by the total number of moles of all of the components of the mixture.

$$\text{Mole fraction of A } (X_A) = \frac{n_A}{n_A + n_B + n_C + \ldots}$$

Equation 13.3 (page 566) Weight percent is the mass of one component divided by the total mass of the mixture (multiplied by 100%).

$$\text{Weight \% A} = \frac{\text{mass of A}}{\text{mass of A + mass of B + mass of C + } \ldots} \times 100\%$$

Equation 13.4 (page 574) Henry's law: The solubility of a gas, S_g, is equal to the product of the partial pressure of the gaseous solute (P_g) and a constant (k_H) characteristic of the solute and solvent.

$$S_g = k_H P_g$$

Equation 13.5 (page 577) Raoult's law: The equilibrium vapor pressure of a solvent over a solution at a given temperature, $P_{solvent}$, is the product of the mole fraction of the solvent ($X_{solvent}$) and the vapor pressure of the pure solvent ($P°_{solvent}$).

$$P_{solvent} = X_{solvent}\ P°_{solvent}$$

Equation 13.6 (page 578) The decrease in the vapor pressure of the solvent over a solution, $\Delta P_{solvent}$, depends on the mole fraction of the solute (X_{solute}) and the vapor pressure of the pure solvent ($P°_{solvent}$).

$$\Delta P_{solvent} = -X_{solute}\ P°_{solvent}$$

Equation 13.7 (page 580) The elevation in boiling point of the solvent in a solution, ΔT_{bp}, is the product of the molality of the solute, m_{solute}, and a constant characteristic of the solvent, K_{bp}.

$$\text{Elevation in boiling point} = \Delta T_{bp} = K_{bp} m_{solute}$$

Equation 13.8 (page 583) The depression of the freezing point of the solvent in a solution, ΔT_{fp}, is the product of the molality of the solute, m_{solute}, and a constant characteristic of the solvent, K_{fp}.

$$\text{Freezing point depression} = \Delta T_{fp} = K_{fp} m_{solute}$$

Equation 13.9 (page 585) The osmotic pressure, Π, is the product of the solute concentration c (in mol/L), the universal gas constant R (0.082057 L · atm/K · mol), and the temperature T (in kelvins).

$$\Pi = cRT$$

Equation 13.10 (page 590) This modified equation for freezing point depression accounts for the possible dissociation of a solute. The van't Hoff factor, i, the ratio of the measured freezing point depression and the freezing point depression calculated assuming no solute dissociation, is related to the relative number of particles produced by a dissolved solute.

$$\Delta T_{fp}\ \text{measured} = K_{fp} \times m \times i$$

STUDY QUESTIONS

▲ denotes challenging questions. **Blue-numbered questions** have answers in Appendix N and fully worked solutions in the *Student Solutions Manual.*

Practicing Skills

Concentration

(See Section 13.1 and Example 13.1.)

1. You dissolve 2.56 g of succinic acid, $C_2H_4(CO_2H)_2$, in 500. mL of water. Assuming that the density of water is 1.00 g/cm^3, calculate the molality, mole fraction, and weight percent of acid in the solution.
2. You dissolve 45.0 g of camphor, $C_{10}H_{16}O$, in 425 mL of ethanol, C_2H_5OH. Calculate the molality, mole fraction, and weight percent of camphor in this solution. (The density of ethanol is 0.785 g/mL.)
3. Fill in the blanks in the table. Aqueous solutions are assumed.

Compound	Molality	Weight Percent	Mole Fraction
NaI	0.15	_____	_____
C_2H_5OH	_____	5.0	_____
$C_{12}H_{22}O_{11}$	0.15	_____	_____

4. Fill in the blanks in the table. Aqueous solutions are assumed.

Compound	Molality	Weight Percent	Mole Fraction
KNO_3	_____	10.0	_____
CH_3CO_2H	0.0183	_____	_____
$HOCH_2CH_2OH$	_____	18.0	_____

5. What mass of Na_2CO_3 must you add to 125 g of water to prepare 0.200 *m* Na_2CO_3? What is the mole fraction of Na_2CO_3 in the resulting solution?
6. What mass of $NaNO_3$ must be added to 500. g of water to prepare a solution that is 0.0512 *m* in $NaNO_3$? What is the mole fraction of $NaNO_3$ in the solution?
7. You wish to prepare an aqueous solution of glycerol, $C_3H_5(OH)_3$, in which the mole fraction of the solute is 0.093. What mass of glycerol must you add to 425 g of water to make this solution? What is the molality of the solution?
8. You want to prepare an aqueous solution of ethylene glycol, $HOCH_2CH_2OH$, in which the mole fraction of solute is 0.125. What mass of ethylene glycol, in grams, should you combine with 955 g of water? What is the molality of the solution?
9. Hydrochloric acid is sold as a concentrated aqueous solution. If the concentration of commercial HCl is 12.0 M and its density is 1.18 g/cm^3, calculate the following:
   (a) the molality of the solution
   (b) the weight percent of HCl in the solution
10. Concentrated sulfuric acid has a density of 1.84 g/cm^3 and is 95.0% by weight H_2SO_4. What is the molality of this acid? What is its molarity?
11. The average lithium ion concentration in seawater is 0.18 ppm. What is the molality of Li^+ in seawater?
12. Silver ion has an average concentration of 28 ppb (parts per billion) in U.S. water supplies.
   (a) What is the molality of the silver ion?
   (b) If you wanted 1.0×10^2 g of silver and could recover it chemically from water supplies, what volume of water in liters would you have to treat? (Assume the density of water is 1.0 g/cm^3.)

The Solution Process

(See Section 13.2 and Example 13.2.)

13. Which pairs of liquids will be miscible?
   (a) H_2O and $CH_3CH_2CH_2CH_3$
   (b) C_6H_6 (benzene) and CCl_4
   (c) H_2O and CH_3CO_2H
14. Acetone, CH_3COCH_3, is quite soluble in water. Explain why this should be so.

Acetone

15. Use the data of Table 13.1 to calculate the enthalpy of solution of LiCl.
16. Use the following data to calculate the enthalpy of solution of sodium perchlorate, $NaClO_4$:

$$\Delta_f H°(s) = -382.9 \text{ kJ/mol}$$

and

$$\Delta_f H°(aq, 1\ m) = -369.5 \text{ kJ/mol}$$

17. You make a saturated solution of NaCl at 25 °C. No solid is present in the beaker holding the solution. What can be done to increase the amount of dissolved NaCl in this solution? (See Figure 13.11.)
    (a) Add more solid NaCl.
    (b) Raise the temperature of the solution.
    (c) Raise the temperature of the solution, and add some NaCl.
    (d) Lower the temperature of the solution, and add some NaCl.

18. Some lithium chloride, LiCl, is dissolved in 100 mL of water in one beaker, and some Li_2SO_4 is dissolved in 100 mL of water in another beaker. Both are at 10 °C, and both are saturated solutions; some solid remains undissolved in each beaker. Describe what you would observe as the temperature is raised. The following data are available to you from a handbook of chemistry:

	Solubility (g/100 mL)	
Compound	10 °C	40 °C
Li_2SO_4	35.5	33.7
LiCl	74.5	89.8

Henry's Law

(See Section 13.3 and Example 13.3.)

19. The partial pressure of O_2 in your lungs varies from 25 mm Hg to 40 mm Hg. What mass of O_2 can dissolve in 1.0 L of water at 25 °C if the partial pressure of O_2 is 40 mm Hg?

20. The Henry's law constant for O_2 in water at 25 °C is given in Table 13.2. Which of the following is a reasonable constant when the temperature is 50 °C? Explain the reason for your choice.
    (a) 6.7×10^{-4} mol/kg·bar
    (b) 2.6×10^{-3} mol/kg·bar
    (c) 1.3×10^{-3} mol/kg·bar
    (d) 6.4×10^{-2} mol/kg·bar

21. An unopened soda can has an aqueous CO_2 concentration of 0.0506 *m* at 25 °C. What is the pressure of CO_2 gas in the can?

22. Hydrogen gas has a Henry's law constant of 7.8×10^{-4} mol/kg·bar at 25 °C when dissolving in water. If the total pressure of gas (H_2 gas plus water vapor) over water is 1.00 bar, what is the concentration of H_2 in the water in grams per milliliter? (See Appendix G for the vapor pressure of water.)

Le Chatelier's Principle

(See Section 13.3.)

23. A sealed flask contains water and oxygen gas at 25 °C. The O_2 gas has a partial pressure of 1.5 atm.
    (a) What is the concentration of O_2 in the water?
    (b) If the pressure of O_2 in the flask is raised to 1.7 atm, what happens to the amount of dissolved O_2? What happens to the amount of dissolved O_2 when the pressure of O_2 gas drops to 1.0 atm?

24. Butane, C_4H_{10}, has been suggested as the refrigerant in household compressors such as those found in air conditioners.
    (a) To what extent is butane soluble in water? Calculate the butane concentration in water if the pressure of the gas is 0.21 atm. (k_H = 0.0011 mol/kg·bar at 25 °C)
    (b) If the pressure of butane is increased to 1.0 atm, does the butane concentration increase or decrease?

Raoult's Law

(See Section 13.4 and Example 13.4.)

25. A 35.0-g sample of ethylene glycol, $HOCH_2CH_2OH$, is dissolved in 500.0 g of water. The vapor pressure of water at 32 °C is 35.7 mm Hg. What is the vapor pressure of the water–ethylene glycol solution at 32 °C? (Ethylene glycol is nonvolatile.)

26. Urea, $(NH_2)_2CO$, which is widely used in fertilizers and plastics, is quite soluble in water. If you dissolve 9.00 g of urea in 10.0 mL of water, what is the vapor pressure of the solution at 24 °C? Assume the density of water is 1.00 g/mL.

27. Pure ethylene glycol, $HOCH_2CH_2OH$, is added to 2.00 kg of water in the cooling system of a car. The vapor pressure of the water in the system when the temperature is 90 °C is 457 mm Hg. What mass of glycol was added? (Assume the solution is ideal. See Appendix G for the vapor pressure of water.)

28. Pure iodine (105 g) is dissolved in 325 g of CCl_4 at 65 °C. Given that the vapor pressure of CCl_4 at this temperature is 531 mm Hg, what is the vapor pressure of the CCl_4–I_2 solution at 65 °C? (Assume that I_2 does not contribute to the vapor pressure.)

Boiling Point Elevation

(See Section 13.4 and Example 13.5.)

29. What is the boiling point of a solution containing 0.200 mol of a nonvolatile solute in 125 g of benzene (C_6H_6)?

30. What is the boiling point of a solution composed of 15.0 g of urea, $(NH_2)_2CO$, in 0.500 kg of water?

31. What is the boiling point of a solution composed of 15.0 g of $CHCl_3$ and 0.515 g of the nonvolatile solute acenaphthene, $C_{12}H_{10}$, a component of coal tar?

32. A solution of glycerol, $C_3H_5(OH)_3$, in 735 g of water has a boiling point of 104.4 °C at a pressure of 760 mm Hg. What is the mass of glycerol in the solution? What is the mole fraction of the solute?

Freezing Point Depression

(See Section 13.4 and Example 13.6.)

33. A mixture of ethanol, C_2H_5OH, and water has a freezing point of −16.0 °C.
    (a) What is the molality of the alcohol?
    (b) What is the weight percent of alcohol in the solution?

34. Some ethylene glycol, $HOCH_2CH_2OH$, is added to your car's cooling system along with 5.0 kg of water. If the freezing point of the water–glycol solution is −15.0 °C, what mass of $HOCH_2CH_2OH$ must have been added?

35. You dissolve 15.0 g of sucrose, $C_{12}H_{22}O_{11}$, in a cup of water (225 g). What is the freezing point of the solution?

36. A typical bottle of wine consists of an 11% solution (by weight) of ethanol (C_2H_5OH) in water. If the wine is chilled to −20 °C, will the solution begin to freeze?

Osmosis

(See Section 13.4 and Example 13.7.)

37. An aqueous solution contains 3.00% phenylalanine ($C_9H_{11}NO_2$) by mass. (Phenylalanine is nonionic and nonvolatile.) Find the following:
    (a) the freezing point of the solution
    (b) the boiling point of the solution
    (c) the osmotic pressure of the solution at 25 °C

    In your view, which of these values is most easily measurable in the laboratory?

38. Estimate the osmotic pressure of human blood at 37 °C. Assume blood is isotonic with a 0.154 M NaCl solution, and assume the van't Hoff factor, *i*, is 1.90 for NaCl.

39. An aqueous solution containing 1.00 g of bovine insulin (a protein, not ionized) per liter has an osmotic pressure of 3.1 mm Hg at 25 °C. Calculate the molar mass of bovine insulin.

40. Calculate the osmotic pressure of a 0.0120 M solution of NaCl in water at 0 °C. Assume the van't Hoff factor, *i*, is 1.94 for this solution.

Colligative Properties and Molar Mass Determination

(See Section 13.4 and Examples 13.8 and 13.9.)

41. You add 0.255 g of an orange, crystalline compound whose empirical formula is $C_{10}H_8Fe$ to 11.12 g of benzene. The boiling point of the benzene rises from 80.10 °C to 80.26 °C. What are the molar mass and molecular formula of the compound?

42. Butylated hydroxyanisole (BHA) is used in margarine and other fats and oils. (It is used as an antioxidant and prolongs the shelf life of the food.) What is the molar mass of BHA if 0.640 g of the compound, dissolved in 25.0 g of chloroform, produces a solution whose boiling point is 62.22 °C?

43. Benzyl acetate is one of the active components of oil of jasmine. If 0.125 g of the compound is added to 25.0 g of chloroform ($CHCl_3$), the boiling point of the solution is 61.82 °C. What is the molar mass of benzyl acetate?

44. Anthracene, a hydrocarbon obtained from coal, has an empirical formula of C_7H_5. To find its molecular formula, you dissolve 0.500 g in 30.0 g of benzene. The boiling point of pure benzene is 80.10 °C, whereas the solution has a boiling point of 80.34 °C. What is the molecular formula of anthracene?

45. An aqueous solution contains 0.180 g of an unknown, nonionic solute in 50.0 g of water. The solution freezes at −0.040 °C. What is the molar mass of the solute?

46. Aluminon, an organic compound, is used as a reagent to test for the presence of the aluminum ion in aqueous solution. A solution of 2.50 g of aluminon in 50.0 g of water freezes at −0.197 °C. What is the molar mass of aluminon?

Colligative Properties of Ionic Compounds

(See Section 13.4 and Example 13.10.)

47. If 52.5 g of LiF is dissolved in 306 g of water, what is the expected freezing point of the solution? (Assume the van't Hoff factor, *i*, for LiF is 2.)

48. To make homemade ice cream, you cool the milk and cream by immersing the container in ice and a concentrated solution of rock salt (NaCl) in water. If you want to have a water–salt solution that freezes at −10. °C, what mass of NaCl must you add to 3.0 kg of water? (Assume the van't Hoff factor, *i*, for NaCl is 1.85.)

49. List the following aqueous solutions in order of increasing melting point. (The last three are all assumed to dissociate completely into ions in water.)
(a) 0.1 *m* sugar
(b) 0.1 *m* NaCl
(c) 0.08 *m* $CaCl_2$
(d) 0.04 *m* Na_2SO_4

50. Arrange the following aqueous solutions in order of decreasing freezing point. (The last three are all assumed to dissociate completely into ions in water.)
(a) 0.20 *m* ethylene glycol (nonvolatile, nonelectrolyte)
(b) 0.12 *m* K_2SO_4
(c) 0.10 *m* $MgCl_2$
(d) 0.12 *m* KBr

Colloids

(See Section 13.5.)

51. When solutions of $BaCl_2$ and Na_2SO_4 are mixed, the mixture becomes cloudy. After a few days, a white solid is observed on the bottom of the beaker with a clear liquid above it.
(a) Write a balanced equation for the reaction that occurs.
(b) Why is the solution cloudy at first?
(c) What happens during the few days of waiting?

52. The dispersed phase of a certain colloidal dispersion consists of spheres of diameter 1.0×10^2 nm.
(a) What are the volume ($V = {}^4/_3\pi r^3$) and surface area ($A = 4\pi r^2$) of each sphere?
(b) How many spheres are required to give a total volume of 1.0 cm^3? What is the total surface area of these spheres in square meters?

General Questions

These questions are not designated as to type or location in the chapter. They may combine several concepts.

53. Phenylcarbinol is used in nasal sprays as a preservative. A solution of 0.52 g of the compound in 25.0 g of water has a melting point of −0.36 °C. What is the molar mass of phenylcarbinol?

54. (a) Which aqueous solution is expected to have the higher boiling point: 0.10 *m* Na_2SO_4 or 0.15 *m* sugar?
(b) For which aqueous solution is the vapor pressure of water higher: 0.30 *m* NH_4NO_3 or 0.15 *m* Na_2SO_4?

55. Arrange the following aqueous solutions in order of (i) increasing vapor pressure of water and (ii) increasing boiling point.
(a) 0.35 *m* $HOCH_2CH_2OH$ (a nonvolatile solute)
(b) 0.50 *m* sugar
(c) 0.20 *m* KBr (a strong electrolyte)
(d) 0.20 *m* Na_2SO_4 (a strong electrolyte)

56. Making homemade ice cream is one of life's great pleasures. Fresh milk and cream, sugar, and flavorings are churned in a bucket suspended in an ice–water mixture, the freezing point of which has been lowered by adding salt. One manufacturer of home ice cream freezers recommends adding 2.50 lb (1130 g) of salt (NaCl) to 16.0 lb of ice (7250 g) in a 4-qt freezer. For the solution when this mixture melts, calculate the following:
(a) the weight percent of NaCl
(b) the mole fraction of NaCl
(c) the molality of the solution

57. Dimethylglyoxime [DMG, $(CH_3CNOH)_2$] is used as a reagent to precipitate nickel ion. Assume that 53.0 g of DMG has been dissolved in 525 g of ethanol (C_2H_5OH).

© Cengage Learning/Charles D. Winters

The red, insoluble compound formed between nickel(II) ion and dimethylglyoxime (DMG) is precipitated when DMG is added to a basic solution of Ni^{2+}(aq).

(a) What is the mole fraction of DMG?
(b) What is the molality of the solution?
(c) What is the vapor pressure of the ethanol over the solution at ethanol's normal boiling point of 78.4 °C?
(d) What is the boiling point of the solution? (DMG does not produce ions in solution.) (K_{bp} for ethanol = +1.22 °C/*m*)

58. A 10.7 *m* solution of NaOH has a density of 1.33 g/cm^3 at 20 °C. Calculate the following:
(a) the mole fraction of NaOH
(b) the weight percent of NaOH
(c) the molarity of the solution

59. Concentrated aqueous ammonia has a molarity of 14.8 mol/L and a density of 0.90 g/cm^3. What is the molality of the solution? Calculate the mole fraction and weight percent of NH_3.

60. If you dissolve 2.00 g of $Ca(NO_3)_2$ in 750 g of water, what is the molality of $Ca(NO_3)_2$? What is the total molality of ions in solution? (Assume total dissociation of the ionic solid.)

61. If you want a solution that is 0.100 *m* in ions, what mass of Na_2SO_4 must you dissolve in 125 g of water? (Assume total dissociation of the ionic solid.)

62. Consider the following aqueous solutions: (i) 0.20 *m* $HOCH_2CH_2OH$ (nonvolatile, nonelectrolyte); (ii) 0.10 *m* $CaCl_2$; (iii) 0.12 *m* KBr; and (iv) 0.12 *m* Na_2SO_4.
(a) Which solution has the highest boiling point?
(b) Which solution has the lowest freezing point?
(c) Which solution has the highest water vapor pressure?

63. (a) Which solution is expected to have the higher boiling point: 0.20 *m* KBr or 0.30 *m* sugar?
(b) Which aqueous solution has the lower freezing point: 0.12 *m* NH_4NO_3 or 0.10 *m* Na_2CO_3?

64. The solubility of NaCl in water at 100 °C is 39.1 g/100. g of water. Calculate the boiling point of this solution. (Assume $i = 1.85$ for NaCl.)

65. Instead of using NaCl to melt the ice on your sidewalk, you decide to use $CaCl_2$. If you add 35.0 g of $CaCl_2$ to 150. g of water, what is the freezing point of the solution? (Assume $i = 2.7$ for $CaCl_2$.)

66. The smell of ripe raspberries is due to 4-(*p*-hydroxyphenyl)-2-butanone, which has the empirical formula C_5H_6O. To find its molecular formula, you dissolve 0.135 g in 25.0 g of chloroform, $CHCl_3$. The boiling point of the solution is 61.82 °C. What is the molecular formula of the solute?

67. Hexachlorophene has been used in germicidal soap. What is its molar mass if 0.640 g of the compound, dissolved in 25.0 g of chloroform, produces a solution whose boiling point is 61.93 °C?

68. The solubility of ammonium formate, NH_4CHO_2, in 100. g of water is 102 g at 0 °C and 546 g at 80 °C. A solution is prepared by dissolving NH_4CHO_2 in 200. g of water until no more will dissolve at 80 °C. The solution is then cooled to 0 °C. What mass of NH_4CHO_2 precipitates? (Assume that no water evaporates and that the solution is not supersaturated.)

69. How much N_2 can dissolve in water at 25 °C if the N_2 partial pressure is 585 mm Hg?

70. Cigars are best stored in a "humidor" at 18 °C and 55% relative humidity. This means the pressure of water vapor should be 55% of the vapor pressure of pure water at the same temperature. The proper humidity can be maintained by placing a solution of glycerol [$C_3H_5(OH)_3$] and water in the humidor. Calculate the percent by mass of glycerol that will lower the vapor pressure of water to the desired value. (The vapor pressure of glycerol is negligible.)

71. An aqueous solution containing 10.0 g of starch per liter has an osmotic pressure of 3.8 mm Hg at 25 °C.
(a) What is the average molar mass of starch? (The result is an average because not all starch molecules are identical.)
(b) What is the freezing point of the solution? Would it be easy to determine the molecular weight of starch by measuring the freezing point depression? (Assume that the molarity and molality are the same for this solution.)

72. Vinegar is a 5% solution (by weight) of acetic acid in water. Determine the mole fraction and molality of acetic acid. What is the concentration of acetic acid in parts per million (ppm)? Explain why it is not possible to calculate the molarity of this solution from the information provided.

73. Calculate the enthalpies of solution for Li_2SO_4 and K_2SO_4. Are the solution processes exothermic or endothermic? Compare them with LiCl and KCl. What similarities or differences do you find?

Compound	$\Delta_f H°$(s) (kJ/mol)	$\Delta_f H°$(aq, 1 *m*) (kJ/mol)
Li_2SO_4	−1436.4	−1464.4
K_2SO_4	−1437.7	−1413.0

74. ▲ Water at 25 °C has a density of 0.997 g/cm^3. Calculate the molality and molarity of pure water at this temperature.

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

75. ▲ If a volatile solute is added to a volatile solvent, both substances contribute to the vapor pressure over the solution. Assuming an ideal solution, the vapor pressure of each is given by Raoult's law, and the total vapor pressure is the sum of the vapor pressures for each component. A solution, assumed to be ideal, is made from 1.0 mol of toluene ($C_6H_5CH_3$) and 2.0 mol of benzene (C_6H_6). The vapor pressures of the pure solvents are 22 mm Hg and 75 mm Hg, respectively, at 20 °C. What is the total vapor pressure of the mixture? What is the mole fraction of each component in the liquid and in the vapor?

76. A solution is made by adding 50.0 mL of ethanol (C_2H_5OH, d = 0.789 g/mL) to 50.0 mL of water (d = 0.998 g/mL). What is the total vapor pressure over the solution at 20 °C? (See Study Question 75.) The vapor pressure of ethanol at 20 °C is 43.6 mm Hg.

77. A 2.0% (by mass) aqueous solution of novocainium chloride ($C_{13}H_{21}ClN_2O_2$) freezes at −0.237 °C. Calculate the van't Hoff factor, i. How many moles of ions are in the solution per mole of compound?

78. A solution is 4.00% (by mass) maltose and 96.00% water. It freezes at −0.229 °C.
   (a) Calculate the molar mass of maltose (which is not an ionic compound).
   (b) The density of the solution is 1.014 g/mL. Calculate the osmotic pressure of the solution.

79. ▲ The following table lists the concentrations of the principal ions in seawater:

Ion	Concentration (ppm)
Cl^-	1.95×10^4
Na^+	1.08×10^4
Mg^{2+}	1.29×10^3
SO_4^{2-}	9.05×10^2
Ca^{2+}	4.12×10^2
K^+	3.80×10^2
Br^-	67

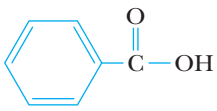
   (a) Calculate the freezing point of seawater.
   (b) Calculate the osmotic pressure of seawater at 25 °C. What is the minimum pressure needed to purify seawater by reverse osmosis?

80. ▲ A tree is 10.0 m tall.
   (a) What must be the total molarity of the solutes if sap rises to the top of the tree by osmotic pressure at 20 °C? Assume the groundwater outside the tree is pure water and that the density of the sap is 1.0 g/mL. (1 mm Hg = 13.6 mm H_2O.)
   (b) If the only solute in the sap is sucrose, $C_{12}H_{22}O_{11}$, what is its percent by mass?

81. A 2.00% solution of H_2SO_4 in water freezes at −0.796 °C.
   (a) Calculate the van't Hoff factor, i.
   (b) Which of the following best represents sulfuric acid in a dilute aqueous solution: H_2SO_4, $H_3O^+ + HSO_4^-$, or $2\ H_3O^+ + SO_4^{2-}$?

82. A compound is known to be a potassium halide, KX. If 4.00 g of the salt is dissolved in exactly 100 g of water, the solution freezes at −1.28 °C. Identify the halide ion in this formula.

83. Nitrous oxide, N_2O, laughing gas, is used as an anesthetic. Its Henry's law constant is 2.4×10^{-2} mol/kg·bar. Determine the mass of N_2O that will dissolve in 500. mL of water, under an N_2O pressure of 1.00 bar. What is the concentration of N_2O in this solution, expressed in ppm (d (H_2O) = 1.00 g/mL)?



84. If a carbonated beverage is bottled under 1.5 bar CO_2 pressure, what will be the concentration of dissolved CO_2 in that beverage? (k_H for CO_2 is 0.034 mol/kg bar.) After the pressure is released, what fraction of the dissolved gas will escape before equilibrium with the CO_2 in the atmosphere is reached?

85. You are given a flask filled with a colored liquid. Suggest several tests that would allow you to determine whether this is a solution or a colloid.

86. If one is very careful, it is possible to float a needle on the surface of water. (If the needle is magnetized, it will turn to point north and south and become a makeshift compass.) What would happen to the needle if a drop of liquid soap is added to the solution? Explain the observation.

In the Laboratory

87. ▲ A solution of benzoic acid in benzene has a freezing point of 3.1 °C and a boiling point of 82.6 °C. (The freezing point of pure benzene is 5.50 °C, and its boiling point is 80.1 °C.) The structure of benzoic acid is

Benzoic acid, $C_6H_5CO_2H$

What can you conclude about the state of the benzoic acid molecules at the two different temperatures? Recall the discussion of hydrogen bonding in Section 11.3.

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

88. ▲ You dissolve 5.0 mg of iodine, I_2, in 25 mL of water. You then add 10.0 mL of CCl_4 and shake the mixture. If I_2 is 85 times more soluble in CCl_4 than in H_2O (on a volume basis), what are the masses of I_2 in the water and CCl_4 layers after shaking? (Figure 13.5.)

89. ▲ A solution of 5.00 g of acetic acid in 100. g of benzene freezes at 3.37 °C. A solution of 5.00 g of acetic acid in 100. g of water freezes at −1.49 °C. Find the molar mass of acetic acid from each of these experiments. What can you conclude about the state of the acetic acid molecules dissolved in each of these solvents? Recall the discussion of hydrogen bonding in Section 11.3, and propose a structure for the species in benzene solution.

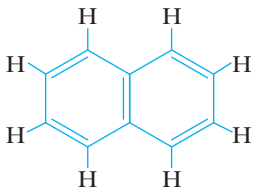
90. ▲ In a police forensics lab, you examine a package that may contain heroin. However, you find the white powder is not pure heroin but a mixture of heroin ($C_{21}H_{23}O_5N$) and lactose ($C_{12}H_{22}O_{11}$). To determine the amount of heroin in the mixture, you dissolve 1.00 g of the white powdery mixture in water in a 100.0-mL volumetric flask. You find that the solution has an osmotic pressure of 539 mm Hg at 25 °C. What is the composition of the mixture?

91. An organic compound contains carbon (71.17%), hydrogen (5.12%) with the remainder nitrogen. Dissolving 0.177 g of the compound in 10.0 g of benzene gives a solution with a vapor pressure of 94.16 mm Hg at 25 °C. (The vapor pressure of pure benzene at this temperature is 95.26 mm Hg.) What is the molecular formula for the compound?

92. In chemical research we often send newly synthesized compounds to commercial laboratories for analysis. These laboratories determine the weight percent of C and H by burning the compound and collecting the evolved CO_2 and H_2O. They determine the molar mass by measuring the osmotic pressure of a solution of the compound. Calculate the empirical and molecular formulas of a compound, C_xH_yCr, given the following information:
   (a) The compound contains 73.94% C and 8.27% H; the remainder is chromium.
   (b) At 25 °C, the osmotic pressure of a solution containing 5.00 mg of the unknown dissolved in exactly 100 mL of chloroform solution is 3.17 mm Hg.

Summary and Conceptual Questions

The following questions may use concepts from this and previous chapters.



93. When salts of Mg^{2+}, Ca^{2+}, and Be^{2+} are placed in water, the positive ion is hydrated (as is the negative ion). Which of these three cations is most strongly hydrated? Which one is least strongly hydrated?

94. Explain why a cucumber shrivels up when it is placed in a concentrated solution of salt.

95. If you dissolve equal molar amounts of NaCl and $CaCl_2$ in water, the $CaCl_2$ lowers the freezing point of the water almost 1.5 times as much as the NaCl. Why?

96. A 100.-gram sample of sodium chloride (NaCl) is added to 100. mL of water at 0 °C. After equilibrium is reached, about 64 g of solid remains undissolved. Describe the equilibrium that exists in this system at the particulate level.

97. Which of the following substances is/are likely to dissolve in water, and which is/are likely to dissolve in benzene (C_6H_6)?
   (a) $NaNO_3$
   (b) diethyl ether, $CH_3CH_2OCH_2CH_3$
   (c) NH_4Cl
   (d) naphthalene, $C_{10}H_8$

Naphthalene, $C_{10}H_8$

98. Account for the fact that alcohols such as methanol (CH_3OH) and ethanol (C_2H_5OH) are quite miscible with water, whereas an alcohol with a long-carbon chain, such as octanol ($C_8H_{17}OH$), is poorly soluble in water.

99. Starch contains C—C, C—H, C—O, and O—H bonds. Hydrocarbons have only C—C and C—H bonds. Both starch and hydrocarbons can form colloidal dispersions in water. Which dispersion is classified as hydrophobic? Which is hydrophilic? Explain briefly.

100. Which substance would have the greater influence on the vapor pressure of water when added to 1000. g of water: 10.0 g of sucrose ($C_{12}H_{22}O_{11}$) or 10.0 g of ethylene glycol ($HOCH_2CH_2OH$)?

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

101. You have two aqueous solutions separated by a semipermeable membrane. One contains 5.85 g of NaCl dissolved in 100. mL of solution, and the other contains 8.88 g of KNO_3 dissolved in 100. mL of solution. In which direction will solvent flow: from the NaCl solution to the KNO_3 solution, or from KNO_3 to NaCl? Explain briefly.

102. A protozoan (single-celled animal) that normally lives in the ocean is placed in freshwater. Will it shrivel or burst? Explain briefly.

103. ▲ In the process of distillation, a mixture of two (or more) volatile liquids is first heated to convert the volatile materials to the vapor state. Then the vapor is condensed, reforming the liquid. The net result of this liquid → vapor → liquid conversion is to enrich the fraction of a more volatile component in the mixture in the condensed vapor. We can describe how this occurs using Raoult's law. Imagine that you have a mixture of 12% (by weight) ethanol and water (as formed, for example, by fermentation of grapes).

(a) What are the mole fractions of ethanol and water in this mixture?

(b) This mixture is heated to 78.5 °C (the normal boiling point of ethanol). What are the equilibrium vapor pressures of ethanol and water at this temperature, assuming Raoult's law (ideal) behavior? (You will need to derive the equilibrium vapor pressure of water at 78.5 °C from data in Appendix G.)

(c) What are the mole fractions of ethanol and water in the vapor?

(d) After this vapor is condensed to a liquid, to what extent has the mole fraction of ethanol been enriched? What is the mass fraction of ethanol in the condensed vapor?

104. Sodium chloride (NaCl) is commonly used to melt ice on roads during the winter. Calcium chloride ($CaCl_2$) is sometimes used for this purpose too. Let us compare the effectiveness of equal masses of these two compounds in lowering the freezing point of water, by calculating the freezing point depression of solutions containing 200. g of each salt in 1.00 kg of water. (An advantage of $CaCl_2$ is that it acts more quickly because it is hygroscopic, that is, it absorbs moisture from the air to give a solution and begin the process. A disadvantage is that this compound is more costly.)

105. Review the trend in values of the van't Hoff factor *i* as a function of concentration (Table 13.4). Use the following data to calculate the van't Hoff factor for a NaCl concentration of 5.00% (by weight) (for which $\Delta T = -3.05$ °C) and a Na_2SO_4 concentration of 5.00% (by weight) (for which $\Delta T = -1.36$ °C). Are these values in line with your expectations based on the trend in the values given in Table 13.4? Speculate on why this trend is seen.

106. The table below gives experimentally determined values for freezing points of 1.00% solutions (mass %) of a series of acids.

(a) Calculate the molality of each solution, determine the calculated freezing points, and then calculate the values of the van't Hoff factor *i*. Fill these values into the table.

Acid (1.00 mass %)	Molality (mol/kg H_2O)	$T_{measured}$ (°C)	$T_{calculated}$ (°C)	*i*
HNO_3	_____	−0.56	_____	_____
CH_3CO_2H	_____	−0.32	_____	_____
H_2SO_4	_____	−0.42	_____	_____
$H_2C_2O_4$	_____	−0.30	_____	_____
HCO_2H	_____	−0.42	_____	_____
CCl_3CO_2H	_____	−0.21	_____	_____

(b) Analyze the results, comparing the values of *i* for the various acids. How do these data relate to acid strengths? (The discussion of strong and weak acids in Section 3.6 will assist you to answer this question.)

107. It is interesting how the Fahrenheit temperature scale was established. One report, given by Fahrenheit in a paper in 1724, stated that the value of 0 °F was established as the freezing temperature of saturated solutions of sea salt. From the literature we find that the freezing point of a 20% by mass solution of NaCl is −16.46 °C. (This is the lowest freezing temperature reported for solutions of NaCl.) Does this value lend credence to this story of the establishment of the Fahrenheit scale?

108. The osmotic pressure exerted by seawater at 25 °C is about 27 atm. Calculate the concentration of ions dissolved in seawater that is needed to give an osmotic pressure of this magnitude. (Desalinization of seawater is accomplished by reverse osmosis. In this process an applied pressure forces water through a membrane against a concentration gradient. The minimum external force needed for this process will be 27 atm. Actually, to accomplish the process at a reasonable rate, the applied pressure needs to be about twice this value.)

CHAPTER OUTLINE

14.1 Rates of Chemical Reactions

14.2 Reaction Conditions and Rate

14.3 Effect of Concentration on Reaction Rate

14.4 Concentration–Time Relationships: Integrated Rate Laws

14.5 A Microscopic View of Reaction Rates

14.6 Catalysts

14.7 Reaction Mechanisms

14.1 Rates of Chemical Reactions

Goals for Section 14.1

- Calculate the average rate of a reaction from concentration-time data.
- Relate the rates for the disappearance of reactants and formation of products for a chemical reaction.

Chemical kinetics is the study of the rates of chemical reactions. On the *macroscopic level*, the field of chemical kinetics addresses what reaction rate means, how to determine a reaction rate experimentally, and how factors such as temperature and reactant concentrations influence rates. At the *particulate level*, the concern is with the **reaction mechanism**, the detailed pathway taken by atoms and molecules as a reaction proceeds. The goal is to use data from the macroscopic world of chemistry to understand how chemical reactions occur at the particulate level—and then to apply this information to control important reactions.

You have encountered the concept of rates in your daily lives. The speed of an automobile is the distance traveled per unit time (for example, kilometers per hour) and the rate of flow of water from a faucet is the volume delivered per unit time (perhaps liters per minute). In each case, a change is measured over an interval of time. Similarly, the rate of a chemical reaction refers to the change in concentration of a reactant or product per unit of time.

$$\text{Reaction rate} = \frac{\text{change in concentration}}{\text{change in time}}$$

◀ **Catalysts speed up chemical reactions.** This chapter is about *chemical kinetics*, the study of reaction rates. Factors that can affect reaction rates include concentration, temperature, and the presence of a catalyst. Catalysts are substances that speed up a chemical reaction without being permanently changed in the process. Biological catalysts are called enzymes. In this photo, ground beef liver that contains the enzyme catalase is added to the solution of hydrogen peroxide in the beaker. The enzyme speeds up the decomposition of hydrogen peroxide into water and oxygen gas.

A few drops of blue food dye were added to water, followed by a solution of bleach.

The color fades as the dye reacts with the bleach.

Figure 14.1 An experiment to measure rate of reaction. The absorbance of the solution can be measured at various times using a spectrophotometer (see Section 4.9), and these values can be used to determine the concentration of the dye.

Calculating a Rate

The average speed of an automobile is the distance traveled divided by the time elapsed, or Δ(distance)/Δ(time). If an automobile travels 3.9 km in 4.5 min (0.075 h), its average speed is (3.9 km/0.075 h), or 52 km/h. Average rates of chemical reactions can be determined similarly. Two quantities, concentration and time, are measured. Concentrations can be determined in a variety of ways, such as by measuring the absorbance of light by a solution, a property that can be related to the concentration of a species in solution (Figure 14.1). The average rate of the reaction is the change in the concentration per unit time.

Let's consider the decomposition of N_2O_5 in a solvent. This reaction occurs according to the following equation:

$$N_2O_5 \rightarrow 2\ NO_2 + \tfrac{1}{2}\ O_2$$

Concentrations and time elapsed for a typical experiment done at 30.0 °C are illustrated by the graph in Figure 14.2.

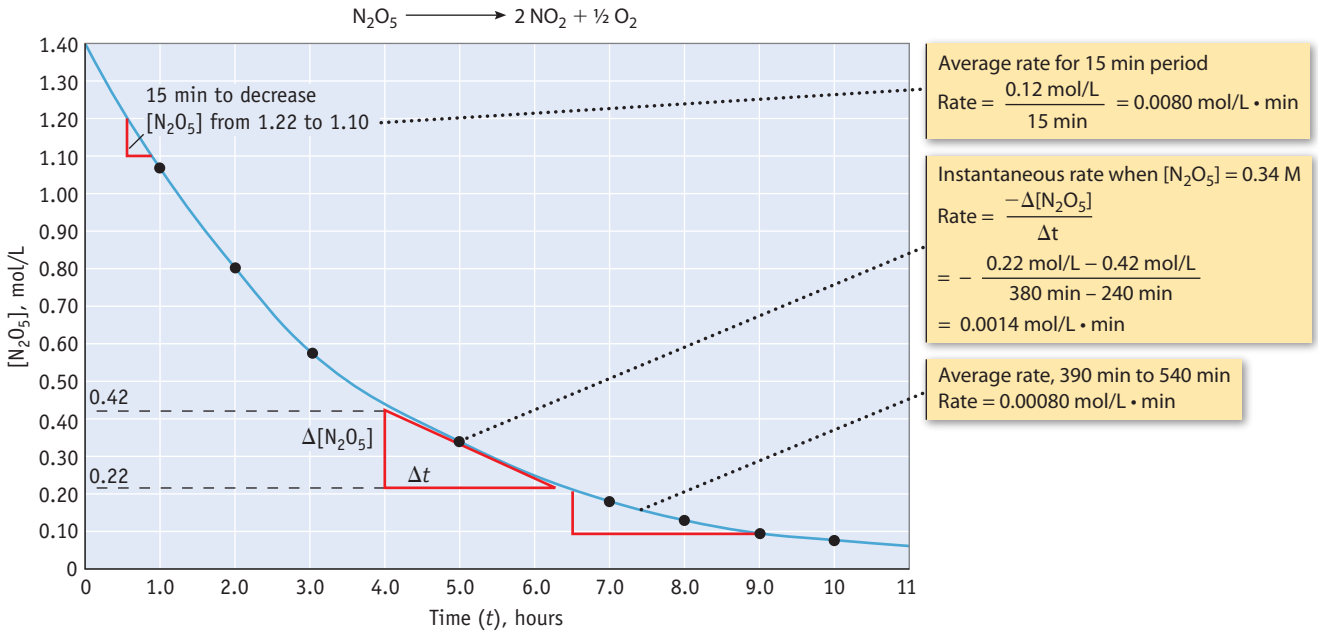

Figure 14.2 A plot of reactant concentration versus time for the decomposition of N_2O_5.

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

The *average* rate of this reaction for any interval of time can be expressed as the negative of the change in concentration of N_2O_5 divided by the change in time:

$$\text{Rate of decomposition of } N_2O_5 = -\frac{\text{change in } [N_2O_5]}{\text{change in time}} = -\frac{\Delta[N_2O_5]}{\Delta t}$$

The negative sign is required because N_2O_5 is a reactant and its concentration decreases with time (that is, $\Delta[N_2O_5] = [N_2O_5]_{final} - [N_2O_5]_{initial}$ is negative), but rate is always expressed as a positive quantity. For example, using data from Figure 14.2, the average rate of disappearance of N_2O_5 between 40 and 55 minutes is given by

$$\text{Rate} = -\frac{\Delta[N_2O_5]}{\Delta t} = -\frac{(1.10 \text{ mol/L}) - (1.22 \text{ mol/L})}{55 \text{ min} - 40 \text{ min}} = +\frac{0.12 \text{ mol/L}}{15 \text{ min}}$$

$$\text{Rate} = 0.0080 \text{ mol } N_2O_5 \text{ consumed/L} \cdot \text{min}$$

Calculating Changes When calculating a change in a quantity, we always subtract the initial quantity from the final quantity: $\Delta c = c_{final} - c_{initial}$.

Note the units for reaction rates; if concentration is expressed in mol/L, the units for rate will be mol/(L · time). Also notice that the average rate for the decomposition of N_2O_5 is the negative of the slope of a line connecting the two points of interest on the concentration-time graph.

The rate of the reaction decreases during the course of the reaction. We can verify this by comparing the average rate of disappearance of N_2O_5 calculated previously (when the concentration decreased by 0.12 mol/L in 15 minutes) to the average rate of reaction calculated for the time interval from 390 min to 540 min (when the concentration drops by 0.12 mol/L in 150 minutes). The average rate in this later stage of this reaction is only one tenth of the previous value.

$$-\frac{\Delta[N_2O_5]}{\Delta t} = -\frac{(0.10 \text{ mol/L}) - (0.22 \text{ mol/L})}{540 \text{ min} - 390 \text{ min}} = +\frac{0.12 \text{ mol/L}}{150 \text{ min}}$$

$$= 0.00080 \text{ mol/L} \cdot \text{min}$$

We might also ask what the *instantaneous* rate is at a single point in time. In an automobile, the instantaneous rate can be read from the speedometer. For a chemical reaction, we can extract the instantaneous rate from the concentration–time graph by drawing a line tangent to the concentration–time curve at a particular time and determining the slope of this line (Figure 14.2). For example, when $[N_2O_5] = 0.34$ mol/L and $t = 300$ min, the rate is

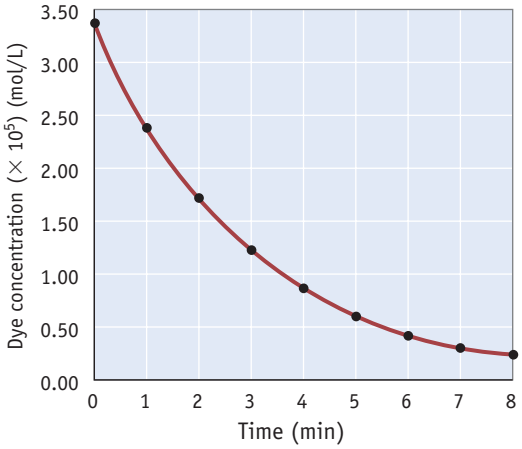
$$\text{Rate when } [N_2O_5] \text{ is } 0.34 \text{ M} = -\frac{\Delta[N_2O_5]}{\Delta t} = +\frac{0.20 \text{ mol/L}}{140 \text{ min}}$$

$$= 0.0014 \text{ mol/L} \cdot \text{min}$$

At that particular moment in time ($t = 300$ min), N_2O_5 is being consumed at a rate of 0.0014 mol/L · min.

EXAMPLE 14.1

Rate of Reaction



Problem Data collected on the concentration of a dye as a function of time are given in the graph below. Using these data estimate the value of (a) the average rate of change of the dye concentration over the first 2 minutes, and (b) the average rate of change during the fifth minute (from $t = 4.0$ minutes to $t = 5.0$ minutes).

What Do You Know? The concentration of dye as a function of time is presented as a graph. From this curve you can identify the concentration of dye at a specific time. Notice that the label of the y-axis tells us that the concentrations plotted have been multiplied by 10^5. The point plotted at t = 0 min thus corresponds to a concentration of 3.4×10^{-5} mol/L.

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Strategy To find the average rate, calculate the difference in concentration at the beginning and end of a time period ($\Delta c = c_{final} - c_{initial}$) and divide by the elapsed time. The negative of this value is the average rate.

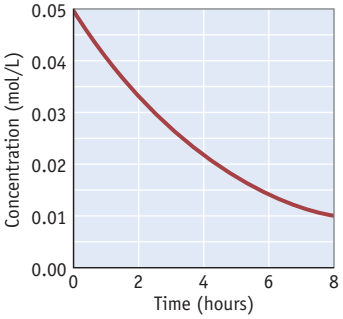
SOLUTION

(a) Average rate over first 2 minutes: The concentration of dye decreases from 3.4×10^{-5} mol/L at $t = 0$ minutes to 1.7×10^{-5} mol/L at $t = 2.0$ minutes. The average rate of the reaction in this interval of time is

$$\text{Average rate} = -\frac{\Delta[\text{Dye}]}{\Delta t} = -\frac{(1.7 \times 10^{-5}\ \text{mol/L}) - (3.4 \times 10^{-5}\ \text{mol/L})}{2.0\ \text{min}}$$

$$\text{Average rate} = 8.5 \times 10^{-6}\ \text{mol/L} \cdot \text{min}$$

(b) Average rate during the fifth minute: The concentration of dye decreases from 0.90×10^{-5} mol/L at $t = 4.0$ minutes to 0.60×10^{-5} mol/L at $t = 5.0$ minutes. The average rate of the reaction in this interval of time is



$$\text{Average rate} = -\frac{\Delta[\text{Dye}]}{\Delta t} = -\frac{(0.60 \times 10^{-5}\ \text{mol/L}) - (0.90 \times 10^{-5}\ \text{mol/L})}{1.0\ \text{min}}$$

$$\text{Average rate} = 3.0 \times 10^{-6}\ \text{mol/L} \cdot \text{min}$$

Think about Your Answer Notice that the rate of reaction decreases as the concentration of dye decreases. This tells us that the rate of the reaction is related to the concentration of dye.

Check Your Understanding

Sucrose decomposes to fructose and glucose in acid solution. A plot of the concentration of sucrose as a function of time is given in the margin. What is the rate of change of the sucrose concentration over the first 2 hours? What is the rate of change over the last 2 hours?

Concentration versus time for the decomposition of sucrose. ("Check Your Understanding" in Example 14.1.)

Relative Rates and Stoichiometry

During a chemical reaction, amounts of reactants decrease with time, and amounts of products increase. For the decomposition of N_2O_5, we could express the rate of appearance of products, either as $\Delta[NO_2]/\Delta t$ or as $\Delta[O_2]/\Delta t$. Rates based on changes in concentrations of products do not require the negative sign in the Δ(concentration)/Δt expression because the concentration of a product increases, and the expression will already have a positive value. Furthermore, the numerical

values of rates defined in terms of NO_2 or O_2 will be different from the value of $\Delta[N_2O_5]/\Delta t$ due to the different stoichiometric coefficients for the substances in the chemical equation. For example, the rate of appearance of NO_2 will be *twice* the rate of disappearance of N_2O_5 because the stoichiometry requires *two* NO_2 molecules to be formed for each N_2O_5 molecule consumed. To take the stoichiometry into account when defining the rate of a reaction, we include a factor for each reactant and product of $1/x$ where x is the substance's stoichiometric coefficient. This gives us a single value of the reaction rate regardless of which reactant or product is being monitored. For the general reaction

$$a\ A + b\ B \rightarrow c\ C + d\ D$$

the reaction rate is defined as

$$\text{Reaction rate} = -\frac{1}{a}\frac{\Delta[A]}{\Delta t} = -\frac{1}{b}\frac{\Delta[B]}{\Delta t} = +\frac{1}{c}\frac{\Delta[C]}{\Delta t} = +\frac{1}{d}\frac{\Delta[D]}{\Delta t}$$

Note that this gives us the reaction rate on a "per mole of reaction" basis. In our example above using the decomposition of N_2O_5 reaction, the rate expression relating all of the reactants and products is

$$\text{Reaction rate} = -\frac{\Delta[N_2O_5]}{\Delta t} = +\frac{1}{2}\frac{\Delta[NO_2]}{\Delta t} = +2\frac{\Delta[O_2]}{\Delta t}$$

Mole of Reaction One mole of reaction is said to occur when the reaction has taken place according to the number of moles given by the coefficients in the chemical equation (Chapter 4, page 181). For the chemical equation $2\ H_2(g) + O_2(g) \rightarrow 2\ H_2O(\ell)$, one mole of reaction has occurred when 2 moles of hydrogen gas react with 1 mole of oxygen gas to form 2 moles of liquid water.

EXAMPLE 14.2

Relative Rates and Stoichiometry

Problem Relate the rates for the disappearance of reactants and formation of products for the following reaction:

$$4\ PH_3(g) \rightarrow P_4(g) + 6\ H_2(g)$$

What Do You Know? The stoichiometric coefficients in the balanced equation can be used to evaluate the relative rates for the disappearance of the starting material and formation of the products.

Strategy In this reaction, PH_3 disappears, and P_4 and H_2 are formed. Consequently, the value of $\Delta[PH_3]/\Delta t$ will be negative, whereas $\Delta[P_4]/\Delta t$ and $\Delta[H_2]/\Delta t$ will be positive. To relate the rates to each other, we divide each Δ[reagent]$/\Delta t$ by its stoichiometric coefficient in the balanced equation.

SOLUTION Because four moles of PH_3 disappear for every one mole of P_4 formed, the numerical value of the rate of formation of P_4 is one fourth of the rate of disappearance of PH_3. Similarly, P_4 is formed at only one sixth of the rate that H_2 is formed.

$$\text{Reaction rate} = -\frac{1}{4}\left(\frac{\Delta[PH_3]}{\Delta t}\right) = +\frac{\Delta[P_4]}{\Delta t} = +\frac{1}{6}\left(\frac{\Delta[H_2]}{\Delta t}\right)$$

Think about Your Answer In determining the rate of a chemical reaction you should take into account (1) whether a substance is a reactant or product and (2) the stoichiometric coefficient of the substance in the balanced chemical equation for the reaction.

Check Your Understanding

What are the relative rates of appearance or disappearance of each product and reactant in the decomposition of nitrosyl chloride, NOCl?

$$2\ NOCl(g) \rightarrow 2\ NO(g) + Cl_2(g)$$

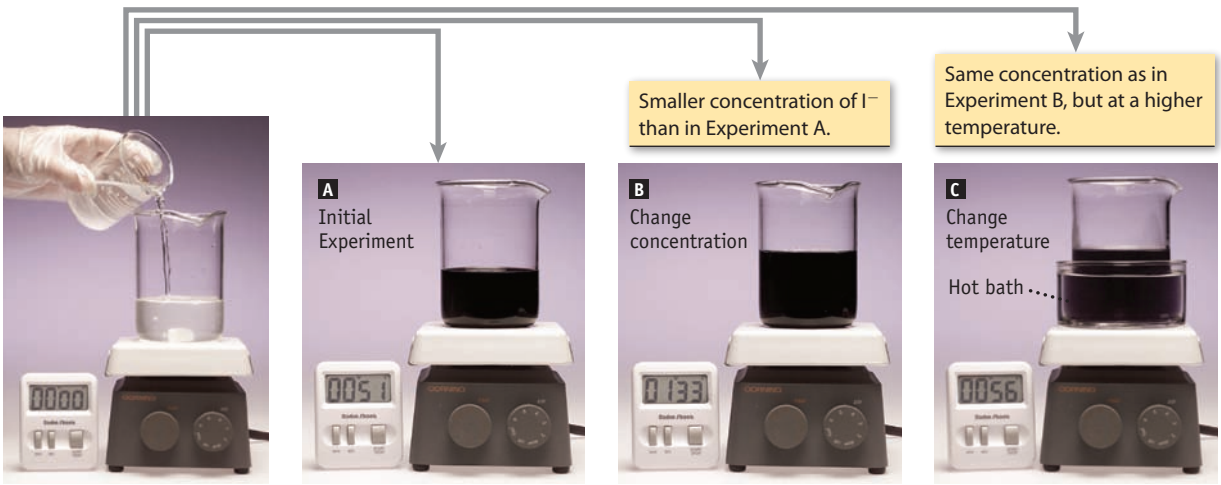
14.2 Reaction Conditions and Rate

Goal for Section 14.2

- Describe how reaction conditions (reactant concentrations, temperature, presence of a catalyst, and the state of the reactants) affect reaction rate.

Several factors—reactant concentrations, temperature, and presence of catalysts—affect the rate of a reaction. If the reactant is a solid, the surface area available for reaction is also a factor.

The "iodine clock reaction" (Figure 14.3) illustrates the **effects of concentration and temperature**. The reaction mixture contains hydrogen peroxide (H_2O_2), iodide ion (I^-), ascorbic acid (vitamin C), and starch (which is an indicator of the presence of iodine, I_2). A sequence of reactions begins with the slow oxidation of iodide ion to I_2 by H_2O_2.



$$H_2O_2(aq) + 2\ I^-(aq) + 2\ H_3O^+(aq) \rightarrow 4\ H_2O(\ell) + I_2(aq)$$

As I_2 is formed in the solution, vitamin C rapidly reduces it back to I^-.

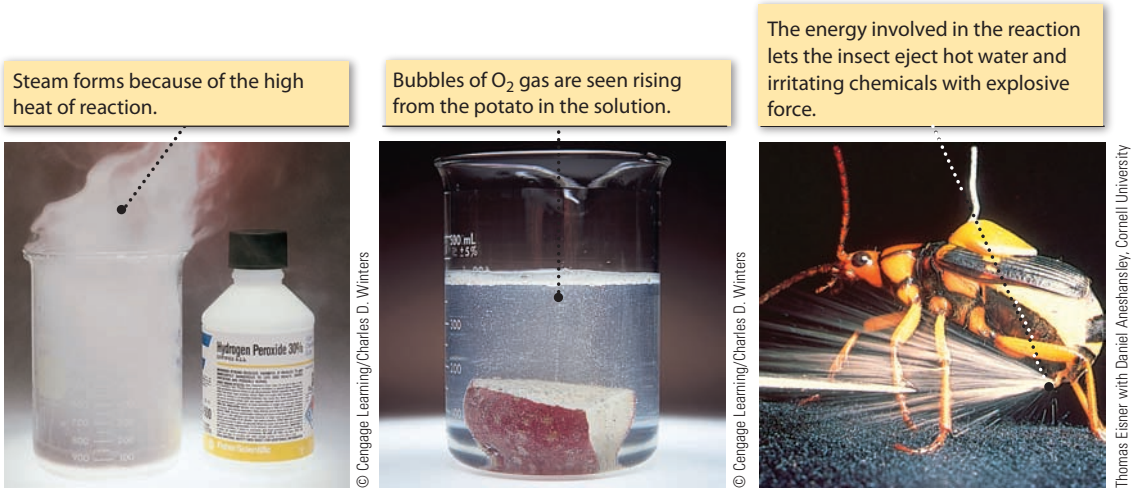
$$2\ H_2O(\ell) + I_2(aq) + C_6H_8O_6(aq) \rightarrow C_6H_6O_6(aq) + 2\ H_3O^+(aq) + 2\ I^-(aq)$$

When all of the vitamin C has been consumed, I_2 remains in solution and forms a blue-black complex with starch. The time it takes for the given amount of vitamin C to react is measured. For the first experiment (A in Figure 14.3) the time required is 51 seconds. When the concentration of iodide ion is smaller (B), the time required for the vitamin C to be consumed is longer, 1 minute 33 seconds. Finally, when the concentrations are again the same as in experiment B but the reaction mixture is heated, the reaction occurs more rapidly (56 seconds). This experiment illustrates two features that are true of most reactions:

- If the concentration of a reactant is increased, the reaction rate will increase as well.
- Chemical reactions occur more rapidly at higher temperatures.

Solutions containing vitamin C, H_2O_2, I^-, and starch are mixed.

Initial Experiment
The blue color of the starch-iodine complex develops in 51 seconds.



Change Concentration
The blue color of the starch-iodine complex develops in 1 minute 33 seconds when the solution is less concentrated than in A.

Change Temperature
The blue color of the starch-iodine complex develops in 56 seconds when the solution is the same concentration as in B but at a higher temperature.

Figure 14.3 The iodine clock reaction. This reaction illustrates the effects of concentration and temperature on reaction rate. (You can do these experiments yourself with reagents available in the supermarket. For details, see S. W. Wright: "The vitamin C clock reaction," *Journal of Chemical Education*, Vol. 79, p. 41, 2002.)

The rate of decomposition of hydrogen peroxide is increased by the catalyst MnO_2. Here, H_2O_2 (as a 30% aqueous solution) is poured onto the black solid MnO_2 and rapidly decomposes to O_2 and H_2O.

The enzyme catalase, found in potatoes and other sources, is used to catalyze H_2O_2 decomposition.

A bombardier beetle uses the catalase catalyzed decomposition of H_2O_2 as a defense mechanism.

Figure 14.4 Catalyzed decomposition of H_2O_2.

Catalysts are substances that accelerate chemical reactions but are not themselves consumed. Consider the effect of a catalyst on the decomposition of hydrogen peroxide, H_2O_2, to form water and oxygen.

$$2\ H_2O_2(aq) \rightarrow O_2(g) + 2\ H_2O(\ell)$$

This decomposition is very slow; a solution of H_2O_2 can be stored for many months with only minimal change in concentration. Adding manganese(IV) oxide, an iodide-containing salt, or the enzyme catalase—a biological catalyst—causes this reaction to occur rapidly, as shown by vigorous bubbling as gaseous oxygen escapes from the solution (Figure 14.4 and Chapter Opening Photograph).

The *surface area* of a solid reactant can also affect the reaction rate. Only molecules at the surface of a solid can come in contact with other reactants. The smaller the particles of a solid, the more molecules are found on the solid's surface. With very small particles, the effect of surface area on rate can be quite dramatic (Figure 14.5). Farmers know that fine dust particles (suspended in the air in an enclosure used for grain storage such as a silo or a feed mill) represent a major explosion hazard.

The spores of the common lycopodium clubmoss burn only with difficulty when piled in a dish.

If the spores are ground to a fine powder and sprayed into a flame, combustion is rapid.

Figure 14.5 The contrasting rates of combustion of lycopodium powder in bulk and finely powdered form.

14.3 Effect of Concentration on Reaction Rate

Goal for Section 14.3

- Derive a rate equation from experimental information using the method of initial rates.

One important goal in studying the kinetics of a reaction is to determine its mechanism; that is, how the reaction occurs at the molecular level. The place to begin is to learn, by experiment, how reactant concentrations affect the reaction rate. The resulting relationship between reactant concentrations and reaction rate is expressed by an equation called a **rate equation**, or **rate law**.

Rate Equations

The effect of concentration can be determined by evaluating how the rate is affected when the concentrations of the reactants are varied (with the temperature held constant). Consider, for example, the gas-phase decomposition of N_2O_5 to NO_2 and O_2.

$$N_2O_5(g) \longrightarrow 2\ NO_2(g) + \tfrac{1}{2}\ O_2(g)$$

Figure 14.6 presents data on the concentration of N_2O_5 as a function of time for reactions beginning with two different concentrations of N_2O_5. The initial rate for the first 15 minutes (0.25 h) of the reaction is calculated in each case. When we start with 0.500 M N_2O_5, the initial rate is 0.12 mol/ L · h and when we start with 1.00 M N_2O_5, the initial rate is 0.24 mol/ L · h. That is, doubling the concentration of N_2O_5 doubles the reaction rate. From this result, we know that the rate for this reaction must be directly proportional to the N_2O_5 concentration:

$$N_2O_5(g) \longrightarrow 2\ NO_2(g) + \tfrac{1}{2}\ O_2(g)$$

$$\text{Rate of reaction} \propto [N_2O_5]$$

where the symbol $\propto$ means "proportional to." This proportionality is expressed by the rate equation

$$\text{Rate of reaction} = -\Delta[N_2O_5]/\Delta t = k[N_2O_5]$$

where the proportionality constant, k, is called the **rate constant**. This rate equation tells us that this reaction rate is proportional to the concentration of the reactant.

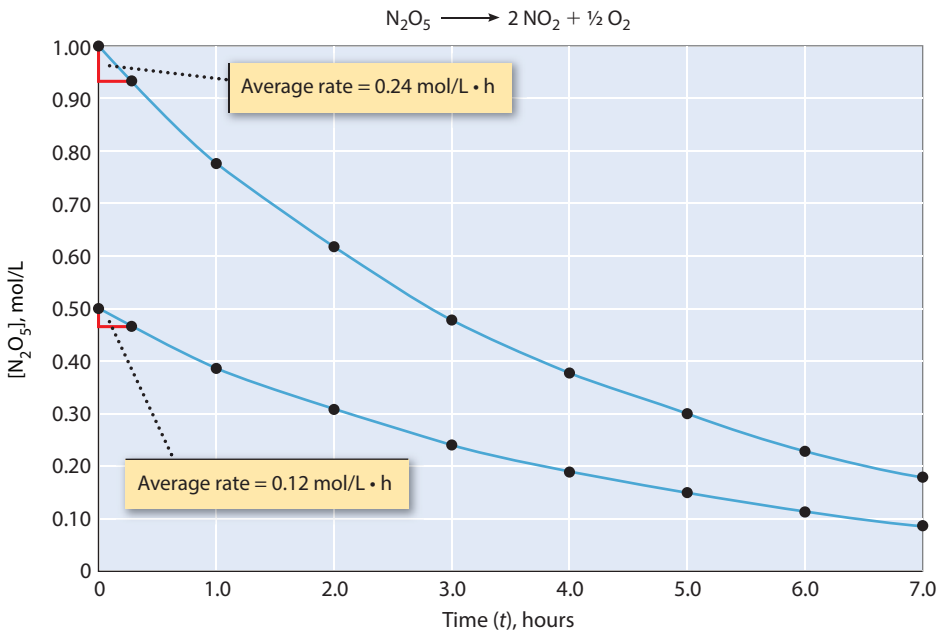

Figure 14.6 Reactant concentration versus time data for the gas-phase decomposition of N_2O_5, beginning with two different concentrations of N_2O_5.

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Based on this equation, we can determine that when $[N_2O_5]$ is doubled, the reaction rate doubles, for example.

Generally, for a reaction such as

$$a\ A + b\ B \rightarrow x\ X$$

the rate equation has the form

$$\text{Rate of reaction} = k[A]^m[B]^n$$

Exponents on Reactant Concentrations and Reaction Stoichiometry The exponents m and n are not necessarily the stoichiometric coefficients (a and b) for the balanced chemical equation.

The rate equation expresses the fact that the rate of reaction is proportional to the reactant concentrations, each concentration being raised to some power. The exponents in this equation are often positive whole numbers, but they can also be negative numbers, fractions, or zero. *They must be determined by experiment.*

If a homogeneous catalyst is present, its concentration might also be included in the rate equation, even though the catalytic species is not a product or reactant in the equation for the reaction. Consider, for example, the decomposition of hydrogen peroxide in the presence of a catalyst such as iodide ion.

$$H_2O_2(aq) \xrightarrow{I^-(aq)} H_2O(\ell) + \tfrac{1}{2}\ O_2(g)$$

The Nature of Catalysts A catalyst does not appear as a reactant in the balanced, overall equation for the reaction (Section 14.6), but it may appear in the rate expression. A common practice is to identify catalysts by name or symbol above the reaction arrow, as shown in the example. A *homogeneous* catalyst is one in the same phase as the reactants. For example, in the iodide ion-catalyzed decomposition of H_2O_2 in water, the I^- ion is a homogeneous catalyst.

Experiments show that this reaction has the following rate equation:

$$\text{Reaction rate} = -\Delta[H_2O_2]/\Delta t = k[H_2O_2][I^-]$$

Here, the concentration of the catalyst, I^-, appears in the rate law, even though it is not part of the balanced equation.

The Order of a Reaction

The **order** of a reaction with respect to a particular reactant is the exponent of its concentration term in the rate law expression, and the **overall reaction order** is the sum of the exponents on all concentration terms. For example, the reaction of NO and Cl_2:

$$NO(g) + \tfrac{1}{2}\ Cl_2(g) \rightarrow NOCl(g)$$

has the following experimentally determined rate law:

$$\text{Reaction rate} = -\Delta[NO]/\Delta t = k[NO]^2[Cl_2]$$

This reaction is second-order in NO, first-order in Cl_2, and third-order overall.

While first- and second-order reactions are common, other reaction orders are also observed, including zero-order reactions. An example of a zero-order reaction is the decomposition of ammonia on a platinum surface at 856 °C.

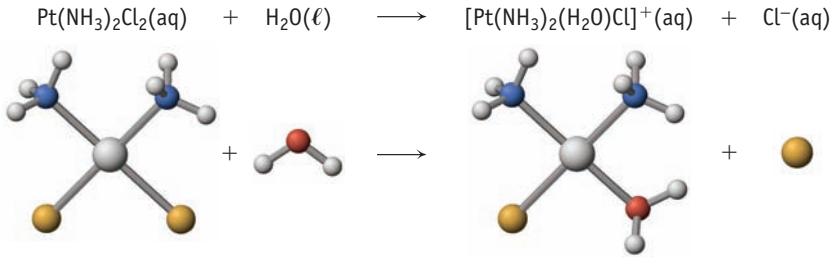
$$NH_3(g) \rightarrow \tfrac{1}{2}\ N_2(g) + \tfrac{3}{2}\ H_2(g)$$

When the concentration of ammonia is high, the reaction rate is independent of NH_3 concentration. The rate law for this reaction is

$$\text{Reaction rate} = k[NH_3]^0 = k$$

Reaction order is important because it gives some insight into the most interesting question of all—how the reaction occurs. This is described further in Section 14.7.

The Rate Constant, *k*



The rate constant, k, is a proportionality constant that relates rate and concentration *at a given temperature.* It is an important quantity because it enables you to find the reaction rate for a new set of concentrations. To see how to use k, consider

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

the substitution of Cl^- ion by water in the cancer chemotherapy agent cisplatin, $Pt(NH_3)_2Cl_2$.

Pseudo–First Order Reaction Actually, the reaction of cisplatin and water is a second-order reaction where Rate = $k[Pt(NH_3)_2Cl_2][H_2O]$. If the reaction is done in a great excess of water, however, the concentration of water does not change by a significant amount over the course of the reaction, that is, $[H_2O]$ = constant. Under such circumstances, the reaction is said to be run under *pseudo–first-order conditions*, and the rate law is given by the equation Rate = $k'[Pt(NH_3)_2Cl_2]$ where $k' = k[H_2O]$.

The rate law for this reaction is

$$\text{Reaction rate} = -\Delta[Pt(NH_3)_2Cl_2]/\Delta t = k[Pt(NH_3)_2Cl_2]$$

and the rate constant, k, is 0.27/h at 25 °C. Knowing k allows you to calculate the rate at a particular reactant concentration—for example, when $[Pt(NH_3)_2Cl_2] = 0.018$ mol/L:

$$\text{Reaction rate} = (0.27/\text{h})(0.018\ \text{mol/L}) = 0.0049\ \text{mol/L} \cdot \text{h}$$

As noted earlier, reaction rates have units of mol/L · time when concentrations are given as moles per liter. Rate constants must have units consistent with the units for the other terms in the rate equation.

- First-order reactions: The units of k are 1/time.
- Second-order reactions: The units of k are L/mol · time.
- Zero-order reaction: The units of k are mol/L · time.

Time and Rate Constants The time in a rate constant can be seconds, minutes, hours, days, years, or whatever time unit is appropriate. The fraction 1/time can also be written as time^{-1}. For example, 1/y is equivalent to y^{-1}, and 1/s is equivalent to s^{-1}.

Finally, you should recognize that reactions can range from excruciatingly slow to lightning fast, and this is reflected in wide-ranging values of k. The platinum reaction above has a value of k of 0.27/h at 25 °C. In contrast, sucrose decomposes in a first-order reaction to fructose and glucose with a rate constant of 0.0036/h at 25 °C. And the very rapid combination of I atoms to form I_2 molecules in the gas phase has $k = 4 \times 10^{11}$ L/mol · s at 23 °C.

Determining a Rate Equation

One way to determine a rate equation is by using the **method of initial rates**. *The initial rate is the instantaneous reaction rate at the start of the reaction* (the rate at $t = 0$). An approximate value of the initial rate can be obtained by mixing the reactants and determining the reaction rate after 1% to 2% of the limiting reactant has been consumed. Measuring the rate during the initial stage of a reaction is convenient because initial concentrations are known (Figure 14.6).

As an example of the determination of a reaction rate law using initial rates, let us consider the following reaction of nitrogen monoxide with chlorine.

$$NO(g) + \tfrac{1}{2}\,Cl_2(g) \rightarrow NOCl(g)$$

Reactant concentrations and initial rates for this reaction for several experiments at 50 °C are collected in the table below.

Experiment	INITIAL CONCENTRATIONS (mol/L)		Initial Rate, $-\Delta[NO]/\Delta t$ (mol/L · s)
	[NO]	$[Cl_2]$	
1	0.250 ↓ × 2	0.250 ↓ No change	1.43×10^{-6} ↓ × 4
2	0.500	0.250	5.72×10^{-6}
3	0.250	0.500	2.86×10^{-6}
4	0.500	0.500	11.4×10^{-6}

- *Compare Experiments 1 and 2:* Here, $[Cl_2]$ is held constant, and [NO] is doubled. This change in [NO] by a factor of 2 leads to a reaction rate increase by a factor of 4; that is, the rate is proportional to the *square* of the NO concentration.
- *Compare Experiments 1 and 3:* In experiments 1 and 3, [NO] is held constant, and $[Cl_2]$ is doubled, causing the rate to double. That is, the rate is proportional to $[Cl_2]$.

The rate law that reflects these experimental observations is

$$\text{Reaction rate} = -\Delta[NO]/\Delta t = k[NO]^2[Cl_2]$$

Using this equation, we can predict that doubling both concentrations at the same time should cause the rate to go up by a factor of 8, as is determined if experiments 1 and 4 are compared [$(1.43 \times 10^{-6}$ mol/L · s) × 8 = 11.4×10^{-6} mol/L · s].

If the rate equation is known, the value of k, the rate constant, can be found by substituting values for the rate and concentration into the rate equation. Using the data for the NO/Cl_2 reaction from the first experiment, we have

$$\text{Reaction rate} = 1.43 \times 10^{-6} \text{ mol/L} \cdot \text{s} = k(0.250 \text{ mol/L})^2(0.250 \text{ mol/L})$$

$$k = \frac{1.43 \times 10^{-6} \text{ mol/L} \cdot \text{s}}{(0.250 \text{ mol/L})^2(0.250 \text{ mol/L})} = 9.15 \times 10^{-5} \text{ L}^2/\text{mol}^2 \cdot \text{s}$$

EXAMPLE 14.3

Determining a Rate Equation

Problem The rate of the reaction between CO and NO_2 at 540 K

$$CO(g) + NO_2(g) \rightarrow CO_2(g) + NO(g)$$

was measured starting with various concentrations of CO and NO_2. Determine the rate equation and the value of the rate constant.

Experiment	INITIAL CONCENTRATIONS (mol/L) [CO]	[NO_2]	Initial Rate (mol/L · h)
1	5.10×10^{-4}	0.350×10^{-4}	3.4×10^{-8}
2	5.10×10^{-4}	0.700×10^{-4}	6.8×10^{-8}
3	5.10×10^{-4}	0.175×10^{-4}	1.7×10^{-8}
4	1.02×10^{-3}	0.350×10^{-4}	6.8×10^{-8}
5	1.53×10^{-3}	0.350×10^{-4}	10.2×10^{-8}

What Do You Know? The table contains concentrations of the two reactants and initial rates for five experiments.

Strategy For a reaction involving several reactants, the general approach is to keep the concentration of one reactant constant and then decide how the rate of reaction changes as the concentration of the other reactant is varied.

SOLUTION The initial concentration of CO is the same in the first three experiments. Comparing experiments 1 and 2, we can set up the following ratios:

$$\frac{\text{Rate 2}}{\text{Rate 1}} = \frac{k[CO]_2^m[NO_2]_2^n}{k[CO]_1^m[NO_2]_1^n}$$

Strategy Map 14.3

PROBLEM

Derive the **rate equation** and **value of *k*** for a given reaction.

DATA/INFORMATION

- **5 experiments** measuring ***initial rate*** as a function of **reactant concentration**

STEP 1. **Compare rates** for two experiments where the concentration of reactant **A** is ***constant*** and reactant **B** is ***varied***.

Gives the **dependence of rate** on one reactant **(B)**

STEP 2. **Compare rates** for two experiments where the concentration of reactant **B** is ***constant*** and reactant **A** is ***varied***.

Gives the **dependence of rate** on the other reactant **(A)**

STEP 3. Use the ***rate dependence*** on **A** and **B** to write the **rate equation**.

Rate = $k[A]^n[B]^m$

STEP 4. Substitute the **rate data** for one experiment into the **rate equation** to calculate ***k***.

Value of rate constant ***k***

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Because k and the concentration of CO are constant in these two cases, they cancel, leaving

$$\frac{\text{Rate 2}}{\text{Rate 1}} = \left(\frac{[NO_2]_2}{[NO_2]_1}\right)^n$$

Substituting the values from the table, we obtain

$$\frac{6.8 \times 10^{-8}\ \text{mol/L} \cdot \text{h}}{3.4 \times 10^{-8}\ \text{mol/L} \cdot \text{h}} = \left(\frac{0.700 \times 10^{-4}\ \text{mol/L}}{0.350 \times 10^{-4}\ \text{mol/L}}\right)^n$$

$$2.0 = (2.00)^n$$

$$n = 1$$

Thus, doubling the NO_2 concentration in experiment 2 relative to experiment 1, led to a twofold increase in the rate. The reaction is first-order in NO_2. This finding is confirmed by experiment 3. Decreasing $[NO_2]$ in experiment 3 to half its original value causes the rate to decrease by half.

In a similar fashion, the data in experiments 1 and 4 (with constant $[NO_2]$) show that doubling [CO] doubles the rate, and the data from experiments 1 and 5 show that tripling the concentration of CO triples the rate. These results mean that the reaction is first-order in [CO]. Thus, we now know the rate equation is

$$\text{Reaction rate} = k[CO][NO_2]$$

The rate constant, k, can be found by inserting data for one of the experiments into the rate equation. Using data from experiment 1, for example,

$$\text{Rate} = 3.4 \times 10^{-8}\ \text{mol/L} \cdot \text{h} = k(5.10 \times 10^{-4}\ \text{mol/L})(0.350 \times 10^{-4}\ \text{mol/L})$$

$$k = 1.9\ \text{L/mol} \cdot \text{h}$$

Think about Your Answer To check your answer, calculate k for two or more of the experiments. If these values differ significantly, then you know that you have made a mistake in calculating the reaction orders.

Check Your Understanding

The initial rate $(-\Delta[NO]/\Delta t)$ of the reaction of nitrogen monoxide and oxygen

$$NO(g) + \tfrac{1}{2}\,O_2(g) \rightarrow NO_2(g)$$

was measured for various initial concentrations of NO and O_2 at 25 °C. Determine the rate equation from these data. What is the value of the rate constant, k, and what are its units?

Experiment	INITIAL CONCENTRATIONS (mol/L)		Initial Rate (mol NO/L · s)
	[NO]	$[O_2]$	
1	0.020	0.010	0.028
2	0.020	0.020	0.057
3	0.020	0.040	0.114
4	0.040	0.020	0.227
5	0.010	0.020	0.014

Problem Solving Tip 14.1 Determining a Rate Equation: A Logarithmic Approach

In the examples shown, we could determine the exponents because the ratios used were easy to recognize: $2 = 2^1$, $4 = 2^2$, etc. What if the relationships are not easily recognizable? Consider if we had obtained the following ratios:

$$\frac{\text{Rate in experiment 2}}{\text{Rate in experiment 1}} = \left(\frac{[R]_2}{[R]_1}\right)^n$$

$$\frac{4.05 \times 10^{-8}\ \text{mol/L} \cdot \text{h}}{1.80 \times 10^{-8}\ \text{mol/L} \cdot \text{h}} = \left(\frac{5.25 \times 10^{-3}\ \text{mol/L}}{3.50 \times 10^{-3}\ \text{mol/L}}\right)^n$$

$$2.25 = (1.50)^n$$

We can solve this problem by taking the logarithm of both sides of the equation.

$$\log(2.25) = \log(1.50)^n$$

Using a property of logarithms, this equation becomes

$$\log(2.25) = n\log(1.50)$$

Solving for n, we obtain

$$n = \frac{\log(2.25)}{\log(1.50)} = 2.000$$

Thus, the reaction is second-order with respect to reactant R.

EXAMPLE 14.4

Using a Rate Equation to Determine Rates

Problem Using the rate equation and rate constant determined for the reaction of CO and NO_2 at 540 K in Example 14.3, determine the initial rate of the reaction when $[CO] = 3.8 \times 10^{-4}$ mol/L and $[NO_2] = 0.650 \times 10^{-4}$ mol/L.

What Do You Know? The rate law and the value for the rate constant (1.9 L/mol · h) are both known. The concentrations of the two reactants are given.

Strategy A rate equation consists of three parts: a rate, a rate constant (k), and the concentration terms. If two of these parts are known (here k and the concentrations), the third can be calculated.

SOLUTION Substitute k (= 1.9 L/mol · h) and the concentration of each reactant into the rate law determined in Example 14.3.

$$\text{Reaction rate} = k[CO][NO_2] = (1.9\ \text{L/mol} \cdot \text{h})(3.8 \times 10^{-4}\ \text{mol/L})(0.650 \times 10^{-4}\ \text{mol/L})$$

$$\text{Reaction rate} = 4.7 \times 10^{-8}\ \text{mol/L} \cdot \text{h}$$

Think about Your Answer As a check on the calculated result, it is often useful to make an educated guess at the answer before carrying out the mathematical solution. We know the reaction here is first-order in both reactants. Comparing the concentration values given in this problem with the concentration values in experiment 1 in Example 14.3, we notice that [CO] is about three fourths of the concentration value, whereas $[NO_2]$ is almost twice the value. The effects do not precisely offset each other, but we might predict that the difference in rates between this experiment and experiment 1 will be fairly small, with the rate in this experiment being just a little greater. The calculated value bears this out.

Check Your Understanding

The rate constant, k, at 25 °C is 0.27/h for the reaction

$$Pt(NH_3)_2Cl_2(aq) + H_2O(\ell) \rightarrow [Pt(NH_3)_2(H_2O)Cl]^+(aq) + Cl^-(aq)$$

and the rate equation is

$$\text{Reaction rate} = k[Pt(NH_3)_2Cl_2]$$

Calculate the rate of reaction when the concentration of $Pt(NH_3)_2Cl_2$ is 0.020 M.

14.4 Concentration–Time Relationships: Integrated Rate Laws

Goals for Section 14.4

- Use the relationships between reactant concentration and time for zero-order, first-order, and second-order reactions.
- Apply graphical methods for determining reaction order and the rate constant from experimental data.
- Use the concept of half-life ($t_{1/2}$), especially for first-order reactions.

It is often important for a chemist to know how long a reaction must proceed to reach a predetermined concentration of some reactant or product, or what the reactant and product concentrations will be after some time has elapsed. For this reason it would be useful to have a mathematical equation that relates time and concentration—an equation that describes concentration–time curves like the one shown in Figure 14.2. With such an equation, we could calculate the concentration at any given time or the length of time needed for a given amount of reactant to react.

First-Order Reactions

Suppose the reaction "R → products" is first-order. This means the reaction rate is directly proportional to the concentration of R raised to the first power, or, mathematically,

$$-\frac{\Delta[\mathrm{R}]}{\Delta t} = k[\mathrm{R}]$$

This relationship can be transformed into a very useful equation called an **integrated rate equation** (because integral calculus is used in its derivation).

$$\ln\frac{[\mathrm{R}]_t}{[\mathrm{R}]_0} = -kt \qquad (14.1)$$

Here, $[\mathrm{R}]_0$ and $[\mathrm{R}]_t$ are concentrations of the reactant at time $t = 0$ and at a later time, t, respectively. The ratio of concentrations, $[R]_t/[R]_0$, *is the fraction of reactant that remains after a given time has elapsed.*

Equation 14.1 can be used to carry out many useful calculations. For example,

- If $[\mathrm{R}]_t/[\mathrm{R}]_0$ is measured in the laboratory after some amount of time has elapsed, then k can be determined.
- If $[\mathrm{R}]_0$ and k are known, then the concentration of material remaining after a given amount of time ($[\mathrm{R}]_t$) can be calculated.
- If k is known, then the time elapsed until a specific fraction ($[\mathrm{R}]_t/[\mathrm{R}]_0$) remains can be determined.

Finally, notice that *k for a first-order reaction is independent of concentration*; k has units of time^{-1} (y^{-1} or s^{-1}, for example). This means we can choose any convenient unit for $[\mathrm{R}]_t$ and $[\mathrm{R}]_0$: moles per liter, moles, grams, number of atoms, number of molecules, or gas pressure.

EXAMPLE 14.5

The First-Order Rate Equation

Problem In the past, cyclopropane, C_3H_6, was used in a mixture with oxygen as an anesthetic. (This practice has almost ceased today because the compound is flammable.) When heated, cyclopropane rearranges to propene in a first-order process.

Rate = k[cyclopropane] $\quad k = 2.42\ h^{-1}$ at 500 °C

If the initial concentration of cyclopropane is 0.050 mol/L, how much time (in hours) must elapse for its concentration to drop to 0.010 mol/L?

What Do You Know? The reaction is first-order in cyclopropane. You know the rate constant, k, and the initial and final concentrations of this reactant, $[R]_0$ and $[R]_t$.

Strategy Use Equation 14.1 to calculate the time (t) elapsed to reach a concentration of 0.010 mol/L.

SOLUTION Values for $[\text{cyclopropane}]_t$, $[\text{cyclopropane}]_0$, and k are substituted into Equation 14.1; t (time) is the unknown:

$$\ln\frac{[0.010]}{[0.050]} = -(2.42\ h^{-1})t$$

$$t = \frac{-\ln(0.20)}{2.42\ h^{-1}} = \frac{-(-1.609)}{2.42\ h^{-1}} = 0.665\ h$$

Think about Your Answer A cycloalkane, a carbon ring containing only CH_2 groups, that has only three or four carbons is strained because the C—C—C bond angles cannot match the preferred 109.5°. Thus, the cyclopropane ring opens readily at moderate temperatures.

Check Your Understanding

Sucrose, a sugar, decomposes in acid solution to give glucose and fructose. The reaction is first-order in sucrose, and the rate constant at 25 °C is $k = 0.21\ h^{-1}$. If the initial concentration of sucrose is 0.010 mol/L, what is its concentration after 5.0 h?

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

EXAMPLE 14.6

Using the First-Order Rate Equation

Problem Hydrogen peroxide decomposes in a dilute sodium hydroxide solution at 20 °C in a first-order reaction:

$$H_2O_2(aq) \longrightarrow H_2O(\ell) + \tfrac{1}{2}\, O_2(g)$$

$$\text{Rate} = k[H_2O_2] \text{ with } k = 1.06 \times 10^{-3}\ \text{min}^{-1}$$

What is the fraction remaining after 100. min? What is the concentration of H_2O_2 after 100. minutes if the initial concentration of H_2O_2 is 0.020 mol/L?

What Do You Know? This is a first-order reaction. The rate constant k, initial concentration of H_2O_2, and elapsed time are given.

Strategy Because the reaction is first-order in H_2O_2, use Equation 14.1. Here, $[H_2O_2]_0$, k, and t are known, and you are asked to find the value of the fraction remaining, $[H_2O_2]_t/[H_2O_2]_0$. Once this value is known, and knowing $[H_2O_2]_0$, you can calculate $[H_2O_2]_t$.

SOLUTION Substitute the rate constant and time into Equation 14.1.

$$\ln \frac{[H_2O_2]_t}{[H_2O_2]_0} = -kt = -(1.06 \times 10^{-3}\ \text{min}^{-1})(100.\ \text{min})$$

$$\ln \frac{[H_2O_2]_t}{[H_2O_2]_0} = -0.1060$$

Taking the antilogarithm of -0.1060 [that is, the inverse of the natural logarithm of -0.1060 or $e^{-0.1060}$], we find the fraction remaining to be 0.90.

$$\text{Fraction remaining} = \frac{[H_2O_2]_t}{[H_2O_2]_0} = 0.899 = 0.90$$

The calculated fraction remaining is 0.90, thus the concentration of H_2O_2 remaining is 90% of the initial concentration.

$$[H_2O_2]_t = 0.899\,[H_2O_2]_0 = 0.899\,(0.020\ \text{mol/L}) = 0.018\ \text{mol/L}$$

Think about Your Answer Although H_2O_2 is unstable, its rate of decomposition is very slow, particularly in a dilute solution. However, sodium hydroxide catalyzes the decomposition. The rate of the reaction can be studied by measuring the volume of O_2 gas evolved as a function of time.

Check Your Understanding

Gaseous azomethane ($CH_3N_2CH_3$) decomposes to ethane and nitrogen when heated:

$$CH_3N_2CH_3(g) \longrightarrow CH_3CH_3(g) + N_2(g)$$

The decomposition of azomethane is a first-order reaction with $k = 3.6 \times 10^{-4}\ \text{s}^{-1}$ at 600 K.

(a) A sample of gaseous $CH_3N_2CH_3$ is placed in a flask and heated at 600 K for 150 seconds. What fraction of the initial sample remains after this time?

(b) How long must a sample be heated so that 99% of the sample has decomposed?

Second-Order Reactions

Suppose the reaction "R → products" is second-order. The rate equation is

$$-\frac{\Delta[R]}{\Delta t} = k[R]^2$$

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Using calculus, this relationship can be transformed into the following equation that relates reactant concentration and time:

$$\frac{1}{[R]_t} - \frac{1}{[R]_0} = kt \qquad (14.2)$$

The same symbolism used with first-order reactions applies: $[R]_0$ is the concentration of reactant at time $t = 0$; $[R]_t$ is the concentration at a later time; and k is the second-order rate constant, which has the units of L/mol · time.

EXAMPLE 14.7

Using the Second-Order Integrated Rate Equation

Problem The gas-phase decomposition of HI

$$HI(g) \rightarrow {}^1/_2\ H_2(g) + {}^1/_2\ I_2(g)$$

has the rate equation

$$-\frac{\Delta[HI]}{\Delta t} = k[HI]^2$$

where $k = 30.$ L/mol · min at 443 °C. How much time does it take for the concentration of HI to drop from 0.010 mol/L to 0.0050 mol/L at 443 °C?

What Do You Know? Equation 14.2 is used for a second-order reaction. The rate constant, k, and the initial and final concentrations of HI are given; the elapsed time is the unknown.

Strategy Substitute the values of $[HI]_0$, $[HI]_t$, and k into Equation 14.2, and solve for the unknown, t.

SOLUTION Here, $[HI]_0 = 0.010$ mol/L and $[HI]_t = 0.0050$ mol/L. Using Equation 14.2, we have

$$\frac{1}{0.0050\ \text{mol/L}} - \frac{1}{0.010\ \text{mol/L}} = (30.\ \text{L/mol} \cdot \text{min})t$$

$$(2.00 \times 10^2\ \text{L/mol}) - (1.00 \times 10^2\ \text{L/mol}) = (30.\ \text{L/mol} \cdot \text{min})t$$

$$t = 3.3\ \text{minutes}$$

Think about Your Answer In the solution of this problem, we kept track of the units for each quantity. This leads to an answer for time elapsed with the unit minutes.

Check Your Understanding

Using the rate constant for HI decomposition given in this example, calculate the concentration of HI after 12 minutes if $[HI]_0 = 0.010$ mol/L.

Zero-Order Reactions

If a reaction (R → products) is zero-order, the rate equation is

$$-\frac{\Delta[R]}{\Delta t} = k[R]^0$$

This equation leads to the integrated rate equation

$$[R]_t - [R]_0 = -kt \qquad (14.3)$$

where the units of k are mol/L · s.

Graphical Methods for Determining Reaction Order and the Rate Constant

Finding the Slope of a Line
See *Let's Review: Tools of Quantitative Chemistry (pages 45–46)*, for a description of methods for finding the slope of a line.

Chemists find it is convenient to determine the order of a reaction and its rate constant using graphical methods. If rearranged slightly, Equations 14.1, 14.2, and 14.3 have the form $y = mx + b$. This is the equation for a straight line, where m is the slope of the line and b is the y-intercept. In each of these equations, $x = t$.

Zero-order	First-order	Second-order
$[R]_t = -kt + [R]_0$	$\ln [R]_t = -kt + \ln [R]_0$	$\frac{1}{[R]_t} = +kt + \frac{1}{[R]_0}$
$y \quad mx \quad b$	$y \quad mx \quad b$	$y \quad mx \quad b$

As an example of the graphical method for determining reaction order, consider the decomposition of azomethane.

$$CH_3N_2CH_3(g) \longrightarrow CH_3CH_3(g) + N_2(g)$$

The decomposition of azomethane was followed at 600 K by observing the decrease in its partial pressure ($P(CH_3N_2CH_3)$) with time. (Recall from Chapter 10 that pressure is proportional to concentration at a given temperature and volume.) As shown in Figure 14.7a, a graph of $\ln P(CH_3N_2CH_3)$ versus time produces a straight line, which shows that the reaction is first-order in $CH_3N_2CH_3$. The slope of the line can be determined, and the negative of the slope equals the rate constant for the reaction, $3.6 \times 10^{-4}\ s^{-1}$.

The decomposition of NO_2 is a second-order process.

$$NO_2(g) \longrightarrow NO(g) + \tfrac{1}{2}\, O_2(g)$$

$$\text{Rate} = k[NO_2]^2$$

This fact can be verified by showing that a plot of $1/[NO_2]$ versus time is a straight line (Figure 14.7b). Here, the slope of the line is equal to k.

For a zero-order reaction (Figure 14.7c), a plot of concentration versus time gives a straight line with a slope equal to the negative of the rate constant.

Table 14.1 summarizes the relationships between concentration and time for first-, second-, and zero-order processes.

Half-Life and First-Order Reactions

The **half-life**, $t_{1/2}$, of a reaction is the time required for the concentration of a reactant ($[R]_t$) to decrease to one half its initial value ($[R]_0$). It is a convenient way to describe the rate at which a reactant is consumed in a chemical reaction: *The longer the half-life, the slower the reaction.*

$$[R]_t = \tfrac{1}{2}[R]_0 \quad \text{or} \quad \frac{[R]_t}{[R]_0} = \tfrac{1}{2}$$

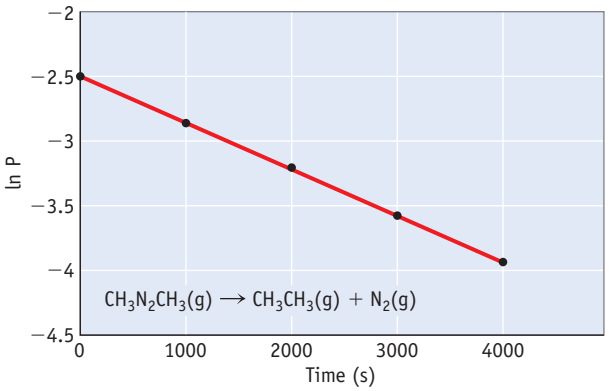

TABLE 14.1 Characteristic Properties of Reactions of the Type "R ⟶ Products"

Order	Rate Equation	Integrated Rate Equation	Straight-Line Plot	Slope	*k* Units
0	$-\Delta[R]/\Delta t = k[R]^0$	$[R]_t - [R]_0 = -kt$	$[R]_t$ vs. t	$-k$	mol/L · time
1	$-\Delta[R]/\Delta t = k[R]^1$	$\ln([R]_t/[R]_0) = -kt$	$\ln [R]_t$ vs. t	$-k$	1/time
2	$-\Delta[R]/\Delta t = k[R]^2$	$(1/[R]_t) - (1/[R]_0) = kt$	$1/[R]_t$ vs. t	k	L/mol · time

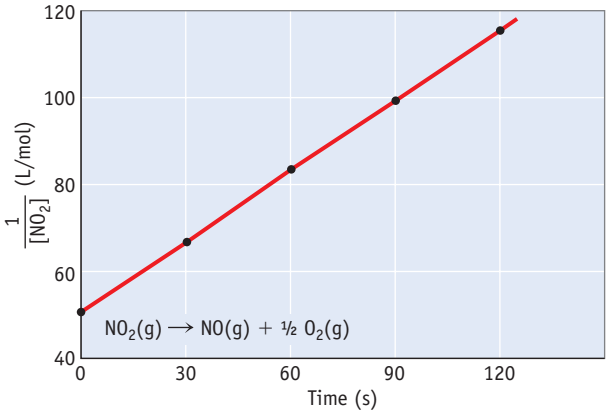
Time (s)	$P \times 10^2$ atm	ln P
0	8.20	−2.50
1000	5.72	−2.86
2000	3.99	−3.22
3000	2.78	−3.58
4000	1.94	−3.94

Rate = $k[CH_3N_2CH_3]$



Slope = $-k$

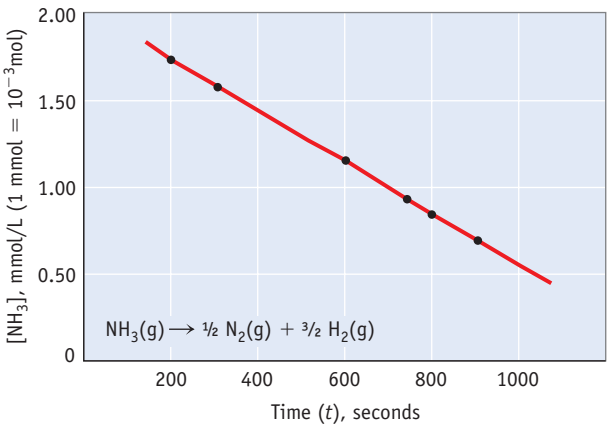
$= \dfrac{[(-3.76) - (-3.04)]}{(3500 - 1500)\ s}$

$k = 3.6 \times 10^{-4}\ s^{-1}$

(a) First-order reaction. A plot of the natural logarithm of the $CH_3N_2CH_3$ pressure versus time for the decomposition of azomethane results in a straight line with a negative slope. The rate constant $k = -$slope.

Time (s)	$[NO_2]$ (mol/L)	$1/[NO_2]$ (L/mol)
0	0.020	50
30	0.015	67
60	0.012	83
90	0.010	100
120	0.0087	115

Rate = $k[NO_2]^2$



Slope = k

$= \dfrac{(105 - 61)\ mol/L}{(100 - 20)\ s}$

$k = 0.55\ L/mol \cdot s$

(b) Second-order reaction. A plot of $1/[NO_2]$ versus time for the decomposition of NO_2 results in a straight line. The rate constant k = slope.

Time (s)	$[NO_3]$ (mmol/L)
200	1.75
280	1.65
600	1.15
750	0.94
800	0.85
900	0.70

Rate = $k[NH_3]^0$

Slope = $-k$

$= \dfrac{(0.540 - 1.29)\ mmol/L}{(1000 - 500)\ s}$

$= -1.5 \times 10^{-3}\ mmol/L \cdot s$

$k = 1.5 \times 10^{-3}\ mmol/L \cdot s$

(c) Zero-order reaction. A plot of the concentration of ammonia, $[NH_3]_t$, against time for the decomposition of NH_3 on a metal surface at 856 °C is a straight line, indicating that this is a zero-order reaction. The rate constant $k = -$slope.

Figure 14.7 Graphical methods for determining reaction order.

Half-life is used primarily when dealing with first-order processes. To evaluate $t_{1/2}$ for a first-order reaction, we substitute $[R]_t/[R]_0 = {}^1/_2$ and $t = t_{1/2}$ into the integrated first-order rate equation (Equation 14.1),

$$\ln(\tfrac{1}{2}) = -kt_{1/2} \quad \text{or} \quad \ln 2 = kt_{1/2}$$

Half-Life and Radioactivity *Half-life* is a term often encountered when dealing with radioactive elements. Radioactive decay is a first-order process, and half-life is commonly used to describe how rapidly a radioactive element decays. See Chapter 25 and Example 14.9.

Rearranging this equation (and substituting ln 2 = 0.693) provides a useful equation that relates half-life and the first-order rate constant:

$$t_{1/2} = \frac{0.693}{k} \qquad (14.4)$$

This equation identifies an important feature of first-order reactions: $t_{1/2}$ *is independent of concentration.*

To illustrate the concept of half-life, consider again the first-order decomposition of azomethane, $CH_3N_2CH_3$.

$$CH_3N_2CH_3(g) \rightarrow CH_3CH_3(g) + N_2(g)$$

$$\text{Rate} = k[CH_3N_2CH_3] \text{ with } k = 3.6 \times 10^{-4}\ s^{-1} \text{ at } 600\ K$$

Given a rate constant of $3.6 \times 10^{-4}\ s^{-1}$, we calculate a half-life of 1.9×10^3 s or 32 minutes.

$$t_{1/2} = \frac{0.693}{3.6 \times 10^{-4}\ s^{-1}} = 1.9 \times 10^3 \text{ s (or 32 min)}$$

Half-Life Equations for Other Reaction Orders For a zero-order reaction, R → products

$$t_{1/2} = \frac{[R]_0}{2k}$$

For a second-order reaction, R → products

$$t_{1/2} = \frac{1}{k[R]_0}$$

Note that in both cases the half-life depends on the initial concentration.

The partial pressure of azomethane has been plotted as a function of time in Figure 14.8, and this graph shows that *P*(azomethane) decreases by half every 32 minutes. The initial pressure of azomethane was 820 mm Hg, but it dropped to 410 mm Hg in 32 minutes, and then dropped to 205 mm Hg in another 32 minutes. That is, after two half-lives (64 minutes), the partial pressure is $(1/2) \times (1/2) = (1/2)^2 = 1/4$ or 25% of the initial pressure. After three half-lives, the partial pressure has dropped further to 102 mm Hg or 12.5% of the initial value and is equal to $(1/2) \times (1/2) \times (1/2) = (1/2)^3 = 1/8$ of the initial value.

It can be hard to visualize whether a reaction is fast or slow from the rate constant value. Can you tell from the rate constant, $k = 3.6 \times 10^{-4}\ s^{-1}$, whether the azomethane decomposition will take seconds, hours, or days to reach completion? Probably not, but you can get a better sense of reaction rate from the value of the half-life for the reaction (32 minutes). Now you know that you would only have to wait a few hours for the reactant to be essentially consumed.

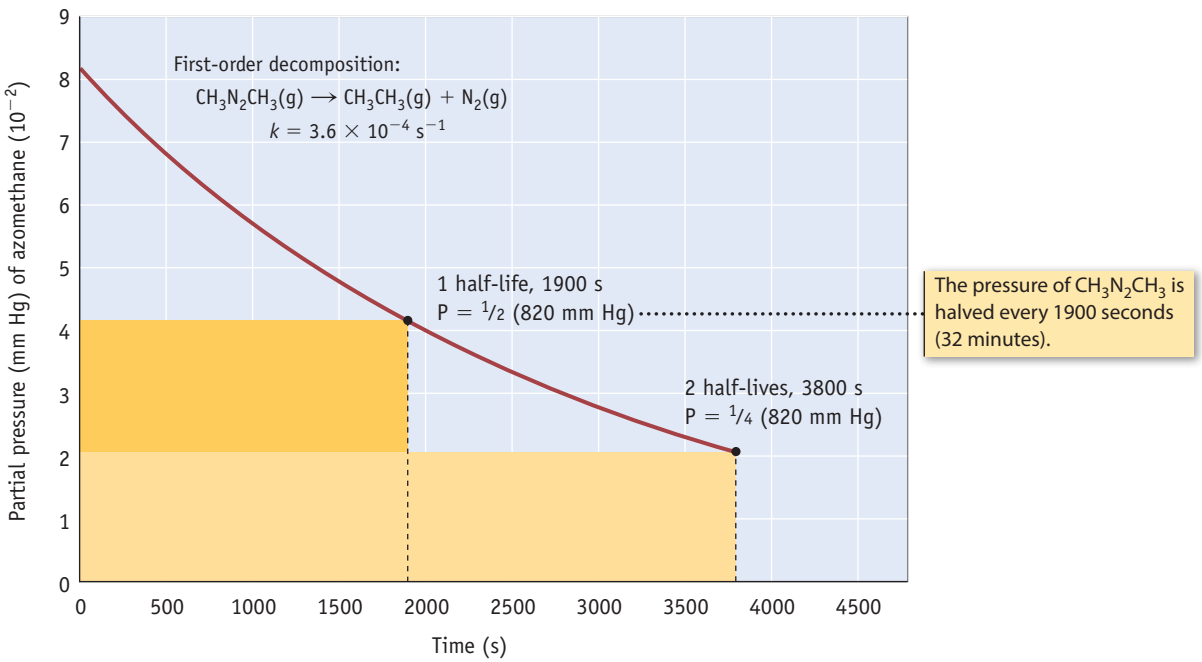

Figure 14.8 Half-life of a first-order reaction. This plot of pressure versus time is similar in shape to plots of concentration versus time for all other first-order reactions.

EXAMPLE 14.8

Half-Life and a First-Order Process

Problem Sucrose, $C_{12}H_{22}O_{11}$, decomposes to fructose and glucose in acid solution with the rate law

$$\text{Rate} = k[C_{12}H_{22}O_{11}] \qquad k = 0.216\ h^{-1} \text{ at } 25\ °C$$

(a) What is the half-life of sucrose at this temperature?

(b) What amount of time is required for 87.5% of the initial concentration of sucrose to decompose?

What Do You Know? The decomposition of sucrose is a first-order reaction. The rate constant for the reaction (at 25 °C) is given.

Strategy (a) Use Equation 14.4 to calculate the half-life from the rate constant. (b) After 87.5% of the $C_{12}H_{22}O_{11}$ has decomposed, 12.5% (or one eighth of the sample) remains. To reach this point, three half-lives are required.

Half-Life	Fraction Remaining
1	0.5
2	0.25
3	0.125

Therefore, we multiply the half-life calculated in part (a) by 3.

SOLUTION

(a) The half-life for the reaction is

$$t_{1/2} = 0.693/k = 0.693/(0.216\ h^{-1}) = 3.208 \text{ hours} = 3.21 \text{ hours}$$

(b) Three half-lives must elapse before the fraction remaining is 0.125, so

$$\text{Time elapsed} = 3 \times 3.208\ h = 9.63 \text{ hours}$$

Think about Your Answer Half-life is a convenient way to describe the speed of a first-order reaction. In this example, you can quickly see that complete decomposition of a sample of sucrose requires many hours.

Check Your Understanding

The catalyzed decomposition of hydrogen peroxide is first-order in $[H_2O_2]$. It was found that the concentration of H_2O_2 decreased from 0.24 M to 0.060 M over a period of 282 minutes. What is the half-life of H_2O_2? What is the rate constant for this reaction? What is the initial rate of decomposition at the beginning of this experiment (when $[H_2O_2] = 0.24$ M)?

EXAMPLE 14.9

Half-Life and Radioactive Decay

Problem Radioactive decay is a first-order process. Radioactive radon-222 gas (^{222}Rn) occurs naturally as a product of the uranium decay series. The half-life of ^{222}Rn is 3.8 days. Suppose a flask originally contained 4.0×10^{13} atoms of ^{222}Rn. How many atoms of ^{222}Rn will remain after one month (30. days)?

What Do You Know? This process follows first-order kinetics. The half-life of ^{222}Rn and the number of atoms initially present are known.

Strategy Map 14.9

PROBLEM

Find the **final number of atoms** of a radioactive isotope after a **given time period.**

DATA/INFORMATION

- Half-life for decay
- Initial number of atoms
- Time elapsed

STEP 1. Use Equation 14.4 to calculate ***k*** from $t_{1/2}$.

Value of *k*

STEP 2. Use Equation 14.1 where ***k***, $[R]_0$, and ***t*** are known to calculate $[R]_t$.

Value of $[R]_t$, the ***final number of atoms*** of radioactive isotope after time ***t***.

Strategy First, the rate constant, *k*, must be found from the half-life using Equation 14.4. Then, using Equation 14.1, and knowing the number of atoms at the beginning ($[R]_0$), the elapsed time (30. days), and the rate constant, we can calculate the number of atoms remaining ($[R]_t$).

SOLUTION The rate constant, *k*, is

$$k = \frac{0.693}{t_{1/2}} = \frac{0.693}{3.8\ \text{d}} = 0.182\ \text{d}^{-1}$$

Now use Equation 14.1 to calculate the number of atoms remaining after 30. days.

$$\ln \frac{[\text{Rn}]_t}{4.0 \times 10^{13}\ \text{atoms}} = -(0.182\ \text{d}^{-1})(30.\ \text{d}) = -5.47$$

$$\frac{[\text{Rn}]_t}{4.0 \times 10^{13}\ \text{atoms}} = e^{-5.47} = 0.0042$$

$$[\text{Rn}]_t = 2 \times 10^{11}\ \text{atoms}$$

Think about Your Answer Thirty days is approximately 8 half-lives for this element. This means that the number of atoms present at the end of the month is approximately $(\frac{1}{2})^8$ or $\frac{1}{256}$th of the original number.

Check Your Understanding

Americium is used in smoke detectors and in medicine for the treatment of certain malignancies. One isotope of americium, ^{241}Am, has a rate constant, *k*, for radioactive decay of 0.0016 y^{-1}. In contrast, radioactive iodine-125, which is used for studies of thyroid functioning, has a rate constant for decay of 0.011 d^{-1}.

(a) What are the half-lives of these isotopes?

(b) Which isotope decays faster?

(c) If you are given a dose of iodine-125 containing 1.6×10^{15} atoms, how many atoms remain after 2.0 days?

14.5 A Microscopic View of Reaction Rates

Goals for Section 14.5

- Describe the collision theory of reaction rates and use collision theory to describe the effects of reactant concentration, molecular orientation, and temperature on reaction rate.
- Relate activation energy (E_a) to the rate of a reaction.
- Understand reaction coordinate diagrams.
- Use the Arrhenius equation, or one of its modified forms, to calculate the activation energy from rate constants at different temperatures.

Chemists often turn to the particulate level of chemistry to explain chemical phenomena. Looking at the way reactions occur at the atomic and molecular levels can give some insight into the various influences on rates of reactions.

Let us review the macroscopic observations we have made so far concerning reaction rates. There are wide differences in rates of reactions—from very fast reactions like the explosion that occurs when hydrogen and oxygen are exposed to a spark or flame (Figure 1.16), to slow reactions like the formation of rust that occurs over days, weeks, or years. For a specific reaction, factors that influence reaction rate include the concentrations of the reactants, the temperature of the reaction system,

A CLOSER LOOK

Rate Laws, Rate Constants, and Reaction Stoichiometry

Qualitatively, the rate of a reaction is easy to understand: it represents the change in concentration of the reactants and products over time. When we deal with reaction rates quantitatively, however, we need to be specific about the reaction stoichiometry.

Consider the first-order decomposition of N_2O_5, a reaction we mentioned earlier.

$$N_2O_5(g) \rightarrow 2\ NO_2(g) + \tfrac{1}{2}\ O_2(g)$$

The rate of the reaction can be expressed (and measured in the lab) as

$$\text{Rate} = -\left(\frac{\Delta[N_2O_5]}{\Delta t}\right) = +\frac{1}{2}\left(\frac{\Delta[NO_2]}{\Delta t}\right) = +2\left(\frac{\Delta[O_2]}{\Delta t}\right)$$

If we were to follow the disappearance of N_2O_5 as a measure of reaction rate and base our definition of rate on the stoichiometry above, we should write the following differential form of the rate law.

$$\text{Rate} = -\left(\frac{\Delta[N_2O_5]}{\Delta t}\right) = k[N_2O_5]$$

From this definition, it also follows that the integrated rate equation is

$$\ln\frac{[N_2O_5]_t}{[N_2O_5]_0} = -kt$$

and the half-life equation is

$$t_{1/2} = 0.693/k$$

We can also, however, write the equation for the decomposition of N_2O_5 as follows:

$$2\ N_2O_5(g) \rightarrow 4\ NO_2(g) + O_2(g)$$

Following the reasoning above, the reaction rate would be written as follows:

$$\text{Rate} = -\frac{1}{2}\left(\frac{\Delta[N_2O_5]}{\Delta t}\right) = +\frac{1}{4}\left(\frac{\Delta[NO_2]}{\Delta t}\right) = +\left(\frac{\Delta[O_2]}{\Delta t}\right)$$

This leads to the following differential rate law:

$$\text{Rate} = -\frac{1}{2}\left(\frac{\Delta[N_2O_5]}{\Delta t}\right) = k'[N_2O_5]$$

Rearranging this to solve for the rate of disappearance of N_2O_5 yields the following equation:

$$-\left(\frac{\Delta[N_2O_5]}{\Delta t}\right) = 2k'[N_2O_5]$$

with the following integrated rate equation and half-life equation.

Integrated rate equation:

$$\ln\frac{[N_2O_5]_t}{[N_2O_5]_0} = -2k't$$

Half-life equation:

$$t_{1/2} = 0.693/2k'$$

Note that the differential and integrated rate laws derived based on the two different chemical equations have the same form, but k and k' do not have the same values; instead $k = 2k'$. Notice, however, that both calculations give the same value for the half-life, as they should; half-life does not depend on how the equation is written.

For more on these issues, see K. T. Quisenberry and J. Tellinghuisen, *Journal of Chemical Education*, Vol. 83, pp. 510–512, 2006.

and the presence of catalysts. Each of these influences can be explained using the **collision theory of reaction rates**, which states that three conditions must be met for a reaction to occur:

1. The reacting molecules must collide with one another.
2. The reacting molecules must collide with sufficient energy to initiate the process of breaking and forming bonds.
3. The molecules must collide in an orientation that can lead to rearrangement of the atoms and the formation of products.

Collision Theory: Concentration and Reaction Rate

Consider the gas-phase reaction of nitric oxide and ozone, an environmentally important reaction that contributes to both natural and human-caused ozone decomposition:

$$NO(g) + O_3(g) \rightarrow NO_2(g) + O_2(g)$$

The rate law for this product-favored reaction is first-order in each reactant: Rate = $k[NO][O_3]$. How can this reaction have this rate law?

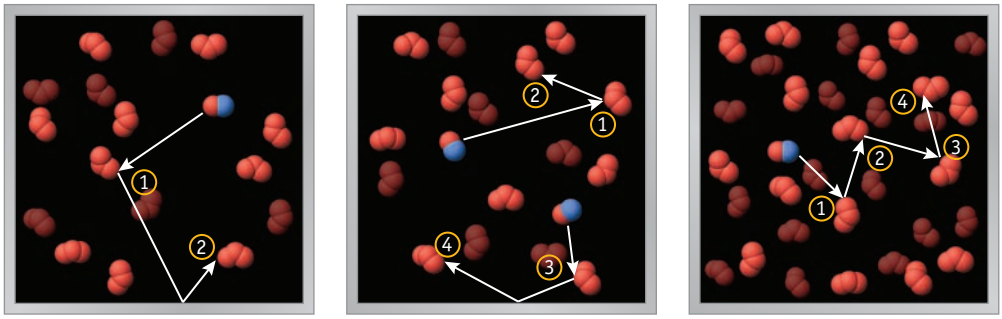

Figure 14.9 The effect of concentration on the frequency of molecular collisions.

(a) 1 NO : 16 O_3 — *2 hits/second.*
A single NO molecule, moving among 16 O_3 molecules, is shown colliding with two of them per second.

(b) 2 NO : 16 O_3 — *4 hits/second.*
If two NO molecules move among 16 O_3 molecules, we would predict that four NO—O_3 collisions would occur per second.

(c) 1 NO : 32 O_3 — *4 hits/second.*
If the number of O_3 molecules is doubled (to 32), the frequency of NO—O_3 collisions is also doubled, to four per second.

Imagine a flask containing a mixture of NO and O_3 molecules in the gas phase. Both kinds of molecules are in rapid and random motion within the flask. They strike the walls of the vessel, but they also collide with other molecules. It is reasonable to propose that the rate of their reaction should be related to the number of collisions, which is in turn related to their concentrations (Figure 14.9). Doubling the concentration of one reactant in the NO + O_3 reaction, say NO, will lead to twice the number of molecular collisions. Figure 14.9a shows a single molecule of one of the reactants (NO) moving randomly among sixteen O_3 molecules. In a given time period, it might collide with two O_3 molecules. The number of NO—O_3 collisions will double, however, if the concentration of NO molecules is doubled (to 2, as shown in Figure 14.9b) or if the number of O_3 molecules is doubled (to 32, as in Figure 14.9c). Thus, the dependence of reaction rate on concentration can be explained: The number of collisions between the two reactant molecules is directly proportional to the concentration of each reactant, and the rate of the reaction shows a first-order dependence on each reactant.

Phil Walter/Getty Images Sport/Getty Images

Figure 14.10 **An analogy to chemical activation energy.** For the volleyball to go over the net, the player must give it sufficient energy.

Collision Theory: Activation Energy

Molecules require some minimum energy to react. Chemists visualize this as an energy barrier that must be surmounted by the reactants for a reaction to occur (Figure 14.10). The energy required to cross the barrier is called the **activation energy**, E_a. If the activation energy is low, a high proportion of the molecules in a sample may have sufficient energy to react. The reaction will be fast. If the activation energy is high, only a few reactant molecules in a sample may have enough energy. The reaction will be slow.

To further illustrate an activation energy barrier, consider the high temperature conversion of NO_2 and CO to NO and CO_2. At the molecular level, we imagine that the reaction involves the transfer of an O atom from an NO_2 molecule to a CO molecule.

$$NO_2(g) + CO(g) \rightleftharpoons NO(g) + CO_2(g)$$

We can describe this process by using an energy diagram called a **reaction coordinate** diagram (Figure 14.11). The horizontal axis describes the reaction progress as the reaction proceeds, and the vertical axis represents the potential energy of the system during the reaction. When NO_2 and CO approach and O atom transfer begins, an N—O bond is being broken, and a C═O bond is forming. Energy input (the activation energy) is required for this to occur. The energy of the system reaches a maximum at the **transition state**. At the transition state, sufficient energy has been concentrated in the appropriate bonds; bonds in the reactants can now break, and

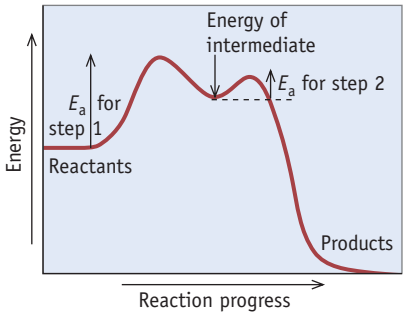
A CLOSER LOOK

More About Molecular Orientation and Reaction Coordinate Diagrams

The Arrhenius equation tells us, among other things, that the rate constant depends on the proper alignment of reactants. A reaction will occur only if the reactants are in the proper orientation. A well-studied example of this is the substitution of a chlorine atom of CH_3Cl by an ion such as F^-. Here, the F^- ion attacks the molecule from the side opposite the Cl substituent. As F^- begins to form a bond to carbon, the C—Cl bond weakens, and the CH_3 portion of the molecule changes shape. As time progresses, the products CH_3F and Cl^- are formed.

But what happens if F^- approaches from the side of the molecule with the Cl atom or along one of the C—H bonds? There will be no reaction, no matter how much energy the reactants have! The misalignment of reactants is one reason that reactions can be slow, particularly when the reactants have complex structures.



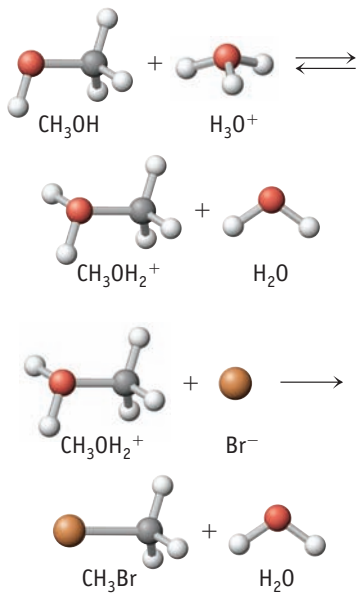


Figure A **A reaction coordinate diagram for a two-step reaction, a process involving an intermediate.**

Assuming the reactants are aligned properly, the CH_3Cl/F^- reaction would follow a reaction coordinate diagram such as that in Figure 14.11.

Another substitution reaction that has been thoroughly studied is the reaction of methanol, CH_3OH, with Br^- ion in the presence of an acid. This is a two-step reaction, which is described by the reaction coordinate diagram in Figure A.

In the first step, an H^+ ion attaches to the O of the C—O—H group in a rapid, reversible reaction. The energy of this protonated species, $CH_3OH_2^+$, a reaction intermediate, is higher than the energies of the reactants. The reaction intermediate is represented by the dip in the curve shown in Figure A. In the second step, a halide ion, say Br^-, attacks the intermediate to produce methyl bromide, CH_3Br, and water. There is an activation energy barrier in both the first step and second step.

Notice in Figure A, as in Figure 14.11, that the energy of the products is lower than the energy of the reactants. The reaction is exothermic.

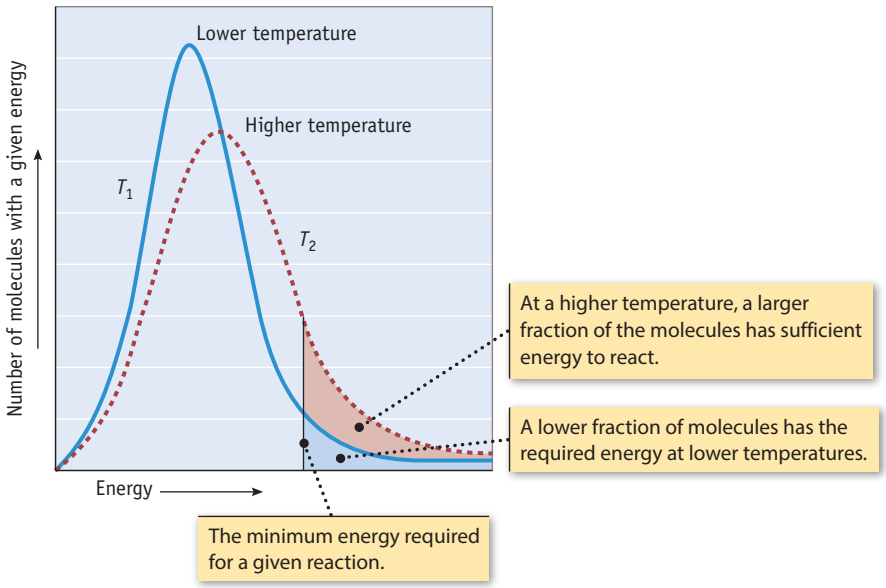

Figure 14.12 Energy distribution curve. Note that this resembles Figure 10.13, the Boltzmann distribution function, for a collection of gas molecules.

new bonds can form to give products. The system is poised to go on to products, but it could also return to the reactants. Because the transition state is at a maximum in potential energy, a molecular species with this structure cannot be isolated. Using computer molecular modeling techniques, however, chemists can describe what the transition state must look like.

In the $NO_2 + CO$ reaction, 132 kJ/mol is required to reach the transition state, that is, the top of the energy barrier. As the reaction continues toward the products—as the N—O bond breaks and a C═O bond forms—the reaction evolves energy, 358 kJ/mol. The net energy change involved in this *exo*thermic reaction is −226 kJ/mol.

$$\Delta H = +132 \text{ kJ/mol} + (-358 \text{ kJ/mol}) = -226 \text{ kJ/mol}$$

What happens if the reverse reaction is carried out? That reaction requires 358 kJ/mol to reach the transition state, and 132 kJ/mol is evolved on proceeding to the products, NO_2 and CO. The reaction in this direction is *endo*thermic, requiring a net input of +226 kJ/mol.

Collision Theory: Activation Energy and Temperature

In a laboratory or in the chemical industry, a chemical reaction is often carried out at elevated temperatures because this allows the reaction to occur more rapidly. Conversely, it is sometimes desirable to lower the temperature to slow down a chemical reaction (to avoid an uncontrollable reaction or a potentially dangerous explosion).

A discussion of the effect of temperature on reaction rate begins by recalling there is a distribution of energies for molecules in a sample of a gas or liquid. The molecules in a sample have a wide range of energies, described earlier as a Boltzmann distribution of energies (Figure 10.11). In any sample of a gas or liquid, some molecules have very low energies, others have very high energies, but most have some intermediate energy. As the temperature increases, the average energy of the molecules in the sample increases, as does the fraction having higher energies. For example, in the reaction discussed above the conversion of NO_2 and CO to products at room temperature is slow because only a small fraction of the molecules have enough energy to reach the transition state. The rate can be increased by heating the sample. Raising the temperature increases the reaction rate by increasing the fraction of molecules with enough energy to surmount the activation energy barrier (Figure 14.12).

Collision Theory: Effect of Molecular Orientation on Reaction Rate

Not only must reacting molecules have sufficient energy to react, but the reactant molecules must also come together in the correct orientation. For the reaction of NO_2 and CO, we can imagine that the transition state structure has one of the O atoms of NO_2 beginning to bind to the C atom of CO in preparation for O atom transfer (Figure 14.11). The lower the probability of achieving the proper alignment, the smaller the value of k, and the slower the reaction.

Imagine what happens when two or more complicated molecules collide. In only a small fraction of the collisions will the molecules come together in exactly the right orientation. Thus, only a tiny fraction of the collisions can be effective. No wonder some reactions are slow. Conversely, it is amazing that so many are fast!

The Arrhenius Equation

The observation that reaction rates depend on the energy and frequency of collisions between reacting molecules, on the temperature, and on whether the collisions have the correct geometry is summarized by the **Arrhenius equation**:

$$k = Ae^{-E_a/RT} \qquad (14.5)$$

Frequency factor; Fraction of molecules with minimum energy for reaction

Interpreting the Arrhenius Equation

(a) The exponential term gives the fraction of molecules having sufficient energy for reaction and is a function of T.

(b) Although a complete understanding of the frequency factor goes beyond the level of this text, note that A becomes smaller as the reactants become larger. This reflects the fact that larger molecules have a smaller probability of coming together in the appropriate geometry.

In this equation, k is the rate constant, R is the gas constant with a value of 8.31446×10^{-3} kJ/K · mol, and T is the kelvin temperature. The parameter A is called the **frequency factor**. It is related to the number of collisions and to the fraction of collisions that have the correct geometry; A is specific to each reaction and is temperature dependent. The factor $e^{-E_a/RT}$, which always has a value less than 1, represents *the fraction of molecules having the minimum energy required for reaction*. As the following table shows, this fraction changes significantly with temperature.

Temperature (K)	Value of $e^{-E_a/RT}$ for E_a = 40 kJ/mol-rxn
298	9.7×10^{-8}
400	6.0×10^{-6}
600	3.3×10^{-4}

The Arrhenius equation is significant because

- it can be used to calculate E_a from the temperature dependence of the rate constant.
- it can be used to calculate the rate constant, if E_a, T, and A are known.

E_a, Reaction Rates, and Temperature

An often-used rule of thumb is that reaction rates double for every 10 °C rise in temperature in the vicinity of room temperature.

If rate constants for a given reaction are measured at several temperatures then you can use graphical techniques to determine the activation energy of a reaction. Taking the natural logarithm of each side of Equation 14.5, we have

$$\ln k = \ln A + \left(-\frac{E_a}{RT}\right)$$

Rearranging this expression slightly shows that $\ln k$ and $1/T$ are related linearly.

$$\ln k = -\frac{E_a}{R}\left(\frac{1}{T}\right) + \ln A \qquad (14.6)$$

← Arrhenius equation

$$y = mx + b$$

← Equation for straight line

Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

This means that, if the natural logarithm of k ($\ln k$) is plotted versus $1/T$, the result is a downward-sloping straight line with a slope of $(-E_a/R)$. The activation energy, E_a, can be obtained from the slope of this line ($E_a = -R \times$ slope).

EXAMPLE 14.10

Determination of E_a Using the Arrhenius Equation

Problem Using the experimental data shown in the table, calculate the activation energy E_a for the reaction

$$2\ N_2O(g) \rightarrow 2\ N_2(g) + O_2(g)$$

Experiment	Temperature (K)	k (L/mol · s)
1	1125	11.59
2	1053	1.67
3	1001	0.380
4	838	0.0011

What Do You Know? Rate constants are given at several temperatures.

Strategy To solve this problem graphically, you first need to calculate $\ln k$ and $1/T$ for each data point. These data are then plotted, and E_a is calculated from the resulting straight line (slope $= -E_a/R$).

SOLUTION First, calculate $1/T$ and $\ln k$.

Experiment	$1/T$ (K^{-1})	$\ln k$
1	8.889×10^{-4}	2.4501
2	9.497×10^{-4}	0.513
3	9.990×10^{-4}	−0.968
4	11.9×10^{-4}	−6.81

Plotting these data gives the graph shown in Figure 14.13. A linear least squares fit of the line by Microsoft Excel gives the slope as -3.03×10^4 K. The activation energy is evaluated from this slope.

$$\text{Slope} = -\frac{E_a}{R} = -\frac{E_a}{8.31 \times 10^{-3}\ \text{kJ/K} \cdot \text{mol}} = -3.03 \times 10^4\ \text{K}$$

$$E_a = 250\ \text{kJ/mol}$$

Think about Your Answer Notice the units of the answer. Using the value for $R = 8.31 \times 10^{-3}$ kJ/K · mol will give an answer with the units kJ/mol.

Check Your Understanding

Rate constants were determined for the decomposition of acetaldehyde (CH_3CHO) in the temperature range 700 to 1000 K. Use these data to determine E_a for the reaction using a graphical method.

T (K)	700	760	840	1000
k (L/mol · s)	0.011	0.105	2.17	145

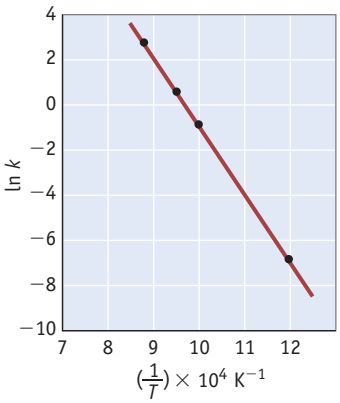

Figure 14.13 Arrhenius plot. A plot of $\ln k$ versus $1/T$ for the reaction $2\ N_2O(g) \rightarrow 2\ N_2(g) + O_2(g)$. The slope of the line can be used to calculate E_a. See Example 14.10.

Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

The activation energy, E_a, for a reaction can be obtained algebraically if k is known at two different temperatures. You can write an equation for each set of these conditions:

$$\ln k_1 = -\left(\frac{E_a}{RT_1}\right) + \ln A \quad \text{and} \quad \ln k_2 = -\left(\frac{E_a}{RT_2}\right) + \ln A$$

If one of these equations is subtracted from the other, we have

$$\ln k_2 - \ln k_1 = \ln \frac{k_2}{k_1} = -\frac{E_a}{R}\left[\frac{1}{T_2} - \frac{1}{T_1}\right] \tag{14.7}$$

Example 14.11 demonstrates the use of this equation.

EXAMPLE 14.11

Calculating E_a Numerically

Problem Use values of k determined at two different temperatures to calculate the value of E_a for the decomposition of HI:

$$2\ HI(g) \rightarrow H_2(g) + I_2(g)$$

$$k_1 = 2.15 \times 10^{-8}\ \text{L/(mol} \cdot \text{s)}\ \text{at}\ 6.50 \times 10^2\ \text{K}\ (T_1)$$

$$k_2 = 2.39 \times 10^{-7}\ \text{L/(mol} \cdot \text{s)}\ \text{at}\ 7.00 \times 10^2\ \text{K}\ (T_2)$$

What Do You Know? Values for the rate constant at two temperatures are given.

Strategy Substitute values of k_1, k_2, T_1, and T_2 into Equation 14.7 and solve for E_a.

SOLUTION

$$\ln \frac{2.39 \times 10^{-7}\ \text{L/(mol} \cdot \text{s)}}{2.15 \times 10^{-8}\ \text{L/(mol} \cdot \text{s)}} = -\frac{E_a}{8.314 \times 10^{-3}\ \text{kJ/K} \cdot \text{mol}} \times \left[\frac{1}{7.00 \times 10^2\ \text{K}} - \frac{1}{6.50 \times 10^2\ \text{K}}\right]$$

Solving this equation gives $E_a = 180$ kJ/mol.

Think about Your Answer Another way to write the difference in fractions in brackets is

$$\left[\frac{1}{T_2} - \frac{1}{T_1}\right] = \frac{T_1 - T_2}{T_1 T_2}$$

This expression is sometimes easier to use.

Check Your Understanding

The colorless gas N_2O_4 decomposes to the brown gas NO_2 in a first-order reaction.

$$N_2O_4(g) \rightarrow 2\ NO_2(g)$$

The rate constant $k = 4.5 \times 10^3\ \text{s}^{-1}$ at 274 K and $k = 1.00 \times 10^4\ \text{s}^{-1}$ at 283 K. What is the activation energy, E_a?

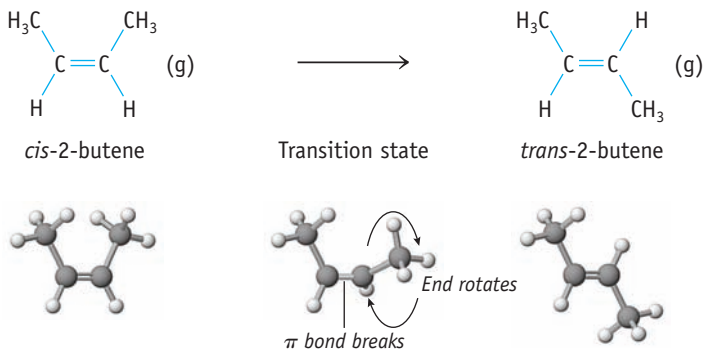
14.6 Catalysts

Goals for Section 14.6

- Describe the functioning of a catalyst and its effect on the activation energy of a reaction.
- Understand the lock-and-key and induced-fit models for substrate binding to enzymes.
- Understand the basics of the Michaelis-Menten model of enzyme kinetics.



A catalyst is a substance that speeds up the rate of a chemical reaction, and you have seen several examples of catalysts in earlier discussions in this chapter; MnO_2, iodide ion, the enzyme catalase, and hydroxide ion all catalyze the decomposition of hydrogen peroxide (Figure 14.4).

Catalysts are not consumed in a chemical reaction. They are, however, intimately involved in the details of the reaction at the particulate level. Their function is to provide *a different pathway with a lower activation energy for the reaction*.

Effect of Catalysts on Reaction Rate

Catalysts and the Economy "One third of [the] material gross national product in the United States involves a catalytic process somewhere in the production chain." (Quoted in A. Bell, *Science,* Vol. 299, p. 1688, 2003.)

To illustrate how a catalyst participates in a reaction, let us consider the isomerization of *cis*-2-butene to the slightly more stable isomer *trans*-2-butene.

The activation energy for the uncatalyzed conversion is relatively large—264 kJ/mol—because the π bond must be broken to allow one end of the molecule to rotate into a new position. Because of the high activation energy, this is a slow reaction, and rather high temperatures are required for it to occur at a reasonable rate.

The *cis*- to *trans*-2-butene reaction is greatly accelerated by a catalyst, iodine, and the reaction can be carried out in the presence of iodine at a temperature several hundred degrees lower than for the uncatalyzed reaction. Iodine is not consumed

A CLOSER LOOK

Thinking About Kinetics, Catalysis, and Bond Energies

As you will see in Section 14.7, one of the most important uses of chemical kinetics is to give us an idea as to the reaction mechanism, the step-by-step process by which a chemical reaction occurs. These individual steps involve bond breaking and bond formation and guide the chemical reaction from reactants to products. Bond breaking requires energy, while bond formation evolves energy.

Consider the uncatalyzed conversion between *cis*- and *trans*-2-butene. The postulated mechanism for this reaction involves rotation around the double bond, which would occur if the two ends of the molecule twist out of alignment by 90° resulting in the π bond being broken. We can estimate the energy of the π bond in this species using data from the table of bond dissociation enthalpies (Table 8.8). The average bond dissociation enthalpies of C═C double and C—C single bonds are 610 kJ/mol and 346 kJ/mol, respectively; the difference between these two values is 264 kJ/mol-rxn.

Note the correspondence between this value and the measured value for the activation energy of this reaction, 264 kJ/mol-rxn. Matching the estimated bond energy and the activation energy is taken to be evidence in support this mechanism.

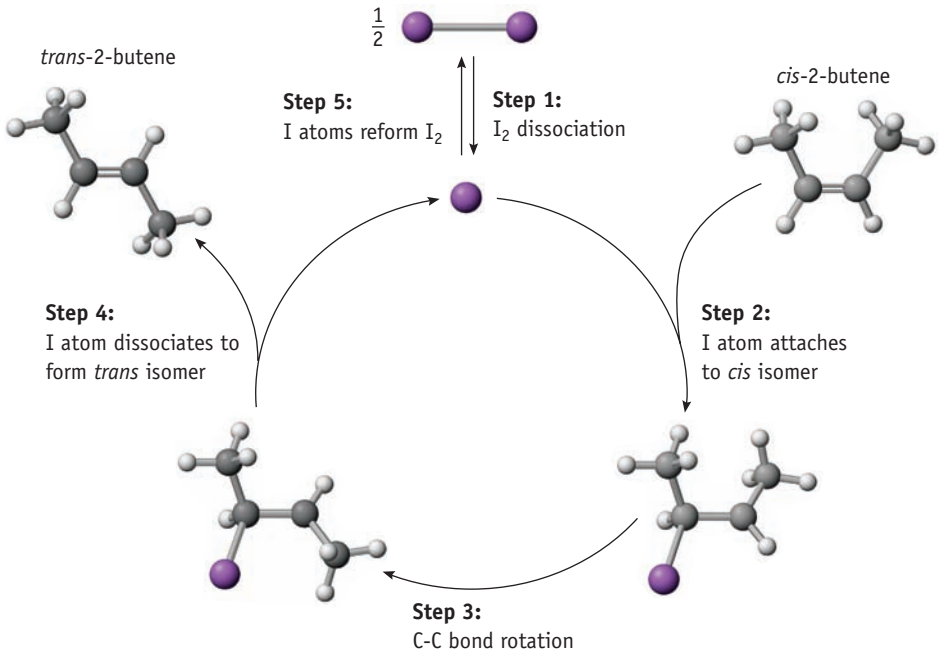

Figure 14.14 The mechanism of the iodine-catalyzed isomerization of *cis*-2-butene to *trans*-2-butene. In the text and in this figure, the addition of an iodine atom to *cis*-2-butene to eventually form *trans*-2-butene is emphasized. The iodine atom, however, can also add to *trans*-2-butene to form *cis*-2-butene. Both the forward and the reverse reactions are sped up, so that the system reaches equilibrium (Chapter 15) more quickly.

(nor is it a product), and it does not appear in the overall balanced equation. It does appear in the reaction rate law, however; the rate of the reaction depends on the square root of the iodine concentration:

$$\text{Rate} = k[\textit{cis}\text{-2-butene}][I_2]^{1/2}$$

The presence of I_2 changes the way the butene isomerization reaction occurs; that is, it changes the mechanism of the reaction (Figure 14.14). The best hypothesis is that iodine molecules first dissociate to form iodine atoms (Step 1). This requires much less energy input than rotation of the C═C double bond. An iodine atom then adds to one of the C atoms of the C═C double bond (Step 2). This converts the double bond between the carbon atoms to a single bond (the π bond is broken) and allows the ends of the molecule to twist freely relative to each other (Step 3). If the iodine atom then dissociates from the intermediate, the double bond can re-form in the *trans* configuration (Step 4). The iodine atom is now free to add to another molecule of *cis*-2-butene. The result is a kind of chain reaction, as one molecule of *cis*-2-butene after another is converted to the *trans* isomer. The chain is broken if the iodine atom recombines with another iodine atom to re-form molecular iodine.

An energy profile for the catalyzed reaction (Figure 14.15) shows that the overall energy barrier is much lower than for the uncatalyzed reaction. Five separate steps are identified for the mechanism in the energy profile. This proposed mechanism also includes a series of **reaction intermediates**, species formed in one step of the reaction and consumed in a later step. Iodine atoms are intermediates, as are the free radical species formed when an iodine atom adds to *cis*-2-butene.

Five important points are associated with this mechanism:

- Iodine molecules, I_2, dissociate to atoms and then re-form. On the macroscopic level, the concentration of I_2 is unchanged. Iodine does not appear in the balanced, stoichiometric equation even though it appears in the rate equation. This is generally true of catalysts.
- Both the catalyst I_2 and the reactant *cis*-2-butene are in the gas phase. If a catalyst is present in the same phase as the reacting substance, it is called a *homogeneous catalyst.* On the other hand, if the catalyst is in a different phase than the reacting substance, it is called a *heterogeneous catalyst*; an example of this is the solid MnO_2 catalyst used to decompose aqueous H_2O_2 in Figure 14.4.

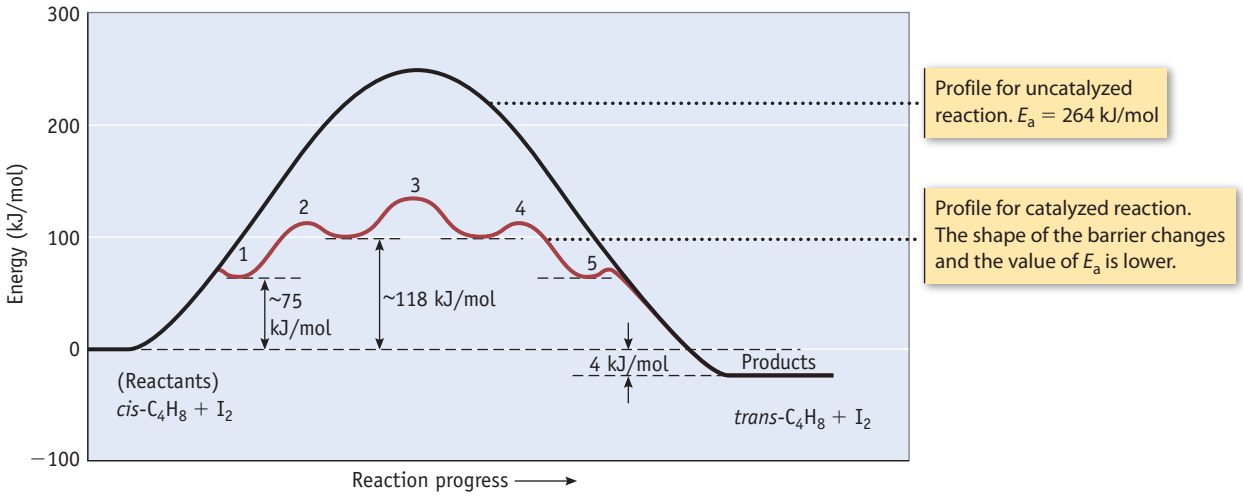

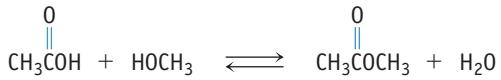

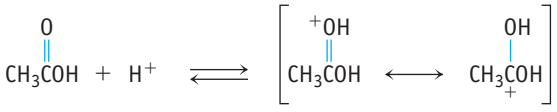

Figure 14.15 Energy profile for the iodine-catalyzed reaction of *cis*-2-butene to form *trans*-2-butene. A catalyst accelerates a reaction by altering the mechanism so that the activation energy is lowered. With a smaller barrier to overcome, more reacting molecules have sufficient energy to surmount the barrier, and the reaction occurs more rapidly.

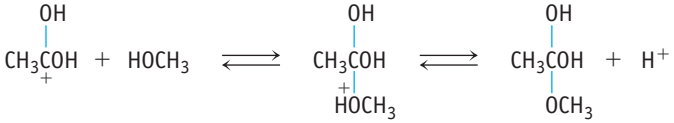
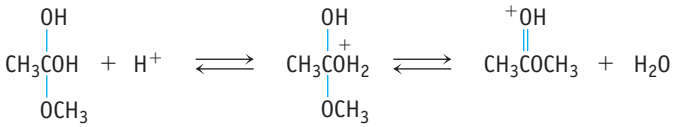
- Iodine atoms and the radical species formed by addition of an iodine atom to a 2-butene molecule are intermediates.
- The activation energy barrier to reaction is significantly lower because the mechanism changed. Dropping the activation energy from 264 kJ/mol for the uncatalyzed reaction to about 150 kJ/mol for the catalyzed process makes the catalyzed reaction 10^{15} times faster!
- The diagram of energy-versus-reaction progress has five energy barriers (five humps appear in the curve). This feature in the diagram means that the reaction occurs in a series of five steps.



Many reactions are catalyzed by acids and bases. Acid catalysts are often used in the synthesis of organic molecules, and an example is an esterification reaction. An ester is produced from the condensation reaction of a carboxylic acid and an alcohol (Section 23.4). For example, the reaction of acetic acid with methanol produces methyl acetate and water.

Without a catalyst, the system is slow to reach equilibrium, but the rate of the process is greatly increased by the addition of a strong acid (such as HCl or H_2SO_4). The acid catalyzes two steps in the reaction mechanism. First, the acid protonates the carbonyl oxygen (the O atom of the C=O group) on the acetic acid molecule.



Protonation weakens the carbon-oxygen double bond and increases the positive character of the carbon atom. The carbon atom bonds to the oxygen atom of methanol, producing a tetrahedral intermediate, and a proton is returned to the solution.

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

In the second catalyzed part of the reaction, a hydroxyl group is protonated, then removed as water.

Finally, a proton is lost, resulting in the formation of methyl acetate.

Remember, catalysts are not consumed in chemical reactions. Although protons appear twice in the mechanism as reactants, they also appear twice as products. Overall, there is no net production or consumption of protons in the reaction.

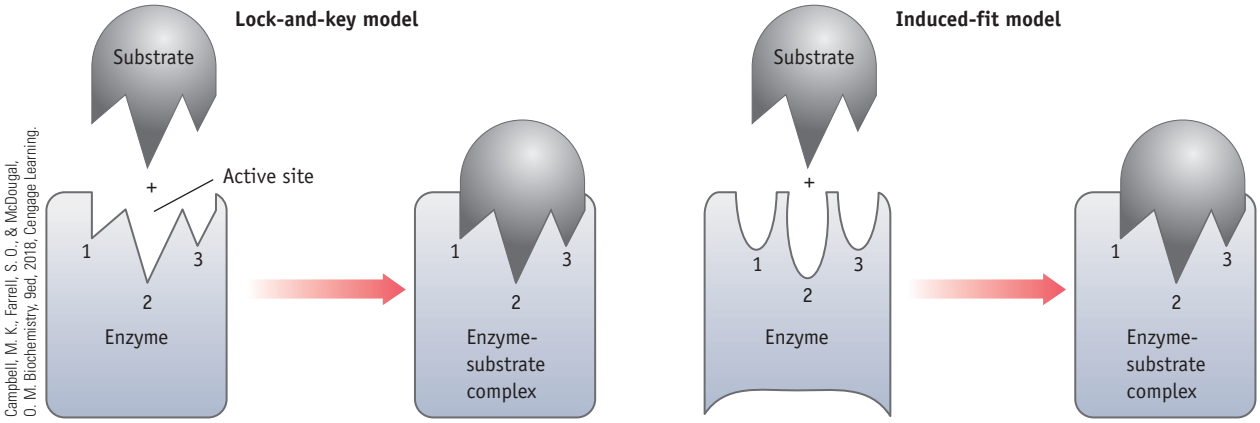
It is important to know that although a catalyst increases the rate of a chemical reaction, it does not influence whether a reaction is product-favored or reactant-favored at equilibrium. A catalyst simply enables a reaction to reach equilibrium more quickly.

Enzymes

Most reactions required for life occur too slowly on their own, so organisms have developed biological catalysts to speed them up to the appropriate levels. These biological catalysts are called **enzymes**, which are typically large proteins (Chapter 24). Enzyme-catalyzed reactions are often 10^7 to 10^{14} times faster than uncatalyzed reactions.

For an enzyme to catalyze a reaction, several key steps must occur:

1. The reactant (often called the **substrate**) must bind to the enzyme.
2. The chemical reaction must take place.
3. The products(s) of the reaction must leave the enzyme so that more substrate can bind and the process can be repeated.



The location in the enzyme where the substrate binds and the reaction occurs is called the **active site**. The active site often consists of a cavity or cleft in the structure of the enzyme into which the substrate or part of the substrate can fit in just the right orientation so that specific bonds can be broken and/or made.

How do enzymes bring about such fast and specific chemical reactions? An early model of enzyme binding is the **lock-and-key model** (Figure 14.16a). The shape of the substrate is pictured as fitting into the enzyme's active site precisely, much like a key (the substrate) fits a lock (the enzyme). This model has been supplanted by the **induced-fit model** (Figure 14.16b) in which the enzyme is not viewed as a rigid structure like a lock, but instead as a macromolecule that has some three-dimensional flexibility. The enzyme begins with a structure that does not match the shape of the substrate exactly. Instead, binding of the substrate causes the structure of the enzyme to change so that it fits the substrate.

This model can also incorporate another feature of enzyme action. A catalyst functions by providing a pathway for reaction that has a lower activation energy for the reaction. An enzyme's active site, therefore, should optimally bind to and thus stabilize not the substrate for the reaction but the *transition state*. When a substrate binds, it undergoes changes in its shape, referred to as conformational changes, that push it in the direction that leads to the formation of the transition state of the reaction. In the modern induced-fit model, therefore, both the enzyme and the substrate undergo conformational changes upon binding that lower the activation energy for the reaction, leading to a faster reaction.

(a) In the lock-and-key model, the enzyme's active site is pictured as being complementary to the structure of the substrate.

(b) In the induced-fit model, the enzyme's structure is viewed as being flexible so that, upon binding of the substrate, it changes to become complementary to the substrate.

Figure 14.16 Models of Substrate Binding.

The rate laws of enzyme-catalyzed reactions demonstrate an interesting property. At low substrate concentrations, the rate law of the reaction is often first-order in substrate, S (Figure 14.17). At high substrate concentrations, however, the rate of the reaction levels off and the rate law is zero-order in S. In 1913, Leonor Michaelis and Maud L. Menten proposed a general theory of enzyme action based on these kinetic observations. They assumed that the substrate and the enzyme, E, form a complex, ES. The chemical reaction then occurs, and the enzyme and the product, P, are released.

$$E + S \rightleftharpoons ES$$

$$ES \rightarrow P + E$$

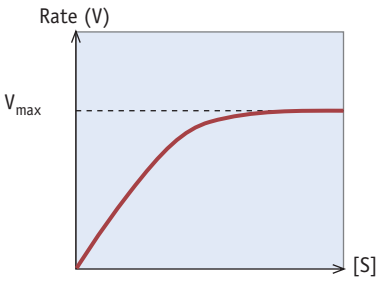

Figure 14.17 Rate of enzyme-catalyzed reaction. This plot of reaction rate versus substrate concentration [S] is typical of reactions catalyzed by enzymes that follow the Michaelis–Menten model.

At low substrate concentrations, the first-order kinetics indicates that adding more substrate will increase the rate of the reaction. Why then do the kinetics change at high substrate concentration? Because there is only so much enzyme present, the active sites in the available enzyme molecules become saturated at high substrate concentrations, and the rate reaches its maximum value.

Michaelis and Menten were further able to show that their mechanism led to the following equation for the rate (or velocity) of the reaction, V.

$$V = \frac{V_{max}[S]}{K_M + [S]}$$

where V_{max} is the maximum rate of the reaction and K_M is a constant called the Michaelis constant. When V is plotted versus [S], this equation fits the curve in Figure 14.17 well.

14.7 Reaction Mechanisms

Goals for Section 14.7

- Understand the concept of a reaction mechanism and the relation of the mechanism to the overall, stoichiometric equation for a reaction.
- Describe the elementary steps of a mechanism, and give their molecularity.
- Identify reaction intermediates in elementary steps.
- Predict the rate law for a reaction, given a simple mechanism and the identity of the rate-determining step.

Why study chemical kinetics? Beyond simply telling us what factors influence the rate of a chemical reaction and how we might be able to speed up or slow down a particular reaction, chemical kinetics also gives us insight into how a chemical reaction actually occurs. The **reaction mechanism** for a chemical reaction is the sequence of bond-making and bond-breaking steps that occurs during the conversion of reactants to products. Based on the rate equation for a reaction, and by applying chemical intuition, chemists can often make an educated guess about the mechanism for the reaction.

In some reactions, the conversion of reactants to products in a single step is envisioned as the logical mechanism. For example, the *uncatalyzed* isomerization of *cis*-2-butene to *trans*-2-butene is best described as a single-step reaction (see Figure 14.15).

Most chemical reactions occur in a sequence of steps, however. A multiple-step mechanism was proposed for the iodine-catalyzed 2-butene isomerization reaction. Another example of a multistep reaction is the reaction of bromine and NO:

$$Br_2(g) + 2\ NO(g) \rightarrow 2\ BrNO(g)$$

A single-step reaction would require that three reactant molecules collide simultaneously in just the right orientation. The probability of this occurring is small; thus, it is reasonable to look for a mechanism that occurs in a series of steps, with each step involving only one or two molecules. In one possible mechanism, Br_2 and NO might combine in an initial step to produce an intermediate species, Br_2NO.

Step 1

This intermediate would then react with another NO molecule to give the reaction products.

Step 2

The equation for the overall reaction is obtained by adding the equations for these two steps:

Step 1: $Br_2(g) + NO(g) \rightleftharpoons Br_2NO(g)$

Step 2: $NO(g) + Br_2NO(g) \rightarrow 2\ BrNO(g)$

Overall Reaction: $Br_2(g) + 2\ NO(g) \rightarrow 2\ BrNO(g)$

Each step in a multistep reaction sequence is an **elementary step**, defined by a chemical equation that describes a single molecular event such as the formation or rupture of a chemical bond resulting from a molecular collision. Each step has its own activation energy, E_a, and rate constant, k. Adding the equations for each step must give the balanced equation for the overall reaction, and the time required to complete all of the steps defines the overall reaction rate. The series of steps constitutes a possible reaction mechanism.

Molecularity of Elementary Steps

Elementary steps are classified by the number of reactant molecules (or ions, atoms, or free radicals) that come together. This whole, positive number is called the **molecularity** of the elementary step. When one molecule is the only reactant in an elementary step, the reaction is a **unimolecular** process. A **bimolecular** elementary process involves two molecules, which may be identical ($A + A \rightarrow$ products) or different ($A + B \rightarrow$ products). The mechanism proposed for the decomposition of ozone in the stratosphere illustrates the use of these terms.

Step 1:	Unimolecular	$O_3(g) \rightarrow O_2(g) + O(g)$
Step 2:	Bimolecular	$O_3(g) + O(g) \rightarrow 2\ O_2(g)$
Overall Reaction:		$2\ O_3(g) \rightarrow 3\ O_2(g)$

A **termolecular** elementary step involves three molecules, which could be the same or different ($3\ A \rightarrow$ products; $2\ A + B \rightarrow$ products; or $A + B + C \rightarrow$ products). Be aware, however, the simultaneous collision of three molecules has a low probability, unless one of the molecules involved is in high concentration, such as a solvent molecule. In fact, most termolecular processes involve the collision of two reactant molecules and a third, inert molecule. The function of the inert molecule is to absorb the excess energy produced when a new chemical bond is formed by the first two molecules. For example, N_2 is unchanged in a termolecular reaction between oxygen molecules and oxygen atoms that produces ozone in the upper atmosphere:

$$O(g) + O_2(g) + N_2(g) \rightarrow O_3(g) + \text{energetic } N_2(g)$$

The probability that four or more molecules will simultaneously collide with sufficient kinetic energy and proper orientation to react is so small that reaction molecularities greater than three are never proposed.

Before leaving this discussion of molecularity, let us go back to our previous description of collision theory. We can see how bimolecular or termolecular reactions can occur by collisions of reactant molecules with sufficient energy and in the correct orientation to react. But what about a unimolecular reaction? How can collisions be involved? In a unimolecular reaction, the reacting species must acquire enough energy to break apart. This energy can come from collisions of the reacting molecule with other molecules, such as with other molecules of the same kind, with solvent molecules, or with some high-energy background molecule. Atmospheric ozone, for example, disintegrates into O_2 molecules and O atoms by colliding with high-energy nitrogen molecules.

Rate Equations for Elementary Steps

The rate equation for a reaction must be determined by experiment; it cannot be predicted from the overall stoichiometry. In contrast, the rate equation for any elementary step is defined by its reaction stoichiometry. The rate equation of an elementary step is given by the product of its rate constant and the concentrations of the reactants in that step. We can therefore write the rate equation for any elementary step, as shown by examples in the following table:

Elementary Step	Molecularity	Rate Equation
$A \rightarrow$ product	Unimolecular	Rate $= k[A]$
$A + B \rightarrow$ product	Bimolecular	Rate $= k[A][B]$
$A + A \rightarrow$ product	Bimolecular	Rate $= k[A]^2$
$2\ A + B \rightarrow$ product	Termolecular	Rate $= k[A]^2[B]$

A CLOSER LOOK

Organic Bimolecular Substitution Reactions

Experimentally determined rate laws can be used to propose mechanisms and to eliminate other mechanisms from consideration. To decide among possible mechanisms, however, additional experimental information and chemical intuition are also required.

Consider the reaction between 2-bromooctane and iodide ion (Figure A) (a reaction similar to the reaction of fluoride ion and chloromethane (page 634)). This reaction follows second-order kinetics; it is first-order in each of the reagents, and from this we know that a single-step mechanism is one possibility. A possible single-step mechanism is shown in Figure B. This involves attack of iodide ion on the side of the carbon atom opposite to Br, which leads to breaking of the carbon-bromine bond concurrent with formation of a carbon-iodine bond.

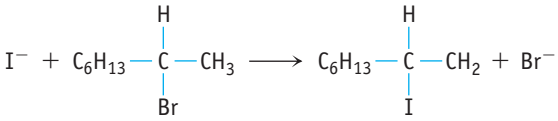

Figure A Reaction of 2-Bromooctane with Iodide ion.

Notice that the geometry around the carbon atom in 2-bromooctane inverts in the course of this mechanism. (The geometry around the carbon has been inverted like an umbrella inverts in a strong wind.) If this is the correct mechanism, and if we start with a compound having the geometry shown, then the product of the reaction should have the inverted geometry. This is exactly what is found in the laboratory and provides strong evidence in support of this mechanism.

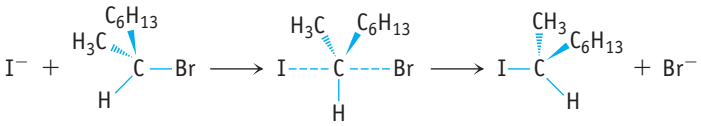

Figure B Proposed Mechanism for the Reaction of 2-Bromooctane with Iodide ion.

For example, the rate laws for each of the two elementary steps in the decomposition of ozone are

$$\text{Rate for (unimolecular) Step 1} = k[O_3]$$

$$\text{Rate for (bimolecular) Step 2} = k'[O_3][O]$$

The two rate constants (k and k' in this example) are not expected to have the same value (nor the same units, because the two steps have different molecularities).

EXAMPLE 14.12

Elementary Steps

Problem The hypochlorite ion undergoes self-oxidation–reduction to give chlorate, ClO_3^-, and chloride ions.

$$3\ ClO^-(aq) \rightarrow ClO_3^-(aq) + 2\ Cl^-(aq)$$

This reaction is thought to occur in two steps:

Step 1: $ClO^-(aq) + ClO^-(aq) \rightarrow ClO_2^-(aq) + Cl^-(aq)$

Step 2: $ClO_2^-(aq) + ClO^-(aq) \rightarrow ClO_3^-(aq) + Cl^-(aq)$

What is the molecularity of each step? Write the rate equation for each elementary step. Show that the sum of these reactions gives the equation for the net reaction.

What Do You Know? A two-step mechanism for the reaction of ClO^- to form Cl^- and ClO_3^- is proposed.

Strategy The molecularity is the number of ions or molecules involved in a reaction step. The rate equation for each elementary step involves the concentration of each ion or molecule in the elementary step, raised to the power of its stoichiometric coefficient.

SOLUTION Because two ions are involved in each elementary step, each step is bimolecular. The rate equation for any elementary step involves the product of the concentrations of the reactants. Thus, in this case, the rate equations are

Step 1: $\text{Rate} = k_1[ClO^-]^2$

Step 2: $\text{Rate} = k_2[ClO_2^-][ClO^-]$

From the equations for the two elementary steps, we see that the ClO_2^- ion is an intermediate, a product of the first step and a reactant in the second step. It therefore cancels out, and we are left with the balanced equation for the overall reaction:

Step 1: $ClO^-(aq) + ClO^-(aq) \rightarrow \cancel{ClO_2^-(aq)} + Cl^-(aq)$

Step 2: $\cancel{ClO_2^-(aq)} + ClO^-(aq) \rightarrow ClO_3^-(aq) + Cl^-(aq)$

Sum of steps: $3\ ClO^-(aq) \rightarrow ClO_3^-(aq) + 2\ Cl^-(aq)$

Think about Your Answer Other mechanisms are possible. The next question to ask is "What is the evidence that will let you decide between several different mechanisms?"

Check Your Understanding

Nitrogen monoxide is reduced by hydrogen to give nitrogen and water:

$$2\ NO(g) + 2\ H_2(g) \rightarrow N_2(g) + 2\ H_2O(g)$$

One possible mechanism for this reaction involves the following reactions:

$$2\ NO(g) \rightarrow N_2O_2(g)$$

$$N_2O_2(g) + H_2(g) \rightarrow N_2O(g) + H_2O(g)$$

$$N_2O(g) + H_2(g) \rightarrow N_2(g) + H_2O(g)$$

What is the molecularity of each of the three steps? What is the rate equation for the third step? Identify the intermediates in this reaction; how many different intermediates are there? Show that the sum of these elementary steps gives the equation for the overall reaction.

Reaction Mechanisms and Rate Equations

The dependence of rate on concentration is an experimental fact. Mechanisms, in contrast, are constructs of our imagination, intuition, and good "chemical sense." To describe a mechanism, we need to make a hypothesis about how the reaction occurs at the particulate level. Several mechanisms can often be proposed that correspond to the observed rate equation. A good mechanism is a worthy goal because it allows us to understand the chemistry better and perhaps to predict how to control a reaction better and how to design new experiments.

One of the important guidelines of kinetics is that *products of a reaction can never be produced at a rate faster than the rate of the slowest step.* If one step in a multistep

reaction is slower than the others, then *the rate of the overall reaction is limited by the combined rates of all elementary steps up through the slowest step in the mechanism*. Often the overall reaction rate and the rate of the slow step are nearly the same. If the slow step determines the rate of the reaction, it is called the **rate-determining step**, or rate-limiting step.

Imagine that a reaction takes place with a mechanism involving two sequential steps, and assume that we know the rates of both steps. The first step is slow and the second is fast:

Elementary Step 1: $A + B \xrightarrow[\text{Slow, } E_a \text{ large}]{k_1} X + M$

Elementary Step 2: $M + A \xrightarrow[\text{Fast, } E_a \text{ small}]{k_2} Y$

Overall Reaction: $2A + B \longrightarrow X + Y$

In the first step, A and B come together and slowly react to form one of the products (X) plus another reactive species, M. Almost as soon as M is formed, however, it is rapidly consumed by reacting with another molecule of A to form the second product Y. The rate-determining elementary step in this example is the first step. That is, the rate of the first step is equal to the rate of the overall reaction. This step is bimolecular and so it has the rate equation:

$$\text{Rate} = k_1[A][B]$$

where k_1 is the rate constant for that step. The overall reaction is expected to have this same second-order rate equation.

Let us apply these ideas to the mechanism of a real reaction: the second-order reaction of nitrogen dioxide with fluorine.

$$2\ NO_2(g) + F_2(g) \longrightarrow 2\ FNO_2(g)$$

$$\text{Rate} = k[NO_2][F_2]$$

Can You Derive a Mechanism?
At this introductory level, you cannot be expected to derive reaction mechanisms. Given a mechanism, however, you can decide whether it agrees with experimental rate laws.

The rate equation immediately rules out the possibility that the reaction occurs in a single step. If this was a single-step reaction, the rate law would have a second-order dependence on $[NO_2]$. Because a single-step reaction is ruled out, the mechanism must include at least two steps. We can also conclude from the rate law that the rate-determining elementary step must involve NO_2 and F_2 in a 1:1 ratio.

One possible mechanism for the NO_2/F_2 reaction proposes that NO_2 and F_2 first react to produce one molecule of the product (FNO_2) plus one F atom. In a second step, the fluorine atom produced in the first step reacts with additional NO_2 to give a second molecule of product. If the first, bimolecular step is rate determining, the rate equation would be "Rate = $k_1[NO_2][F_2]$," the same as the experimentally observed rate equation. The experimental rate constant would be the same as k_1.

Elementary Step 1: Slow $\quad NO_2(g) + F_2(g) \xrightarrow{k_1} FNO_2(g) + F(g)$

Elementary Step 2: Fast $\quad NO_2(g) + F(g) \xrightarrow{k_2} FNO_2(g)$

Overall Reaction: $\quad 2\ NO_2(g) + F_2(g) \longrightarrow 2\ FNO_2(g)$

The fluorine atom formed in the first step of the NO_2/F_2 reaction is a reaction intermediate. It does not appear in the equation describing the overall reaction. Reaction intermediates usually have only a fleeting existence, but in some instances they have long enough lifetimes to be observed. When this is possible, the detection and identification of an intermediate provide strong evidence supporting the proposed mechanism.

EXAMPLE 14.13

Elementary Steps and Reaction Mechanisms

Problem Oxygen atom transfer from NO_2 to CO produces nitrogen monoxide and carbon dioxide.

$$NO_2(g) + CO(g) \longrightarrow NO(g) + CO_2(g)$$

The mechanism for this reaction depends on the temperature, with one mechanism followed at low temperatures (less than 500 K) and another mechanism followed at high temperatures. The rate equation for this reaction at temperatures less than 500 K is Rate $= k[NO_2]^2$. Can the low-temperature reaction occur in one bimolecular step?

What Do You Know? The reaction equation and the rate law for the reaction are given.

Strategy Write the rate law based on the equation for the NO_2 + CO reaction occurring as if it were an elementary step. If this rate law corresponds to the observed rate law, then a one-step mechanism is possible.

SOLUTION If the reaction occurs by the collision of one NO_2 molecule with one CO molecule, the rate equation would be

$$\text{Rate} = k[NO_2][CO]$$

This does *not* agree with experiment, so the mechanism must involve more than a single step. In one possible mechanism, the reaction occurs in two bimolecular steps, the first one slow and the second one fast:

Elementary Step 1:	Slow, rate-determining	$2\ NO_2(g) \longrightarrow \cancel{NO_3(g)} + NO(g)$
Elementary Step 2:	Fast	$\cancel{NO_3(g)} + CO(g) \longrightarrow NO_2(g) + CO_2(g)$
Overall Reaction:		$NO_2(g) + CO(g) \longrightarrow NO(g) + CO_2(g)$

The first (rate-determining) step has a rate equation that agrees with experiment, so this is a possible mechanism.

Think about Your Answer Because the rate equation is second-order in $[NO_2]$, the rate-determining step in this multistep reaction must involve the collision of two NO_2 molecules.

Check Your Understanding

The Raschig reaction produces hydrazine, N_2H_4, an industrially important reducing agent, from NH_3 and OCl^- in basic, aqueous solution. A proposed mechanism is

Step 1:	Fast	$NH_3(aq) + OCl^-(aq) \rightarrow NH_2Cl(aq) + OH^-(aq)$
Step 2:	Slow	$NH_2Cl(aq) + NH_3(aq) \rightarrow N_2H_5^+(aq) + Cl^-(aq)$
Step 3:	Fast	$N_2H_5^+(aq) + OH^-(aq) \rightarrow N_2H_4(aq) + H_2O(\ell)$

(a) What is the overall equation?

(b) Which step of the three is rate determining?

(c) Write the rate equation for the rate-determining elementary step.

(d) What reaction intermediates are involved?

Reaction Mechanisms Involving an Initial Equilibrium Step

A common two-step reaction mechanism involves an initial fast reaction that produces an intermediate, followed by a slower second step in which the intermediate is converted to the final product. The rate of the reaction is determined by the second step, for which a rate law can be written. The rate of that step, however, depends on the concentration of the intermediate. The concentration of an intermediate should not appear as a term in the overall rate equation because this concentration will probably not be measurable and because such a rate law cannot be compared directly with the experimentally determined rate law. Therefore, we must find a way to replace the expression for the intermediate with another expression in terms of quantities measurable in the lab.

The reaction of nitrogen monoxide and oxygen is an example of a two-step reaction where the first step is fast and the second step is rate determining.

$$2\ NO(g) + O_2(g) \longrightarrow 2\ NO_2(g)$$

$$\text{Rate} = k[NO]^2[O_2]$$

The experimentally determined rate law shows second-order dependence on NO and first-order dependence on O_2. Although this rate law would be correct for a termolecular reaction, experimental evidence indicates that an intermediate is formed in this reaction. A possible two-step mechanism that proceeds through an intermediate is

Elementary Step 1:	Fast, equilibrium	$NO(g) + O_2(g) \underset{k_{-1}}{\overset{k_1}{\rightleftharpoons}} OONO(g)$ intermediate
Elementary Step 2:	Slow, rate-determining	$NO(g) + OONO(g) \xrightarrow{k_2} 2\ NO_2(g)$
Overall Reaction:		$2\ NO(g) + O_2(g) \longrightarrow 2\ NO_2(g)$

The second step of this reaction is the slow step and determines the overall rate. We can write a rate law for the second step, but this rate law cannot be compared directly with the experimental rate law because it contains the concentration of an intermediate, OONO:

$$\text{Rate} = k_2[NO][OONO]$$

To eliminate the concentration of intermediate from this rate expression, we look at the rapid first step, which involves an equilibrium between the intermediate species and the reactants.

At the beginning of the reaction, NO and O_2 react rapidly and produce the intermediate OONO. The rate of formation can be defined by a rate law with a rate constant k_1:

$$\text{Rate of production of OONO } (NO + O_2 \longrightarrow OONO) = k_1[NO][O_2]$$

Because the intermediate is consumed only very slowly in the second step, it is possible for the OONO to revert to NO and O_2 before it reacts further:

$$\text{Rate of reverse reaction } (OONO \longrightarrow NO + O_2) = k_{-1}[OONO]$$

As NO and O_2 form OONO, their concentrations drop, so the rate of the forward reaction decreases. At the same time, the concentration of OONO builds up, so the rate of the reverse reaction increases. At equilibrium, the rates of the forward and reverse reactions become the same.

$$\text{Rate of forward reaction} = \text{rate of reverse reaction}$$

$$k_1[NO][O_2] = k_{-1}[OONO]$$

Rearranging this equation, we find

$$\frac{k_1}{k_{-1}} = \frac{[OONO]}{[NO][O_2]} = K$$

Mechanisms with an Initial Equilibrium In this mechanism, the forward and reverse reactions in the first elementary step are so much faster than the second elementary step that equilibrium is established before any significant amount of OONO is consumed by NO to give NO_2. The state of equilibrium for the first step remains throughout the lifetime of the overall reaction.

Equilibrium Constant The important concept of chemical equilibrium was introduced in Chapter 3 and will be described in more detail in Chapters 15–18.

Both k_1 and k_{-1} are constants (they will change only if the temperature changes). We can define a new constant K equal to the ratio of these two constants and called the **equilibrium constant**, which in this case is equal to the quotient $[OONO]/[NO][O_2]$. From this, we can derive an expression for the concentration of OONO:

$$[OONO] = K[NO][O_2]$$

If $K[NO][O_2]$ is substituted for [OONO] in the rate law for the rate-determining elementary step, we have

$$\text{Rate} = k_2[NO][OONO] = k_2[NO]\{K[NO][O_2]\}$$
$$= k_2K[NO]^2[O_2]$$

Because both k_2 and K are constants, their product is another constant k', and we have

$$\text{Rate} = k'[NO]^2[O_2]$$

This is exactly the rate law derived from experiment. Thus, the sequence of reactions on which the rate law is based may be a reasonable mechanism for this reaction. It is not the only possible mechanism, however. This rate equation is also consistent with the reaction occurring in a single termolecular step, and another possible mechanism is illustrated in Example 14.14.

EXAMPLE 14.14

Reaction Mechanism Involving an Equilibrium Step

Problem The NO + O_2 reaction described in the text could also occur by the following mechanism:

Elementary Step 1: Fast, equilibrium

$$NO(g) + NO(g) \underset{k_{-1}\ \text{intermediate}}{\overset{k_1}{\rightleftharpoons}} N_2O_2(g)$$

Elementary Step 2: Slow, rate-determining

$$N_2O_2(g) + O_2(g) \xrightarrow{k_2} 2\ NO_2(g)$$

Overall Reaction: $2\ NO(g) + O_2(g) \rightarrow 2\ NO_2(g)$

Show that this mechanism leads to the following experimental rate law: Rate $= k[NO]^2[O_2]$.

What Do You Know? A possible mechanism for the reaction of NO and O_2 is given.

Strategy The rate law for the reaction is derived using the stoichiometry of the rate-determining step. If this step involves an intermediate, an expression for the concentration of this intermediate will need to be found that has only the concentrations of species in the overall balanced equation.

SOLUTION The rate law for the rate-determining elementary step is

$$\text{Rate} = k_2[N_2O_2][O_2]$$

The intermediate N_2O_2 cannot appear in the final derived rate law. However, we can find an expression relating the concentration of the intermediate to the concentrations of the reactants, using the equilibrium constant expression for the first step. $[N_2O_2]$ and [NO] are related by the equilibrium constant.

$$\frac{k_1}{k_{-1}} = \frac{[N_2O_2]}{[NO]^2} = K$$

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Solving this equation for $[N_2O_2]$ gives $[N_2O_2] = K[NO]^2$. When this is substituted into the derived rate law

$$\text{Rate} = k_2\{K[NO]^2\}[O_2]$$

the resulting equation is identical with the experimental rate law where $k_2K = k$.

Think about Your Answer Three mechanisms have been proposed for the NO + O_2 reaction. The challenge for chemists is to decide which is correct. In this case, further experimentation detected the species OONO as a short-lived intermediate, thus providing evidence for the mechanism involving this intermediate.

Check Your Understanding

One possible mechanism for the decomposition of nitryl chloride, NO_2Cl, is

Elementary Step 1: Fast, equilibrium $\quad NO_2Cl(g) \underset{k_{-1}}{\overset{k_1}{\rightleftharpoons}} NO_2(g) + Cl(g)$

Elementary Step 2: Slow $\quad NO_2Cl(g) + Cl(g) \xrightarrow{k_2} NO_2(g) + Cl_2(g)$

What is the overall reaction? What rate law would be derived from this mechanism? What effect does increasing the concentration of the product NO_2 have on the reaction rate?

Reaction Mechanisms Involving a Free-Radical Chain Reaction

Chain reactions, in which one of the products of the reaction feeds back into an earlier step of the reaction and thus serves to keep the reaction going in a self-sustaining fashion, are sometimes encountered. These reactions are important in the synthesis of some organic chemicals and in some types of polymerization reactions, but chain reactions can become uncontrolled and can lead to explosions.

An example of a chain reaction process is the reaction of methane and chlorine, which results in the formation of chloroalkanes. This exothermic reaction requires either ultraviolet light or temperatures in the range of 300 °C to occur; the reaction does not occur when these reactants are mixed at room temperature and in the dark. If the reactants are present in a 1:1 ratio, the products are mainly CH_3Cl and HCl, along with smaller amounts of CH_2Cl_2 and other chlorinated methanes.

$$CH_4(g) + Cl_2(g) \rightarrow HCl(g) + CH_3Cl(g)$$

(plus lesser amounts of CH_2Cl_2, $CHCl_3$, and CCl_4)

The mechanism is believed to involve a series of steps:

1. Initiation Step. Heat or UV light causes the chlorine molecule to dissociate into two chlorine atoms. Only a few chlorine atoms are needed to initiate the chain reaction.

$$Cl_2 \rightarrow 2\ \cdot Cl \qquad \Delta H = 242\ \text{kJ/mol-rxn}$$

2. Propagation Steps. The highly energetic chlorine atom is a free radical (Section 8.5). As the ·Cl atom moves randomly in the system, various molecular collisions with other species (CH_4, Cl_2, and Cl) are expected to occur. Collision with a Cl_2 molecule is not productive, but collision with a methane molecule can result in the formation of a Cl—H bond concurrent with C—H bond breaking. An estimate of the enthalpy of this process using bond dissociation enthalpy values (Table 8.8) indicates that this reaction should be slightly exothermic.

$$CH_3{-}H + \cdot Cl \rightarrow \cdot CH_3 + HCl \qquad \Delta H = D(C{-}H) - D(H{-}Cl)$$

$$\Delta H = 413\ \text{kJ/mol-rxn} - 432\ \text{kJ/mol-rxn} = -19\ \text{kJ/mol-rxn}$$

***D*, Bond Dissociation Enthalpy** *D* is commonly used as a symbol for bond dissociation enthalpies.

Problem Solving Tip 14.2 Relating Rate Equations and Reaction Mechanisms

The connection between an experimental rate equation and the proposed reaction mechanism is important in chemistry.

1. Experiments are performed to determine the experimental rate equation.
2. A mechanism for the reaction is proposed on the basis of the experimental rate equation, the principles of stoichiometry, molecular structure and bonding, general chemical experience, and intuition.
3. The proposed reaction mechanism is used to derive a rate equation. This rate equation can contain only those species involved in the overall chemical reaction. If the derived and experimental rate equations are the same, the postulated mechanism *may* be a reasonable hypothesis.
4. If more than one mechanism can be proposed and they all predict derived rate equations in agreement with the experiment, then more experiments must be done.

The methyl radical, $\cdot CH_3$, generated in the previous step is also highly reactive. A collision with a Cl_2 molecule can result in the formation of a C—Cl bond and a chlorine atom. This is also an exothermic reaction.

$$\cdot CH_3 + Cl{-}Cl \rightarrow CH_3Cl + \cdot Cl \qquad \Delta H = D(Cl{-}Cl) - D(C{-}Cl)$$

$$\Delta H = 242 \text{ kJ/mol-rxn} - 339 \text{ kJ/mol-rxn} = -97 \text{ kJ/mol-rxn}$$

The chlorine atom formed in this step is now available to react with another molecule of CH_4. The propagation steps can repeat over and over, in a self-sustaining fashion, a feature characteristic of a chain reaction.

H_2 and Cl_2 Chain Reaction. These two gases react in a chain reaction to produce HCl gas. The reaction occurs when the Cl—Cl bond is broken by blue or UV light, but not by red or green light. There are many videos of the explosive reaction on the internet.

As the reaction progresses, the concentration of CH_4 decreases and the concentration of the product, CH_3Cl, increases. With these changes, the probability of collisions between CH_3Cl and $\cdot Cl$ atoms increases. These collisions lead to the formation of small amounts of CH_2Cl_2 and the other more highly chlorinated species.

3. Termination Step. The chain reaction will continue as long as the free radicals ($\cdot Cl$ or $\cdot CH_3$) are present. It will end if the radicals cease to be present. This will happen if two Cl radicals (or any two radicals) collide and react.

$$2 \cdot Cl \rightarrow Cl_2 \qquad \Delta H = -242 \text{ kJ/mol-rxn}$$

The concentration of the various radical species in these reactions is exceedingly small. Thus, the probability of such a reaction is fairly low and the radical chain reaction will have a long lifetime before it stops.

Summing the equations for the individual steps to give CH_3Cl gives the overall reaction equation. The enthalpy change for this reaction, $\Delta H = -116$ kJ/mol-rxn, is the sum of the enthalpies of the individual steps.

APPLYING CHEMICAL PRINCIPLES

14.1 Enzymes–Nature's Catalysts

Many natural systems are controlled by catalysts called enzymes. One example is catalase (Chapter Opening Photograph and Figure 14.4), whose function is to speed up the decomposition of hydrogen peroxide. In the process of aerobic metabolism, molecular oxygen is reduced predominantly to water. A small amount of the oxygen, however, is reduced only partially, to hydrogen peroxide, which is highly toxic. Catalase ensures that the hydrogen peroxide formed does not build up in the body.

Carbon dioxide is another product of aerobic metabolism. Carbon dioxide dissolves in water to a small extent to produce carbonic acid, which ionizes to give H_3O^+ and HCO_3^- ions.

$$CO_2(g) \rightleftharpoons CO_2(aq) \quad (1)$$

$$CO_2(aq) + H_2O(\ell) \rightleftharpoons H_2CO_3(aq) \quad (2)$$

$$H_2CO_3(aq) + H_2O(\ell) \rightleftharpoons H_3O^+(aq) + HCO_3^-(aq) \quad (3)$$

(a) $t = 0$ A few drops of blood are added to a cold solution of CO_2 in water. (You can use commercial soda water.)

(b) $t = 3$ sec A few drops of a dye (bromthymol blue) are added to the solution, the yellow color indicating an acidic solution.

(c) $t = 15$ sec A less-than-stoichiometric amount of sodium hydroxide is added, converting the H_2CO_3 to HCO_3^- (and CO_3^{2-}). The blue color of the dye indicates a basic solution.

(d) $t = 17$ sec The blue color begins to fade after some seconds as CO_2 forms more H_2CO_3. The amount of H_2CO_3 formed is finally sufficient to consume the added NaOH, and the solution is again acidic.

(e) $t = 21$ sec

CO_2 in water.

The enzyme carbonic anhydrase speeds up reactions 2 and 3. Many of the H_3O^+ ions produced by ionization of H_2CO_3 (reaction 3) are picked up by hemoglobin in the blood as hemoglobin loses O_2. The resulting HCO_3^- ions are transported back to the lungs. When hemoglobin again takes on O_2, it releases H_3O^+ ions. These ions and HCO_3^- re-form H_2CO_3, from which CO_2 is liberated and exhaled.

You can do an experiment that illustrates the effect of carbonic anhydrase. First, add a small amount of NaOH to a cold, aqueous solution of CO_2. The solution becomes basic immediately because there is not enough H_2CO_3 in the solution to use up the NaOH. After some seconds, however, dissolved CO_2 slowly produces more H_2CO_3, which consumes NaOH, and the solution is again acidic.

Now try the experiment again, this time adding a few drops of blood to the solution (Figure). The solution becomes acidic very quickly. Carbonic anhydrase in blood speeds up the reaction of $CO_2(aq)$ to $HCO_3^-(aq)$ by a factor of about 10^7, as evidenced by the more rapid reaction under these conditions.

Questions:

1. Catalase can decompose hydrogen peroxide to O_2 and water about 10^7 times faster than the uncatalyzed reaction. If the latter requires one year, about how much time is required by the enzyme-catalyzed reaction?
2. How many moles of carbonic anhydrase (approximate molar mass = 29,000 g/mol) are present in 100. mL of a solution containing a 2 mg/mL concentration (approximately physiological concentration) of carbonic anhydrase? Carbonic anhydrase can catalyze very fast reactions. Some forms of this enzyme have a turnover number equal to 1×10^6 s^{-1}. This means that they can convert substrate to products at a rate of 1×10^6 moles of CO_2 per mole of enzyme per second. What mass of CO_2 could be converted to HCO_3^- in 1 second by the amount of enzyme calculated for the solution in the first part of this question?

14.2 Kinetics and Mechanisms: A 70-Year-Old Mystery Solved

Toward the end of the 19th century, the gas phase reaction of H_2 with I_2 was shown to be first-order for each reactant.

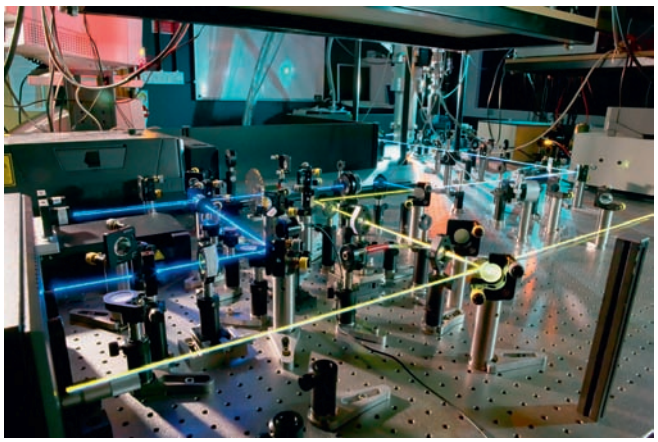
$$H_2(g) + I_2(g) \rightleftharpoons 2\ HI(g)$$

For approximately 70 years, the accepted mechanism was an elementary bimolecular collision that results in an exchange of atoms.

However, in 1967, John H. Sullivan determined that this single-step mechanism is incorrect. Sullivan provided evidence that the reaction actually occurs in two steps. The first step of the mechanism is the dissociation of elemental iodine into iodine atoms. The dissociation of I_2 is a fast equilibrium process that produces a relatively constant concentration of iodine atoms.

Fast equilibrium $\quad I_2(g) \rightleftharpoons 2\ I(g)$

The second step of the mechanism is a slow termolecular reaction between two iodine atoms and elemental hydrogen.



Slow $\quad H_2(g) + 2\ I(g) \rightarrow 2\ HI$

What was Sullivan's evidence for the revised mechanism? First, he worked at temperatures too low to allow thermal decomposition of I_2. At these temperatures, little or no hydrogen iodide is formed. Second, he used a technique called *flash photolysis* to create iodine atoms from I_2. In this technique a mixture of hydrogen and iodine was irradiated with a strong pulse of light. Sullivan found that the rate of the reaction was dependent on the square of the concentration of iodine atoms created by flash photolysis, which is consistent with the second elementary step in his reaction mechanism.

The story of the mechanism of the hydrogen-iodine reaction is a good lesson: chemists should not trust a proposed mechanism

Colin Cuthbert/Science Source

An apparatus for carrying out flash photolysis experiments in the study of kinetics.

just because it fits with an experimentally determined reaction order. Verifying mechanisms often requires identifying intermediates during the course of a reaction. Sullivan was not only able to identify an intermediate, he controlled its production.

Questions:

1. Sullivan used 578-nm light to dissociate I_2 molecules to I atoms.
   a. What is the energy (in kJ/mol) of 578-nm light?
   b. Breaking an I_2 bond requires 151 kJ/mol of energy. What is the longest wavelength of light that has enough energy to dissociate I_2?
2. Show that the two-step mechanism proposed by Sullivan yields the correct (overall second-order) rate law.
3. Why is a termolecular elementary step likely to be the slowest in a mechanism?
4. Determine the activation energy for the reaction of H_2 and I_2 to produce HI, given the data in the table.

Temperature (°C)	Rate Constant ($M^{-1}\ s^{-1}$)
144.7	1.40×10^{-12}
207.5	1.52×10^{-9}
246.9	5.15×10^{-8}

CHAPTER GOALS REVISITED

The goals for this chapter are keyed to specific Study Questions to help you organize your review.

14.1 Rates of Chemical Reactions

- Calculate the average rate of a reaction from concentration-time data. **5, 6.**
- Relate the rates for the disappearance of reactants and formation of products for a chemical reaction. **1–4.**

14.2 Reaction Conditions and Rate

- Describe how reaction conditions (reactant concentrations, temperature, presence of a catalyst, and the state of the reactants) affect reaction rate. **8–10, 91–93.**

14.3 Effect of Concentration on Reaction Rate

- Derive a rate equation from experimental information using the method of initial rates. **11–14, 56, 64.**

14.4 Concentration–Time Relationships: Integrated Rate Laws

- Use the relationships between reactant concentration and time for zero-order, first-order, and second-order reactions. **15–24.**
- Apply graphical methods for determining reaction order and the rate constant from experimental data. **31–36, 58, 59, 61.**
- Use the concept of half-life ($t_{1/2}$), especially for first-order reactions. **25–30, 68, 85.**

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

14.5 A Microscopic View of Reaction Rates

- Describe the collision theory of reaction rates and use collision theory to describe the effects of reactant concentration, molecular orientation, and temperature on reaction rate. **96, 101.**
- Relate activation energy (E_a) to the rate of a reaction. **37, 38, 40.**
- Understand reaction coordinate diagrams. **41, 42, 51, 99.**
- Use the Arrhenius equation, or one of its modified forms, to calculate the activation energy from rate constants at different temperatures. **37, 39, 40, 66, 73, 74.**

14.6 Catalysts

- Describe the functioning of a catalyst and its effect on the activation energy of a reaction. **94, 100.**
- Understand the lock-and-key and induced-fit models for substrate binding to enzymes. **43, 44.**
- Understand the basics of the Michaelis-Menten model of enzyme kinetics. **45, 46, 87.**

14.7 Reaction Mechanisms

- Understand the concept of a reaction mechanism and the relation of the mechanism to the overall, stoichiometric equation for a reaction. **50, 52.**
- Describe the elementary steps of a mechanism, and give their molecularity. **47–52, 88.**
- Identify reaction intermediates in elementary steps. **75, 94.**
- Predict the rate law for a reaction, given a simple mechanism and the identity of the rate-determining step. **50, 52, 63, 71, 75, 84, 89.**

KEY EQUATIONS

Equation 14.1 (page 622) Integrated rate equation for a first-order reaction (in which $-\Delta[\mathrm{R}]/\Delta t = k[\mathrm{R}]$).

$$\ln \frac{[\mathrm{R}]_t}{[\mathrm{R}]_0} = -kt$$

Here, $[\mathrm{R}]_0$ and $[\mathrm{R}]_t$ are concentrations of the reactant at time $t = 0$ and at a later time, t. The ratio of concentrations, $[\mathrm{R}]_t/[\mathrm{R}]_0$, is the fraction of reactant that remains after a given time has elapsed.

Equation 14.2 (page 625) Integrated rate equation for a second-order reaction (in which $-\Delta[\mathrm{R}]/\Delta t = k[\mathrm{R}]^2$).

$$\frac{1}{[\mathrm{R}]_t} - \frac{1}{[\mathrm{R}]_0} = kt$$

Equation 14.3 (page 625) Integrated rate equation for a zero-order reaction (in which $-\Delta[\mathrm{R}]/\Delta t = k[\mathrm{R}]^0$).

$$[\mathrm{R}]_t - [\mathrm{R}]_0 = -kt$$

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Equation 14.4 (page 628) The relation between the half-life ($t_{1/2}$) and the rate constant (k) for a first-order reaction.

$$t_{1/2} = \frac{0.693}{k}$$

Equation 14.5 (page 635) Arrhenius equation in exponential form.

$$k = \underbrace{A}_{\text{Frequency factor}} \underbrace{e^{-E_a/RT}}_{\text{Fraction of molecules with minimum energy for reaction}}$$

k is the rate constant, A is the frequency factor; E_a is the activation energy; T is the temperature (in kelvins); and R is the gas constant ($= 8.31446 \times 10^{-3}$ kJ/K · mol).

Equation 14.6 (page 635) Expanded Arrhenius equation in logarithmic form.

$$\ln k = -\frac{E_a}{R}\left(\frac{1}{T}\right) + \ln A \longleftarrow \text{Arrhenius equation}$$

$$\downarrow \quad\quad \downarrow \quad\quad \downarrow$$

$$y \quad = \quad mx \quad + b \longleftarrow \text{Equation for straight line}$$

Equation 14.7 (page 637) A version of the Arrhenius equation used to calculate the activation energy for a reaction when you know the values of the rate constant at two temperatures (in kelvins).

$$\ln k_2 - \ln k_1 = \ln \frac{k_2}{k_1} = -\frac{E_a}{R}\left[\frac{1}{T_2} - \frac{1}{T_1}\right]$$

STUDY QUESTIONS

▲ denotes challenging questions. **Blue-numbered questions** have answers in Appendix N and fully worked solutions in the *Student Solutions Manual.*

Practicing Skills

Reaction Rates

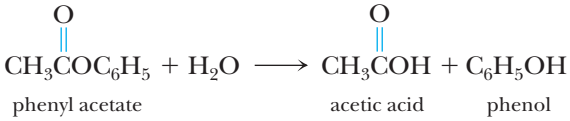
(See Section 14.1 and Examples 14.1–14.2.)

1. Give the relative rates of disappearance of reactants and formation of products for each of the following reactions.
   (a) $2\ O_3(g) \rightarrow 3\ O_2(g)$
   (b) $2\ HOF(g) \rightarrow 2\ HF(g) + O_2(g)$
2. Give the relative rates of disappearance of reactants and formation of products for each of the following reactions.
   (a) $2\ NO(g) + Br_2(g) \rightarrow 2\ NOBr(g)$
   (b) $N_2(g) + 3\ H_2(g) \rightarrow 2\ NH_3(g)$
3. In the reaction $2\ O_3(g) \rightarrow 3\ O_2(g)$, the rate of formation of O_2 is 1.5×10^{-3} mol/L·s. What is the rate of decomposition of O_3?
4. In the synthesis of ammonia, if $-\Delta[H_2]/\Delta t = 4.5 \times 10^{-4}$ mol/L·min, what is $\Delta[NH_3]/\Delta t$?

   $$N_2(g) + 3\ H_2(g) \rightarrow 2\ NH_3(g)$$

5. Experimental data are listed here for the reaction $A \rightarrow 2\ B$.

Time (s)	[B] (mol/L)
0.00	0.000
10.0	0.326
20.0	0.572
30.0	0.750
40.0	0.890



Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

(a) Prepare a graph from these data; connect the points with a smooth line; and calculate the rate of change of [B] for each 10-second interval from 0.0 to 40.0 seconds. Does the rate of change decrease from one time interval to the next? Suggest a reason for this result.

(b) How is the rate of change of [A] related to the rate of change of [B] in each time interval? Calculate the rate of change of [A] for the time interval from 10.0 to 20.0 seconds.

6. Phenyl acetate, an ester, reacts with water according to the equation

The data in the table were collected for this reaction at 5 °C.

Time (s)	[Phenyl acetate] (mol/L)
0	0.55
15.0	0.42
30.0	0.31
45.0	0.23
60.0	0.17
75.0	0.12
90.0	0.085

(a) Plot the phenyl acetate concentration versus time, and describe the shape of the curve observed.

(b) Calculate the rate of change of the phenyl acetate concentration during the period 15.0 seconds to 30.0 seconds and also during the period 75.0 seconds to 90.0 seconds. Why is one value smaller than the other?

Concentration and Rate Equations

(See Section 14.3 and Examples 14.3–14.4.)

7. Using the rate equation Rate = $k[A]^2[B]$, define the order of the reaction with respect to A and B. What is the total order of the reaction?

8. A reaction has the experimental rate equation Rate = $k[A]^2$. How will the rate change if the concentration of A is tripled? If the concentration of A is halved?

9. The reaction between ozone and nitrogen dioxide at 231 K is first-order in both $[NO_2]$ and $[O_3]$.

$$2\ NO_2(g) + O_3(g) \rightarrow N_2O_5(g) + O_2(g)$$

(a) Write the rate equation for the reaction.

(b) If the concentration of NO_2 is tripled (and $[O_3]$ is not changed), what is the change in the reaction rate?

(c) What is the effect on reaction rate if the concentration of O_3 is halved (with no change in $[NO_2]$)?

10. Nitrosyl bromide, NOBr, is formed from NO and Br_2:

$$2\ NO(g) + Br_2(g) \rightarrow 2\ NOBr(g)$$

Experiments show that this reaction is second-order in NO and first-order in Br_2.

(a) Write the rate equation for the reaction.

(b) How does the initial reaction rate change if the concentration of Br_2 is changed from 0.0022 mol/L to 0.0066 mol/L?

(c) What is the change in the initial rate if the concentration of NO is changed from 0.0024 mol/L to 0.0012 mol/L?

11. The data in the table are for the reaction of NO and O_2 at 660 K.

$$NO(g) + {}^1/_2\ O_2(g) \rightarrow NO_2(g)$$

Reactant Concentration (mol/L)		Rate of Disappearance of NO (mol/L · s)
[NO]	$[O_2]$	
0.010	0.010	2.5×10^{-5}
0.020	0.010	1.0×10^{-4}
0.010	0.020	5.0×10^{-5}

(a) Determine the order of the reaction for each reactant.

(b) Write the rate equation for the reaction.

(c) Calculate the rate constant.

(d) Calculate the rate (in mol/L·s) at the instant when [NO] = 0.015 mol/L and $[O_2]$ = 0.0050 mol/L.

(e) At the instant when NO is reacting at the rate 1.0×10^{-4} mol/L·s, what is the rate at which O_2 is reacting and NO_2 is forming?

Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

12. The reaction

$$2\ NO(g) + 2\ H_2(g) \rightarrow N_2(g) + 2\ H_2O(g)$$

was studied at 904 °C, and the data in the table were collected.

Reactant Concentration (mol/L)		Rate of Appearance of N_2 (mol/L · s)
[NO]	$[H_2]$	
0.420	0.122	0.136
0.210	0.122	0.0339
0.210	0.244	0.0678
0.105	0.488	0.0339

(a) Determine the order of the reaction for each reactant.

(b) Write the rate equation for the reaction.

(c) Calculate the rate constant for the reaction.

(d) Find the rate of appearance of N_2 at the instant when [NO] = 0.350 mol/L and $[H_2]$ = 0.205 mol/L.

13. Data for the reaction $NO(g) + {}^1/_2\ O_2(g) \rightarrow NO_2(g)$ are given (for a particular temperature) in the table.

Experiment	Concentration (mol/L) [NO]	Concentration (mol/L) $[O_2]$	Initial Rate (mol NO/L · h)
1	3.6×10^{-4}	5.2×10^{-3}	3.4×10^{-8}
2	3.6×10^{-4}	1.04×10^{-2}	6.8×10^{-8}
3	1.8×10^{-4}	1.04×10^{-2}	1.7×10^{-8}
4	1.8×10^{-4}	5.2×10^{-3}	?

(a) What is the rate law for this reaction?

(b) What is the rate constant for the reaction?

(c) What is the initial rate of the reaction in experiment 4?

14. Data for the following reaction are given in the table below.

$$CO(g) + NO_2(g) \rightarrow CO_2(g) + NO(g)$$

Experiment	Concentration (mol/L) [CO]	Concentration (mol/L) $[NO_2]$	Initial Rate (mol/L · h)
1	5.0×10^{-4}	0.36×10^{-4}	3.4×10^{-8}
2	5.0×10^{-4}	0.18×10^{-4}	1.7×10^{-8}
3	1.0×10^{-3}	0.36×10^{-4}	6.8×10^{-8}
4	1.5×10^{-3}	0.72×10^{-4}	?

(a) What is the rate law for this reaction?

(b) What is the rate constant for the reaction?

(c) What is the initial rate of the reaction in experiment 4?

Concentration–Time Relationships

(See Section 14.4 and Examples 14.5–14.7.)

15. The rate equation for the hydrolysis of sucrose to fructose and glucose

$$C_{12}H_{22}O_{11}(aq) + H_2O(\ell) \rightarrow 2\ C_6H_{12}O_6(aq)$$

is $-\Delta[\text{sucrose}]/\Delta t = k[C_{12}H_{22}O_{11}]$. After 27 minutes at 27 °C, the sucrose concentration decreased from 0.0146 M to 0.0132 M. Find the rate constant, k.

16. The decomposition of N_2O_5 in CCl_4 is a first-order reaction. If 2.56 mg of N_2O_5 is present initially and 2.50 mg is present after 4.26 minutes at 55 °C, what is the value of the rate constant, k?

17. The decomposition of SO_2Cl_2 is a first-order reaction:

$$SO_2Cl_2(g) \rightarrow SO_2(g) + Cl_2(g)$$

The rate constant for the reaction is 2.8×10^{-3} min^{-1} at 600 K. If the initial concentration of SO_2Cl_2 is 1.24×10^{-3} mol/L, how long will it take for the concentration to drop to 0.31×10^{-3} mol/L?

18. The conversion of cyclopropane to propene (Example 14.5) occurs with a first-order rate constant of 2.42×10^{-2} h^{-1}. How long will it take for the concentration of cyclopropane to decrease from an initial concentration of 0.080 mol/L to 0.020 mol/L?

19. Hydrogen peroxide, $H_2O_2(aq)$, decomposes to $H_2O(\ell)$ and $O_2(g)$ in a reaction that is first-order in H_2O_2 and has a rate constant $k = 1.06 \times 10^{-3}$ min^{-1} at a given temperature.

(a) How long will it take for 15% of a sample of H_2O_2 to decompose?

(b) How long will it take for 85% of the sample to decompose?

20. The decomposition of nitrogen dioxide at a high temperature

$$NO_2(g) \rightarrow NO(g) + {}^1/_2\ O_2(g)$$

is second-order in this reactant. The rate constant for this reaction is 3.40 L/mol·min. Determine the time needed for the concentration of NO_2 to decrease from 2.00 mol/L to 1.50 mol/L.

21. At 573 K, gaseous $NO_2(g)$ decomposes, forming $NO(g)$ and $O_2(g)$. If a vessel containing $NO_2(g)$ has an initial concentration of 1.9×10^{-2} mol/L, how long will it take for 75% of the $NO_2(g)$ to decompose? The decomposition of $NO_2(g)$ is second-order in the reactant and the rate constant for this reaction, at 573 K, is 1.1 L/mol·s.

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

22. The dimerization of butadiene, C_4H_6, to form 1,5-cyclooctadiene is a second-order process that occurs when the diene is heated. In an experiment, a sample of 0.0087 mol of C_4H_6 was heated in a 1.0-L flask. After 600. seconds, 21% of the butadiene had dimerized. Calculate the rate constant for this reaction.

23. The decomposition of ammonia on a metal surface to form N_2 and H_2 is a zero-order reaction (Figure 14.7c). At 873 °C, the value of the rate constant is 1.5×10^{-3} mol/L·s. How long it will take to completely decompose 0.16 g of NH_3 in a 1.0-L flask?

24. Hydrogen iodide decomposes when heated, forming $H_2(g)$ and $I_2(g)$. The rate law for this reaction is $-\Delta[HI]/\Delta t = k[HI]^2$. At 443 °C, $k = 30.$ L/mol · min. If the initial HI(g) concentration is 1.5×10^{-2} mol/L, what concentration of HI(g) will remain after 10. minutes?

Half-Life

(See Section 14.4 and Examples 14.8 and 14.9.)

25. The rate equation for the decomposition of N_2O_5 (giving NO_2 and O_2) is Rate $= k[N_2O_5]$. The value of k is 6.7×10^{-5} s^{-1} for the reaction at a particular temperature.

(a) Calculate the half-life of N_2O_5.

(b) How long does it take for the N_2O_5 concentration to drop to one tenth of its original value?

26. Gaseous azomethane, $CH_3N{=}NCH_3$, decomposes in a first-order reaction when heated:

$$CH_3N{=}NCH_3(g) \rightarrow N_2(g) + C_2H_6(g)$$

The rate constant for this reaction at 600 K is 0.0216 min^{-1}. If the initial quantity of azomethane in the flask is 2.00 g, how much remains after 0.0500 hour? What mass of N_2 is formed in this time?

27. The decomposition of SO_2Cl_2

$$SO_2Cl_2(g) \rightarrow SO_2(g) + Cl_2(g)$$

is first-order in SO_2Cl_2, and the reaction has a half-life of 245 minutes at 600 K. If you begin with 3.6×10^{-3} mol of SO_2Cl_2 in a 1.0-L flask, how long will it take for the amount of SO_2Cl_2 to decrease to 2.00×10^{-4} mol?

28. The compound $Xe(CF_3)_2$ decomposes in a first-order reaction to elemental Xe with a half-life of 30. minutes. If you place 7.50 mg of $Xe(CF_3)_2$ in a flask, how long must you wait until only 0.25 mg of $Xe(CF_3)_2$ remains?

29. The radioactive isotope ^{64}Cu is used in the form of copper(II) acetate to study Wilson's disease. The isotope has a half-life of 12.70 hours. What fraction of radioactive copper(II) acetate remains after 64 hours?

30. Radioactive gold-198 is used in the diagnosis of liver problems. The half-life of this isotope is 2.7 days. If you begin with a 5.6-mg sample of the isotope, how much of this sample remains after 1.0 day?

Graphical Analysis: Rate Equations and *k*

(See Section 14.4.)

31. Data for the decomposition of dinitrogen monoxide

$$N_2O(g) \rightarrow N_2(g) + \tfrac{1}{2}\, O_2(g)$$

on a gold surface at 900 °C are given below. Verify that the reaction is first-order by preparing a graph of $\ln[N_2O]$ versus time. Derive the rate constant from the slope of the line in this graph. Using the rate law and value of k, determine the decomposition rate at 900 °C when $[N_2O] = 0.035$ mol/L.

Time (min)	$[N_2O]$ (mol/L)
15.0	0.0835
30.0	0.0680
80.0	0.0350
120.0	0.0220

32. Ammonia decomposes when heated according to the equation

$$NH_3(g) \rightarrow NH_2(g) + H(g)$$

The data in the table for this reaction were collected at a high temperature.

Time (h)	$[NH_3]$ (mol/L)
0	8.00×10^{-7}
25	6.75×10^{-7}
50	5.84×10^{-7}
75	5.15×10^{-7}

Plot ln $[NH_3]$ versus time and $1/[NH_3]$ versus time. What is the order of this reaction with respect to NH_3? Find the rate constant for the reaction from the slope.

33. Gaseous NO_2 decomposes at 573 K.

$$NO_2(g) \rightarrow NO(g) + \tfrac{1}{2}\, O_2(g)$$

The concentration of NO_2 was measured as a function of time. A graph of $1/[NO_2]$ versus time gives a straight line with a slope of 1.1 L/mol·s. What is the rate law for this reaction? What is the rate constant?

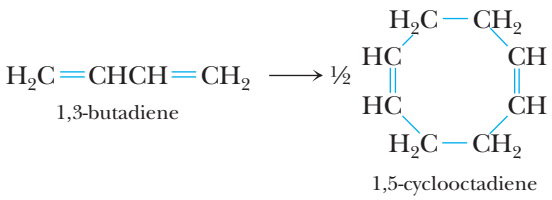
34. The decomposition of HOF occurs at 25 °C.



$$HOF(g) \rightarrow HF(g) + \tfrac{1}{2}\, O_2(g)$$

Using the data in the table below, determine the rate law, and then calculate the rate constant.

[HOF] (mol/L)	Time (min)
0.850	0
0.810	2.00
0.754	5.00
0.526	20.0
0.243	50.0

35. For the reaction $C_2F_4 \rightarrow \frac{1}{2}\, C_4F_8$, a graph of $1/[C_2F_4]$ versus time gives a straight line with a slope of +0.04 L/mol·s. What is the rate law for this reaction?

36. Butadiene, $C_4H_6(g)$, dimerizes when heated, forming 1,5-cyclooctadiene, C_8H_{12}. The data in the table were collected.

$[C_4H_6]$ (mol/L)	Time (s)
1.0×10^{-2}	0
8.7×10^{-3}	200.
7.7×10^{-3}	500.
6.9×10^{-3}	800.
5.8×10^{-3}	1200.

(a) Use a graphical method to verify that this is a second-order reaction.

(b) Calculate the rate constant for the reaction.

Kinetics and Energy

(See Section 14.5 and Examples 14.10 and 14.11.)

37. Calculate the activation energy, E_a, for the reaction

$$2\ N_2O_5(g) \rightarrow 4\ NO_2(g) + O_2(g)$$

from the observed rate constants: k at 25 °C = $3.46 \times 10^{-5}\ s^{-1}$ and k at 55 °C = $1.5 \times 10^{-3}\ s^{-1}$.

38. If the rate constant for a reaction triples when the temperature rises from 3.00×10^2 K to 3.10×10^2 K, what is the activation energy of the reaction?

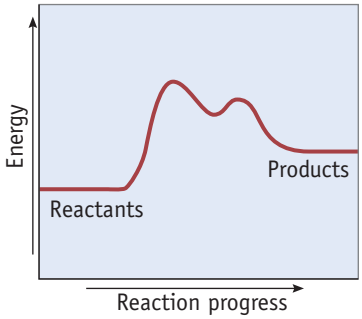
39. When heated to a high temperature, cyclobutane, C_4H_8, decomposes to ethylene:

$$C_4H_8(g) \rightarrow 2\ C_2H_4(g)$$

The activation energy, E_a, for this reaction is 260 kJ/mol. At 800 K, the rate constant k = $0.0315\ s^{-1}$. Determine the value of k at 850 K.

40. When heated, cyclopropane is converted to propene (Example 14.5). Rate constants for this reaction at 470 °C and 510 °C are k = $1.10 \times 10^{-4}\ s^{-1}$ and $k = 1.02 \times 10^{-3}\ s^{-1}$, respectively. Determine the activation energy, E_a, from these data.

41. The reaction of H_2 molecules with F atoms



$$H_2(g) + F(g) \rightarrow HF(g) + H(g)$$

has an activation energy of 8 kJ/mol and an enthalpy change of −133 kJ/mol. Draw a diagram similar to Figure 14.11 for this process. Indicate the activation energy and enthalpy change on this diagram.

42. Answer the following questions based on the diagram below.

(a) Is the reaction exothermic or endothermic?

(b) Does the reaction occur in more than one step? If so, how many?

Enzymes

(See Section 14.6.)

43. Compare the lock-and-key and induced-fit models for substrate binding to an enzyme.

44. To which species should an enzyme bind best: the substrate, transition state, or product of a reaction?

45. According to the Michaelis–Menten model, if 1/Rate is plotted versus 1/[S], the intercept of the plot (when 1/[S] = 0) is $1/Rate_{max}$. Using the data below at a given temperature, for a given enzyme and its substrate (S), calculate the maximum rate of the reaction, $Rate_{max}$.

[S], mol/L	Rate, mmol/min
2.500	0.588
1.00	0.500
0.714	0.417
0.526	0.370
0.250	0.256

46. The enzyme carbonic anhydrase catalyzes the transformation of carbon dioxide into hydrogen carbonate ions. This reaction was studied by H. DeVoe and G. B. Kistiakowsky (*Journal of the American Chemical Society*, Vol. 83, p. 274, 1961) and found to obey the Michaelis-Menten model. Use the data below at a given temperature to calculate the maximum rate of the reaction, $Rate_{max}$. See Question 45 for the graphical method to use.

$[CO_2]$ (mol/L)	Reaction Rate (mol/L · s)
1.3×10^{-3}	2.8×10^{-5}
2.5×10^{-3}	5.0×10^{-5}
5.0×10^{-3}	8.3×10^{-5}
20.0×10^{-3}	17×10^{-5}

Reaction Mechanisms

(See Section 14.7 and Examples 14.12–14.14.)

47. What is the rate law for each of the following elementary reactions?

(a) $NO(g) + NO_3(g) \rightarrow 2\ NO_2(g)$

(b) $Cl(g) + H_2(g) \rightarrow HCl(g) + H(g)$

(c) $(CH_3)_3CBr(aq) \rightarrow (CH_3)_3C^+(aq) + Br^-(aq)$

48. What is the rate law for each of the following elementary reactions?

(a) $Cl(g) + ICl(g) \rightarrow I(g) + Cl_2(g)$

(b) $O(g) + O_3(g) \rightarrow 2\ O_2(g)$

(c) $2\ NO_2(g) \rightarrow N_2O_4(g)$

49. Ozone, O_3, in the Earth's upper atmosphere decomposes according to the equation

$$2\ O_3(g) \rightarrow 3\ O_2(g)$$

The mechanism of the reaction is thought to proceed through an initial fast, reversible step followed by a slow, second step.

Step 1: Fast, reversible

$$O_3(g) \rightleftharpoons O_2(g) + O(g)$$

Step 2: Slow

$$O_3(g) + O(g) \rightarrow 2\ O_2(g)$$

(a) Which of the steps is rate-determining?

(b) Write the rate equation for the rate-determining step.

50. The reaction of $NO_2(g)$ and $CO(g)$ is thought to occur in two steps to give NO and CO_2:

Step 1: Slow

$$NO_2(g) + NO_2(g) \rightarrow NO(g) + NO_3(g)$$

Step 2: Fast

$$NO_3(g) + CO(g) \rightarrow NO_2(g) + CO_2(g)$$

(a) Show that the elementary steps add up to give the overall, stoichiometric equation.

(b) What is the molecularity of each step?

(c) For this mechanism to be consistent with kinetic data, what must be the experimental rate equation?

(d) Identify any intermediates in this reaction.

51. A proposed mechanism for the reaction of NO_2 and CO is

Step 1: Slow, endothermic

$$2\ NO_2(g) \rightarrow NO(g) + NO_3(g)$$

Step 2: Fast, exothermic

$$NO_3(g) + CO(g) \rightarrow NO_2(g) + CO_2(g)$$

Overall Reaction: Exothermic

$$NO_2(g) + CO(g) \rightarrow NO(g) + CO_2(g)$$

(a) Identify each of the following as a reactant, product, or intermediate: $NO_2(g)$, $CO(g)$, $NO_3(g)$, $CO_2(g)$, $NO(g)$.

(b) Draw a reaction coordinate diagram for this reaction. Indicate on this drawing the activation energy for each step and the overall enthalpy change.

52. The mechanism for the reaction of CH_3OH and HBr is believed to involve two steps. The overall reaction is exothermic.

Step 1: Fast, endothermic

$$CH_3OH + H^+ \rightleftharpoons CH_3OH_2^+$$

Step 2: Slow

$$CH_3OH_2^+ + Br^- \rightarrow CH_3Br + H_2O$$

(a) Write an equation for the overall reaction.

(b) Draw a reaction coordinate diagram for this reaction.

(c) Show that the rate law for this reaction is $Rate = k[CH_3OH][H^+][Br^-]$.

General Questions

These questions are not designated as to type or location in the chapter. They may combine several concepts.

53. A reaction has the following experimental rate equation: Rate = $k[A]^2[B]$. If the concentration of A is doubled and the concentration of B is halved, what happens to the reaction rate?

54. For a first-order reaction, what fraction of reactant remains after five half-lives have elapsed?

55. To determine the concentration dependence of the rate of the reaction

$$H_2PO_3^-(aq) + OH^-(aq) \rightarrow HPO_3^{2-}(aq) + H_2O(\ell)$$

you might measure $[OH^-]$ as a function of time using a pH meter. (To do so, you would set up conditions under which $[H_2PO_3^-]$ remains constant by using a large excess of this reactant.) How would you prove a second-order rate dependence for $[OH^-]$?

56. Data for the following reaction are given in the table.

$$2\ NO(g) + Br_2(g) \rightarrow 2\ NOBr(g)$$

Experiment	[NO] (M)	$[Br_2]$ (M)	Initial Rate (mol/L · s)
1	1.0×10^{-2}	2.0×10^{-2}	2.4×10^{-2}
2	4.0×10^{-2}	2.0×10^{-2}	0.384
3	1.0×10^{-2}	5.0×10^{-2}	6.0×10^{-2}

What is the order of the reaction with respect to [NO] and $[Br_2]$, and what is the overall order of the reaction?

57. Formic acid decomposes at 550 °C according to the equation

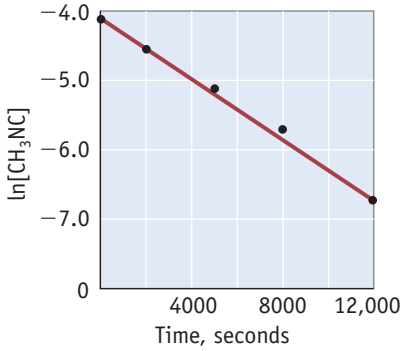
$$HCO_2H(g) \rightarrow CO_2(g) + H_2(g)$$

The reaction follows first-order kinetics. In an experiment, it is determined that 75% of a sample of HCO_2H has decomposed in 72 seconds. Determine $t_{1/2}$ for this reaction.

58. Isomerization of CH_3NC occurs slowly when CH_3NC is heated.

$$CH_3NC(g) \rightarrow CH_3CN(g)$$

To study the rate of this reaction at 488 K, data on $[CH_3NC]$ were collected at various times. Analysis led to the following graph.



(a) What is the rate law for this reaction?

(b) What is the equation for the straight line in this graph?

(c) Calculate the rate constant for this reaction.

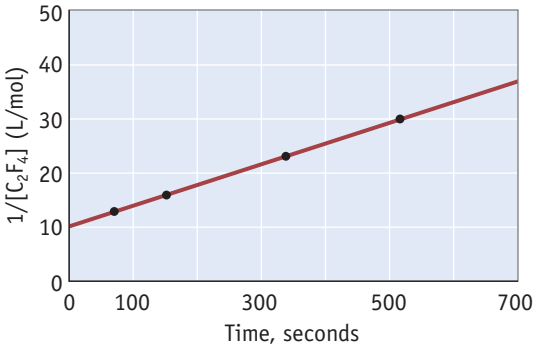
(d) How long does it take for half of the sample to isomerize?

(e) What is the concentration of CH_3NC after 1.0×10^4 s?

59. When heated, tetrafluoroethylene dimerizes to form octafluorocyclobutane.

$$C_2F_4(g) \rightarrow {}^1/_2\ C_4F_8(g)$$

To determine the rate of this reaction at 488 K, the data in the table were collected. Analysis was done graphically, as shown below:



$[C_2F_4]$ (M)	Time (s)
0.100	0
0.080	56
0.060	150.
0.040	335
0.030	520.

(a) What is the rate law for this reaction?

(b) What is the value of the rate constant?

(c) What is the concentration of C_2F_4 after 600 s?

(d) How long will it take until the reaction is 90% complete?

60. Data in the table were collected at 540 K for the following reaction:

$$CO(g) + NO_2(g) \rightarrow CO_2(g) + NO(g)$$

Initial Concentration (mol/L)		Initial Rate (mol/L · h)
[CO]	[NO_2]	
5.1×10^{-4}	0.35×10^{-4}	3.4×10^{-8}
5.1×10^{-4}	0.70×10^{-4}	6.8×10^{-8}
5.1×10^{-4}	0.18×10^{-4}	1.7×10^{-8}
1.0×10^{-3}	0.35×10^{-4}	6.8×10^{-8}
1.5×10^{-3}	0.35×10^{-4}	10.2×10^{-8}

Using the data in the table:

(a) Determine the reaction order with respect to each reactant.

(b) Derive the rate equation.

(c) Calculate the rate constant, giving the correct units for k.

61. Ammonium cyanate, NH_4NCO, rearranges in water to give urea, $(NH_2)_2CO$.

$$NH_4NCO(aq) \rightarrow (NH_2)_2CO(aq)$$

Time (min)	[NH_4NCO] (mol/L)
0	0.458
4.50×10^1	0.370
1.07×10^2	0.292
2.30×10^2	0.212
6.00×10^2	0.114

Using the data in the table:

(a) Decide whether the reaction is first-order or second-order.

(b) Calculate k for this reaction.

(c) Calculate the half-life of ammonium cyanate under these conditions.

(d) Calculate the concentration of NH_4NCO after 12.0 hours.

62. NO_x, a mixture of NO and NO_2, plays an essential role in the production of pollutants found in photochemical smog. The NO_x in the atmosphere is slowly broken down to N_2 and O_2 in a first-order reaction. The average half-life of NO_x in the smokestack emissions in a large city during daylight is 3.9 hours.

(a) Starting with 1.50 mg in an experiment, what quantity of NO_x remains after 5.25 hours?

(b) How many hours of daylight must have elapsed to decrease 1.50 mg of NO_x to 2.50×10^{-6} mg?

63. At temperatures below 500 K, the reaction between carbon monoxide and nitrogen dioxide

$$CO(g) + NO_2(g) \rightarrow CO_2(g) + NO(g)$$

has the following rate equation: Rate $= k[NO_2]^2$. Which of the three mechanisms suggested here best agrees with the experimentally observed rate equation?

Mechanism 1 — Single, elementary step

$$NO_2 + CO \rightarrow CO_2 + NO$$

Mechanism 2 — Two steps

Slow $\quad NO_2 + NO_2 \rightarrow NO_3 + NO$

Fast $\quad NO_3 + CO \rightarrow NO_2 + CO_2$

Mechanism 3 — Two steps

Slow $\quad NO_2 \rightarrow NO + O$

Fast $\quad CO + O \rightarrow CO_2$

64. ▲ Nitryl fluoride can be made by treating nitrogen dioxide with fluorine:

$$2\ NO_2(g) + F_2(g) \rightarrow 2\ NO_2F(g)$$

Use the rate data in the table to do the following:

(a) Write the rate equation for the reaction.

(b) Indicate the order of reaction with respect to each component of the reaction.

(c) Find the numerical value of the rate constant, k.

Experiment	Initial Concentrations (mol/L)			Initial Rate (mol F_2/L · s)
	[NO_2]	[F_2]	[NO_2F]	
1	0.001	0.005	0.001	2.0×10^{-4}
2	0.002	0.005	0.001	4.0×10^{-4}
3	0.006	0.002	0.001	4.8×10^{-4}
4	0.006	0.004	0.001	9.6×10^{-4}
5	0.001	0.001	0.001	4.0×10^{-5}
6	0.001	0.001	0.002	4.0×10^{-5}

65. The decomposition of dinitrogen pentaoxide

$$N_2O_5(g) \rightarrow 2\ NO_2(g) + {}^1/_2\ O_2(g)$$

has the following rate equation: Rate $= k[N_2O_5]$. It has been found experimentally that the decomposition is 20.5% complete in 13.0 hours at 298 K. Calculate the rate constant and the half-life at 298 K.

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

66. The data in the table give the temperature dependence of the rate constant for the reaction $N_2O_5(g) \rightarrow 2\ NO_2(g) + {}^1/_2\ O_2(g)$. Plot these data in the appropriate way to derive the activation energy for the reaction.

T(K)	k (s^{-1})
338	4.87×10^{-3}
328	1.50×10^{-3}
318	4.98×10^{-4}
308	1.35×10^{-4}
298	3.46×10^{-5}
273	7.87×10^{-7}

67. The decomposition of gaseous dimethyl ether at ordinary pressures is first-order. Its half-life is 25.0 minutes at 500 °C:

$$CH_3OCH_3(g) \rightarrow CH_4(g) + CO(g) + H_2(g)$$

(a) Starting with 8.00 g of dimethyl ether, what mass remains (in grams) after 125 minutes and after 145 minutes?

(b) Calculate the time in minutes required to decrease 7.60 ng (nanograms) to 2.25 ng.

(c) What fraction of the original dimethyl ether remains after 150 minutes?

68. The decomposition of phosphine, PH_3, proceeds according to the equation

$$PH_3(g) \rightarrow {}^1/_4\ P_4(g) + {}^3/_2\ H_2(g)$$

It is found that the reaction has the following rate equation: Rate $= k[PH_3]$. The half-life of PH_3 is 37.9 seconds at 120 °C.

(a) How much time is required for three fourths of the PH_3 to decompose?

(b) What fraction of the original sample of PH_3 remains after 1.00 minute?

69. The thermal decomposition of diacetylene, C_4H_2, was studied at 950 °C. Use the following data (K. C. Hou and H. B. Palmer, *Journal of Physical Chemistry*, Vol. 69, p. 858, 1965) to determine the order of the reaction.

Time (ms)	Concentration of C_4H_2 (mol/L)
0	1.02×10^{-4}
50.	5.05×10^{-5}
100.	2.59×10^{-5}
150.	2.01×10^{-5}
200.	1.44×10^{-5}
250.	1.30×10^{-5}

70. Kinetic experiments were conducted to determine the value of the rate constant, k, for the thermal decomposition of diacetylene, C_4H_2, at temperatures below 1100 K (K. C. Hou and H. B. Palmer, *Journal of Physical Chemistry*, Vol. 69, p. 858, 1965). Calculate E_a for this reaction from a plot of ln k versus 1/T.

T(K)	k(L mol^{-1} min^{-1})
973	10.6
1023	29.8
1073	71.1

71. The ozone in the Earth's ozone layer decomposes according to the equation

$$2\ O_3(g) \rightarrow 3\ O_2(g)$$

The mechanism of the reaction is thought to proceed through an initial fast equilibrium and a slow step:

Step 1: Fast, reversible $\quad O_3(g) \rightleftharpoons O_2(g) + O(g)$

Step 2: Slow $\quad O_3(g) + O(g) \rightarrow 2\ O_2(g)$

Show that the mechanism agrees with this experimental rate law:

$$\text{Rate} = -(1/2)\Delta[O_3]/\Delta t = k[O_3]^2/[O_2].$$

72. Hundreds of different reactions occur in the stratosphere, among them reactions that destroy the Earth's ozone layer. The table below lists several (second-order) reactions of Cl atoms with ozone and organic compounds; each is given with its rate constant.

Reaction	Rate Constant (298 K, cm^3/molecule · s)
(a) $Cl + O_3 \rightarrow ClO + O_2$	1.2×10^{-11}
(b) $Cl + CH_4 \rightarrow HCl + CH_3$	1.0×10^{-13}
(c) $Cl + C_3H_8 \rightarrow HCl + C_3H_7$	1.4×10^{-10}
(d) $Cl + CH_2FCl \rightarrow HCl + CHFCl$	3.0×10^{-18}

For equal concentrations of Cl and the other reactant, which is the slowest reaction? Which is the fastest reaction?

73. Data for the reaction

$$[Mn(CO)_5(CH_3CN)]^+ + NC_5H_5 \longrightarrow [Mn(CO)_5(NC_5H_5)]^+ + CH_3CN$$

are given in the table. Calculate E_a from a plot of ln k versus $1/T$.

T(K)	k(min^{-1})
298	0.0409
308	0.0818
318	0.157

74. The gas-phase reaction

$$2\ N_2O_5(g) \rightarrow 4\ NO_2(g) + O_2(g)$$

has an activation energy of 103 kJ/mol, and the rate constant is 0.0900 min^{-1} at 328.0 K. Find the rate constant at 318.0 K.

75. A reaction that occurs in our atmosphere is the oxidation of NO to the brown gas NO_2.

$$2\ NO(g) + O_2(g) \rightarrow 2\ NO_2(g)$$

The mechanism of the reaction is thought to be

Step 1: $2\ NO(g) \rightleftharpoons N_2O_2(g)$ rapidly established equilibrium

Step 2: $N_2O_2(g) + O_2(g) \rightarrow 2\ NO_2(g)$ slow

Which is the rate determining step? Is there an intermediate in the reaction? If this is the correct mechanism for this reaction, what is the experimentally determined rate law?

76. The decomposition of SO_2Cl_2 to SO_2 and Cl_2 is first-order in SO_2Cl_2.

$$SO_2Cl_2(g) \rightarrow SO_2(g) + Cl_2(g)$$

$$\text{Rate} = k[SO_2Cl_2] \text{ where } k = 0.17/\text{hr}$$

(a) What is the rate of decomposition when $[SO_2Cl_2] = 0.010$ M?

(b) What is the half-life of the reaction?

(c) If the initial pressure of SO_2Cl_2 in a flask is 0.050 atm, what is the pressure of all gases (i.e., the total pressure) in the flask after the reaction has proceeded for one half-life?

77. The decomposition of nitrogen dioxide at a high temperature

$$NO_2(g) \rightarrow NO(g) + \tfrac{1}{2}\ O_2(g)$$

is second-order in this reactant.

(a) Determine the rate constant for this reaction if it takes 1.76 min for the concentration of NO_2 to fall from 0.250 mol/L to 0.100 mol/L.

(b) If the chemical equation is written as

$$2\ NO_2(g) \rightarrow 2\ NO(g) + O_2(g)$$

what is the value of the rate constant?

78. Hydrogen peroxide, $H_2O_2(aq)$, decomposes to $H_2O(\ell)$ and $O_2(g)$

$$2\ H_2O_2(aq) \rightarrow 2\ H_2O(\ell) + O_2(g)$$

At a particular temperature, the following data were collected for the initial rate of appearance O_2.

$[H_2O_2]$ (mol/L)	Initial Reaction Rate (mol O_2/L · min)
0.0500	5.30×10^{-5}
0.100	1.06×10^{-4}
0.200	2.12×10^{-4}

(a) What is the rate law for this reaction?

(b) Calculate the value of the rate constant for this reaction.

(c) If the chemical equation for this reaction is written as

$$H_2O_2(aq) \rightarrow H_2O(\ell) + \tfrac{1}{2}\ O_2(g)$$

what is the value of the rate constant?

79. ▲ Egg protein albumin is precipitated when an egg is cooked in boiling (100 °C) water. E_a for this first-order reaction is 52.0 kJ/mol. Estimate the time to prepare a 3-minute egg at an altitude at which water boils at 90 °C.

80. ▲ The compound 1,3-butadiene (C_4H_6) forms 1,5-cyclooctadiene, C_8H_{12} at higher temperatures.

$$C_4H_6(g) \rightarrow \tfrac{1}{2}\ C_8H_{12}(g)$$

Use the following data to determine the order of the reaction and the rate constant, k. (Note that the total pressure is the pressure of the unreacted C_4H_6 at any time plus the pressure of the C_8H_{12}.)

Time (min)	Total Pressure (mm Hg)
0	436
3.5	428
11.5	413
18.3	401
25.0	391
32.0	382
41.2	371

81. ▲ Hypofluorous acid, HOF, is very unstable, decomposing in a first-order reaction to give HF and O_2, with a half-life of 30. minutes at room temperature:

$$HOF(g) \rightarrow HF(g) + \tfrac{1}{2}\ O_2(g)$$

If the partial pressure of HOF in a 1.00-L flask is initially 1.00×10^2 mm Hg at 25 °C, what are the total pressure in the flask and the partial pressure of HOF after exactly 30 minutes? After 45 minutes?

82. ▲ We know that the decomposition of SO_2Cl_2 is first-order in SO_2Cl_2,

$$SO_2Cl_2(g) \rightarrow SO_2(g) + Cl_2(g)$$

with a half-life of 245 minutes at 600 K. If you begin with a partial pressure of SO_2Cl_2 of 25 mm Hg in a 1.0-L flask, what is the partial pressure of each reactant and product after 245 minutes? What is the partial pressure of each reactant and product after 12 hours?

83. ▲ Nitramide, NO_2NH_2, decomposes slowly in aqueous solution according to the following reaction:

$$NO_2NH_2(aq) \rightarrow N_2O(g) + H_2O(\ell)$$

The reaction follows the experimental rate law

$$\text{Rate} = \frac{k[NO_2NH_2]}{[H_3O^+]}$$

(a) What is the apparent order of the reaction in a pH buffered solution? (In a pH buffered solution, the concentration of H_3O^+ is a constant.)

(b) Which of the following mechanisms is the most appropriate for the interpretation of this rate law? Explain. (Note that when writing the expression for K, the equilibrium constant, $[H_2O]$ is not involved. See Chapter 15.)

Mechanism 1

$$NO_2NH_2 \xrightarrow{k_1} N_2O + H_2O$$

Mechanism 2

$$NO_2NH_2 + H_3O^+ \underset{k_2'}{\overset{k_2}{\rightleftharpoons}} NO_2NH_3^+ + H_2O \quad \text{(rapid equilibrium)}$$

$$NO_2NH_3^+ \xrightarrow{k_3} N_2O + H_3O^+ \quad \text{(rate-limiting step)}$$

Mechanism 3

$$NO_2NH_2 + H_2O \underset{k_4'}{\overset{k_4}{\rightleftharpoons}} NO_2NH^- + H_3O^+ \quad \text{(rapid equilibrium)}$$

$$NO_2NH^- \xrightarrow{k_5} N_2O + OH^- \quad \text{(rate-limiting step)}$$

$$H_3O^+ + OH^- \xrightarrow{k_6} 2\ H_2O \quad \text{(very fast reaction)}$$

(c) Show the relationship between the experimentally observed rate constant, k, and the rate constants in the selected mechanism.

(d) Based on the experimental rate law, will the reaction rate increase or decrease if the pH of the solution is increased?

84. Many biochemical reactions are catalyzed by acids. A typical mechanism consistent with the experimental results (in which HA is the acid and X is the reactant) is

Step 1: Fast, reversible: $HA \rightleftharpoons H^+ + A^-$

Step 2: Fast, reversible: $X + H^+ \rightleftharpoons XH^+$

Step 3: Slow $XH^+ \rightarrow$ products

What rate law is derived from this mechanism? What is the order of the reaction with respect to HA? How would doubling the concentration of HA affect the reaction?

In the Laboratory

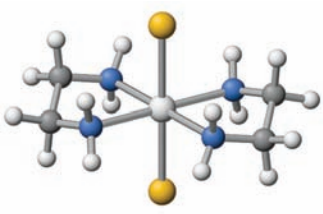
85. The color change accompanying the reaction of phenolphthalein with strong base is illustrated below. The change in concentration of the dye can be followed by spectrophotometry (Section 4.9), and some data collected by that approach are given below. The initial concentrations were [phenolphthalein] = 0.0050 mol/L and $[OH^-]$ = 0.61 mol/L. (Data are taken from review materials for kinetics at chemed.chem.purdue.edu.) (For more details on this reaction see L. Nicholson, *Journal of Chemical Education*, Vol. 66, p. 725, 1989.)

Fading of the color of phenolphthalein with time
(elapsed time about 3 minutes)

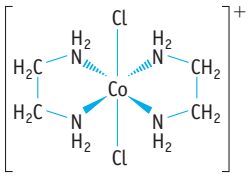
© Cengage Learning/Charles D. Winters

Time (s)	Concentration of Phenolphthalein (mol/L)
0.00	0.0050
10.5	0.0045
22.3	0.0040
35.7	0.0035
51.1	0.0030
69.3	0.0025
91.6	0.0020
120.4	0.0015
160.9	0.0010
230.3	0.00050
299.6	0.00025

(a) Plot the data above as [phenolphthalein] versus time, and determine the average rate from $t = 0$ to $t = 15$ seconds and from $t = 100$ seconds to $t = 125$ seconds. Does the rate change? If so, why?



(b) Use a graphical method to determine the order of the reaction with respect to phenolphthalein. Write the rate law, and determine the rate constant.



(c) What is the half-life for the reaction?

86. ▲ You want to study the hydrolysis of the beautiful green, cobalt-based complex called *trans*-dichlorobis-(ethylenediamine)cobalt(III) ion,

In this hydrolysis reaction, the green complex ion *trans*–$[Co(en)_2Cl_2]^+$ forms the red complex ion $[Co(en)_2(H_2O)Cl]^{2+}$ as a Cl^- ion is replaced with a water molecule on the Co^{3+} ion (en = $H_2NCH_2CH_2NH_2$).

$$\underset{\text{green}}{trans\text{–}[Co(en)_2Cl_2]^+(aq)} + H_2O(\ell) \rightarrow \underset{\text{red}}{[Co(en)_2(H_2O)Cl]^{2+}(aq)} + Cl^-(aq)$$

The reaction progress is followed by observing the color of the solution. The original solution is green, and the final solution is red, but at some intermediate stage when both the reactant and product are present, the solution is gray.

original solution

intermediate solution

final solution

Photos: © Cengage Learning/Charles D. Winters

Changes in color with time as Cl^- ion is replaced by H_2O in a cobalt(III) complex. The shape in the middle of the beaker is a vortex that arises because the solutions are being stirred using a magnetic stirring bar in the bottom of the beaker.

Reactions such as this have been studied extensively, and experiments suggest that the initial, slow step in the reaction is the breaking of the Co—Cl bond to give a five-coordinate intermediate. The intermediate is then attacked rapidly by water.

Slow: $trans\text{–}[Co(en)_2Cl_2]^+(aq) \rightarrow [Co(en)_2Cl]^{2+}(aq) + Cl^-(aq)$

Fast: $[Co(en)_2Cl]^{2+}(aq) + H_2O(\ell) \rightarrow [Co(en)_2(H_2O)Cl]^{2+}(aq)$

(a) Based on the reaction mechanism, what is the predicted rate law?

(b) As the reaction proceeds, the color changes from green to red with an intermediate stage where the color is gray. The gray color is reached at the same time, no matter what the concentration of the green starting material (at the same temperature). How does this show the reaction is first-order in the green form? Explain.

(c) The activation energy for a reaction can be found by plotting ln k versus $1/T$. However, here we do not need to measure k directly. Instead, because $k = -(1/t)\ln([R]/[R]_0)$, the time needed to achieve the gray color is a measure of k. Use the data below to find the activation energy.

Temperature (° C)	Time Needed to Achieve Gray Color (for the Same Initial Concentration)
56	156 s
60	114 s
65	88 s
75	47 s

87. The enzyme chymotrypsin catalyzes the hydrolysis of a peptide containing phenylalanine. Using the data below at a given temperature, calculate the maximum rate of the reaction, $Rate_{max}$.

Peptide Concentration (mol/L)	Reaction Rate (mol/L · min)
2.5×10^{-4}	2.2×10^{-6}
5.0×10^{-4}	3.8×10^{-6}
10.0×10^{-4}	5.9×10^{-6}
15.0×10^{-4}	7.1×10^{-6}

88. ▲ The substitution of CO in $Ni(CO)_4$ by another molecule L [where L is an electron-pair donor such as $P(CH_3)_3$] was studied some years ago and led to an understanding of some of the general principles that govern the chemistry of compounds having metal–CO bonds. (See J. P. Day, F. Basolo, and R. G. Pearson: *Journal of the American Chemical Society*, Vol. 90, p. 6927, 1968.) A detailed study of the kinetics of the reaction led to the following mechanism:

Slow: $Ni(CO)_4 \rightarrow Ni(CO)_3 + CO$

Fast: $Ni(CO)_3 + L \rightarrow Ni(CO)_3L$

(a) What is the molecularity of each of the elementary reactions?

(b) Doubling the concentration of $Ni(CO)_4$ increased the reaction rate by a factor of 2. Doubling the concentration of L had no effect on the reaction rate. Based on this information, write the rate equation for the reaction. Does this agree with the mechanism described?

(c) The experimental rate constant for the reaction, when $L = P(C_6H_5)_3$, is $9.3 \times 10^{-3}\ s^{-1}$ at 20 °C. If the initial concentration of $Ni(CO)_4$ is 0.025 M, what is the concentration of the product after 5.0 minutes?

89. ▲ The oxidation of iodide ion by the hypochlorite ion in the presence of hydroxide ions

$$I^-(aq) + ClO^-(aq) \rightarrow IO^-(aq) + Cl^-(aq)$$

was studied at 25 °C, and the following initial rates data (Y. Chia and R. E. Connick, *Journal of Physical Chemistry*, Vol. 63, p. 1518, 1959) were collected:

	Initial Concentrations (mol/L)			Initial Rate
Experiment	$[ClO^-]$	$[I^-]$	$[OH^-]$	(mol IO^-/L · s)
1	4.0×10^{-3}	2.0×10^{-3}	1.0	4.8×10^{-4}
2	2.0×10^{-3}	4.0×10^{-3}	1.0	5.0×10^{-4}
3	2.0×10^{-3}	2.0×10^{-3}	1.0	2.4×10^{-4}
4	2.0×10^{-3}	2.0×10^{-3}	0.50	4.6×10^{-4}

(a) Determine the rate law for this reaction.

(b) One mechanism that has been proposed for this reaction is the following:

Step 1: $ClO^- + H_2O \rightleftharpoons HOCl + OH^-$ fast, reversible

Step 2: $I^- + HOCl \rightarrow HOI + Cl^-$ slow

Step 3: $HOI + OH^- \rightarrow IO^- + H_2O$ fast

Show that the rate law predicted by this mechanism matches the experimentally determined rate law in part a. (Note that when writing the expression for *K*, the equilibrium constant, $[H_2O]$ is not involved. See Chapter 15.)

90. The acid-catalyzed iodination of acetone

$$CH_3COCH_3(aq) + I_2(aq) \rightarrow CH_3COCH_2I(aq) + HI(aq)$$

is a common laboratory experiment used in general chemistry courses to teach the method of initial rates. The reaction is followed spectrophotometrically by the disappearance of the color of iodine in the solution. The following data (J. P. Birk and D. L. Walters, *Journal of Chemical Education*, Vol. 69, p. 585, 1992) were collected at 23 °C for this reaction.

	Initial Concentrations (mol/L)			Initial Rate
Experiment	$[CH_3COCH_3]$	$[H^+]$	$[I_2]$	(mol I_2/L · s)
1	1.33	0.162	0.00665	8.1×10^{-6}
2	1.33	0.323	0.00665	1.7×10^{-5}
3	0.667	0.323	0.00665	7.6×10^{-6}
4	0.333	0.323	0.00665	3.8×10^{-6}
5	0.333	0.323	0.00332	3.6×10^{-6}

Determine the rate law for this reaction.

Summary and Conceptual Questions

The following questions may use concepts from this and previous chapters.

91. Hydrogenation reactions, processes wherein H_2 is added to a molecule, are usually catalyzed. An excellent catalyst is a very finely divided metal suspended in the reaction solvent. Explain why finely divided rhodium, for example, is a much more efficient catalyst than a small block of the metal.

92. ▲ Suppose you have 1000 blocks, each of which is 1.0 cm on a side. If all 1000 of these blocks are stacked to give a cube that is 10. cm on a side, what fraction of the 1000 blocks have at least one surface on the outside surface of the cube? Next, divide the 1000 blocks into eight equal piles of blocks and form them into eight cubes, 5.0 cm on a side. What fraction of the blocks now have at least one surface on the outside of the cubes? How does this mathematical model pertain to Study Question 91?

93. The following statements relate to the reaction for the formation of HI:

$$H_2(g) + I_2(g) \rightarrow 2\ HI(g) \qquad \text{Rate} = k[H_2][I_2]$$

Determine which of the following statements are true. If a statement is false, indicate why it is incorrect.

(a) The reaction must occur in a single step.

(b) This is a second-order reaction overall.

(c) Raising the temperature will cause the value of *k* to decrease.

(d) Raising the temperature lowers the activation energy for this reaction.

(e) If the concentrations of both reactants are doubled, the rate will double.

(f) Adding a catalyst in the reaction will cause the initial rate to increase.

94. Chlorine atoms contribute to the destruction of the Earth's ozone layer by the following sequence of reactions:

$$Cl + O_3 \rightarrow ClO + O_2$$

$$ClO + O \rightarrow Cl + O_2$$

where the O atoms in the second step come from the decomposition of ozone by sunlight:

$$O_3(g) \rightarrow O(g) + O_2(g)$$

What is the net equation on summing these three equations? Why does this lead to ozone loss in the stratosphere? What is the role played by Cl in this sequence of reactions? What name is given to species such as ClO?

95. Describe each of the following statements as true or false. If false, rewrite the sentence to make it correct.

(a) The rate-determining elementary step in a reaction is the slowest step in a mechanism.

(b) It is possible to change the rate constant by changing the temperature.

(c) As a reaction proceeds at constant temperature, the rate remains constant.

(d) A reaction that is third-order overall must involve more than one step.

96. Identify which of the following statements are incorrect. If the statement is incorrect, rewrite it to be correct.

(a) Reactions are faster at a higher temperature because activation energies are lower.

(b) Rates increase with increasing concentration of reactants because there are more collisions between reactant molecules.

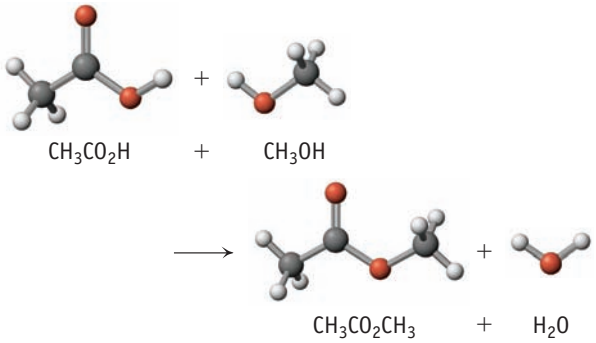
(c) At higher temperatures, a larger fraction of molecules have enough energy to get over the activation energy barrier.

(d) Catalyzed and uncatalyzed reactions have identical mechanisms.

97. The reaction cyclopropane → propene occurs on a platinum metal surface at 200 °C. (The platinum is a catalyst.) The reaction is first-order in cyclopropane. Indicate how the following quantities change (increase, decrease, or no change) as this reaction progresses, assuming constant temperature.

(a) [cyclopropane]

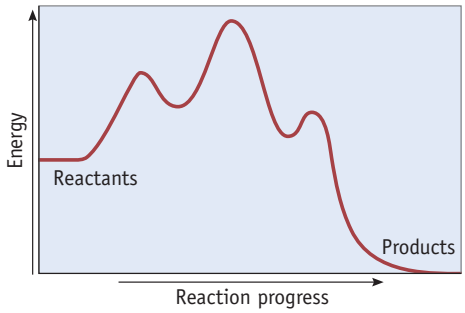
(b) [propene]



(c) [catalyst]

(d) the rate constant, k

(e) the order of the reaction



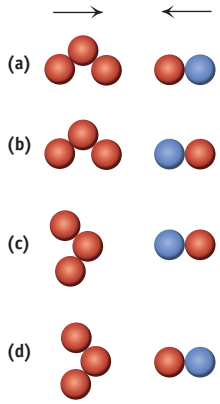
(f) the half-life of cyclopropane

98. Isotopes are often used as "tracers" to follow an atom through a chemical reaction, and the following is an example. Acetic acid reacts with methanol.

Explain how you could use the isotope ^{18}O to show whether the oxygen atom in the water comes from the —OH of CH_3CO_2H or the —OH of CH_3OH.

99. Examine the reaction coordinate diagram given here.

(a) How many steps are in the mechanism for the reaction described by this diagram?

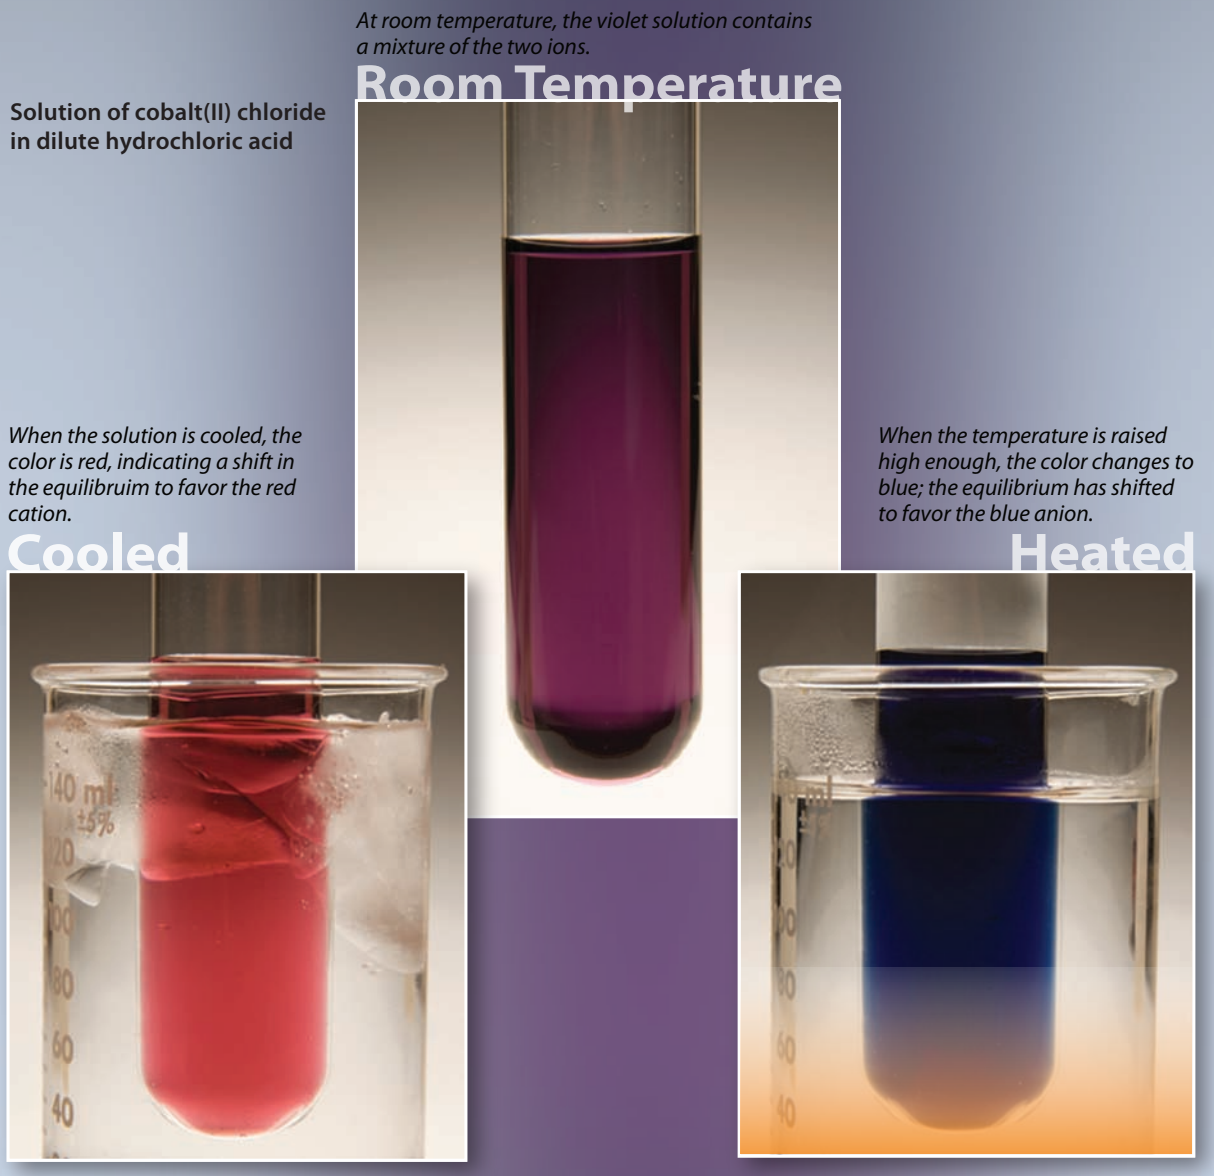


(b) Is the reaction overall exothermic or endothermic?

100. Draw a reaction coordinate diagram for an exothermic reaction that occurs in a single step. Identify the activation energy and the net energy change for the reaction on this diagram. Draw a second diagram that represents the same reaction in the presence of a catalyst, assuming a single-step reaction is involved here also. Identify the activation energy of this reaction and the energy change. Is the activation energy in the two drawings different? Does the energy evolved in the two reactions differ?

101. Consider the reaction of ozone and nitrogen monoxide to form nitrogen dioxide and oxygen.

$$O_3(g) + NO(g) \rightarrow NO_2(g) + O_2(g)$$



Which of the following orientations for the collision between ozone and nitrogen monoxide could perhaps lead to an effective collision between the molecules?

CHAPTER OUTLINE

15.1 Chemical Equilibrium: A Review

15.2 The Equilibrium Constant and Reaction Quotient

15.3 Determining an Equilibrium Constant

15.4 Using Equilibrium Constants in Calculations

15.5 More about Balanced Equations and Equilibrium Constants

15.6 Disturbing a Chemical Equilibrium

15.1 Chemical Equilibrium: A Review

Goal for Section 15.1

- Understand that chemical reactions are reversible and that chemical equilibria are dynamic.

If you mix solutions of $CaCl_2$ and $NaHCO_3$, a chemical reaction is immediately detected: a gas (CO_2) bubbles from the mixture, and an insoluble white solid, $CaCO_3$, forms (Figure 15.1a). The reaction occurring is

$$Ca^{2+}(aq) + 2\ HCO_3^-(aq) \rightarrow CaCO_3(s) + CO_2(g) + H_2O(\ell)$$

If you next add pieces of dry ice (solid CO_2) to the suspension of $CaCO_3$ (or if you bubble gaseous CO_2 into the mixture), the solid $CaCO_3$ dissolves (Figures 15.1b and 15.1c). This happens because a reaction occurs that is the reverse of the reaction that led to precipitation of $CaCO_3$; that is:

$$CaCO_3(s) + CO_2(g) + H_2O(\ell) \rightarrow Ca^{2+}(aq) + 2\ HCO_3^-(aq)$$

Now imagine what will happen if the solution of Ca^{2+} and HCO_3^- ions is in a *closed* container (unlike the reaction in Figure 15.1). As the reaction begins, Ca^{2+} and HCO_3^- react to give products at some rate. As the reactants are depleted, the rate of this reaction slows. At the same time, however, the reaction products ($CaCO_3$, CO_2, and H_2O) begin to combine to re-form Ca^{2+} and HCO_3^-. Eventually, the rate of the forward reaction, the formation of $CaCO_3$, and the rate of the reverse reaction, the redissolving of $CaCO_3$, become equal. Both the forward and reverse reactions continue to occur, but no further macroscopic change is observed. Equilibrium has been achieved.

◀ **Dynamic and Reversible.** A chemical equilibrium exists between the following ions containing Co^{2+}:

$$\underset{\text{red}}{[Co(H_2O)_6]^{2+}(aq)} + 4\ Cl^-(aq) \rightleftharpoons \underset{\text{blue}}{[CoCl_4]^{2-}(aq)} + 6\ H_2O(\ell)$$

At room temperature (center), the violet solution contains a mixture of the two ions. When the solution is cooled (left), the color is red, indicating a shift in the equilibrium to favor the red cation. When the temperature is raised high enough (right), the color changes to blue; the equilibrium has shifted to favor the blue anion.

Problem Solving Tip 15.1 A Review of Concepts of Equilibrium

The concept of an equilibrium, which is so fundamental in chemistry, was introduced in Chapter 3, and you have already encountered its importance in explaining phenomena such as solubility, acid–base behavior, and changes of state. These previous discussions emphasized the following concepts:

1. Chemical reactions are reversible.
2. Chemical reactions proceed spontaneously in the direction that leads toward equilibrium.
3. In a closed system a state of equilibrium between reactants and products is achieved eventually and remains unless there is an outside disturbance.
4. Outside forces can disturb the equilibrium.

A major goal of our further exploration of chemical equilibria in this and the next two chapters will be to describe chemical equilibria in quantitative terms.

Photos: © Cengage Learning/Charles D. Winters

(a) Combining solutions of $NaHCO_3$ and $CaCl_2$ produces solid $CaCO_3$ and CO_2 gas.

(b) Dry ice (the white solid) is added to the slurry of $CaCO_3$ precipitated in (a).

(c) The calcium carbonate dissolves on adding sufficient dry ice (CO_2) to give $Ca^{2+}(aq)$ and $HCO_3^-(aq)$.

Figure 15.1 The $CO_2/Ca^{2+}/H_2O$ system. See Figure 3.5, which shows the same reaction and illustrates the chemistry of the system.

We denote an equilibrium system with a chemical equation that connects reactants and products with double arrows. The double arrow symbol, $\rightleftharpoons$, indicates that the reaction is reversible and is a signal to you that the reaction will be studied using the concepts of chemical equilibria.

Cave Chemistry This same chemistry accounts for stalactites and stalagmites in caves (Section 3.3).

$$Ca^{2+}(aq) + 2\ HCO_3^-(aq) \rightleftharpoons CaCO_3(s) + CO_2(g) + H_2O(\ell)$$

The calcium carbonate equilibrium illustrates an important feature of chemical reactions: *All chemical reactions are reversible, at least in principle*. This was a key point in our earlier discussion of equilibrium (Chapter 3).

15.2 The Equilibrium Constant and Reaction Quotient

Goals for Section 15.2

- Write the equilibrium constant expression, K, for a chemical reaction.
- Recognize that the equilibrium constant can be written relating K to concentrations (K_c) or, if the equilibrating species are gases, to partial pressures (K_p). Convert between K_c and K_p values.

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

- Predict whether a reaction is reactant-favored or product-favored at equilibrium based on the value of K.
- Write the reaction quotient expression, Q, for a chemical reaction and use Q to decide whether a reaction is at equilibrium ($Q = K$), or if there will be a net conversion of reactants to products ($Q < K$) or products to reactants ($Q > K$) to attain equilibrium.

The concentrations of reactants and products for a reaction at equilibrium are related by a mathematical equation. For example, for the reaction of hydrogen and iodine to produce hydrogen iodide, experiments have shown that at equilibrium the ratio of the square of the HI concentration to the product of the H_2 and I_2 concentrations is a constant.

$$H_2(g) + I_2(g) \rightleftharpoons 2\ HI(g)$$

$$\frac{[HI]^2}{[H_2][I_2]} = \text{constant } (K) \text{ at equilibrium}$$

This constant, ***K***, the **equilibrium constant**, is always the same within experimental error for all experiments done *at a given temperature*. Suppose, for example, the concentrations of H_2 and I_2 in a flask are each initially 0.0175 mol/L at 425 °C and no HI is present. Over time, the concentrations of H_2 and I_2 will decrease, and the concentration of HI will increase until a state of equilibrium is reached (Figure 15.2). If the gases in the flask are then analyzed, the observed concentrations would be $[H_2] = [I_2] = 0.0037$ mol/L and $[HI] = 0.0276$ mol/L. The following table—which is often called an **ICE table** for **initial, change,** and **equilibrium concentrations**—summarizes these results:

ICE Table: Initial, Change, and Equilibrium Throughout our discussions of chemical equilibria, we shall express the quantitative information for reactions in an amounts table or ICE table (Section 4.1). These tables show what the initial (I) concentrations are, how those concentrations change (C) on proceeding to equilibrium, and what the concentrations are at equilibrium (E).

Equation	$H_2(g)$	+	$I_2(g)$	$\rightleftharpoons$	2 HI(g)
I = *Initial* concentration (M)	0.0175		0.0175		0
C = *Change* in concentration as reaction proceeds to equilibrium (M)	−0.0138		−0.0138		+0.0276
E = *Equilibrium* concentration (M)	0.0037		0.0037		0.0276

The second line in the table gives the change in concentration of reactants and products on proceeding to equilibrium. Changes are always equal to the difference between the equilibrium and initial concentrations.

$$\text{Change in concentration} = \text{equilibrium concentration} - \text{initial concentration}$$

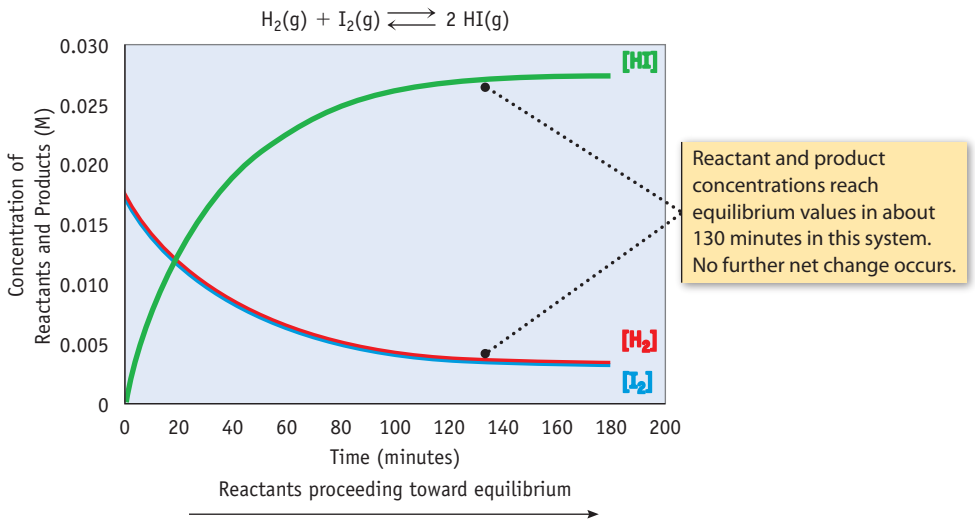

Figure 15.2 The reaction of H_2 and I_2 reaches equilibrium. The final concentrations of H_2, I_2, and HI depend on the initial concentrations of H_2 and I_2. If one begins with a different set of initial concentrations, the equilibrium concentrations will be different, but the quotient $[HI]^2/[H_2][I_2]$ will always be the same at a given temperature.

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Putting the equilibrium concentration values from the ICE table into the expression for the constant (K) gives a value of 56.

$$\frac{[HI]^2}{[H_2][I_2]} = \frac{(0.0276)^2}{(0.0037)(0.0037)} = 56$$

Other experiments can be done on the H_2/I_2 reaction with different concentrations of reactants or using mixtures of reactants and products. Regardless of the initial amounts, when equilibrium is achieved, the ratio $[HI]^2/[H_2][I_2]$ is always the same, 56, at this temperature.

The observation that the ratio of the product and reactant concentrations for the H_2 and I_2 reaction is always the same can be generalized to other reactions. For the general chemical reaction

$$aA + bB \rightleftharpoons cC + dD$$

we can define the equilibrium constant, K, which characterizes a reaction at equilibrium.

$$\text{Equilibrium constant} = K = \frac{[C]^c[D]^d}{[A]^a[B]^b} \qquad (15.1)$$

Equation 15.1 is called the **equilibrium constant expression**. If the ratio of products to reactants as defined by Equation 15.1 matches the equilibrium constant value, the system is at equilibrium. Conversely, if the ratio has a different value, the system is *not* at equilibrium.

Writing Equilibrium Constant Expressions

In an equilibrium constant expression,

- all concentrations are equilibrium values.
- product concentrations appear in the numerator, and reactant concentrations appear in the denominator.
- each concentration is raised to the power of its stoichiometric coefficient in the balanced chemical equation.
- the value of the constant K depends on the temperature.
- values of K are dimensionless. (*A Closer Look: Activities and Units of K.*)

Reactions Involving Solid Reagents Although solids do not appear in an equilibrium constant expression, all reactants and products (including solids) must be present for a system to be at equilibrium.

Reactions Involving Solids

The concentrations of any solid reactants and products are not included in the equilibrium constant expression. The oxidation of solid, yellow sulfur produces colorless sulfur dioxide gas (Figure 15.3),

$$S(s) + O_2(g) \rightleftharpoons SO_2(g)$$

a reaction with the following equilibrium constant expression.

$$K = \frac{[SO_2]}{[O_2]}$$

In reactions involving solids, experiments show that the equilibrium concentrations of other reactants or products—here, O_2 and SO_2—do not depend on the amount of solid present (as long as some solid is present at equilibrium).

© Cengage Learning/Charles D. Winters

Figure 15.3 Burning sulfur. Elemental sulfur burns in oxygen with a beautiful blue flame to give SO_2 gas.

Reactions in Solution

There are also special considerations for reactions occurring in solution when the solvent (water, for example) is either a reactant or a product. Consider ammonia, which is a weak base owing to its (incomplete) reaction with water.

$$NH_3(aq) + H_2O(\ell) \rightleftharpoons NH_4^+(aq) + OH^-(aq)$$

A CLOSER LOOK

Activities and Units of *K*

In the text we state that "values of *K* are dimensionless." After all our care in using units in this book, this might seem sloppy. However, advanced thermodynamics informs us that equilibrium constants should really be calculated from the "activities" of reactants and products and not from their concentrations or partial pressures. Activities can be thought of as "effective" concentrations or partial pressures.

The activity of a substance in solution is obtained by calculating the ratio of its concentration, [X], relative to a standard concentration (1 M) and then multiplying this ratio by a correction factor called an *activity coefficient.* Because it involves a ratio of concentrations, the activity is dimensionless. (Likewise, the activity of a gas is obtained from the ratio of its partial pressure, P_X, relative to a standard pressure [1 bar] and then multiplying by an activity coefficient.) In general chemistry, we assume all the activity coefficients are equal to 1 and so the activity of a solute or a gas is numerically the same as its concentration or partial pressure, respectively. This assumption is best met for solutes in very dilute solutions or gases at low pressures. Regardless of the values of activity coefficients, values of *K* are properly calculated using dimensionless quantities and so they have no units.

Another consequence of using activities is that the "concentration" of solids does not appear in the *K* expression. This is because the activity of a solid is 1. Similarly, pure liquids and solvents are not included because their activities are also 1.

Because the water concentration is very high in a dilute ammonia solution, the concentration of water is essentially unchanged by the reaction. The general rule *for reactions in aqueous solution is that the concentration of water is not included in the equilibrium constant expression.* Thus, for the aqueous ammonia equilibrium we write

$$K = \frac{[NH_4^+][OH^-]}{[NH_3]}$$

Reactions Involving Gases: K_c and K_p

Concentration data can be used to calculate equilibrium constants for both aqueous and gaseous systems. In these cases, the symbol *K* is sometimes given the subscript "c" for "concentration," as in K_c. For gases, however, equilibrium constant expressions can also be written in terms of partial pressures of reactants and products. If reactant and product quantities are given in partial pressures (in atmospheres or in bars), then *K* is given the subscript "p," as in K_p.

Using Partial Pressures in Place of Concentrations If you rearrange the ideal gas law, [$PV = nRT$], you find that the "gas concentration," (n/V), is equivalent to P/RT. Thus, the partial pressure of a gas is proportional to its concentration [$P = (n/V)RT$].

$$H_2(g) + I_2(g) \rightleftharpoons 2\ HI(g)$$

$$K_p = \frac{P_{HI}^2}{P_{H_2} P_{I_2}}$$

Notice that the basic form of the equilibrium constant expression is the same as for K_c. In some cases, the numerical values of K_c and K_p are the same, but they are different when the numbers of moles of gaseous reactants and products are different. *A Closer Look: Equilibrium Constant Expressions for Gases—*K_c *and* K_p shows how K_c and K_p are related and how to convert from one to the other.

EXAMPLE 15.1

Writing Equilibrium Constant Expressions

Problem Write the equilibrium constant expressions (K_c) for the following reactions.

(a) $N_2(g) + 3\ H_2(g) \rightleftharpoons 2\ NH_3(g)$

(b) $H_2CO_3(aq) + H_2O(\ell) \rightleftharpoons HCO_3^-(aq) + H_3O^+(aq)$

What Do You Know? You have balanced chemical equations, from which you can write the equilibrium constant expressions.

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Strategy Product concentrations always appear in the numerator and reactant concentrations appear in the denominator. Each concentration should be raised to a power equal to the stoichiometric coefficient in the balanced equation. In reaction (b), the water concentration does not appear in the equilibrium constant expression.

SOLUTION

(a) $K_c = \dfrac{[NH_3]^2}{[N_2][H_2]^3}$ (b) $K_c = \dfrac{[HCO_3^-][H_3O^+]}{[H_2CO_3]}$

Think about Your Answer Always check to make sure you have the products in the numerator and reactants in the denominator. Confusing these is *a common source of student error*.

Check Your Understanding

Write the equilibrium constant expression for each of the following reactions in terms of concentrations.

(a) $CO_2(g) + C(s) \rightleftharpoons 2\ CO(g)$

(b) $[Cu(NH_3)_4]^{2+}(aq) \rightleftharpoons Cu^{2+}(aq) + 4\ NH_3(aq)$

(c) $CH_3CO_2H(aq) + H_2O(\ell) \rightleftharpoons CH_3CO_2^-(aq) + H_3O^+(aq)$

A CLOSER LOOK

Equilibrium Constant Expressions for Gases—K_c and K_p

Many metal carbonates, such as limestone, decompose on heating to give the metal oxide and CO_2 gas.

$$CaCO_3(s) \rightleftharpoons CaO(s) + CO_2(g)$$

The equilibrium constant for this reaction can be expressed either in terms of the number of moles per liter of CO_2, $K_c = [CO_2]$, or in terms of the partial pressure of CO_2, $K_p = P_{CO_2}$. From the ideal gas law, you know that

$$P = (n/V)RT$$
$$= (\text{concentration in mol/L}) \times RT$$

Therefore, for this reaction $K_p = P_{CO_2} = [CO_2]RT$. Because $K_c = [CO_2]$, this leads to the conclusion that $K_p = K_c(RT)$. For the decomposition of calcium carbonate, K_p is the product of K_c and the factor RT. That is, the values of K_p and K_c are not the same.

Consider the equilibrium constant for the reaction of N_2 and H_2 to produce ammonia in terms of partial pressures, K_p.

$$N_2(g) + 3\ H_2(g) \rightleftharpoons 2\ NH_3(g)$$

$$K_p = \frac{(P_{NH_3})^2}{(P_{N_2})(P_{H_2})^3}$$

Does K_c, the equilibrium constant in terms of concentrations, have the same value as K_p? We can answer this question by substituting for each pressure in K_p the equivalent expression $[C](RT)$. That is,

$$K_p = \frac{\{[NH_3](RT)\}^2}{\{[N_2](RT)\}\{[H_2](RT)\}^3}$$
$$= \frac{[NH_3]^2}{[N_2][H_2]^3} \times \frac{1}{(RT)^2} = \frac{K_c}{(RT)^2}$$
$$\text{or } K_p = K_c(RT)^{-2}$$

Once again, you see that K_p and K_c are not the same but are related by some function of RT.

Looking carefully at these examples and others, we find that

$$K_p = K_c(RT)^{\Delta n}$$

where Δn is the change in the number of moles of gas on going from reactants to products.

Δn = total moles of gaseous products − total moles of gaseous reactants

For the decomposition of $CaCO_3$,

$$\Delta n = 1 - 0 = 1$$

whereas the value of Δn for the ammonia synthesis is

$$\Delta n = 2 - 4 = -2$$

What about a reaction in which Δn is zero, such as the oxidation of NO by ozone?

$$NO(g) + O_3(g) \rightleftharpoons NO_2(g) + O_2(g)$$

Now $K_p = K_c$.

The Magnitude of the Equilibrium Constant, *K*

The magnitude of the equilibrium constant can vary over a wide range of values. A large value for the equilibrium constant means that the concentrations of the products are larger than the concentrations of the reactants at equilibrium. That is, the products are favored over the reactants at equilibrium.

> ***K* > 1: Reaction is product-favored at equilibrium.** The concentrations of products are greater than the concentrations of the reactants at equilibrium.

An example is the reaction of nitrogen monoxide and ozone.

$$NO(g) + O_3(g) \rightleftharpoons NO_2(g) + O_2(g)$$

$$K_c = \frac{[NO_2][O_2]}{[NO][O_3]} = 6 \times 10^{34} \text{ at } 25\ ^\circ\text{C}$$

The large value of K indicates that, at equilibrium, $[NO_2][O_2] >> [NO][O_3]$. If stoichiometric amounts of NO and O_3 are mixed and allowed to come to equilibrium, virtually none of the reactants will be found. Essentially, all will have been converted to NO_2 and O_2. A chemist would say that "the reaction has gone to completion."

Conversely, a small value of K means that little of the products exists when equilibrium has been achieved. That is, the reactants are favored over the products at equilibrium.

> ***K* < 1: Reaction is reactant-favored at equilibrium.** Concentrations of reactants are greater than concentrations of products at equilibrium.

This is true for the formation of ozone from oxygen.

$$3/2\ O_2(g) \rightleftharpoons O_3(g)$$

$$K_c = \frac{[O_3]}{[O_2]^{3/2}} = 2.5 \times 10^{-29} \text{ at } 25\ ^\circ\text{C}$$

The small value of K indicates that, at equilibrium, $[O_3] << [O_2]^{3/2}$. If O_2 is placed in a flask, little O_2 will have been converted to O_3 when equilibrium has been achieved.

When K is close to 1, it may not be immediately clear whether the reactant concentrations are larger than the product concentrations, or vice versa. It will depend on the form of the equilibrium expression and thus on the reaction stoichiometry. Calculations of the concentrations will have to be done.

The Reaction Quotient, *Q*

The equilibrium constant, K, for a reaction has a particular numerical value when the reactants and products are at equilibrium at a particular temperature. When the reactants and products in a reaction are not at equilibrium, however, it is useful to calculate the reaction quotient, Q. For the general reaction of A and B to give C and D,

$$aA + bB \rightleftharpoons cC + dD$$

the reaction quotient is defined as

$$\text{Reaction quotient} = Q = \frac{[C]^c[D]^d}{[A]^a[B]^b} \qquad (15.2)$$

While this equation may look identical to the expression for K, there is an important distinction. When K is indicated, the concentrations *must* be those present *at equilibrium*. In contrast, the concentrations of reactants and products in the expression

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

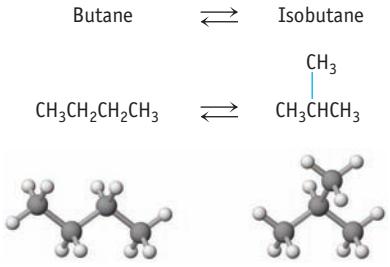
for Q are those that occur at any point as the reaction proceeds from reactants to an equilibrium mixture. Only when the system is at equilibrium does $Q = K$. For any system not at equilibrium the value of Q is different than K.

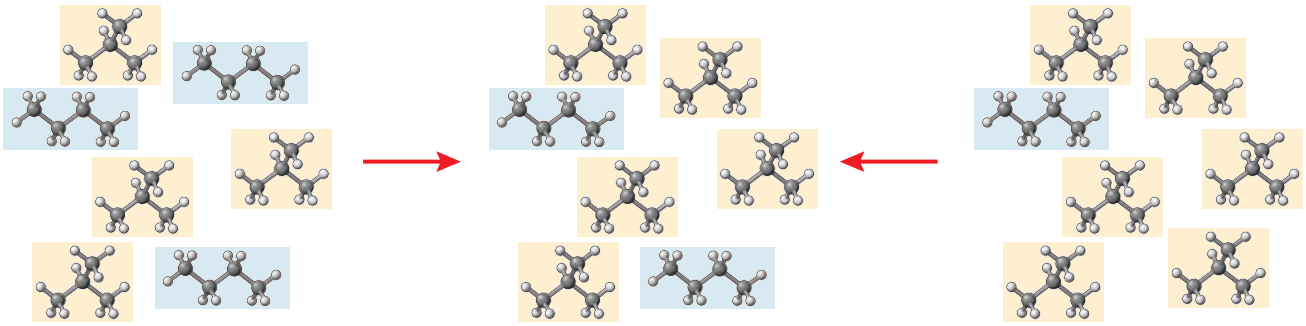


Determining a reaction quotient is useful for two reasons. First, it will tell you whether a system is at equilibrium (when $Q = K$) or is not at equilibrium (when $Q \neq K$). Second, by comparing Q and K, you can predict what changes will occur in reactant and product concentrations as the reaction proceeds to equilibrium.

Comparing *Q* and *K*

Relative Magnitude	Direction of Reaction
Q < K	Reactants → Products
Q = K	Reaction at equilibrium
Q > K	Reactants ← Products

- $Q < K$: If Q is less than K, some reactants must be converted to products for the reaction to reach equilibrium. This will decrease the reactant concentrations and increase the product concentrations.
- $Q > K$: If Q is greater than K, some products must be converted to reactants for the reaction to reach equilibrium. This will increase the reactant concentrations and decrease the product concentrations.



To illustrate these points, let us consider the transformation of butane to isobutane (2-methylpropane).

$$K_c = \frac{[\text{isobutane}]}{[\text{butane}]} = 2.50 \text{ at } 298 \text{ K}$$

Any mixture of butane and isobutane, whether at equilibrium or not, can be represented by the reaction quotient Q (=[isobutane]/[butane]). Suppose you have a mixture composed of 0.0030 mol/L of butane and 0.0040 mol/L of isobutane (at 298 K) (Figure 15.4a). This means that the reaction quotient, Q, is

$$Q = \frac{[\text{isobutane}]}{[\text{butane}]} = \frac{0.0040}{0.0030} = 1.3$$

(a) Not at equilibrium.
***Q* = 4/3 < *K*.**
Here, four isobutane molecules and three butane molecules are present. Reaction will proceed to convert butane into isobutane to reach equilibrium.

(b) At equilibrium.
***Q* = 5/2 = *K*.**
Here, five isobutane molecules and two butane molecules are present. Reaction is at equilibrium.

(c) Not at equilibrium.
***Q* = 6/1 > *K*.**
Here, six isobutane molecules and one butane molecule are present. Reaction will proceed to convert isobutane into butane to reach equilibrium.

Figure 15.4 The interconversion of isobutane and butane. Only when the concentrations of isobutane and butane are in the ratio [isobutane]/[butane] = 2.5 is the system at equilibrium (b). With any other ratio of concentrations, there will be a net conversion of one compound into the other until equilibrium is achieved.

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

This set of concentrations does not represent an equilibrium system because $Q < K_c$. To reach equilibrium, some butane molecules must be converted to molecules of isobutane, thereby lowering [butane] and raising [isobutane]. This transformation will continue until the ratio [isobutane]/[butane] = 2.5; that is, until $Q = K_c$ (Figure 15.4b).

What happens when there is too much isobutane in the system relative to the amount of butane? Suppose [isobutane] = 0.0060 mol/L but [butane] is only 0.0010 mol/L (Figure 15.4c). Now the reaction quotient Q is greater than K_c ($Q > K_c$), and the system is again not at equilibrium. It will proceed to equilibrium by converting isobutane molecules to butane molecules.

EXAMPLE 15.2

The Reaction Quotient

Problem The brown gas nitrogen dioxide, NO_2, can exist in equilibrium with the colorless gas N_2O_4. $K_c = 170$ at 298 K for the reaction

$$2\ NO_2(g) \rightleftharpoons N_2O_4(g) \quad K_c = 170$$

Suppose that the concentration of NO_2 is 0.015 M and the concentration of N_2O_4 is 0.025 M. Is Q larger than, smaller than, or equal to K_c? If the system is not at equilibrium, in which direction will the reaction proceed to achieve equilibrium?

What Do You Know? You are given the balanced chemical equation, the value of the equilibrium constant K_c, and concentrations of reactant and product.

Strategy

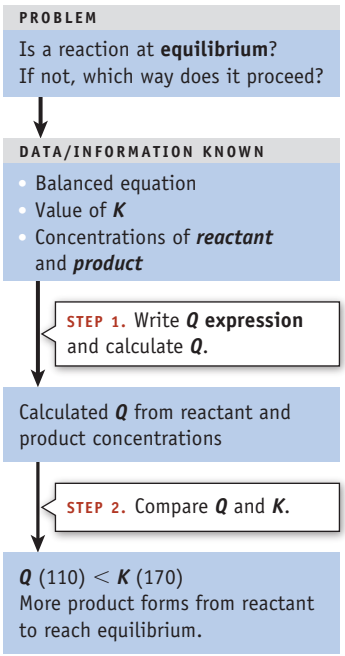
- Write the expression for the reaction quotient, Q, from the balanced equation.
- Substitute concentrations of reactant and product into the expression and calculate Q.
- Decide if Q is greater than, less than, or equal to K_c and in which direction the reaction will proceed.

SOLUTION

$$Q = \frac{[N_2O_4]}{[NO_2]^2} = \frac{(0.025)}{(0.015)^2} = 110$$

The value of Q is less than the value of K_c ($Q < K$), so the reaction is not at equilibrium. The system proceeds to equilibrium by converting NO_2 to N_2O_4, thereby increasing $[N_2O_4]$, and decreasing $[NO_2]$ until $Q = K_c$.

Think about Your Answer When calculating Q, make sure that you raise each concentration to the power corresponding to the stoichiometric coefficient.



Check Your Understanding

Answer the following questions regarding the butane $\rightleftharpoons$ isobutane equilibrium ($K_c = 2.50$ at 298 K).

(a) Is the system at equilibrium when [butane] = 0.00097 M and [isobutane] = 0.00218 M? If not, in which direction will the reaction proceed to achieve equilibrium?

(b) Is the system at equilibrium when [butane] = 0.00075 M and [isobutane] = 0.00260 M? If not, in which direction will the reaction proceed to achieve equilibrium?

15.3 Determining an Equilibrium Constant

Goals for Section 15.3

- Calculate an equilibrium constant given the reactant and product concentrations at equilibrium.
- Calculate an equilibrium constant given the initial concentrations of the reactants and products and the concentration of one of the reactants or products at equilibrium.

When the concentrations of all of the reactants and products are known at equilibrium, an equilibrium constant can be calculated by substituting the data into the equilibrium constant expression. Assume a mixture of SO_2, O_2, and SO_3 is at equilibrium at 852 K.

$$2\ SO_2(g) + O_2(g) \rightleftharpoons 2\ SO_3(g)$$

The equilibrium concentrations are found to be $[SO_2] = 3.61 \times 10^{-3}$ mol/L, $[O_2] = 6.11 \times 10^{-4}$ mol/L, and $[SO_3] = 1.01 \times 10^{-2}$ mol/L. Substituting these data into the equilibrium constant expression, we can calculate the value of K_c.

$$K_c = \frac{[SO_3]^2}{[SO_2]^2[O_2]} = \frac{(1.01 \times 10^{-2})^2}{(3.61 \times 10^{-3})^2(6.11 \times 10^{-4})} = 1.28 \times 10^4 \text{ at } 852 \text{ K}$$

(Notice that K_c has a large value; at 852 K, the oxidation of sulfur dioxide is product-favored at equilibrium.)

More commonly, an experiment will provide information on the initial quantities of reactants and the concentration at equilibrium of only one of the reactants or of one of the products. The equilibrium concentrations of the rest of the reactants and products must then be calculated based on the reaction stoichiometry. As an example, let's again consider the oxidation of sulfur dioxide to sulfur trioxide and suppose that 0.00100 mol each of SO_2 and O_2 are placed in a 1.00-L flask at a high temperature. When equilibrium has been achieved, 0.00054 mol of SO_3 has been formed. Let us use this information to calculate the equilibrium constant for the reaction. After writing the equilibrium constant expression in terms of concentrations, we set up an ICE table (Section 4.1 and Section 15.2) showing the initial concentrations, the changes in those concentrations on proceeding to equilibrium, and the concentrations at equilibrium.

Equation	$2\ SO_2(g)$	+	$O_2(g)$	$\rightleftharpoons$	$2\ SO_3(g)$
Initial (M)	0.00100		0.00100		0
Change (M)	$-2x$		$-x$		$+2x$
Equilibrium (M)	$0.00100 - 2x$ $= 0.00100 - 0.00054$ $= 0.00046$		$0.00100 - x$ $= 0.00100 - 0.00054/2$ $= 0.00073$		$2x$ $= 0.00054$

The quantities in the ICE table come from the following analysis:

- Line 1: Initial concentrations.
- Line 2: The amount of O_2 consumed is designated as $-x$ mol/L. We give it a minus sign because O_2 is consumed. It then follows from the reaction stoichiometry that the amount of SO_2 consumed is $-2x$, and the amount of SO_3 produced is $+2x$.

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

- Line 3:
  (a) We know from experiment that $[SO_3]$ at equilibrium is 0.00054 M. Therefore, $2x = 0.00054$ M.
  (b) The equilibrium concentration of SO_2 is equal to the initial concentration minus what was consumed. Therefore, $[SO_2]$ is $(0.00100 - 2x)$ M or 0.00046 M.
  (c) The amount of O_2 consumed is half of the amount of SO_3 produced or x (= 0.00027 mol/L). Therefore, the equilibrium concentration of O_2 is 0.00073.

With the equilibrium concentrations now known, it is possible to calculate K_c.

$$K_c = \frac{[SO_3]^2}{[SO_2]^2[O_2]} = \frac{(0.00054)^2}{(0.00046)^2(0.00073)} = 1.9 \times 10^3$$

EXAMPLE 15.3

Calculating an Equilibrium Constant (K_c) Using Concentrations

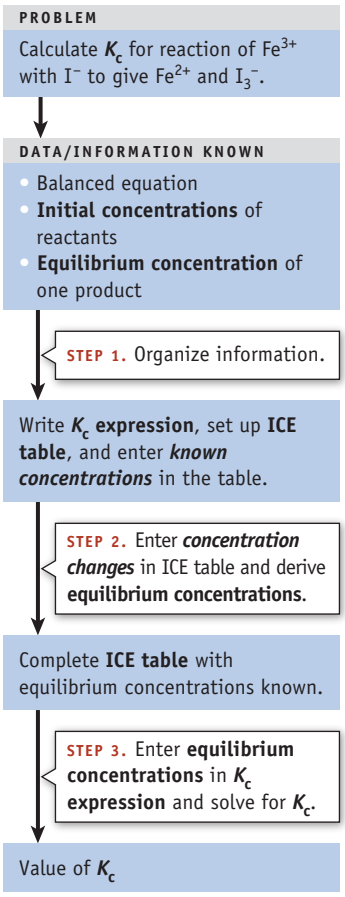
Problem In aqueous solution iron(III) ions react with iodide ions to give iron(II) ions and triiodide ions, I_3^-. Suppose the initial concentration of Fe^{3+} ions is 0.200 M, the initial I^- ion concentration is 0.300 M. When equilibrium has been achieved, the concentration of I_3^- ions is 0.0866 M. What is the value of K_c?

$$2\ Fe^{3+}(aq) + 3\ I^-(aq) \rightleftharpoons 2\ Fe^{2+}(aq) + I_3^-(aq)$$

What Do You Know? You are given the balanced equation (from which the equilibrium constant expression can be written), initial concentrations of the reactants, and the concentration of one product (I_3^-) after equilibrium has been reached.

Strategy

- Set up an ICE table and enter the initial concentrations.
- Decide how each concentration changes. Let us begin by saying that x mol/L of I_3^- ions are produced on proceeding to equilibrium. Based on the reaction stoichiometry, this means that $2x$ mol/L of Fe^{2+} must also be produced, $2x$ mol/L of Fe^{3+} ions are consumed, and $3x$ mol/L of I^- ions are consumed.
- The equilibrium concentration of I_3^- is known (0.0866 M), so this is the quantity x.
- Knowing that $x = 0.0866$ M, calculate the equilibrium concentrations for each species.
- Enter the equilibrium concentrations of reactants and products into the equilibrium constant expression and solve for K_c.



SOLUTION The strategy outlined leads to the ICE table below.

Equation	$2\ Fe^{3+}$	+	$3\ I^-$	$\rightleftharpoons$	$2\ Fe^{2+}$	+	I_3^-
Initial (M)	0.200		0.300		0		0
Change (M)	$-2x$		$-3x$		$+2x$		$+x$
Equilibrium (M)	$0.200 - 2(0.0866) = 0.0268$		$0.300 - 3(0.0866) = 0.0402$		$2(0.0866) = 0.1732$		0.0866

The concentration of each substance at equilibrium is now known, and K_c can be calculated.

$$K_c = \frac{[Fe^{2+}]^2[I_3^-]}{[Fe^{3+}]^2[I^-]^3} = \frac{(0.1732)^2(0.0866)}{(0.0268)^2(0.0402)^3} = 5.6 \times 10^4$$

Strategy Map 15.3

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Think about Your Answer The key to this problem is that the concentration of one product, I_3^-, was known at equilibrium. The concentrations of the other product and of the reactants could be derived from this based on the reaction stoichiometry. Also notice that the calculated K_c is much greater than one, so the reaction is product-favored at equilibrium. This is consistent with the equilibrium concentrations calculated in the ICE table.

Check Your Understanding

A solution is prepared by dissolving 0.050 mol of diiodocyclohexane, $C_6H_{10}I_2$, in the solvent CCl_4. The total solution volume is 1.00 L. When the reaction

$$C_6H_{10}I_2 \rightleftharpoons C_6H_{10} + I_2$$

has come to equilibrium at 35 °C, the concentration of I_2 is 0.035 mol/L.

(a) What are the concentrations of $C_6H_{10}I_2$ and C_6H_{10} at equilibrium?

(b) Calculate K_c, the equilibrium constant.

15.4 Using Equilibrium Constants in Calculations

Strategy Map 15.4

PROBLEM

What are the **concentrations** of H_2, I_2, and **HI** when the system reaches equilibrium?

DATA/INFORMATION KNOWN

- Balanced equation
- Value of K_c
- **Initial concentrations** of reactants

STEP 1. Organize information.

Write K_c **expression**, set up **ICE table**, and enter ***known concentrations*** in the table.

STEP 2. Enter ***concentration changes*** in ICE table and derive **equilibrium concentrations** in terms of unknown quantity ***x***.

Equilibrium concentrations of H_2, I_2, and **HI** are defined in terms of the unknown quantity ***x***.

STEP 3. Enter **equilibrium concentrations** in K_c **expression** and solve for ***x***.

Value of ***x***

STEP 4. Use value of ***x*** to derive **equilibrium concentrations**.

Values of equilibrium concentrations

Goal for Section 15.4

- Use equilibrium constants to calculate the concentration (or pressure) of a reactant or a product at equilibrium.

Suppose the value of K_c or K_p and the initial concentrations of reactants are known, and you want to know the equilibrium concentrations. As we look at several examples of this situation, we will again use ICE tables that summarize the initial conditions, the changes occurring on proceeding to equilibrium, and the final conditions.

EXAMPLE 15.4

Calculating Equilibrium Concentrations

Problem The equilibrium constant K_c (= 55.64) for

$$H_2(g) + I_2(g) \rightleftharpoons 2\ HI(g)$$

has been determined at 425 °C. If 0.130 mol each of H_2 and I_2 is placed in a 25.0-L flask at 425 °C, what are the concentrations of H_2, I_2, and HI when the system reaches equilibrium?

What Do You Know? You are given the balanced equation (from which the equilibrium constant expression can be written), the value of K_c, and the initial amounts of the reactants and the volume of the container (from which initial concentrations of the reactants can be calculated).

Strategy

- Write the equilibrium constant expression and set up an ICE table.
- Enter the initial concentrations of H_2 and I_2 on the first line (Initial).
- Assign the variable x to represent changes in concentration. Based on the reaction stoichiometry the change in $[H_2]$ and $[I_2]$ is $-x$ and the change in [HI] is $+2x$. Enter these values into the second line (Change) of the table.
- Enter the expressions for the final equilibrium concentrations of all three species on the third line (Equilibrium) of the ICE table, and then transfer these expressions to the equilibrium constant expression and solve for x.
- Use the calculated value of x to solve for the final concentration of each species.

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

SOLUTION Write the equilibrium constant expression

$$K_c = \frac{[HI]^2}{[H_2][I_2]} = 55.64$$

and then set up the ICE table as outlined in the Strategy.

Equation	$H_2(g)$	+	$I_2(g)$	$\rightleftharpoons$	2 HI(g)
Initial (M)	0.130 mol/25.0 L $= 5.200 \times 10^{-3}$ M		0.130 mol/25.0 L $= 5.200 \times 10^{-3}$ M		0
Change (M)	$-x$		$-x$		$+2x$
Equilibrium (M)	5.200×10^{-3} M $- x$		5.200×10^{-3} M $- x$		$2x$

Now the expressions for the equilibrium concentrations can be substituted into the equilibrium constant expression.

$$55.64 = \frac{(2x)^2}{(5.200 \times 10^{-3} - x)(5.200 \times 10^{-3} - x)} = \frac{(2x)^2}{(5.200 \times 10^{-3} - x)^2}$$

In this case, you can solve for the unknown quantity x by taking the square root of both sides of the equation,

$$\sqrt{K_c} = 7.4592 = \frac{2x}{5.200 \times 10^{-3} - x}$$

$$7.4592\,(5.200 \times 10^{-3} - x) = 0.03879 - 7.4592x = 2x$$

$$0.03879 = 9.4592x$$

$$x = 4.101 \times 10^{-3}$$

With x known, you can solve for the equilibrium concentrations of the reactants and products.

$$[H_2] = [I_2] = 5.200 \times 10^{-3} - x = 1.099 \times 10^{-3}\ \text{M} = 1.10 \times 10^{-3}\ \text{M}$$

$$[HI] = 2x = 8.202 \times 10^{-3}\ \text{M} = 8.20 \times 10^{-3}\ \text{M}$$

Think about Your Answer It is always wise to verify the answer by substituting the value of each concentration back into the equilibrium constant expression to see if your calculated K_c agrees with the one given in the problem. In this case, $(8.202 \times 10^{-3})^2/(1.099 \times 10^{-3})^2 = 55.7$, which agrees quite well with the value of K_c.

Check Your Understanding

At some temperature, $K_c = 33$ for the reaction

$$H_2(g) + I_2(g) \rightleftharpoons 2\ HI(g)$$

Assume the initial concentrations of both H_2 and I_2 are 6.00×10^{-3} mol/L. Find the concentration of each reactant and product at equilibrium.

Calculations Where the Solution Involves a Quadratic Expression

Suppose you are studying the decomposition of PCl_5 to form PCl_3 and Cl_2. You know that $K_c = 1.20$ at a given temperature.

$$PCl_5(g) \rightleftharpoons PCl_3(g) + Cl_2(g)$$

If the initial concentration of PCl_5 is 0.0920 M, what will be the concentrations of reactant and products when the system reaches equilibrium? Following the proce-

dures outlined in Example 15.4, you would set up an ICE table to define the equilibrium concentrations of reactants and products.

Reaction	$PCl_5(g)$	$\rightleftharpoons$	$PCl_3(g)$	+	$Cl_2(g)$
Initial (M)	0.0920		0		0
Change (M)	$-x$		$+x$		$+x$
Equilibrium (M)	$0.0920 - x$		x		x

Substituting into the equilibrium constant expression, we have

$$K_c = 1.20 = \frac{[PCl_3][Cl_2]}{[PCl_5]} = \frac{(x)(x)}{0.0920 - x}$$

Expanding the algebraic expression results in a quadratic equation,

$$x^2 + 1.20x - 0.1104 = 0$$

Using the quadratic formula (Appendix A; $a = 1$, $b = 1.20$, and $c = -0.1104$), we find two roots to the equation: $x = 0.08586$ and -1.286. Because a negative value of x (which represents a negative concentration) is not chemically meaningful, the answer is $x = 0.08586$ M. Therefore, at equilibrium we have

$$[PCl_5] = 0.0920 - 0.08586 = 0.00614 = 0.0061 \text{ M}$$

$$[PCl_3] = [Cl_2] = 0.08586 = 0.0859 \text{ M}$$

Although a solution to a quadratic equation can always be obtained using the quadratic formula, in many instances an acceptable answer can be obtained by using a realistic approximation to simplify the calculation. To illustrate this, consider another equilibrium, the dissociation of I_2 molecules to form I atoms, for which $K_c = 5.6 \times 10^{-12}$ at 500 *K*.

$$I_2(g) \rightleftharpoons 2\ I(g)$$

$$K_c = \frac{[I]^2}{[I_2]} = 5.6 \times 10^{-12}$$

Assuming the initial I_2 concentration is 0.45 M and setting up the ICE table in the usual manner, we have

Reaction	$I_2(g)$	$\rightleftharpoons$	2 I(g)
Initial (M)	0.45		0
Change (M)	$-x$		$+2x$
Equilibrium (M)	$0.45 - x$		$2x$

Solving Quadratic Equations
Quadratic equations are usually solved using the quadratic formula (Appendix A). An alternative is the *method of successive approximations*, also outlined in Appendix A. Most equilibrium expressions can be solved quickly by this method, and you are urged to try it. This will remove the uncertainty of whether *K* expressions need to be solved exactly.

For the equilibrium constant expression, we again arrive at a quadratic equation.

$$K_c = 5.6 \times 10^{-12} = \frac{(2x)^2}{(0.45 - x)}$$

This could be solved using the quadratic formula, but there is a simpler way to reach an answer. Notice that the value of K_c is very small, indicating that the change in I_2 concentration is very small. In fact, K_c is so small that subtracting x from the original reactant concentration (0.45 mol/L) in the denominator of this equation leaves

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

it essentially unchanged. That is, $(0.45 - x)$ is essentially equal to 0.45. Thus, we drop x in the denominator and have a simpler equation to solve.

$$K_c = 5.6 \times 10^{-12} = \frac{(2x)^2}{(0.45)}$$

The solution to this equation gives $x = 7.94 \times 10^{-7}$ mol/L. From this value, we can determine that $[I_2] = 0.45 - x = 0.45$ mol/L and $[I] = 2x = 1.6 \times 10^{-6}$ mol/L. Notice that the answer confirms the assumption the dissociation of I_2 is so small that $[I_2]$ at equilibrium is essentially equal to the initial concentration.

When is it possible to simplify a quadratic equation? The decision depends on both the value of the initial concentration of the reactant and the value of x, which is in turn related to the value of K. Consider the general reaction

$$A \rightleftharpoons B + C$$

where $K = [B][C]/[A]$. Assume that there is no B or C initially present, that you know K and the initial concentration of A $(= [A]_0)$ and wish to find the equilibrium concentrations of B and C $(= x)$. The equilibrium constant expression now is

$$K_c = \frac{[B][C]}{[A]} = \frac{(x)(x)}{[A]_0 - x}$$

When K_c is very small, the value of x will be much less than $[A]_0$, so $[A]_0 - x \cong [A]_0$. Therefore, we can write the following expression.

$$K_c = \frac{[B][C]}{[A]} \approx \frac{(x)(x)}{[A]_0} \tag{15.3}$$

A good guideline to follow is: *If $100 \times K_c < [A]_0$, the approximate expression will give acceptable values of equilibrium concentrations* (to two significant figures). For more about this, see *Problem Solving Tip 15.2*.

EXAMPLE 15.5

Calculating Equilibrium Concentrations Using an Equilibrium Constant

Problem The reaction

$$N_2(g) + O_2(g) \rightleftharpoons 2\ NO(g)$$

contributes to air pollution whenever a fuel is burned in air at a high temperature, as in a gasoline engine. At 1500 K, $K_c = 1.0 \times 10^{-5}$. Suppose a sample of air has $[N_2] = 0.080$ mol/L and $[O_2] = 0.020$ mol/L before any reaction occurs. Calculate the equilibrium concentrations of reactants and products after the mixture has been heated to 1500 K.

What Do You Know? As in Example 15.4, you know the value of K_c and can write the equilibrium expression from the balanced equation. You also know the initial concentrations of the reactants and can define the equilibrium concentrations in terms of the amounts of N_2 and O_2 consumed $(= x)$.

Strategy Set up an ICE table, and then substitute the equilibrium concentrations into the equilibrium constant expression. The result will be a quadratic equation. This expression can be solved using the methods outlined in Appendix A or by using the guideline in the text to simplify the calculation.

Strategy Map 15.5

PROBLEM

What are the **equilibrium concentrations** of N_2, O_2, and **NO** in formation of NO from N_2 and O_2?

↓

DATA/INFORMATION KNOWN

- Balanced equation
- Value of K_c
- **Initial concentrations** of reactants

STEP 1. Enter ***concentration changes*** in ICE table and derive **equilibrium concentrations** in terms of unknown quantity ***x***.

Equilibrium concentrations of N_2, O_2, and **NO** are defined in terms of the unknown quantity ***x***.

STEP 2. Enter **equilibrium concentrations** in K_c **expression** and solve for ***x***.

Value of ***x***

STEP 3. Use value of ***x*** to derive **equilibrium concentrations.**

Values of equilibrium concentrations

SOLUTION We first set up an ICE table where the amounts of N_2 and O_2 consumed are designated as x.

Equation	$N_2(g)$	+	$O_2(g)$	$\rightleftharpoons$	2 NO(g)
Initial (M)	0.080		0.020		0
Change (M)	$-x$		$-x$		$+2x$
Equilibrium (M)	$0.080 - x$		$0.020 - x$		$2x$

Next, the equilibrium concentrations are substituted into the equilibrium constant expression.

$$K_c = 1.0 \times 10^{-5} = \frac{[NO]^2}{[N_2][O_2]} = \frac{(2x)^2}{(0.080 - x)(0.020 - x)}$$

We refer to the guideline (Equation 15.3) to decide whether an approximate solution is acceptable. Here, $100 \times K_c$ ($= 1.0 \times 10^{-3}$) is smaller than either of the initial reactant concentrations (0.080 and 0.020). This means we can use the approximate expression.

$$K_c = 1.0 \times 10^{-5} = \frac{[NO]^2}{[N_2][O_2]} = \frac{(2x)^2}{(0.080)(0.020)}$$

Solving this expression, we find

$$1.60 \times 10^{-8} = 4x^2$$

$$x = 6.32 \times 10^{-5}\ \text{M}$$

Therefore, the reactant and product concentrations at equilibrium are

$$[N_2] = 0.080 - 6.32 \times 10^{-5} \approx 0.080\ \text{M}$$

$$[O_2] = 0.020 - 6.32 \times 10^{-5} \approx 0.020\ \text{M}$$

$$[NO] = 2x = 1.3 \times 10^{-4}\ \text{M}$$

Think about Your Answer The value of x obtained using the approximation is the same as that obtained from the quadratic formula.

Check Your Understanding

The decomposition of $PCl_5(g)$ to form $PCl_3(g)$ and $Cl_2(g)$ has $K_c = 33.3$ at a high temperature. If the initial concentration of PCl_5 is 0.1000 M, what are the equilibrium concentrations of the reactants and products?

Problem Solving Tip 15.2 When Do You Need to Use the Quadratic Equation?

In most equilibrium calculations, the quantity x may be neglected in the denominator of the equation $K = x^2/([A]_0 - x)$ if x is less than 10% of the concentration of reactant initially present ($= [A]_0$). The guideline presented in the text for making the approximation that $[A]_0 - x = [A]_0$ when $100 \times K < [A]_0$ reflects this fact.

In general, when K is about 1 or greater, the approximation cannot be made. If K is much less than 1 and $100 \times K < [A]_0$ (you will see many such cases in Chapter 16), the approximate expression ($K = x^2/[A]_0$) gives an acceptable answer. If you are not certain, first make the assumption that the unknown (x) is small, and solve the approximate expression ($K = (x)^2/[A]_0$). Next, compare the "approximate" value of x with $[A]_0$. If x has a value equal to or less than 10% of $[A]_0$, there is no need to solve the full equation using the quadratic formula.

15.5 More about Balanced Equations and Equilibrium Constants

Goal for Section 15.5

- Know how K changes as different stoichiometric coefficients are used in a balanced equation, if the equation is reversed, or if several equations are added to give a new net equation.

Using Different Stoichiometric Coefficients

Chemical equations can be balanced using different sets of stoichiometric coefficients. For example, the equation for the oxidation of carbon to give carbon monoxide can be written

$$C(s) + \tfrac{1}{2}\, O_2(g) \rightleftharpoons CO(g)$$

for which the equilibrium constant expression would be

$$K_1 = \frac{[CO]}{[O_2]^{1/2}} = 4.6 \times 10^{23} \text{ at } 25\ ^\circ C$$

You can write the chemical equation equally well, however, as

$$2\ C(s) + O_2(g) \rightleftharpoons 2\ CO(g)$$

and the equilibrium constant expression would now be

$$K_2 = \frac{[CO]^2}{[O_2]} = 2.1 \times 10^{47} \text{ at } 25\ ^\circ C$$

When you compare the two equilibrium constant expressions you find that $K_2 = (K_1)^2$; that is,

$$K_2 = \frac{[CO]^2}{[O_2]} = \left\{\frac{[CO]}{[O_2]^{1/2}}\right\}^2 = K_1{}^2$$

When the stoichiometric coefficients of a balanced equation are multiplied by some factor, the equilibrium constant for the new equation is the old equilibrium constant raised to the power of the multiplication factor.

Reversing a Chemical Equation

Let us consider what happens if a chemical equation is reversed. Here, we will compare the value of K_c for formic acid transferring an H^+ ion to water

$$HCO_2H(aq) + H_2O(\ell) \rightleftharpoons HCO_2^-(aq) + H_3O^+(aq)$$

$$K_1 = \frac{[HCO_2^-][H_3O^+]}{[HCO_2H]} = 1.8 \times 10^{-4} \text{ at } 25\ ^\circ C$$

with the opposite reaction, the gain of an H^+ ion by the formate ion, HCO_2^-.

$$HCO_2^-(aq) + H_3O^+(aq) \rightleftharpoons HCO_2H(aq) + H_2O(\ell)$$

$$K_2 = \frac{[HCO_2H]}{[HCO_2^-][H_3O^+]} = 5.6 \times 10^3 \text{ at } 25\ ^\circ C$$

Here, $K_2 = 1/K_1$.

The equilibrium constants for a reaction and its reverse are the reciprocals of one another.

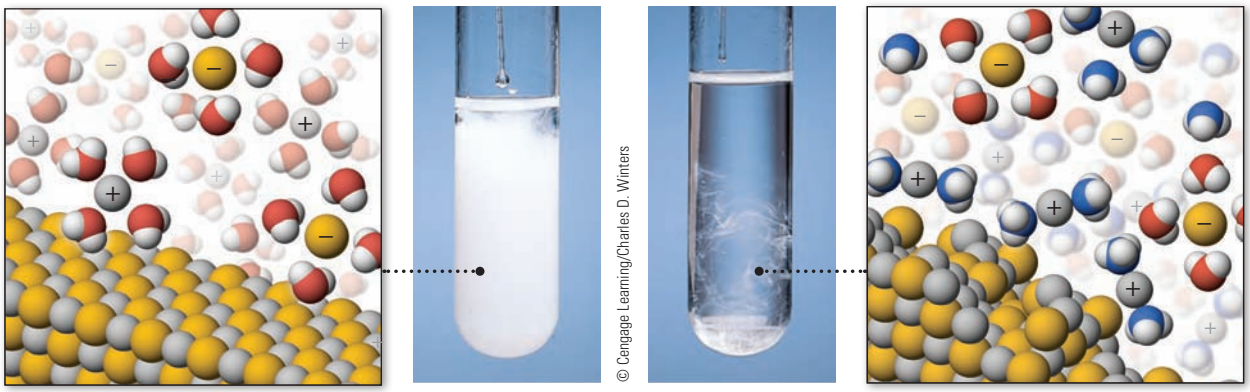

Figure 15.5 Dissolving silver chloride in aqueous ammonia. *(left)* A precipitate of AgCl(s) is suspended in water. *(right)* When aqueous ammonia is added, the ammonia reacts with the trace of silver ion in solution, the equilibrium shifts, and the silver chloride dissolves.

Adding Two Chemical Equations

It is often useful to add two equations to obtain the equation for a net process. As an example, consider the reactions that take place when silver chloride dissolves in water (to a *very* small extent) and ammonia is added to the solution. Ammonia reacts with silver ions to form a water-soluble compound, $Ag(NH_3)_2Cl$ (Figure 15.5). Adding the equation for dissolving solid AgCl to the equation for the reaction of Ag^+ ions with ammonia gives the equation for the net reaction, dissolving solid AgCl in aqueous ammonia. (All equilibrium constants are given at 25 °C.)

$$AgCl(s) \rightleftharpoons Ag^+(aq) + Cl^-(aq) \qquad K_1 = [Ag^+][Cl^-] = 1.8 \times 10^{-10}$$

$$Ag^+(aq) + 2\ NH_3(aq) \rightleftharpoons [Ag(NH_3)_2]^+(aq) \qquad K_2 = \frac{[Ag(NH_3)_2^+]}{[Ag^+][NH_3]^2} = 1.1 \times 10^7$$

Net equation:

$$AgCl(s) + 2\ NH_3(aq) \rightleftharpoons [Ag(NH_3)_2]^+(aq) + Cl^-(aq)$$

To obtain the equilibrium constant for the net reaction, K_{net}, we *multiply* the equilibrium constants for the two reactions, $K_1 \times K_2$.

$$K_{net} = K_1 \times K_2 = [Ag^+][Cl^-] \times \frac{[Ag(NH_3)_2^+]}{[Ag^+][NH_3]^2} = \frac{[Ag(NH_3)_2^+][Cl^-]}{[NH_3]^2}$$

$$K_{net} = K_1 \times K_2 = 2.0 \times 10^{-3}$$

When two or more chemical equations are added to produce a net equation, the equilibrium constant for the net equation is the product of the equilibrium constants for the added equations.

Problem Solving Tip 15.3 Balanced Equations and Equilibrium Constants

You should now know

1. how to write an equilibrium constant expression from the balanced equation, recognizing that the concentrations of solids and liquids used as solvents do not appear in the expression.
2. that when the stoichiometric coefficients in a balanced equation are changed by a factor of n, $K_{new} = (K_{old})^n$.
3. that when a balanced equation is reversed, $K_{new} = 1/K_{old}$.
4. that when several balanced equations (each with its own equilibrium constant, K_1, K_2, etc.) are added to obtain a net, balanced equation, $K_{net} = K_1 \times K_2 \times K_3 \times \ldots$.

EXAMPLE 15.6

Balanced Equations and Equilibrium Constants

Problem A mixture of nitrogen, hydrogen, and ammonia is brought to equilibrium. When the equation is written using whole-number coefficients, as follows, the value of K_c is 3.5×10^8 at 25 °C.

Equation 1: $N_2(g) + 3\ H_2(g) \rightleftharpoons 2\ NH_3(g)$ $\qquad K_1 = 3.5 \times 10^8$

However, the equation can also be written as given in Equation 2. What is the value of K_2?

Equation 2: $\frac{1}{2}\ N_2(g) + \frac{3}{2}\ H_2(g) \rightleftharpoons NH_3(g)$ $\qquad K_2 = ?$

The decomposition of ammonia to the elements (Equation 3) is the reverse of its formation (Equation 1). What is the value of K_3?

Equation 3: $2\ NH_3(g) \rightleftharpoons N_2(g) + 3\ H_2(g)$ $\qquad K_3 = ?$

What Do You Know? You know the value of K_c for a given balanced equation. You want to know how the value of K_c changes as the stoichiometric coefficients change or when the equation is reversed.

Strategy Determine how the desired reaction is related to the given reaction(s). (Was a given chemical reaction multiplied by a factor? Was a reaction reversed? Were two or more reactions added?) Use the relationships discussed to determine the effect(s) of these transformations on the given K value(s). See also *Problem Solving Tip 15.3.*

SOLUTION Equation 2 can be obtained by multiplying Equation 1 by 1/2. Thus K_2 is equal to K_1 raised to the one-half power, $K_1^{1/2}$. To confirm this relationship between K_1 and K_2, write the equilibrium constant expressions for these two balanced equations.

$$K_1 = \frac{[NH_3]^2}{[N_2][H_2]^3} \qquad K_2 = \frac{[NH_3]}{[N_2]^{1/2}[H_2]^{3/2}}$$

Writing these expressions makes it clear that K_2 is the square root of K_1.

$$K_2 = (K_1)^{1/2} = \sqrt{K_1} = \sqrt{3.5 \times 10^8} = 1.9 \times 10^4$$

Equation 3 is the reverse of Equation 1, and its equilibrium constant expression is

$$K_3 = \frac{[N_2][H_2]^3}{[NH_3]^2}$$

In this case, K_3 is the reciprocal of K_1. That is, $K_3 = 1/K_1$.

$$K_3 = \frac{1}{K_1} = \frac{1}{3.5 \times 10^8} = 2.9 \times 10^{-9}$$

Think about Your Answer Notice that the production of ammonia from the elements has a large equilibrium constant and is product-favored at equilibrium (Section 15.2). As expected, the reverse reaction, the decomposition of ammonia to its elements, has a small equilibrium constant and is reactant-favored at equilibrium.

Check Your Understanding

The conversion of oxygen to ozone has a very small equilibrium constant.

$$3/2\ O_2(g) \rightleftharpoons O_3(g) \qquad K = 2.5 \times 10^{-29}$$

(a) What is the value of K when the equation is written using whole-number coefficients?

$$3\ O_2(g) \rightleftharpoons 2\ O_3(g)$$

(b) What is the value of K for the conversion of ozone to oxygen?

$$2\ O_3(g) \rightleftharpoons 3\ O_2(g)$$

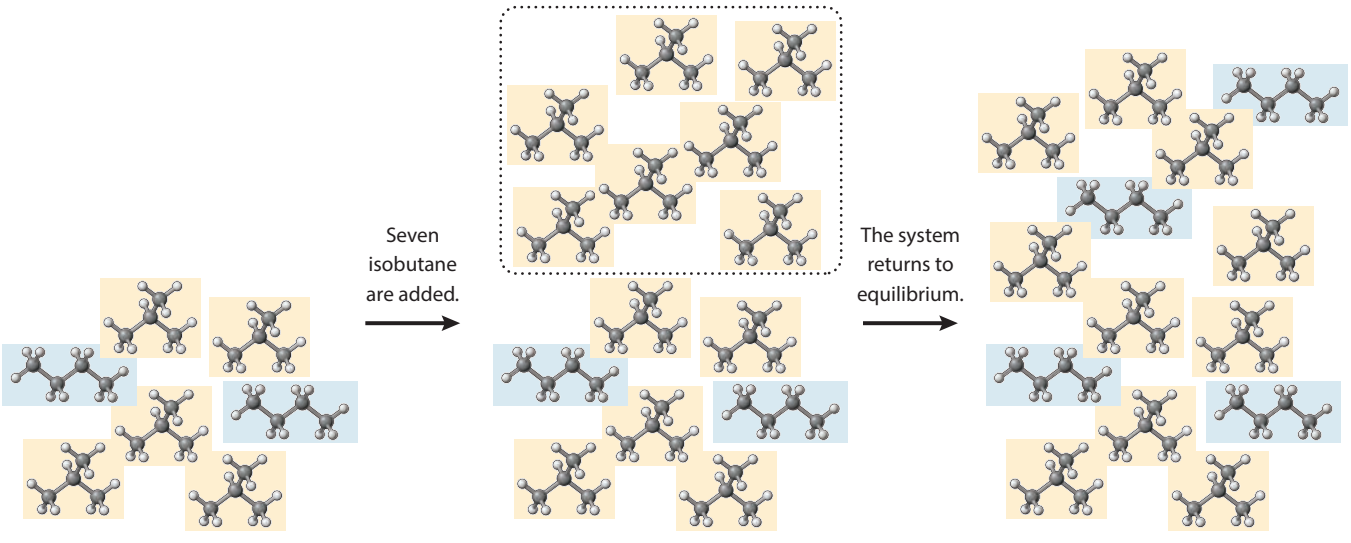
15.6 Disturbing a Chemical Equilibrium

Goal for Section 15.6

- Predict how a system at equilibrium will respond if the reaction conditions are changed.



The equilibrium between reactants and products may be disturbed in three ways: (1) by changing the temperature, (2) by changing the concentration of a reactant or product, or (3) by changing the volume (for systems involving gases) (Table 15.1). *A change in any of the factors that determine the equilibrium conditions of a system will cause the system to change in such a manner as to reduce or counteract the effect of the change.* This statement is often referred to as *Le Chatelier's principle* (Section 13.3). It is a shorthand way of describing how the quantities of reactants and products are adjusted so that equilibrium is restored, that is, so that the reaction quotient is once again equal to the equilibrium constant.

Effect of the Addition or Removal of a Reactant or Product

Consider the following experiment: You have a chemical system initially at equilibrium. To this you add (or take away) one or more of the reactants or products. The system will no longer be at equilibrium. When the system returns to equilibrium the new equilibrium concentrations of reactants and products will be different, but the value of the equilibrium constant expression will still equal K. To illustrate this, let us return to the butane/isobutane equilibrium (with $K_c = 2.5$).

$$\underset{\text{butane}}{CH_3CH_2CH_2CH_3} \rightleftharpoons \underset{\text{isobutane}}{CH_3CH(CH_3)_2} \qquad K_c = 2.5$$

Suppose the equilibrium mixture consists of two molecules of butane and five molecules of isobutane (Figure 15.6). The reaction quotient, Q, is 5/2 (or 2.5/1), the value of the equilibrium constant for the reaction. Now we add seven more

$Q = 5/2 = K$

An equilibrium mixture of five isobutane molecules and two butane molecules.

$Q = 12/2 > K$

Seven isobutane molecules are added, so the system is no longer at equilibrium.

$Q = 10/4 = K$

A net of two isobutane molecules has changed to butane molecules, to once again give an equilibrium mixture where the ratio of isobutane to butane is 5:2 (or 2.5:1).

Figure 15.6 Addition of more reactant or product to an equilibrium system.

molecules of isobutane to the mixture to give a ratio of 12 isobutane molecules to two butane molecules. The reaction quotient is now 6/1. This means Q is greater than K, and the system will change to reestablish equilibrium. To do so, some molecules of isobutane must be changed into butane molecules, a process that continues until the ratio [isobutane]/[butane] is once again 2.5/1. In this particular case, if two of the 12 isobutane molecules change to butane, the ratio of isobutane to butane is again equal to K_c (= 10/4 = 2.5/1), and equilibrium is reestablished.

EXAMPLE 15.7

Effect of Concentration Changes on Equilibrium

Problem Assume equilibrium has been established in a 1.00-L flask with [butane] = 0.00500 mol/L and [isobutane] = 0.0125 mol/L.

$$\text{Butane} \rightleftharpoons \text{Isobutane} \qquad K_c = 2.50$$

Then 0.0150 mol of butane is added. What are the concentrations of butane and isobutane when equilibrium is reestablished?

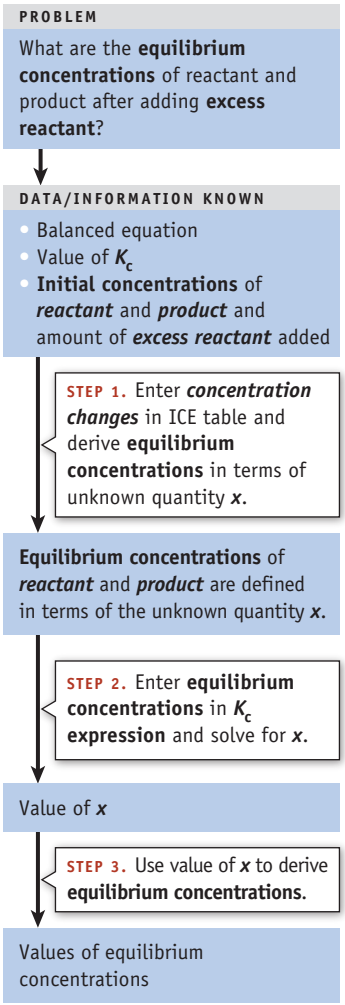
What Do You Know? Here you know the value of K_c, the balanced equation, the original equilibrium concentrations of reactant and product, and the amount of reactant added to the system at equilibrium.

Strategy After adding excess butane, $Q < K_c$. To reestablish equilibrium, the concentration of butane must decrease by an amount x and that of isobutane must increase, also by an amount x. Use an ICE table to track the changes.

SOLUTION First organize the information in a modified ICE table (and convert amounts to concentrations).

Equation	Butane	⇌	Isobutane
Initial (M)	0.00500		0.0125
Concentration immediately on adding butane (M)	0.00500 + 0.0150		0.0125
Change in concentration to reestablish equilibrium (M)	$-x$		$+x$
Equilibrium (M)	0.00500 + 0.0150 − x		0.0125 + x

The entries in this table were obtained as follows:



(a) The concentration of butane when equilibrium is reestablished is the original equilibrium concentration *plus* what was added (0.0150 mol/L) *minus* the concentration of butane that is converted to isobutane to reestablish equilibrium. The concentration of butane converted to isobutane is unknown and so is designated as x.

(b) The concentration of isobutane when equilibrium is reestablished is the concentration that was already present (0.0125 mol/L) plus the concentration formed (x mol/L) on reestablishing equilibrium.

Having defined [butane] and [isobutane] when equilibrium is reestablished and remembering that K_c is a constant (= 2.50), we can write

$$K_c = 2.50 = \frac{[\text{isobutane}]}{[\text{butane}]}$$

Strategy Map 15.7

We now calculate the new equilibrium composition:

$$2.50 = \frac{0.0125 + x}{0.00500 + 0.0150 - x} = \frac{0.0125 + x}{0.0200 - x}$$

$$2.50\,(0.0200 - x) = 0.0125 + x$$

$$x = 0.01071 \text{ mol/L}$$

$$[\text{butane}] = 0.00500 + 0.0150 - x = 0.00929 \text{ M} = 0.0093 \text{ M}$$

$$[\text{isobutane}] = 0.0125 + x = 0.02321 \text{ M} = 0.0232 \text{ M}$$

Answer check: new ratio [isobutane]/[butane] = 0.02321/0.00929 = 2.5

Think about Your Answer As predicted by Le Chatelier's principle, the "stress" on the system from adding butane to the equilibrium mixture is relieved by converting some butane to isobutane to achieve a new equilibrium mixture where Q again equals K_c. In the new equilibrium mixture the butane concentration lies between its initial value and its value immediately upon the addition of excess butane, and the isobutane concentration is greater than the original value.

Check Your Understanding

Equilibrium exists between butane and isobutane when [butane] = 0.020 M and [isobutane] = 0.050 M. An additional 0.0200 mol/L of isobutane is added to the mixture. What are the concentrations of butane and isobutane after equilibrium has again been attained?

Effect of Volume Changes on Gas-Phase Equilibria

For an equilibrium system involving gases, what happens to the gas concentrations or pressures if the size of the container is changed? (Such a change occurs, for example, when fuel and air are compressed in an automobile engine.) The answer is that the gas concentrations also change if the container volume changes. And, if the concentrations change, then, depending on the stoichiometry, the equilibrium composition can change. As an example, consider the following equilibrium:

$$\underset{\text{brown gas}}{2\ NO_2(g)} \rightleftharpoons \underset{\text{colorless gas}}{N_2O_4(g)}$$

$$K_c = \frac{[N_2O_4]}{[NO_2]^2} = 170 \text{ at } 298 \text{ K}$$

What happens if the volume of the flask holding the gases is suddenly halved? The immediate result is that the concentrations of both gases will double. For example, assume equilibrium is initially established when $[N_2O_4]$ is 0.0280 mol/L and $[NO_2]$ is 0.0128 mol/L. When the volume is halved, $[N_2O_4]$ becomes 0.0560 mol/L, and $[NO_2]$ is 0.0256 mol/L. The reaction quotient, Q, under these circumstances is $(0.0560)/(0.0256)^2 = 85.4$. Now, Q is less than K, and to return to equilibrium the quantity of product must increase at the expense of the reactant. Thus, the new equilibrium composition will have a higher concentration of N_2O_4 than immediately after the volume change.

$$2\ NO_2(g) \rightleftharpoons N_2O_4(g)$$

$$\xrightarrow[\substack{NO_2 \text{ is converted to } N_2O_4 \\ \text{until equilibrium is attained}}]{\text{decrease volume of container}}$$

In returning to equilibrium the concentration of NO_2 decreases twice as much as the concentration of N_2O_4 increases because one molecule of N_2O_4 is formed by consuming two molecules of NO_2. This occurs until the reaction quotient, $Q = [N_2O_4]/[NO_2]^2$, is once again equal to K_c. The net effect of the volume decrease is to decrease the number of molecules in the gas phase.

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

The conclusions for the NO_2/N_2O_4 equilibrium can be generalized:

- For reactions involving gases, the stress of a volume decrease (a pressure increase) will be counterbalanced by a change in the equilibrium composition to one having a smaller number of gas molecules.
- For a volume increase (a pressure decrease), the equilibrium composition will favor the side of the reaction with the larger number of gas molecules.
- For a reaction in which there is no change in the number of gas molecules in proceeding from reactants to products, such as in the reaction of H_2 and I_2 to produce HI [$H_2(g) + I_2(g) \rightleftharpoons 2\ HI(g)$], a volume change will have no effect.

Effect of Temperature Changes on Equilibrium Composition

Changing the temperature of a system at equilibrium is different from other equilibrium disturbances because *the value of the equilibrium constant changes with temperature.* You can make a qualitative prediction about the effect if you know whether the reaction is exothermic or endothermic. As an example, consider the endothermic reaction of N_2 with O_2 to give NO.

$$N_2(g) + O_2(g) \rightleftharpoons 2\ NO(g) \qquad \Delta_r H° = +180.6\ kJ/mol\text{-}rxn$$

$$K_c = \frac{[NO]^2}{[N_2][O_2]}$$

Le Chatelier's principle allows you to predict how the value of K will vary with temperature. The formation of NO from N_2 and O_2 is endothermic; that is, energy must be provided as heat for the reaction to occur. You might imagine that heat is a "reactant."

$$heat + N_2(g) + O_2(g) \rightleftharpoons 2\ NO(g)$$

If the system is at equilibrium and the temperature then increases, thus increasing the energy added as heat, the system will adjust to alleviate this "stress." The way to counteract the energy input is to use up some of the energy added as heat by consuming N_2 and O_2 and producing more NO as the system returns to equilibrium. This raises the value of the numerator ($[NO]^2$) and lowers the value of the denominator ($[N_2][O_2]$) in the reaction quotient, Q, resulting in a higher value of K_c.

The prediction regarding the $N_2/O_2/NO$ reaction is correct as you see in the following table of equilibrium constants at various temperatures. The equilibrium constant and thus the proportion of NO in the equilibrium mixture increases with temperature.

Equilibrium Constant, K_c	Temperature (K)
4.5×10^{-31}	298
6.7×10^{-10}	900
1.7×10^{-3}	2300

As another example, consider the combination of molecules of the brown gas NO_2 to form colorless N_2O_4. An equilibrium between these compounds is readily achieved in a closed system (Figure 15.7).

$$2\ NO_2(g) \rightleftharpoons N_2O_4(g) \qquad \Delta_r H° = -57.1\ kJ/mol\text{-}rxn$$

$$K_c = \frac{[N_2O_4]}{[NO_2]^2}$$

Equilibrium Constant, K_c	Temperature (K)
1300	273
170	298

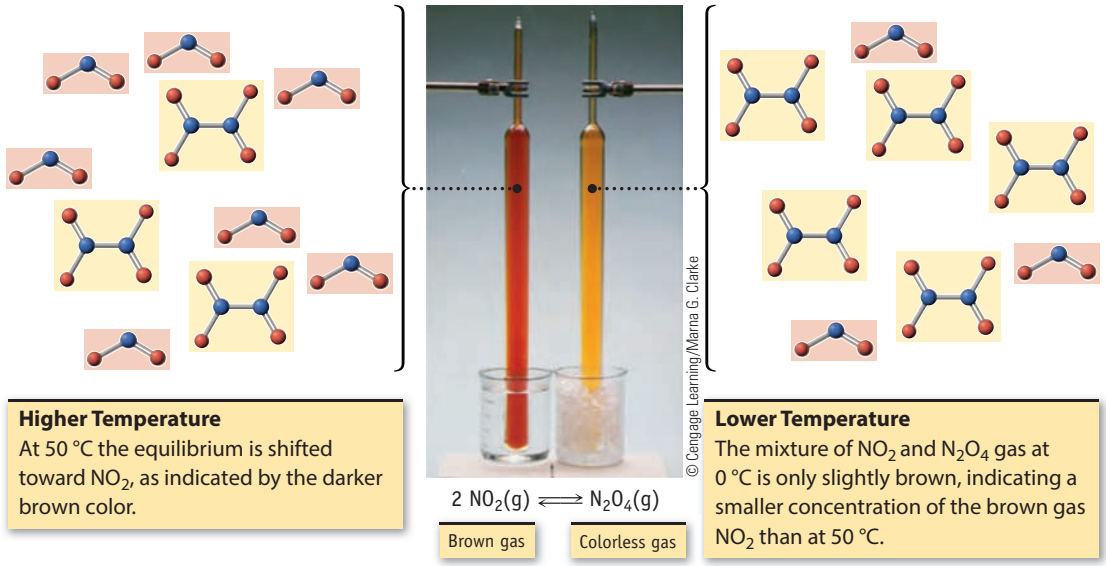

Figure 15.7 Effect of temperature on an equilibrium. The tubes in the photograph both contain gaseous NO_2 (brown) and N_2O_4 (colorless) at equilibrium. Because the equilibrium favors colorless N_2O_4, K_c is larger at the lower temperature.

Here, the reaction is exothermic, so we might imagine heat as being a reaction "product." By lowering the temperature of the system, as in Figure 15.7, some energy is removed as heat. The removal of energy can be counteracted if the reaction produces energy as heat by the combination of NO_2 molecules to give more N_2O_4. Thus, the equilibrium concentration of NO_2 decreases; the concentration of N_2O_4 increases; and the value of K is larger at lower temperatures.

In summary,

- when the temperature of a system at equilibrium increases, the equilibrium will shift in the direction that absorbs energy as heat (Table 15.1)—that is, in the endothermic direction.
- if the temperature decreases, the equilibrium will shift in the direction that releases energy as heat—that is, in the exothermic direction.
- changing the temperature changes the value of K.

TABLE 15.1 Effects of Disturbances on Equilibrium Composition

Disturbance	Change as Mixture Returns to Equilibrium	Effect on Equilibrium	Effect on K
Reactions Involving Solids, Liquids, or Gases			
Addition of reactant*	Some of added reactant is consumed	Product concentration increases	No change
Addition of product*	Some of added product is consumed	Reactant concentration increases	No change
Rise in temperature	Energy is absorbed by system	Shift in endothermic direction	Change
Drop in temperature	Energy is generated by system	Shift in exothermic direction	Change
Reactions Involving Gases			
Decrease in volume, increase in pressure	Pressure decreases	Composition changes to reduce total number of gas molecules	No change
Increase in volume, decrease in pressure	Pressure increases	Composition changes to increase total number of gas molecules	No change

*Does not apply when an insoluble solid reactant or product is added. Their "concentrations" do not appear in the reaction quotient.

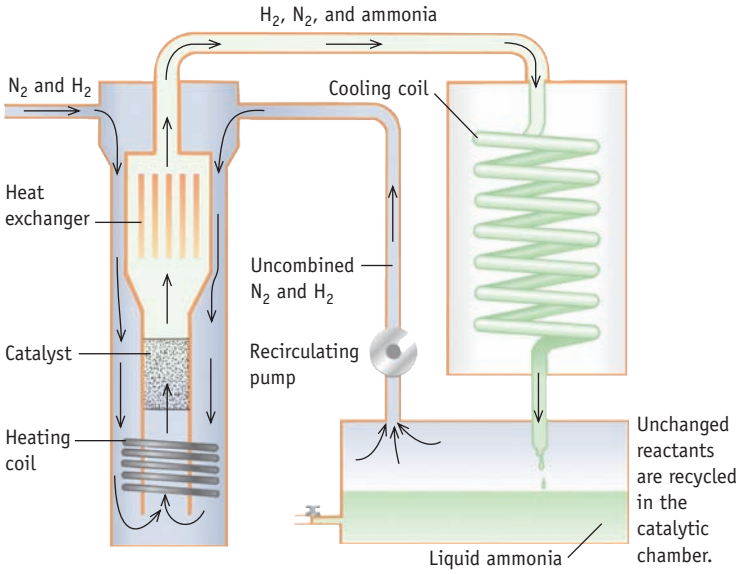
15.1 Applying Equilibrium Concepts—The Haber-Bosch Ammonia Process

Nitrogen-containing substances are used around the world to stimulate the growth of field crops. Farmers from Portugal to Tibet have used animal waste for centuries as a "natural" fertilizer. In the 19th century, industrialized countries imported nitrogen-rich marine bird manure from Peru, Bolivia, and Chile, but the supply of this material was limited. In 1898, William Ramsay (the discoverer of the noble gases, *Applying Chemical Principles, Argon—An Amazing Discovery, page 103*) pointed out that the amount of "fixed nitrogen" in the world was being depleted and predicted that world food shortages would occur by the mid-20th century as a result. That Ramsay's prediction failed to materialize was due in part to the work of Fritz Haber (1868–1934). In about 1908, Haber developed a method to make ammonia directly from the elements,

$$N_2(g) + 3\ H_2(g) \rightleftharpoons 2\ NH_3(g)$$



and, a few years later, Carl Bosch (1874–1940) perfected the industrial scale synthesis. Ammonia is now made for pennies per kilogram and is consistently ranked in the top five chemicals produced in the United States, with 8.7 billion kilograms produced annually. In addition to its direct use as a fertilizer, it is also a starting material for making nitric acid and ammonium nitrate, among other things.

The manufacture of ammonia is a good example of the role that kinetics and chemical equilibria play in practical chemistry. The $N_2 + H_2$ reaction is product-favored at equilibrium at 25 °C (K_c (calc'd value) $= 3.5 \times 10^8$). In addition, the reaction is exothermic ($\Delta_r H° = -92.2$ kJ/mol-rxn). Unfortunately, the production of ammonia at 25 °C is slow, so it is necessary to carry out the reaction at a higher temperature and to use a catalyst to increase the reaction rate.

An effective catalyst for the Haber-Bosch process is Fe_3O_4 mixed with KOH, SiO_2, and Al_2O_3 (all inexpensive chemicals). Because the catalyst is not effective below 400 °C, the process is carried out at 450–500 °C. The problem, however, is that the equilibrium constant declines with temperature, as predicted by Le Chatelier's principle. At 450 °C, K_c (experimental value) = 0.16.

When carrying out the reaction at this high temperature, two things are done to increase ammonia yields. The first is to raise the pressure. This does not change the value of K, but an increase in pressure can be compensated by converting 4 mol of reactants to 2 mol of product, thereby increasing the percent conversion to NH_3. The second is to remove the ammonia as it is produced. Both increasing the pressure and removing ammonia take advantage of Le Chatelier's principle to produce ammonia under reactant-favored conditions.

A mixture of H_2 and N_2 is pumped over a catalytic surface.

The Haber-Bosch process for ammonia synthesis. The NH_3 is collected as a liquid (at −33 °C).

Questions:

1. Anhydrous ammonia is used directly as a fertilizer, but much of it is also converted to other fertilizers such as ammonium nitrate and urea.
   a. Write a balanced equation for the conversion of ammonia to ammonium nitrate.
   b. Urea is formed in the reaction of ammonia and CO_2.

$$2\ NH_3(g) + CO_2(g) \rightleftharpoons (NH_2)_2CO(s) + H_2O(g)$$

   Would high pressure favor urea production? Would high temperature? ($\Delta_f H°$ for solid urea = −333.1 kJ/mol-rxn). Explain your answers.
2. Hydrogen is used in the Haber-Bosch process, and this is made from natural gas in a process called *steam reforming.*

$$CH_4(g) + H_2O(g) \rightarrow CO(g) + 3\ H_2(g)$$

$$CO(g) + H_2O(g) \rightarrow CO_2(g) + H_2(g)$$

   a. Are the two reactions above endo- or exothermic?
   b. To obtain the H_2 necessary to manufacture 15 billion kilograms of NH_3, what mass of CH_4 is required, and what mass of CO_2 is produced as a by-product (assuming complete conversion of the CH_4)?

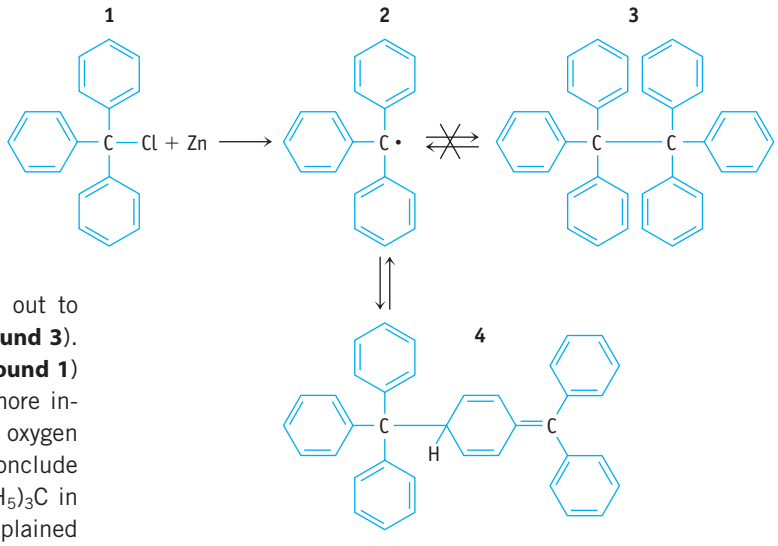
15.2 Trivalent Carbon



The octet rule is a guiding principle in organic chemistry. As a result, when someone discovers a molecule that does not obey the octet rule, organic chemists are always interested. The synthesis of the triphenylmethyl radical, $(C_6H_5)_3C$ was one such event.

The triphenylmethyl radical (**compound 2**), the first known persistent organic free radical, was discovered over 100 years ago by Moses Gomberg, a chemist at the University of Michigan. Gomberg set out to make hexaphenylethane $[(C_6H_5)_3C–C(C_6H_5)_3]$ (**compound 3**). When he combined the reactants $(C_6H_5)_3CCl$ (**compound 1**) and Zn, he obtained a yellow solution that became more intensely yellow when heated and was reactive toward oxygen and halogens. This extreme reactivity led Gomberg to conclude that the yellow color was due to the presence of $(C_6H_5)_3C$ in solution. The existence of the stable free radical was explained by the fact that there are three large phenyl groups around a carbon atom, which prevents the radical from undergoing the expected dimerization to hexaphenylethane.

Actually, the triphenylmethyl radical does dimerize, but not the way Gomberg had expected. A diamagnetic, white solid crystalline dimer (**compound 4**) can be isolated from the solutions containing the radical. The dimerization occurs between a methyl carbon radical on one molecule and the phenyl ring on a second. When redissolved in benzene, the original yellow solution forms.

Studies determined that compounds **4** and **2** exist in solution in equilibrium. The value of K_c for the dimer-monomer equilibrium (**4** $\rightleftharpoons$ **2**) in benzene is 4.1×10^{-4} at 20 °C.

Interestingly, Gomberg finished his initial publication with the following statement: "This work will be continued and I wish to reserve the field for myself." In the United States, chemical research is competitive and Gomberg's wish was not respected.

Questions:

1. Freezing point depression is one means of determining the molar mass of a compound. The freezing point depression constant of benzene is –5.12 °C/*m*.
   a. When a 0.503 g sample of the white crystalline dimer is dissolved in 10.0 g benzene, the freezing point of benzene is decreased by 0.542 °C. Verify that the molar mass of the dimer is 475 g/mol when determined by freezing point depression. Assume no dissociation of the dimer occurs.
   b. The correct molar mass of the dimer is 487 g/mol. Explain why the dissociation equilibrium causes the freezing point depression calculation to yield a lower molar mass for the dimer.
2. What concentration of the monomer (**2**) will exist at equilibrium with 0.015 mol/L of the dimer (**4**) in benzene at 20 °C?
3. A 0.64 g sample of the white crystalline dimer (**4**) is dissolved in 25.0 mL of benzene at 20 °C. Use the equilibrium constant to calculate the concentrations of monomer (**2**) and dimer (**4**) in this solution.
4. Predict whether the dissociation of the dimer to the monomer is exothermic or endothermic, based on the fact that at higher temperatures the yellow color of the solution intensifies.
5. Which of the organic species mentioned in this story is paramagnetic?
   a. triphenylmethyl chloride
   b. triphenylmethyl radical
   c. the triphenylmethyl dimer

CHAPTER GOALS REVISITED

The goals for this chapter are keyed to specific Study Questions to help you organize your review:

15.1 Chemical Equilibrium: A Review

- Understand that chemical reactions are reversible and that chemical equilibria are dynamic. 73, 74.

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

15.2 The Equilibrium Constant and Reaction Quotient

- Write the equilibrium constant expression, K, for a chemical reaction. 1, 2.
- Recognize that the equilibrium constant can be written relating K to concentrations (K_c) or, if the equilibrating species are gases, to partial pressures (K_p). Convert between K_c and K_p values. 25, 26.
- Predict whether a reaction is reactant-favored or product-favored at equilibrium based on the value of K. 71.
- Write the reaction quotient expression, Q, for a chemical reaction and use Q to decide whether a reaction is at equilibrium ($Q = K$), or if there will be a net conversion of reactants to products ($Q < K$) or products to reactants ($Q > K$) to attain equilibrium. 3–6, 37, 38.

15.3 Determining an Equilibrium Constant

- Calculate an equilibrium constant given the reactant and product concentrations at equilibrium. 7, 8, 9.
- Calculate an equilibrium constant given the initial concentrations of the reactants and products and the concentration of one of the reactants or products at equilibrium. 11, 12, 31, 35, 36, 45, 46.

15.4 Using Equilibrium Constants in Calculations

- Use equilibrium constants to calculate the concentration (or pressure) of a reactant or a product at equilibrium. 13–17, 44, 49, 50, 52, 59.

15.5 More about Balanced Equations and Equilibrium Constants

- Know how K changes as different stoichiometric coefficients are used in a balanced equation, if the equation is reversed, or if several equations are added to give a new net equation. 19–24, 32, 33, 39.

15.6 Disturbing a Chemical Equilibrium

- Predict how a system at equilibrium will respond if the reaction conditions are changed. 27–30, 40–43, 56, 66, 67.

KEY EQUATIONS

Equation 15.1 (page 674) The equilibrium constant expression. At equilibrium, the ratio of products to reactants (each raised to the power corresponding to its stoichiometric coefficient) has a constant value, K (at a particular temperature). For the general reaction $aA + bB \rightleftharpoons cC + dD$,

$$\text{Equilibrium constant} = K = \frac{[C]^c[D]^d}{[A]^a[B]^b}$$

Equation 15.2 (page 677) For the general reaction $aA + bB \rightleftharpoons cC + dD$, the ratio of product to reactant concentrations at any point in the reaction is the reaction quotient, Q.

$$\text{Reaction quotient} = Q = \frac{[C]^c[D]^d}{[A]^a[B]^b}$$

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Equation 15.3 (page 685) This approximation is used to solve for the equilibrium concentrations of B and C ($= x$) in the general reaction $A \rightleftharpoons B + C$ when the value of $100 \times K$ is less than the original concentration of $A (= [A]_0)$.

$$K = \frac{[B][C]}{[A]} \approx \frac{(x)(x)}{[A]_0}$$

STUDY QUESTIONS

▲ denotes challenging questions. **Blue-numbered questions** have answers in Appendix N and fully worked solutions in the *Student Solutions Manual*.

Practicing Skills

Writing Equilibrium Constant Expressions

(See Section 15.2 and Example 15.1.)

1. Write equilibrium constant expressions for the following reactions. For gases, use either pressures or concentrations.
   (a) $2\ H_2O_2(g) \rightleftharpoons 2\ H_2O(g) + O_2(g)$
   (b) $CO(g) + {}^1/_2\ O_2(g) \rightleftharpoons CO_2(g)$
   (c) $C(s) + CO_2(g) \rightleftharpoons 2\ CO(g)$
   (d) $NiO(s) + CO(g) \rightleftharpoons Ni(s) + CO_2(g)$

2. Write equilibrium constant expressions for the following reactions. For gases, use either pressures or concentrations.
   (a) $3\ O_2(g) \rightleftharpoons 2\ O_3(g)$
   (b) $Fe(s) + 5\ CO(g) \rightleftharpoons Fe(CO)_5(g)$
   (c) $(NH_4)_2CO_3(s) \rightleftharpoons 2\ NH_3(g) + CO_2(g) + H_2O(g)$
   (d) $Ag_2SO_4(s) \rightleftharpoons 2\ Ag^+(aq) + SO_4^{2-}(aq)$

The Equilibrium Constant and Reaction Quotient

(See Section 15.2 and Example 15.2.)

3. $K_c = 5.6 \times 10^{-12}$ at 500 K for the dissociation of iodine molecules to iodine atoms.

   $$I_2(g) \rightleftharpoons 2\ I(g)$$

   A mixture has $[I_2] = 0.020$ mol/L and $[I] = 2.0 \times 10^{-8}$ mol/L. Is the reaction at equilibrium (at 500 K)? If not, which way must the reaction proceed to reach equilibrium?

4. The reaction

   $$2\ NO_2(g) \rightleftharpoons N_2O_4(g)$$

   has an equilibrium constant, K_c, of 170 at 25 °C. If 2.0×10^{-3} mol of NO_2 is present in a 10.-L flask along with 1.5×10^{-3} mol of N_2O_4, is the system at equilibrium? If it is not at equilibrium, does the concentration of NO_2 increase or decrease as the system proceeds to equilibrium?

5. A mixture of SO_2, O_2, and SO_3 at 1000 K contains the gases at the following concentrations: $[SO_2] = 5.0 \times 10^{-3}$ mol/L, $[O_2] = 1.9 \times 10^{-3}$ mol/L, and $[SO_3] = 6.9 \times 10^{-3}$ mol/L. Is the reaction at equilibrium? If not, which way will the reaction proceed to reach equilibrium?

   $$2\ SO_2(g) + O_2(g) \rightleftharpoons 2\ SO_3(g)\ K_c = 279$$

6. The equilibrium constant, K_c, for the reaction

   $$2\ NOCl(g) \rightleftharpoons 2\ NO(g) + Cl_2(g)$$

   is 3.9×10^{-3} at 300 °C. A mixture contains the gases at the following concentrations: $[NOCl] = 5.0 \times 10^{-3}$ mol/L, $[NO] = 2.5 \times 10^{-3}$ mol/L, and $[Cl_2] = 2.0 \times 10^{-3}$ mol/L. Is the reaction at equilibrium at 300 °C? If not, in which direction does the reaction proceed to come to equilibrium?

Calculating an Equilibrium Constant

(See Section 15.3 and Example 15.3.)

7. The reaction

   $$PCl_5(g) \rightleftharpoons PCl_3(g) + Cl_2(g)$$

   was examined at 250 °C. At equilibrium, $[PCl_5] = 4.2 \times 10^{-5}$ mol/L, $[PCl_3] = 1.3 \times 10^{-2}$ mol/L, and $[Cl_2] = 3.9 \times 10^{-3}$ mol/L. Calculate K_c for the reaction.

8. An equilibrium mixture of SO_2, O_2, and SO_3 at a high temperature contains the gases at the following concentrations: $[SO_2] = 3.77 \times 10^{-3}$ mol/L, $[O_2] = 4.30 \times 10^{-3}$ mol/L, and $[SO_3] = 4.13 \times 10^{-3}$ mol/L. Calculate the equilibrium constant, K_c, for the reaction.

   $$2\ SO_2(g) + O_2(g) \rightleftharpoons 2\ SO_3(g)$$

9. The reaction

$$C(s) + CO_2(g) \rightleftharpoons 2\ CO(g)$$

occurs at high temperatures. At 700 °C, a 200.0-L tank contains 1.0 mol of CO, 0.20 mol of CO_2, and 0.40 mol of C at equilibrium.

(a) Calculate K_c for the reaction at 700 °C.

(b) Calculate K_c for the reaction, also at 700 °C, if the amounts at equilibrium in the 200.0-L tank are 1.0 mol of CO, 0.20 mol of CO_2, and 0.80 mol of C.

(c) Compare the results of (a) and (b). Does the quantity of carbon affect the value of K_c? Explain.

10. Hydrogen and carbon dioxide react at a high temperature to give water and carbon monoxide.

$$H_2(g) + CO_2(g) \rightleftharpoons H_2O(g) + CO(g)$$

(a) Laboratory measurements at 986 °C show that there are 0.11 mol each of CO and H_2O vapor and 0.087 mol each of H_2 and CO_2 at equilibrium in a 50.0-L container. Calculate the equilibrium constant for the reaction at 986 °C.

(b) Suppose 0.010 mol each of H_2 and CO_2 are placed in a 200.0-L container. When equilibrium is achieved at 986 °C, what amounts of CO(g) and H_2O(g), in moles, would be present? [Use the value of K_c from part (a).]

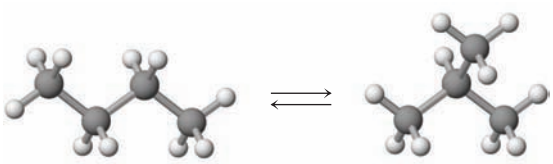
11. A mixture of CO and Cl_2 is placed in a reaction flask: [CO] = 0.0102 mol/L and [Cl_2] = 0.00609 mol/L. When the reaction

$$CO(g) + Cl_2(g) \rightleftharpoons COCl_2(g)$$

has come to equilibrium at 600 K, [Cl_2] = 0.00301 mol/L.

(a) Calculate the concentrations of CO and $COCl_2$ at equilibrium.

(b) Calculate K_c.

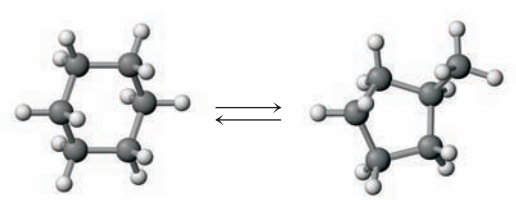


12. You place 0.0300 mol of pure SO_3 in an 8.00-L flask at 1150 K. At equilibrium, 0.0058 mol of O_2 has been formed. Calculate K_c for the reaction at 1150 K.

$$2\ SO_3(g) \rightleftharpoons 2\ SO_2(g) + O_2(g)$$

Using Equilibrium Constants

(See Section 15.4 and Examples 15.4 and 15.5.)



13. The value of K_c for the interconversion of butane and isobutane is 2.5 at 25 °C.

butane isobutane

If you place 0.017 mol of butane in a 0.50-L flask at 25 °C and allow equilibrium to be established, what will be the equilibrium concentrations of the two forms of butane?

14. Cyclohexane, C_6H_{12}, a hydrocarbon, can isomerize or change into methylcyclopentane, a compound of the same formula ($C_5H_9CH_3$) but with a different molecular structure.

Cyclohexane Methylcyclopentane

The equilibrium constant has been estimated to be 0.12 at 25 °C. If you had originally placed 0.045 mol of cyclohexane in a 2.8-L flask, what would be the concentrations of cyclohexane and methylcyclopentane when equilibrium is established?

15. The equilibrium constant for the dissociation of iodine molecules to iodine atoms

$$I_2(g) \rightleftharpoons 2\ I(g)$$

is 3.76×10^{-3} at 1000 K. Suppose 0.105 mol of I_2 is placed in a 12.3-L flask at 1000 K. What are the concentrations of I_2 and I when the system comes to equilibrium?

16. The equilibrium constant, K_c, for the reaction

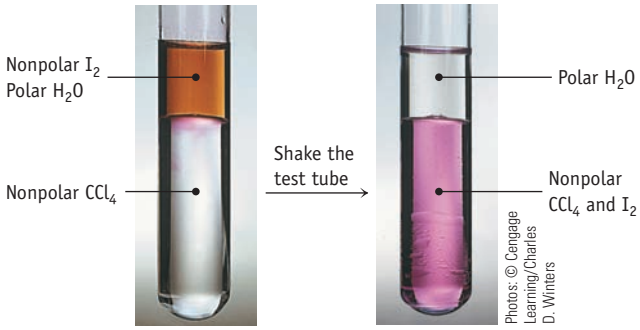
$$N_2O_4(g) \rightleftharpoons 2\ NO_2(g)$$

at 25 °C is 5.9×10^{-3}. Suppose 15.6 g of N_2O_4 is placed in a 5.000-L flask at 25 °C. Calculate the following:

(a) the amount of NO_2 (mol) present at equilibrium;

(b) the percentage of the original N_2O_4 that is dissociated.

17. Carbonyl bromide decomposes to carbon monoxide and bromine.



$$COBr_2(g) \rightleftharpoons CO(g) + Br_2(g)$$

K_c is 0.190 at 73 °C. If you place 0.0500 mol of $COBr_2$ in a 2.00-L flask and heat it to 73 °C, what are the equilibrium concentrations of $COBr_2$, CO, and Br_2? What percentage of the original $COBr_2$ decomposed at this temperature?

18. Iodine dissolves in water, but its solubility in a nonpolar solvent such as CCl_4 is greater.

Extracting iodine (I_2) from water with the nonpolar solvent CCl_4. I_2 is more soluble in CCl_4 and, after shaking a mixture of water and CCl_4, the I_2 has accumulated in the more dense CCl_4 layer.

The equilibrium constant is 85.0 for the process

$$I_2(aq) \rightleftharpoons I_2(CCl_4)$$

You place 0.0340 g of I_2 in 100.0 mL of water. After shaking it with 10.0 mL of CCl_4, how much I_2 remains in the water layer?

Manipulating Equilibrium Constant Expressions

(See Section 15.5 and Example 15.6.)

19. Which of the following correctly relates the equilibrium constants for the two reactions shown?

$$A + B \rightleftharpoons 2\ C \qquad K_1$$

$$2\ A + 2\ B \rightleftharpoons 4\ C \qquad K_2$$

(a) $K_2 = 2K_1$ (c) $K_2 = 1/K_1$

(b) $K_2 = K_1^2$ (d) $K_2 = 1/K_1^2$

20. Which of the following correctly relates the equilibrium constants for the two reactions shown?

$$A + B \rightleftharpoons 2\ C \qquad K_1$$

$$C \rightleftharpoons \tfrac{1}{2}\ A + \tfrac{1}{2}\ B \qquad K_2$$

(a) $K_2 = 1/(K_1)^{1/2}$ (c) $K_2 = K_1^2$

(b) $K_2 = 1/K_1$ (d) $K_2 = -K_1^{1/2}$

21. Consider the following equilibria involving $SO_2(g)$ and their corresponding equilibrium constants.

$$SO_2(g) + \tfrac{1}{2}\ O_2(g) \rightleftharpoons SO_3(g) \qquad K_1$$

$$2\ SO_3(g) \rightleftharpoons 2\ SO_2(g) + O_2(g) \qquad K_2$$

Which of the following expressions relates K_1 to K_2?

(a) $K_2 = K_1^2$ (d) $K_2 = 1/K_1$

(b) $K_2^2 = K_1$ (e) $K_2 = 1/K_1^2$

(c) $K_2 = K_1$

22. The equilibrium constant K for the reaction

$$CO_2(g) \rightleftharpoons CO(g) + \tfrac{1}{2}\ O_2(g)$$

is 6.66×10^{-12} at 1000 K. Calculate K for the reaction

$$2\ CO(g) + O_2(g) \rightleftharpoons 2\ CO_2(g)$$

23. Calculate K for the reaction

$$SnO_2(s) + 2\ CO(g) \rightleftharpoons Sn(s) + 2\ CO_2(g)$$

given the following information:

$$SnO_2(s) + 2\ H_2(g) \rightleftharpoons Sn(s) + 2\ H_2O(g) \qquad K = 8.12$$

$$H_2(g) + CO_2(g) \rightleftharpoons H_2O(g) + CO(g) \qquad K = 0.771$$

24. Calculate K for the reaction

$$Fe(s) + H_2O(g) \rightleftharpoons FeO(s) + H_2(g)$$

given the following information:

$$H_2O(g) + CO(g) \rightleftharpoons H_2(g) + CO_2(g) \qquad K = 1.6$$

$$FeO(s) + CO(g) \rightleftharpoons Fe(s) + CO_2(g) \qquad K = 0.67$$

25. Relationship of K_c and K_p:

(a) K_p for the following reaction is 0.16 at 25 °C. What is the value of K_c?

$$2\ NOBr(g) \rightleftharpoons 2\ NO(g) + Br_2(g)$$

(b) The equilibrium constant, K_c, for the following reaction is 1.05 at 350 K. What is the value of K_p?

$$2\ CH_2Cl_2(g) \rightleftharpoons CH_4(g) + CCl_4(g)$$

26. Relationship of K_c and K_p:

(a) The equilibrium constant, K_c, for the following reaction at 25 °C is 170. What is the value of K_p?

$$N_2O_4(g) \rightleftharpoons 2\ NO_2(g)$$

(b) K_c for the decomposition of ammonium hydrogen sulfide is 1.8×10^{-4} at 25 °C. What is the value of K_p?

$$NH_4HS(s) \rightleftharpoons NH_3(g) + H_2S(g)$$

Disturbing a Chemical Equilibrium

(See Section 15.6 and Example 15.7.)

27. Dinitrogen trioxide decomposes to NO and NO_2 in an endothermic process ($\Delta_r H° = 40.5$ kJ/mol-rxn).

$$N_2O_3(g) \rightleftharpoons NO(g) + NO_2(g)$$

Predict the effect of the following changes on the position of the equilibrium; that is, state which way the equilibrium will shift (left, right, or no change) when each of the following changes is made.

(a) adding more $N_2O_3(g)$

(b) adding more $NO_2(g)$

(c) increasing the volume of the reaction flask

(d) lowering the temperature

Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

28. K_p for the following reaction is 0.16 at 25 °C:

$$2\ NOBr(g) \rightleftharpoons 2\ NO(g) + Br_2(g)$$

The enthalpy change for the reaction at standard conditions is +16.3 kJ/mol-rxn. Predict the effect of the following changes on the position of the equilibrium; that is, state which way the equilibrium will shift (left, right, or no change) when each of the following changes is made.

(a) adding more $Br_2(g)$

(b) removing some NOBr(g)

(c) decreasing the temperature

(d) increasing the container volume

29. Consider the isomerization of butane with an equilibrium constant of $K = 2.5$. (See Study Question 13.) The system is originally at equilibrium with [butane] = 1.0 M and [isobutane] = 2.5 M.

(a) If 0.50 mol/L of isobutane is suddenly added and the system shifts to a new equilibrium position, what is the equilibrium concentration of each gas?

(b) If 0.50 mol/L of butane is added to the original equilibrium mixture and the system shifts to a new equilibrium position, what is the equilibrium concentration of each gas?

30. The decomposition of NH_4HS

$$NH_4HS(s) \rightleftharpoons NH_3(g) + H_2S(g)$$

is an endothermic process. Using Le Chatelier's principle, explain how increasing the temperature would affect the equilibrium. If more NH_4HS is added to a flask in which this equilibrium exists, how is the equilibrium affected? What if some additional NH_3 is placed in the flask? What will happen to the pressure of NH_3 if some H_2S is removed from the flask?

General Questions

These questions are not designated as to type or location in the chapter. They may combine several concepts.

31. Suppose 0.086 mol of Br_2 is placed in a 1.26-L flask and heated to 1756 K, a temperature at which the halogen dissociates to atoms.

$$Br_2(g) \rightleftharpoons 2\ Br(g)$$

If Br_2 is 3.7% dissociated at this temperature, calculate K_c.

32. The equilibrium constant for the reaction

$$N_2(g) + O_2(g) \rightleftharpoons 2\ NO(g)$$

is 1.7×10^{-3} at 2300 *K*.

(a) What is *K* for the reaction when written as follows?

$$\tfrac{1}{2}\ N_2(g) + \tfrac{1}{2}\ O_2(g) \rightleftharpoons NO(g)$$

(b) What is *K* for the following reaction?

$$2\ NO(g) \rightleftharpoons N_2(g) + O_2(g)$$

33. K_p for the formation of phosgene, $COCl_2$, is 6.5×10^{11} at 25 °C.

$$CO(g) + Cl_2(g) \rightleftharpoons COCl_2(g)$$

What is the value of K_p for the dissociation of phosgene?

$$COCl_2(g) \rightleftharpoons CO(g) + Cl_2(g)$$

34. The equilibrium constant, K_c, for the following reaction is 1.05 at 350 K.

$$2\ CH_2Cl_2(g) \rightleftharpoons CH_4(g) + CCl_4(g)$$

If an equilibrium mixture of the three gases at 350 K contains 0.0206 M $CH_2Cl_2(g)$ and 0.0163 M CH_4, what is the equilibrium concentration of CCl_4?

35. Carbon tetrachloride can be produced by the following reaction:

$$CS_2(g) + 3\ Cl_2(g) \rightleftharpoons S_2Cl_2(g) + CCl_4(g)$$

Suppose 0.12 mol of CS_2 and 0.36 mol of Cl_2 are placed in a 10.0-L flask. After equilibrium has been achieved, the mixture contains 0.090 mol CCl_4. Calculate K_c.

36. Equal numbers of moles of H_2 gas and I_2 vapor are mixed in a flask and heated to 700 °C. The initial concentration of each gas is 0.0088 mol/L, and 78.6% of the I_2 is consumed when equilibrium is achieved according to the equation

$$H_2(g) + I_2(g) \rightleftharpoons 2\ HI(g)$$

Calculate K_c for this reaction.

37. The equilibrium constant for the butane $\rightleftharpoons$ isobutane isomerization reaction is 2.5 at 25 °C. If 1.75 mol of butane and 1.25 mol of isobutane are mixed, is the system at equilibrium? If not, when it proceeds to equilibrium, which reagent increases in concentration? Calculate the concentrations of the two compounds when the system reaches equilibrium.

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

38. At 2300 K the equilibrium constant for the formation of NO(g) is 1.7×10^{-3}.

$$N_2(g) + O_2(g) \rightleftharpoons 2\ NO(g)$$

(a) Analysis shows that the concentrations of N_2 and O_2 are both 0.25 M, and that of NO is 0.0042 M under certain conditions. Is the system at equilibrium?

(b) If the system is not at equilibrium, in which direction does the reaction proceed?

(c) When the system is at equilibrium, what are the equilibrium concentrations?

39. Which of the following correctly relates the two equilibrium constants for the two reactions shown?

$$NOCl(g) \rightleftharpoons NO(g) + \tfrac{1}{2}\ Cl_2(g) \qquad K_1$$

$$2\ NO(g) + Cl_2(g) \rightleftharpoons 2\ NOCl(g) \qquad K_2$$

(a) $K_2 = -K_1^2$ (c) $K_2 = 1/K_1^2$

(b) $K_2 = 1/(K_1)^{1/2}$ (d) $K_2 = 2K_1$

40. Consider the following equilibrium:

$$COBr_2(g) \rightleftharpoons CO(g) + Br_2(g) \qquad K_c = 0.190 \text{ at } 73\ ^\circ C$$

(a) A 0.50 mol sample of $COBr_2$ is transferred to a 9.50-L flask and heated until equilibrium is attained. Calculate the equilibrium concentrations of each species.

(b) The volume of the container is decreased to 4.5 L and the system allowed to return to equilibrium. Calculate the new equilibrium concentrations. (*Hint*: The calculation will be easier if you view this as a new problem with 0.5 mol of $COBr_2$ transferred to a 4.5-L flask.)

(c) What is the effect of decreasing the container volume from 9.50 L to 4.50 L?

41. Heating a metal carbonate leads to decomposition.

$$BaCO_3(s) \rightleftharpoons BaO(s) + CO_2(g)$$

Predict the effect on the equilibrium of each change listed below. Answer by choosing (i) no change, (ii) shifts left, or (iii) shifts right.

(a) add $BaCO_3$ (c) add BaO

(b) add CO_2 (d) raise the temperature

(e) increase the volume of the flask containing the reaction

42. Carbonyl bromide decomposes to carbon monoxide and bromine.

$$COBr_2(g) \rightleftharpoons CO(g) + Br_2(g)$$

K_c is 0.190 at 73 °C. Suppose you place 0.500 mol of $COBr_2$ in a 2.00-L flask and heat it to 73 °C (see Study Question 17). After equilibrium has been achieved, you add an additional 2.00 mol of CO.

(a) How is the equilibrium mixture affected by adding more CO?

(b) When equilibrium is reestablished, what are the new equilibrium concentrations of $COBr_2$, CO, and Br_2?

(c) How has the addition of CO affected the percentage of $COBr_2$ that decomposed?

43. Phosphorus pentachloride decomposes at elevated temperatures.

$$PCl_5(g) \rightleftharpoons PCl_3(g) + Cl_2(g)$$

An equilibrium mixture at some temperature consists of 3.120 g of PCl_5, 3.845 g of PCl_3, and 1.787 g of Cl_2 in a 10.0-L flask. If you add 1.418 g of Cl_2, how will the equilibrium be affected? What will the concentrations of PCl_5, PCl_3, and Cl_2 be when equilibrium is reestablished?

44. Ammonium hydrogen sulfide decomposes on heating.

$$NH_4HS(s) \rightleftharpoons NH_3(g) + H_2S(g)$$

If K_p for this reaction is 0.11 at 25 °C (when the partial pressures are measured in atmospheres), what is the total pressure in the flask at equilibrium?

45. Ammonium iodide dissociates reversibly to ammonia and hydrogen iodide if the salt is heated to a sufficiently high temperature.

$$NH_4I(s) \rightleftharpoons NH_3(g) + HI(g)$$

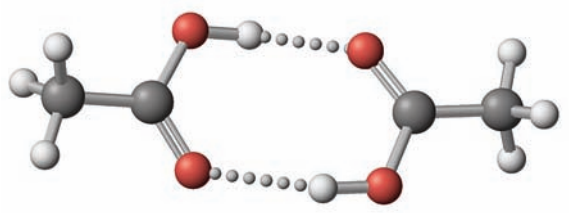
Some ammonium iodide is placed in a flask, which is then heated to 400 °C. If the total pressure in the flask when equilibrium has been achieved is 705 mm Hg, what is the value of K_p (when partial pressures are in atmospheres)?

46. When solid ammonium carbamate sublimes, it dissociates completely into ammonia and carbon dioxide according to the following equation:

$$(NH_4)(H_2NCO_2)(s) \rightleftharpoons 2\ NH_3(g) + CO_2(g)$$

At 25 °C, experiment shows that the total pressure of the gases in equilibrium with the solid is 0.116 atm. What is the equilibrium constant, K_p?

47. The equilibrium reaction $N_2O_4(g) \rightleftharpoons 2\ NO_2(g)$ has been thoroughly studied (Figure 15.7).



(a) If the total pressure in a flask containing NO_2 and N_2O_4 gas at 25 °C is 1.50 atm and the value of K_p at this temperature is 0.148, what fraction of the N_2O_4 has dissociated to NO_2?

(b) What happens to the fraction dissociated if the volume of the container is increased so that the total equilibrium pressure falls to 1.00 atm?

Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

48. In the gas phase, acetic acid exists as an equilibrium of monomer and dimer molecules. (The dimer consists of two molecules linked through hydrogen bonds.)

The equilibrium constant, K_c, at 25 °C for the monomer–dimer equilibrium

$$2\ CH_3CO_2H \rightleftharpoons (CH_3CO_2H)_2$$

has been determined to be 3.2×10^4. Assume that acetic acid is present initially at a concentration of 5.4×10^{-4} mol/L at 25 °C and that no dimer is present initially.

(a) What percentage of the acetic acid is converted to dimer?

(b) As the temperature increases, in which direction does the equilibrium shift? (Recall that hydrogen-bond formation is an exothermic process.)

49. Assume 3.60 mol of ammonia is placed in a 2.00-L vessel and allowed to decompose to the elements at 723 K.

$$2\ NH_3(g) \rightleftharpoons N_2(g) + 3\ H_2(g)$$

If the experimental value of K_c is 6.3 for this reaction at the temperature in the reactor, calculate the equilibrium concentration of each reagent. What is the total pressure in the flask?

50. The total pressure for a mixture of N_2O_4 and NO_2 is 0.15 atm. If $K_p = 7.1$ (at 25 °C), calculate the partial pressure of each gas in the mixture.

$$2\ NO_2(g) \rightleftharpoons N_2O_4(g)$$

51. K_c for the decomposition of ammonium hydrogen sulfide is 1.8×10^{-4} at 25 °C.

$$NH_4HS(s) \rightleftharpoons NH_3(g) + H_2S(g)$$

(a) When the pure salt decomposes in a flask, what are the equilibrium concentrations of NH_3 and H_2S?

(b) If NH_4HS is placed in a flask already containing 0.020 mol/L of NH_3 and then the system is allowed to come to equilibrium, what are the equilibrium concentrations of NH_3 and H_2S?

52. ▲ $COCl_2$ decomposes to CO and Cl_2 at high temperatures. K_c at 600 K for the reaction is 0.0071.

$$COCl_2(g) \rightleftharpoons CO(g) + Cl_2(g)$$

If 0.050 mol of $COCl_2$ is placed in a 12.5-L flask, what is the total pressure at equilibrium at 600 K?

53. ▲ A 15-L flask at 300 K contains 6.44 g of a mixture of NO_2 and N_2O_4 in equilibrium. What is the total pressure in the flask? (K_p for $2\ NO_2\ (g) \rightleftharpoons N_2O_4(g)$ is 7.1.)

54. ▲ Lanthanum oxalate decomposes when heated to lanthanum(III) oxide, CO, and CO_2.

$$La_2(C_2O_4)_3(s) \rightleftharpoons La_2O_3(s) + 3\ CO(g) + 3\ CO_2(g)$$

(a) If, at equilibrium, the total pressure in a 10.0-L flask is 0.200 atm, what is the value of K_p?

(b) Suppose 0.100 mol of $La_2(C_2O_4)_3$ was originally placed in the 10.0-L flask. What quantity of $La_2(C_2O_4)_3$ remains unreacted at equilibrium at 373 K?

55. ▲ The reaction of hydrogen and iodine to give hydrogen iodide has an equilibrium constant, K_c, of 56 at 435 °C.

(a) What is the value of K_p?

(b) Suppose you mix 0.045 mol of H_2 and 0.045 mol of I_2 in a 10.0-L flask at 425 °C. What is the total pressure of the mixture before and after equilibrium is achieved?

(c) What is the partial pressure of each gas at equilibrium?

56. Sulfuryl chloride, SO_2Cl_2, is used as a reagent in the synthesis of organic compounds. When heated to a sufficiently high temperature, it decomposes to SO_2 and Cl_2.

$$SO_2Cl_2(g) \rightleftharpoons SO_2(g) + Cl_2(g) \qquad K_c = 0.045 \text{ at } 375\ ^\circ C$$

(a) A 10.0-L flask containing 6.70 g of SO_2Cl_2 is heated to 375 °C. What is the concentration of each of the compounds in the system when equilibrium is achieved? What fraction of SO_2Cl_2 has dissociated?

(b) What are the concentrations of SO_2Cl_2, SO_2, and Cl_2 at equilibrium in the 10.0-L flask at 375 °C if you begin with a mixture of SO_2Cl_2 (6.70 g) and Cl_2 (0.10 atm)? What fraction of SO_2Cl_2 has dissociated?

(c) Compare the fractions of SO_2Cl_2 in parts (a) and (b). Do they agree with your expectations based on Le Chatelier's principle?

57. ▲ Hemoglobin (Hb) can form a complex with both O_2 and CO. For the reaction

$$HbO_2(aq) + CO(g) \rightleftharpoons HbCO(aq) + O_2(g)$$

at body temperature, K is about 200. If the ratio $[HbCO]/[HbO_2]$ comes close to 1, death is probable. What partial pressure of CO in the air is likely to be fatal? Assume the partial pressure of O_2 is 0.20 atm.

58. ▲ Limestone decomposes at high temperatures.

$$CaCO_3(s) \rightleftharpoons CaO(s) + CO_2(g)$$

At 1000 °C, $K_p = 3.87$. If pure $CaCO_3$ is placed in a 5.00-L flask and heated to 1000 °C, what quantity of $CaCO_3$ must decompose to achieve the equilibrium pressure of CO_2?

59. At 1800 K, oxygen dissociates very slightly into its atoms.

$$O_2(g) \rightleftharpoons 2\ O(g) \qquad K_p = 1.2 \times 10^{-10}$$

If you place 0.050 mol of O_2 in a 10.-L vessel and heat it to 1800 K, how many O atoms are present in the flask?

60. ▲ Nitrosyl bromide, NOBr, dissociates readily at room temperature.

$$NOBr(g) \rightleftharpoons NO(g) + \tfrac{1}{2}\ Br_2(g)$$

Some NOBr is placed in a flask at 25 °C and allowed to dissociate. The total pressure at equilibrium is 190 mm Hg and the compound is found to be 34% dissociated. What is the value of K_p?

61. ▲ Boric acid and glycerin form a complex

$$B(OH)_3(aq) + \text{glycerin}(aq) \rightleftharpoons B(OH)_3 \cdot \text{glycerin}(aq)$$

with an equilibrium constant of 0.90. If the concentration of boric acid is 0.10 M, how much glycerin should be added, per liter, so that 60.% of the boric acid is in the form of the complex?

62. ▲ The dissociation of calcium carbonate has an equilibrium constant of $K_p = 1.16$ at 800 °C.

$$CaCO_3(s) \rightleftharpoons CaO(s) + CO_2(g)$$

(a) What is K_c for the reaction?

(b) If you place 22.5 g of $CaCO_3$ in a 9.56-L container at 800 °C, what is the pressure of CO_2 in the container?

(c) What percentage of the original 22.5-g sample of $CaCO_3$ remains undecomposed at equilibrium?

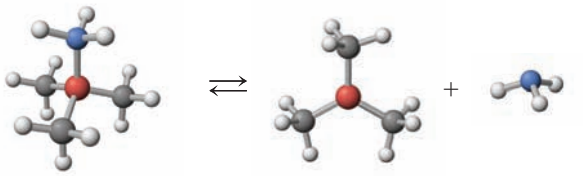
63. ▲ A sample of N_2O_4 gas with a pressure of 1.00 atm is placed in a flask. When equilibrium is achieved, 20.0% of the N_2O_4 has been converted to NO_2 gas.

(a) Calculate K_p.

(b) If the original pressure of N_2O_4 is 0.10 atm, what is the percent dissociation of the gas? Is the result in agreement with Le Chatelier's principle?

64. ▲ A reaction important in smog formation is

$$O_3(g) + NO(g) \rightleftharpoons O_2(g) + NO_2(g) \qquad K_c = 6.0 \times 10^{34}$$



(a) If the initial concentrations are $[O_3] = 1.0 \times 10^{-6}$ M, $[NO] = 1.0 \times 10^{-5}$ M, $[NO_2] = 2.5 \times 10^{-4}$ M, and $[O_2] = 8.2 \times 10^{-3}$ M, is the system at equilibrium? If not, in which direction does the reaction proceed?

(b) If the temperature is increased, as on a very warm day, will the concentrations of the products increase or decrease? (*Hint*: You may have to calculate the enthalpy change for the reaction to find out if it is exothermic or endothermic.)

In the Laboratory

65. ▲ The ammonia complex of trimethylborane, $(NH_3)B(CH_3)_3$, dissociates at 100 °C to its components with $K_p = 4.62$ (when the pressures are in atmospheres).

$$(NH_3)B(CH_3)_3(g) \rightleftharpoons B(CH_3)_3(g) + NH_3(g)$$

If NH_3 is changed to some other molecule, the equilibrium constant is different.

For $[(CH_3)_3P]B(CH_3)_3$ $\qquad K_p = 0.128$

For $[(CH_3)_3N]B(CH_3)_3$ $\qquad K_p = 0.472$

(a) If you begin an experiment by placing 0.010 mol of each complex in a flask, which would have the largest partial pressure of $B(CH_3)_3$ at 100 °C?

(b) If 0.73 g (0.010 mol) of $(NH_3)B(CH_3)_3$ is placed in a 1.25-L flask and heated to 100 °C, what is the partial pressure of each gas in the equilibrium mixture, and what is the total pressure? What is the percent dissociation of $(NH_3)B(CH_3)_3$?

66. The photograph below shows what occurs when a solution of potassium chromate is treated with a few drops of concentrated hydrochloric acid. Some of the bright yellow chromate ion is converted to the orange dichromate ion.

$$2\ CrO_4^{2-}(aq) + 2\ H_3O^+(aq) \rightleftharpoons Cr_2O_7^{2-}(aq) + 3\ H_2O(\ell)$$

Photos: © Cengage Learning/Charles D. Winters

(a) Explain this experimental observation in terms of Le Chatelier's principle.

(b) What would you observe if you treated the orange solution with sodium hydroxide? Explain your observation.

67. The photographs below (a) show what occurs when a solution of iron(III) nitrate is treated with a few drops of aqueous potassium thiocyanate. The nearly colorless iron(III) ion is converted to a red $[Fe(H_2O)_5SCN]^{2+}$ ion. (This is a classic test for the presence of iron(III) ions in solution.)

$$[Fe(H_2O)_6]^{3+}(aq) + SCN^-(aq) \rightleftharpoons [Fe(H_2O)_5SCN]^{2+}(aq) + H_2O(\ell)$$

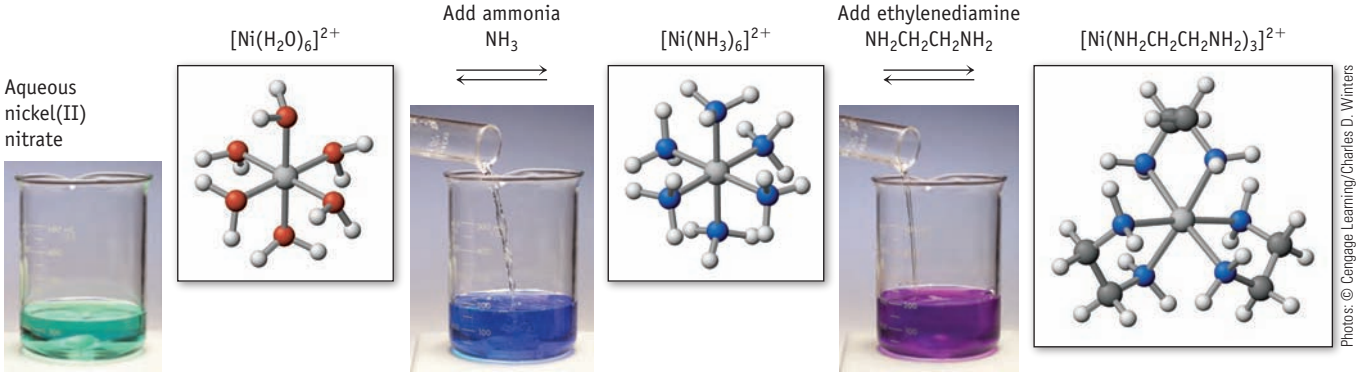
(a) Adding KSCN

(b) Adding Ag^+

Photos: © Cengage Learning/Charles D. Winters

(a) As more KSCN is added to the solution, the color becomes even more red. Explain this observation.

(b) Silver ions form a white precipitate with SCN^- ions. What would you observe on adding a few drops of aqueous silver nitrate to a red solution of $[Fe(H_2O)_5SCN]^+$ ions? Explain your observation.



68. ▲ The photographs below show what occurs when you add ammonia to aqueous nickel(II) nitrate and then add ethylenediamine ($NH_2CH_2CH_2NH_2$) to the intermediate blue-purple solution.

$$\underset{\text{green}}{[Ni(H_2O)_6]^{2+}}(aq) + 6\ NH_3(aq) \rightleftharpoons \underset{\text{blue-purple}}{[Ni(NH_3)_6]^{2+}}(aq) + 6\ H_2O(\ell) \qquad K_1$$

$$\underset{\text{blue-purple}}{[Ni(NH_3)_6]^{2+}}(aq) + 3\ NH_2CH_2CH_2\,NH_2(aq) \rightleftharpoons \underset{\text{violet}}{[Ni(NH_2CH_2CH_2NH_2)_3]^{2+}}(aq) + 6\ NH_3(aq) \qquad K_2$$

(a) Write a chemical equation for the formation of $[Ni(NH_2CH_2CH_2NH_2)_3]^{2+}$ from $[Ni(H_2O)_6]^{2+}$ and ethylenediamine, and relate the value of K for this reaction to K_1 and K_2.

(b) Which species, $[Ni(NH_2CH_2CH_2NH_2)_3]^{2+}$, $[Ni(NH_3)_6]^{2+}$, or $[Ni(H_2O)_6]^{2+}$ is the most stable? Explain.

Summary and Conceptual Questions

The following questions may use concepts from this and previous chapters.

69. Decide whether each of the following statements is true or false. If false, change the wording to make it true.

(a) The magnitude of the equilibrium constant is always independent of temperature.

(b) When two chemical equations are added to give a net equation, the equilibrium constant for the net equation is the product of the equilibrium constants of the summed equations.

(c) The equilibrium constant for a reaction has the same value as K for the reverse reaction.

(d) Only the concentration of CO_2 appears in the equilibrium constant expression for the reaction $CaCO_3(s) \rightleftharpoons CaO(s) + CO_2(g)$.

(e) For the reaction $CaCO_3(s) \rightleftharpoons CaO(s) + CO_2(g)$, the value of K is numerically the same, whether the amount of CO_2 is expressed as moles/liter or as gas pressure.

70. Neither $PbCl_2$ nor PbF_2 is appreciably soluble in water. If solid $PbCl_2$ and solid PbF_2 are placed in equal amounts of water in separate beakers, in which beaker is the concentration of Pb^{2+} greater? Equilibrium constants for these solids dissolving in water are as follows:

$$PbCl_2(s) \rightleftharpoons Pb^{2+}(aq) + 2\ Cl^-(aq) \qquad K_c = 1.7 \times 10^{-5}$$

$$PbF_2(s) \rightleftharpoons Pb^{2+}(aq) + 2\ F^-(aq) \qquad K_c = 3.7 \times 10^{-8}$$

71. Characterize each of the following as product- or reactant-favored at equilibrium.

(a) $CO(g) + {}^1/_2\ O_2(g) \rightleftharpoons CO_2(g)$ $\qquad K_p = 1.2 \times 10^{45}$

(b) $H_2O(g) \rightleftharpoons H_2(g) + {}^1/_2\ O_2(g)$ $\qquad K_p = 9.1 \times 10^{-41}$

(c) $CO(g) + Cl_2(g) \rightleftharpoons COCl_2(g)$ $\qquad K_p = 6.5 \times 10^{11}$

72. ▲ The size of a flask containing colorless $N_2O_4(g)$ and brown $NO_2(g)$ at equilibrium is rapidly reduced to half the original volume.

$$N_2O_4(g) \rightleftharpoons 2\ NO_2(g)$$

(a) What color change (if any) is observed immediately upon halving the flask size?

(b) What color change (if any) is observed during the process in which equilibrium is reestablished in the flask?

73. Describe an experiment that would allow you to prove that the system $3\ H_2(g) + N_2(g) \rightleftharpoons 2\ NH_3(g)$ is a dynamic equilibrium. (*Hint:* Consider using a stable isotope such as ^{15}N or ^2H.)

74. The chapter opening photograph (page 670) showed how the cobalt(II) chloride equilibrium responded to temperature changes.

(a) Look back at that photograph. Is the conversion of the red cation to the blue anion exothermic or endothermic?

(b) If hydrochloric acid is added to the violet mixture of cobalt(II) ions shown below, the blue $CoCl_4^{2-}$ ion is favored. If water is then added to the mixture, a red solution favoring $[Co(H_2O)]^{2+}$ results. Explain these observations in terms of Le Chatelier's principle.

Solution of cobalt(II) chloride in dilute hydrochloric acid

Solution after adding more hydrochloric acid

Solution after adding more water

Photos: © Cengage Learning/Charles D. Winters

(c) How do these observations prove the reaction is reversible?

75. Suppose a tank initially contains H_2S at a pressure of 10.00 atm and a temperature of 800 K. When the reaction has come to equilibrium, the partial pressure of S_2 vapor is 0.020 atm. Calculate K_p.

$$2\ H_2S(g) \rightleftharpoons 2\ H_2(g) + S_2(g)$$

76. Pure PCl_5 gas is placed in a 2.00-L flask. After heating to 250 °C the pressure of PCl_5 is initially 2.000 atm. However, the gas slowly but only partially decomposes to gaseous PCl_3 and Cl_2. When equilibrium is reached, the partial pressure of Cl_2 is 0.814 atm. Calculate K_p for the decomposition.

CHAPTER OUTLINE

16.1 The Brønsted–Lowry Concept of Acids and Bases
16.2 Water and the pH Scale
16.3 Equilibrium Constants for Acids and Bases
16.4 Acid–Base Properties of Salts
16.5 Predicting the Direction of Acid–Base Reactions
16.6 Types of Acid–Base Reactions
16.7 Calculations with Equilibrium Constants
16.8 Polyprotic Acids and Bases
16.9 Molecular Structure, Bonding, and Acid–Base Behavior
16.10 The Lewis Concept of Acids and Bases

16.1 The Brønsted–Lowry Concept of Acids and Bases

Goals for Section 16.1

- Recognize common monoprotic and polyprotic acids and bases, and write balanced equations for their ionization in water.
- Recognize the Brønsted acid and base in a reaction, and identify the conjugate partner of each.
- Identify the acid and base reactions undergone by amphiprotic substances.

Acids and bases are among the most common substances in nature. Amino acids are the building blocks of proteins. The repository of genetic information in your cells is DNA, deoxyribonucleic acid. The pH of lakes, rivers, and oceans is affected by dissolved acids and bases, and many bodily functions depend on acids and bases.

In Chapter 3, you were introduced to two definitions of acids and bases: the Arrhenius definition and the Brønsted–Lowry definition. According to the Arrhenius definition, an acid is any substance that, when dissolved in water, increases the concentration of hydrogen ions, H^+. An Arrhenius base is any substance that increases the concentration of hydroxide ions, OH^-, when dissolved in water.

◀ **Molecular bases where the basic sites are nitrogen atoms are called alkaloids.** A particularly interesting alkaloid is tetrodotoxin. It is present in pufferfish, as well as a handful of other marine animals. In Japan, the pufferfish (known as fugu) is an expensive and dangerous delicacy. Preparation of pufferfish should be left to specially trained and licensed chefs because the toxin is present in lethal quantities in its organs. If it is properly prepared, a diner will feel a tingling sensation on the lips and tongue while eating.

Brønsted–Lowry Theory This chapter limits the discussion to aqueous solutions. However, the theory applies equally well to non-aqueous systems.

The Brønsted–Lowry definition of acids and bases is more general and views acid–base behavior in terms of proton transfer from one substance to another. *A Brønsted–Lowry acid is a proton (H^+) donor, and a Brønsted–Lowry base is a proton acceptor*. This definition extends the list of acids and bases and the scope of acid–base reactions, and it helps chemists make predictions of product- or reactant-favorability based on acid and base strength.

A wide variety of Brønsted–Lowry acids is known. These include molecular compounds such as nitric acid,

$$\underset{\text{acid}}{HNO_3(aq)} + H_2O(\ell) \rightleftharpoons NO_3^-(aq) + H_3O^+(aq)$$

cations such as NH_4^+,

$$\underset{\text{acid}}{NH_4^+(aq)} + H_2O(\ell) \rightleftharpoons NH_3(aq) + H_3O^+(aq)$$

anions such as HSO_4^-,

$$HSO_4^-(aq) + H_2O(\ell) \rightleftharpoons SO_4^{2-}(aq) + H_3O^+(aq)$$

and hydrated metal cations.

$$[Fe(H_2O)_6]^{3+}(aq) + H_2O(\ell) \rightleftharpoons [Fe(H_2O)_5(OH)]^{2+}(aq) + H_3O^+(aq)$$

Similarly, many different species can act as Brønsted–Lowry bases in their reactions with water. These include molecular compounds,

$$\underset{\text{base}}{NH_3(aq)} + H_2O(\ell) \rightleftharpoons NH_4^+(aq) + OH^-(aq)$$

and anions.

$$CO_3^{2-}(aq) + H_2O(\ell) \rightleftharpoons HCO_3^-(aq) + OH^-(aq)$$

Acids such as HF, HCl, HNO_3, and CH_3CO_2H (acetic acid) are capable of donating one proton and so are called **monoprotic acids.** Other acids, called **polyprotic acids** (Table 16.1), are capable of donating two or more protons. Phosphoric acid,

TABLE 16.1 Polyprotic Acids and Bases

Acid Form	Amphiprotic Form	Base Form
H_2S (hydrosulfuric acid or hydrogen sulfide)	HS^- (hydrogen sulfide ion)	S^{2-} (sulfide ion)
H_3PO_4 (phosphoric acid)	$H_2PO_4^-$ (dihydrogen phosphate ion) HPO_4^{2-} (hydrogen phosphate ion)	PO_4^{3-} (phosphate ion)
H_2CO_3 (carbonic acid)	HCO_3^- (hydrogen carbonate ion or bicarbonate ion)	CO_3^{2-} (carbonate ion)
$H_2C_2O_4$ (oxalic acid)	$HC_2O_4^-$ (hydrogen oxalate ion)	$C_2O_4^{2-}$ (oxalate ion)

a familiar example of a polyprotic acid, can undergo three ionization reactions in water.

$$H_3PO_4(aq) + H_2O(\ell) \rightleftharpoons H_3O^+(aq) + H_2PO_4^-(aq)$$

$$H_2PO_4^-(aq) + H_2O(\ell) \rightleftharpoons H_3O^+(aq) + HPO_4^{2-}(aq)$$

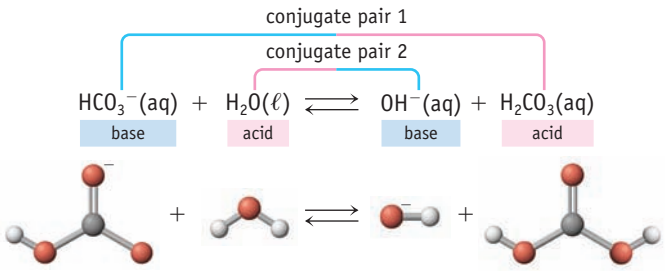
$$HPO_4^{2-}(aq) + H_2O(\ell) \rightleftharpoons H_3O^+(aq) + PO_4^{3-}(aq)$$

Just as there are acids that can donate more than one proton, so there are **polyprotic bases** that can accept more than one proton. The fully deprotonated anions of polyprotic acids are polyprotic bases; examples include S^{2-}, PO_4^{3-}, CO_3^{2-}, and $C_2O_4^{2-}$. The carbonate ion, for example, can accept two protons.

$$CO_3^{2-}(aq) + H_2O(\ell) \rightleftharpoons HCO_3^-(aq) + OH^-(aq)$$

$$HCO_3^-(aq) + H_2O(\ell) \rightleftharpoons H_2CO_3(aq) + OH^-(aq)$$

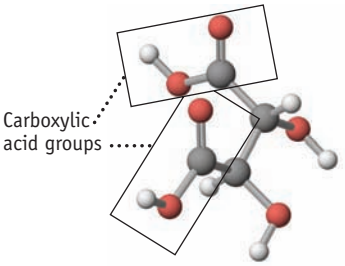
Some molecules (such as water) and ions can behave either as Brønsted acids or bases and are referred to as being **amphiprotic** (Section 3.6). An example of an amphiprotic anion is the dihydrogen phosphate ion (Table 16.1).



$$\underset{\text{acid}}{H_2PO_4^-(aq)} + H_2O(\ell) \rightleftharpoons H_3O^+(aq) + HPO_4^{2-}(aq)$$

$$\underset{\text{base}}{H_2PO_4^-(aq)} + H_2O(\ell) \rightleftharpoons H_3PO_4(aq) + OH^-(aq)$$

As you will learn in Chapter 17 (*Applying Chemical Principles 17.2: Take a Deep Breath*), amphiprotic ions such as $HCO_3^-$and $H_2PO_4^-$ are particularly important in biochemical systems.



Conjugate Acid–Base Pairs

The reaction of the hydrogen carbonate ion and water exemplifies a feature of Brønsted acid–base chemistry: *The reaction of a Brønsted acid and base produces a new acid and base.*

© Cengage Learning/Charles D. Winters

Tartaric acid, $H_2C_4H_4O_6$, is a naturally occurring diprotic acid. Tartaric acid and its potassium salt are found in grapes and other fruits. The acidic protons are the H atoms of the carboxylic acid ($—CO_2H$) groups.

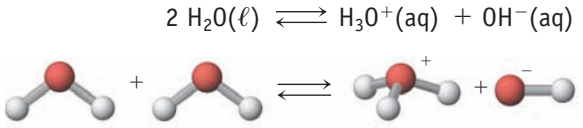
In the forward direction, HCO_3^- is the Brønsted base because it captures H^+ from the Brønsted acid, H_2O. The products are a new Brønsted acid, H_2CO_3, and base, OH^-.

A **conjugate acid–base pair** consists of two species that differ from each other by the presence of one hydrogen ion. Thus, H_2CO_3 and HCO_3^- are a conjugate acid–base pair. In this pair, HCO_3^- is the conjugate base of the acid H_2CO_3, and H_2CO_3 is the conjugate acid of the base HCO_3^-. There is a second conjugate acid–base pair in this reaction: H_2O and OH^-. In fact, *every reaction between a Brønsted acid and a Brønsted base involves two conjugate acid–base pairs.*

16.2 Water and the pH Scale



Goals for Section 16.2

- Use the water ionization constant, K_w.
- Use the pH concept.

Because we generally use aqueous solutions of acids and bases and because the acid–base reactions in your body occur in your aqueous interior, we want to consider the behavior of water in terms of chemical equilibria.

Water Autoionization and the Water Ionization Constant, K_w

In pure water, an equilibrium exists between water and the hydronium and hydroxide ions.

This **autoionization** reaction of water was demonstrated over a century ago by Friedrich Kohlrausch (1840–1910). He found that, even after water is painstakingly purified, it still conducts electricity to a small extent. We now know this is because autoionization produces very low concentrations of H_3O^+ and OH^- ions. Water autoionization is the cornerstone of our concepts of aqueous acid–base behavior.

The water autoionization equilibrium is very reactant-favored at equilibrium. In fact, in pure water at 25 °C, only about two out of a billion (10^9) water molecules are ionized at any instant. To express this idea more quantitatively, we can write the equilibrium constant expression for autoionization.

$$K_w = [H_3O^+][OH^-] = 1.0 \times 10^{-14} \text{ at } 25\ ^\circ\text{C} \qquad (16.1)$$

There are several important aspects of this equation.

- The equilibrium constant is given a special symbol, K_w, and is known as the **autoionization constant for water**.
- Electrical conductivity measurements of pure water show that $[H_3O^+] = [OH^-] = 1.0 \times 10^{-7}$ M at 25 °C, so K_w has a value of 1.0×10^{-14} at 25 °C.
- Based on the rules for writing equilibrium constants, we do not include the concentration of water in the expression for K_w.

In pure water, the hydronium ion and hydroxide ion concentrations are equal, and the water is said to be neutral. If some acid or base is added to pure water, however, the equilibrium

$$2\ H_2O(\ell) \rightleftharpoons H_3O^+(aq) + OH^-(aq)$$

K_w and Temperature The equation $K_w = [H_3O^+][OH^-]$ is valid for pure water and for any aqueous solution. However, the numerical value for K_w is temperature dependent.

T (°C)	K_w
10	0.29×10^{-14}
15	0.45×10^{-14}
20	0.68×10^{-14}
25	1.01×10^{-14}
30	1.47×10^{-14}
50	5.48×10^{-14}

The Magnitude of $[H_3O^+]$ in Pure Water The ionization of two water molecules out of a billion produces an H_3O^+ concentration of 1×10^{-7} M. To have a sense of this tiny amount, this would be like identifying just 14 people out of the current population of the Earth, about 7.28 billion.

is disturbed. Adding an acid such as HCl raises the concentration of the H_3O^+ ions. To oppose this increase, Le Chatelier's principle (Section 15.6) predicts that a small fraction of the H_3O^+ ions will react with OH^- ions from water autoionization to form water. This lowers $[OH^-]$ until the product of $[H_3O^+]$ and $[OH^-]$ is again equal to 1.0×10^{-14} at 25 °C. Similarly, adding a base to pure water gives a basic solution because the OH^- ion concentration has increased. Le Chatelier's principle predicts that some of the added OH^- ions will react with H_3O^+ ions present in the solution from water autoionization, thereby lowering $[H_3O^+]$ until the value of the product of $[H_3O^+]$ and $[OH^-]$ equals 1.0×10^{-14} at 25 °C.

Thus, for aqueous solutions at 25 °C,

- In a neutral solution, $[H_3O^+] = [OH^-]$.
  Both are equal to 1.0×10^{-7} M.
- In an acidic solution, $[H_3O^+] > [OH^-]$.
  $[H_3O^+] > 1.0 \times 10^{-7}$ M and $[OH^-] < 1.0 \times 10^{-7}$ M.
- In a basic solution, $[H_3O^+] < [OH^-]$.
  $[H_3O^+] < 1.0 \times 10^{-7}$ M and $[OH^-] > 1.0 \times 10^{-7}$ M.

EXAMPLE 16.1

Hydronium and Hydroxide Ion Concentrations in a Solution of a Strong Base

Problem What are the hydroxide and hydronium ion concentrations in a 0.0012 M aqueous solution of NaOH at 25 °C?

What Do You Know? You know the concentration of NaOH and that it is a strong base, 100% dissociated into ions in water.

Strategy Because NaOH is a strong base, the OH^- ion concentration is the same as the NaOH concentration. The H_3O^+ ion concentration can then be calculated using Equation 16.1.

SOLUTION The initial concentration of OH^- is 0.0012 M.

$$0.0012 \text{ mol NaOH per liter} \longrightarrow 0.0012 \text{ M } Na^+(aq) + 0.0012 \text{ M } OH^-(aq)$$

Substituting the OH^- concentration into Equation 16.1, we have

$$K_w = 1.0 \times 10^{-14} = [H_3O^+][OH^-] = [H_3O^+](0.0012)$$

and so

$$[H_3O^+] = \frac{1.0 \times 10^{-14}}{0.0012} = 8.3 \times 10^{-12} \text{ M}$$

Think about Your Answer Why didn't we take into account the ions produced by water autoionization when we calculated the concentration of hydroxide ions? It should add OH^- and H_3O^+ ions to the solution. If x is equal to the concentration of OH^- ions generated by the autoionization of water, then, when equilibrium is achieved,

$$[OH^-] = (0.0012 \text{ M} + OH^- \text{ from water autoionization}) = (0.0012 \text{ M} + x)$$

In pure water, the concentration of OH^- ion generated by autoionization is 1.0×10^{-7} M. Le Chatelier's principle (Section 15.6) suggests that the concentration should be even smaller when OH^- ions are already present in solution from NaOH; that is, x should be much less than 1.0×10^{-7} M. This means x in the term $(0.0012 + x)$ is insignificant compared with 0.0012. (Following the rules for significant figures, the sum of 0.0012 and a number even smaller than 1.0×10^{-7} is 0.0012.)

Check Your Understanding

What are the hydronium ion and hydroxide ion concentrations in 4.0×10^{-3} M HCl(aq) at 25 °C? (Recall that because HCl is a strong acid, it is 100% ionized in water.)

The pH Scale

The concentration of hydronium ion in an aqueous solution can vary from less than 10^{-15} M in concentrated strong bases to greater than 10 M in concentrated strong acids—in other words, over 16 orders of magnitude. The **pH** scale compresses this range of concentrations to values from roughly 15 to −1. The pH of a solution is defined as the negative of the base-10 logarithm (log) of the hydronium ion concentration (Section 4.6).

Working with Logarithms See Appendix A for more on using logarithms.

$$pH = -\log[H_3O^+] \qquad (4.3 \text{ and } 16.2)$$

In a similar way, we can define the pOH of a solution as the negative of the base-10 logarithm of the hydroxide ion concentration.

$$pOH = -\log[OH^-] \qquad (16.3)$$

In pure water, the hydronium and hydroxide ion concentrations are both 1.0×10^{-7} M. Therefore, for pure water at 25 °C

$$pH = -\log\,(1.0 \times 10^{-7}) = 7.00$$

In the same way, you can show that the pOH of pure water is also 7.00 at 25 °C.

If we take the negative logarithms of both sides of the expression $K_w = [H_3O^+][OH^-]$, we obtain another useful equation.

$$K_w = 1.0 \times 10^{-14} = [H_3O^+][OH^-]$$

$$-\log K_w = -\log\,(1.0 \times 10^{-14}) = -\log\,([H_3O^+][OH^-])$$

$$pK_w = 14.00 = -\log\,[H_3O^+] + (-\log\,[OH^-])$$

$$pK_w = 14.00 = pH + pOH \qquad (16.4)$$

The sum of the pH and pOH of a solution must be equal to 14.00 at 25 °C.

As illustrated in Figures 4.9 and 16.1, solutions with pH less than 7.00 (at 25 °C) are acidic, whereas solutions with pH greater than 7.00 are basic. Solutions with pH = 7.00 at 25 °C are neutral.

	pH	$[H_3O^+]$	$[OH^-]$	pOH
Basic	**14.00**	1.0×10^{-14}	1.0×10^{0}	**0.00**
	10.00	1.0×10^{-10}	1.0×10^{-4}	**4.00**
Neutral	**7.00**	1.0×10^{-7}	1.0×10^{-7}	**7.00**
Acidic	**4.00**	1.0×10^{-4}	1.0×10^{-10}	**10.00**
	0.00	1.0×10^{0}	1.0×10^{-14}	**14.00**

Figure 16.1 pH and pOH. This figure illustrates the relationship of hydronium ion and hydroxide ion concentrations and of pH and pOH at 25 °C.

16.3 Equilibrium Constants for Acids and Bases

Goals for Section 16.3

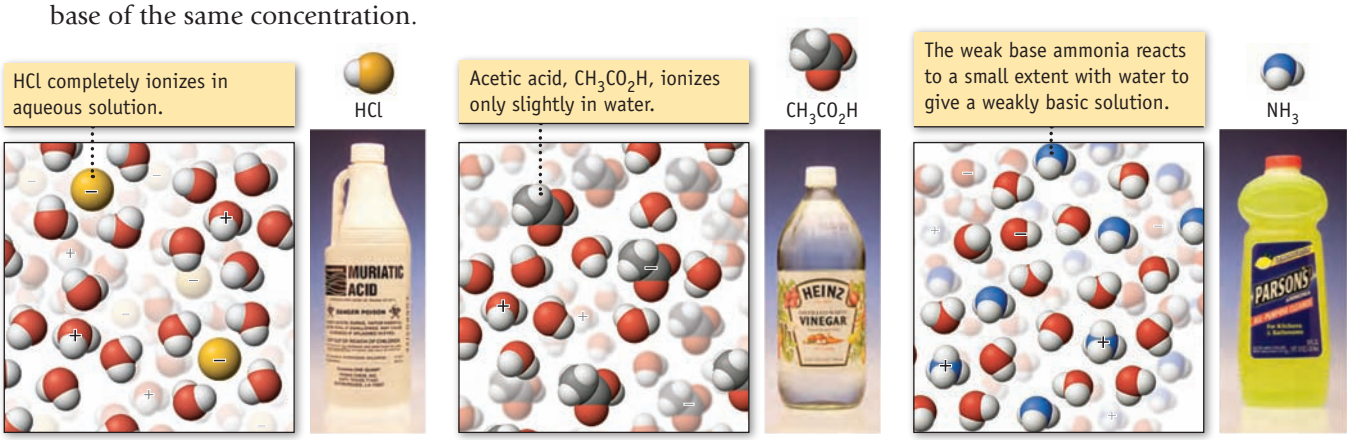
- Write equilibrium constant expressions for acids and bases.
- Understand the relationship between K_a for an acid and K_b for its conjugate base.
- Calculate pK_a from K_a (or K_a from pK_a), and understand how pK_a is correlated with acid strength.

Acids and bases can be divided roughly into two groups: strong electrolytes (such as HCl, HNO_3, and NaOH) and weak electrolytes, such as CH_3CO_2H and NH_3 (Figure 16.2 and Table 3.1). Hydrochloric acid is a strong acid, so 100% of the acid ionizes to produce hydronium and chloride ions. In contrast, acetic acid is a weak electrolyte because it ionizes only to a small extent in water.

$$CH_3CO_2H(aq) + H_2O(\ell) \rightleftharpoons H_3O^+(aq) + CH_3CO_2^-(aq)$$

The acid, its anion, and the hydronium ion are all present at equilibrium in solution, but the ions are present in low concentration relative to the acid concentration. For example, in a 0.100 M solution of acetic acid, $[H_3O^+]$ and $[CH_3CO_2^-]$ are each about 0.0013 M whereas the concentration of un-ionized acetic acid, $[CH_3CO_2H]$, is 0.099 M.

Similarly, ammonia is a weak base.



$$NH_3(aq) + H_2O(\ell) \rightleftharpoons NH_4^+(aq) + OH^-(aq)$$

Only about 1% of ammonia molecules in a 0.100 M solution react with water to produce the ammonium and hydroxide ions.

One way to define the relative strengths of a series of acids is to measure the pH of solutions of acids of equal concentration: the lower the pH, the greater the concentration of hydronium ion, the stronger the acid. Similarly, for a series of weak bases, $[OH^-]$ will increase, and the pH will increase as the bases become stronger.

- For a strong monoprotic acid, $[H_3O^+]$ in solution is equal to the original acid concentration. Similarly, for a strong monoprotic base, $[OH^-]$ is equal to the original base concentration.
- For a weak acid, $[H_3O^+]$ is much less than the original acid concentration. That is, $[H_3O^+]$ is smaller than if the acid were a strong acid of the same concentration. Similarly, a weak base gives a smaller $[OH^-]$ than if the base were a strong base of the same concentration.

The Leveling Effect The acid strengths of strong acids are indistinguishable in water. They all dissociate 100% to produce hydronium ion, H_3O^+, so these acids appear to have the same acid strength in water. This is known as the leveling effect.

Photos: © Cengage Learning/Charles D. Winters

(a) Hydrochloric acid, a strong acid, is sold for household use as "muriatic acid." The acid completely ionizes in water.

(b) Vinegar is a solution of acetic acid, a weak acid that ionizes only to a small extent in water.

(c) Ammonia is a weak base, ionizing to a small extent in water.

- For a series of weak monoprotic acids of the same concentration, $[H_3O^+]$ increases (and the pH will decline) as the acids become stronger. Similarly, for a series of weak bases, $[OH^-]$ increases (and the pH increases) as the bases become stronger.

The relative strength of an acid or base in water can also be expressed quantitatively with an equilibrium constant, often called an **ionization constant**. For the general acid HA, we can write

$$HA(aq) + H_2O(\ell) \rightleftharpoons H_3O^+(aq) + A^-(aq)$$

$$K_a = \frac{[H_3O^+][A^-]}{[HA]} \qquad (16.5)$$

where the equilibrium constant, K, has a subscript "a" to indicate that it is an equilibrium constant for an acid in water. For weak acids, the value of K_a is less than 1 because the product $[H_3O^+][A^-]$ is less than the equilibrium concentration of the weak acid [HA]. For a series of acids, the acid strength increases as the value of K_a increases.

Similarly, we can write the equilibrium expression for a weak base B in water. Here, we label K with a subscript "b." Its value is less than 1 for weak bases.

$$B(aq) + H_2O(\ell) \rightleftharpoons BH^+(aq) + OH^-(aq)$$

$$K_b = \frac{[BH^+][OH^-]}{[B]} \qquad (16.6)$$

Some acids and bases are listed in Table 16.2, each with its value of K_a or K_b. The following are important concepts concerning this table.

- A large value of K indicates that ionization products are strongly favored, whereas a small value of K indicates that reactants are favored.
- The strongest acids are at the upper left. They have the largest K_a values. K_a values become smaller on descending the chart as acid strength declines.
- The strongest bases are at the lower right. They have the largest K_b values. K_b values become larger on descending the chart as base strength increases.
- *The weaker the acid, the stronger its conjugate base.* That is, the smaller the value of K_a, the larger the value of K_b.
- Some acids or bases are listed as having K_a or K_b values that are large or very small. Aqueous acids that are stronger than H_3O^+ are completely ionized (HNO_3, for example), so their K_a values are "large." Their conjugate bases (such as NO_3^-) do not produce meaningful concentrations of OH^- ions, so their K_b values are "very small." Similar arguments follow for strong bases and their conjugate acids.

Problem Solving Tip 16.1 Strong or Weak?

How can you tell whether an acid or a base is weak? The easiest way is to remember those few that are strong. All others are probably weak.

Common strong acids include the following:

Hydrohalic acids: HCl, HBr, and HI (but not HF)

Nitric acid: HNO_3

Sulfuric acid: H_2SO_4 (for loss of first H^+ only)

Perchloric acid: $HClO_4$

Some common strong bases include the following:

All Group 1A hydroxides: LiOH, NaOH, KOH, RbOH, CsOH

Group 2A hydroxides: $Sr(OH)_2$ and $Ba(OH)_2$. [Neither $Mg(OH)_2$ nor $Ca(OH)_2$ dissolve appreciably in water. However, some texts consider them strong bases.]

TABLE 16.2 Ionization Constants for Some Acids and Their Conjugate Bases at 25 °C

Acid Name	Acid	K_a	Base	K_b	Base Name
Perchloric acid	$HClO_4$	Large	ClO_4^-	Very small	Perchlorate ion
Sulfuric acid	H_2SO_4	Large	HSO_4^-	Very small	Hydrogen sulfate ion
Hydrochloric acid	HCl	Large	Cl^-	Very small	Chloride ion
Nitric acid	HNO_3	Large	NO_3^-	Very small	Nitrate ion
Hydronium ion	H_3O^+	1.0	H_2O	1.0×10^{-14}	Water
Sulfurous acid	H_2SO_3	1.2×10^{-2}	HSO_3^-	8.3×10^{-13}	Hydrogen sulfite ion
Hydrogen sulfate ion	HSO_4^-	1.2×10^{-2}	SO_4^{2-}	8.3×10^{-13}	Sulfate ion
Phosphoric acid	H_3PO_4	7.5×10^{-3}	$H_2PO_4^-$	1.3×10^{-12}	Dihydrogen phosphate ion
Hexaaquairon(III) ion	$[Fe(H_2O)_6]^{3+}$	6.3×10^{-3}	$[Fe(H_2O)_5OH]^{2+}$	1.6×10^{-12}	Pentaaquahydroxoiron(III) ion
Hydrofluoric acid	HF	7.2×10^{-4}	F^-	1.4×10^{-11}	Fluoride ion
Nitrous acid	HNO_2	4.5×10^{-4}	NO_2^-	2.2×10^{-11}	Nitrite ion
Formic acid	HCO_2H	1.8×10^{-4}	HCO_2^-	5.6×10^{-11}	Formate ion
Benzoic acid	$C_6H_5CO_2H$	6.3×10^{-5}	$C_6H_5CO_2^-$	1.6×10^{-10}	Benzoate ion
Acetic acid	CH_3CO_2H	1.8×10^{-5}	$CH_3CO_2^-$	5.6×10^{-10}	Acetate ion
Propanoic acid	$CH_3CH_2CO_2H$	1.3×10^{-5}	$CH_3CH_2CO_2^-$	7.7×10^{-10}	Propanoate ion
Hexaaquaaluminum ion	$[Al(H_2O)_6]^{3+}$	7.9×10^{-6}	$[Al(H_2O)_5OH]^{2+}$	1.3×10^{-9}	Pentaaquahydroxoaluminum ion
Carbonic acid	H_2CO_3	4.2×10^{-7}	HCO_3^-	2.4×10^{-8}	Hydrogen carbonate ion
Hexaaquacopper(II) ion	$[Cu(H_2O)_6]^{2+}$	1.6×10^{-7}	$[Cu(H_2O)_5OH]^+$	6.3×10^{-8}	Pentaaquahydroxocopper(II) ion
Hydrogen sulfide	H_2S	1×10^{-7}	HS^-	1×10^{-7}	Hydrogen sulfide ion
Dihydrogen phosphate ion	$H_2PO_4^-$	6.2×10^{-8}	HPO_4^{2-}	1.6×10^{-7}	Hydrogen phosphate ion
Hydrogen sulfite ion	HSO_3^-	6.2×10^{-8}	SO_3^{2-}	1.6×10^{-7}	Sulfite ion
Hypochlorous acid	$HClO$	3.5×10^{-8}	ClO^-	2.9×10^{-7}	Hypochlorite ion
Hexaaqualead(II) ion	$[Pb(H_2O)_6]^{2+}$	1.5×10^{-8}	$[Pb(H_2O)_5OH]^+$	6.7×10^{-7}	Pentaaquahydroxolead(II) ion
Hexaaquacobalt(II) ion	$[Co(H_2O)_6]^{2+}$	1.3×10^{-9}	$[Co(H_2O)_5OH]^+$	7.7×10^{-6}	Pentaaquahydroxocobalt(II) ion
Boric acid	$B(OH)_3(H_2O)$	7.3×10^{-10}	$B(OH)_4^-$	1.4×10^{-5}	Tetrahydroxoborate ion
Ammonium ion	NH_4^+	5.6×10^{-10}	NH_3	1.8×10^{-5}	Ammonia
Hydrocyanic acid	HCN	4.0×10^{-10}	CN^-	2.5×10^{-5}	Cyanide ion
Hexaaquairon(II) ion	$[Fe(H_2O)_6]^{2+}$	3.2×10^{-10}	$[Fe(H_2O)_5OH]^+$	3.1×10^{-5}	Pentaaquahydroxoiron(II) ion
Hydrogen carbonate ion	HCO_3^-	4.8×10^{-11}	CO_3^{2-}	2.1×10^{-4}	Carbonate ion
Hexaaquanickel(II) ion	$[Ni(H_2O)_6]^{2+}$	2.5×10^{-11}	$[Ni(H_2O)_5OH]^+$	4.0×10^{-4}	Pentaaquahydroxonickel(II) ion
Hydrogen phosphate ion	HPO_4^{2-}	3.6×10^{-13}	PO_4^{3-}	2.8×10^{-2}	Phosphate ion
Water	H_2O	1.0×10^{-14}	OH^-	1.0	Hydroxide ion
Hydrogen sulfide ion*	HS^-	1×10^{-19}	S^{2-}	1×10^5	Sulfide ion
Ethanol	C_2H_5OH	Very small	$C_2H_5O^-$	Large	Ethoxide ion
Ammonia	NH_3	Very small	NH_2^-	Large	Amide ion
Hydrogen	H_2	Very small	H^-	Large	Hydride ion

Increasing Acid Strength ↑

Increasing Base Strength ↓

*The values of K_a for HS^- and K_b for S^{2-} are estimates.

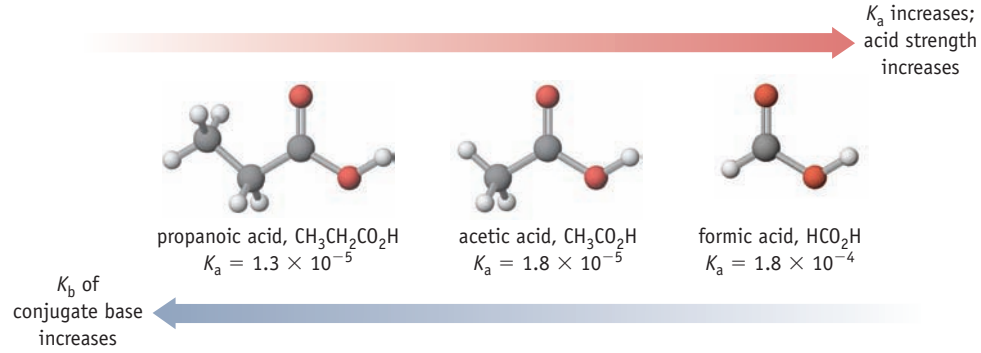
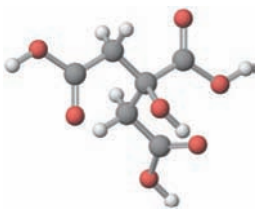
To illustrate some of these ideas, let us compare some common acids and bases. For example, HF is a stronger acid than HClO, which is in turn stronger than HCO_3^-,

Increasing acid strength →

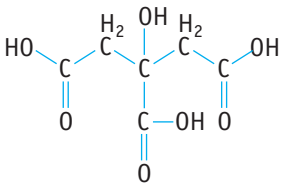


HCO_3^-	HClO	HF
$K_a = 4.8 \times 10^{-11}$	$K_a = 3.5 \times 10^{-8}$	$K_a = 7.2 \times 10^{-4}$

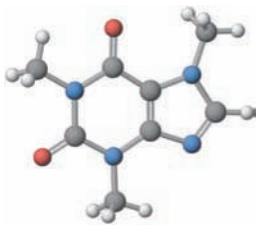
and their conjugate bases become stronger from F^- to ClO^- to CO_3^{2-}.



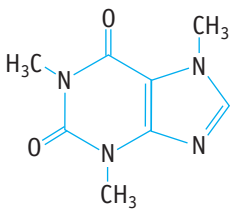
Increasing base strength ←



CO_3^{2-}	ClO^-	F^-
$K_b = 2.1 \times 10^{-4}$	$K_b = 2.9 \times 10^{-7}$	$K_b = 1.4 \times 10^{-11}$



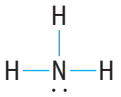
Acids and bases are abundant in nature (Figure 16.3). Many naturally occurring acids contain the carboxylic acid group (—CO_2H), and a few are illustrated here. Notice that the organic portion of the molecule has an effect on its relative strength (as described further in Section 16.9).



There are many naturally occurring weak bases (Figure 16.3). Ammonia and its conjugate acid, the ammonium ion, are part of the nitrogen cycle in the environment (Section 20.1). Biological systems reduce nitrate ion to NH_3 and NH_4^+ and

The tartness of lemons and oranges comes from the weak acid citric acid. The acid is found widely in nature and in many consumer products.

Caffeine is a well-known stimulant and a weak base.



Photos: © Cengage Learning/Charles D. Winters

Figure 16.3 Natural acids and bases. Hundreds of acids and bases occur in nature. Our foods contain a wide variety, and biochemically important molecules are often acids and bases.

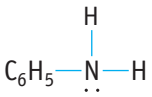
incorporate nitrogen into amino acids and proteins. Many bases are derived from NH_3 by replacement of the H atoms with organic groups.



ammonia

$K_b = 1.8 \times 10^{-5}$

methylamine

$K_b = 5.0 \times 10^{-4}$

aniline

$K_b = 4.0 \times 10^{-10}$

Ammonia is a weaker base than methylamine (K_b for $NH_3 < K_b$ for CH_3NH_2). This means that the conjugate acid of ammonia, NH_4^+ ($K_a = 5.6 \times 10^{-10}$), is stronger than the methylammonium ion, the conjugate acid of methylamine, $CH_3NH_3^+$ ($K_a = 2.0 \times 10^{-11}$).

K_a and K_b Values for Polyprotic Acids

Like all polyprotic acids, phosphoric acid ionizes in a series of steps.

First ionization step: $K_{a1} = 7.5 \times 10^{-3}$

$$H_3PO_4(aq) + H_2O(\ell) \rightleftharpoons H_2PO_4^-(aq) + H_3O^+(aq)$$

Second ionization step: $K_{a2} = 6.2 \times 10^{-8}$

$$H_2PO_4^-(aq) + H_2O(\ell) \rightleftharpoons HPO_4^{2-}(aq) + H_3O^+(aq)$$

Third ionization step: $K_{a3} = 3.6 \times 10^{-13}$

$$HPO_4^{2-}(aq) + H_2O(\ell) \rightleftharpoons PO_4^{3-}(aq) + H_3O^+(aq)$$

We observe that the K_a value for each successive step becomes smaller because it is more difficult to remove H^+ from a negatively charged ion, such as $H_2PO_4^-$, than from a neutral molecule, such as H_3PO_4. Similarly, the larger the negative charge of the anionic acid, the more difficult it is to remove H^+. For many inorganic polyprotic acids, K_a values become smaller by about 10^5 for each proton removed.

Similarly, successive base equilibrium expressions can be written for phosphate ion, PO_4^{3-}, in water.

First step: $K_{b1} = 2.8 \times 10^{-2}$

$$PO_4^{3-}(aq) + H_2O(\ell) \rightleftharpoons HPO_4^{2-}(aq) + OH^-(aq)$$

Second step: $K_{b2} = 1.6 \times 10^{-7}$

$$HPO_4^{2-}(aq) + H_2O(\ell) \rightleftharpoons H_2PO_4^-(aq) + OH^-(aq)$$

Third step: $K_{b3} = 1.3 \times 10^{-12}$

$$H_2PO_4^-(aq) + H_2O(\ell) \rightleftharpoons H_3PO_4(aq) + OH^-(aq)$$

In a trend that is similar to polyprotic acid dissociation, the K_b value for each successive step becomes smaller by about 10^5.

Logarithmic Scale of Relative Acid Strength, pK_a

Many chemists and biochemists use a logarithmic scale to report and compare relative acid strengths.

$$pK_a = -\log K_a \tag{16.7}$$

The pK_a of an acid is the negative log of the K_a value (just as pH is the negative log of the hydronium ion concentration). For example, acetic acid has a pK_a value of 4.74.

$$pK_a = -\log (1.8 \times 10^{-5}) = 4.74$$

The pK_a value becomes smaller as the acid strength increases.

Acid strength increases →

Propanoic Acid	Acetic Acid	Formic Acid
$CH_3CH_2CO_2H$	CH_3CO_2H	HCO_2H
$K_a = 1.3 \times 10^{-5}$	$K_a = 1.8 \times 10^{-5}$	$K_a = 1.8 \times 10^{-4}$
$pK_a = 4.89$	$pK_a = 4.74$	$pK_a = 3.74$

pK_a decreases →

Relating the Ionization Constants for an Acid and Its Conjugate Base

Let us look again at Table 16.2. From the top of the table to the bottom, the strengths of the acids decline (K_a becomes smaller), and the strengths of their conjugate bases increase (the values of K_b increase). Indeed these observations are connected: the product of K_a for an acid and K_b for its conjugate base is equal to a constant, specifically K_w.

Relating p*K* Values
A useful relationship for an acid–conjugate base pair follows from Equation 16.8: $pK_w = pK_a + pK_b$

$$K_a \times K_b = K_w \tag{16.8}$$

Consider the specific case of the ionization of a weak acid, say HCN, and the interaction of its conjugate base, CN^-, with H_2O.

Weak acid:	$HCN(aq) + H_2O(\ell) \rightleftharpoons H_3O^+(aq) + CN^-(aq)$	$K_a = 4.0 \times 10^{-10}$
Conjugate base:	$CN^-(aq) + H_2O(\ell) \rightleftharpoons HCN(aq) + OH^-(aq)$	$K_b = 2.5 \times 10^{-5}$
	$2\ H_2O(\ell) \rightleftharpoons H_3O^+(aq) + OH^-(aq)$	$K_w = 1.0 \times 10^{-14}$

Adding the equations gives the chemical equation for the autoionization of water, and the product of K_a and K_b is indeed 1.0×10^{-14}. That is,

$$K_a \times K_b = \left(\frac{[H_3O^+][CN^-]}{[HCN]}\right)\left(\frac{[HCN][OH^-]}{[CN^-]}\right) = [H_3O^+][OH^-] = K_w$$

Equation 16.8 is useful because K_b for a base can be calculated from the K_a value for its conjugate acid. The value of K_b for the cyanide ion, for example, is

$$K_b \text{ for } CN^- = \frac{K_w}{K_a \text{ for HCN}} = \frac{1.0 \times 10^{-14}}{4.0 \times 10^{-10}} = 2.5 \times 10^{-5}$$

16.4 Acid–Base Properties of Salts

Goal for Section 16.4

- Describe the acid–base properties of salts.

A number of the acids and bases listed in Table 16.2 are cations or anions. As described earlier, anions can act as Brønsted bases because they can accept a proton from an acid to form the conjugate acid of the ion.

$$CO_3^{2-}(aq) + H_2O(\ell) \rightleftharpoons HCO_3^-(aq) + OH^-(aq)$$

$$K_b = 2.1 \times 10^{-4}$$

You should also notice that many metal cations in water are Brønsted acids.

$$[Al(H_2O)_6]^{3+}(aq) + H_2O(\ell) \rightleftharpoons [Al(H_2O)_5(OH)]^{2+}(aq) + H_3O^+(aq)$$

$$K_a = 7.9 \times 10^{-6}$$

© Cengage Learning/Charles D. Winters

Many aqueous metal cations in salts are Brønsted acids. A pH measurement of a dilute solution of copper(II) sulfate shows that the solution is clearly acidic. Among the common cations, Al^{3+} and transition metal ions form acidic solutions in water.

Table 16.3 summarizes the acid–base properties of some common cations and anions in aqueous solution. As you look over this table, notice the following points:

- Anions that are conjugate bases of strong acids (for example, Cl^- and NO_3^-) are such weak bases that they have no effect on solution pH.
- There are numerous basic anions (such as $CH_3CO_2^-$). All are the conjugate bases of weak acids.
- The acid–base behavior of anions of polyprotic acids depends on the extent of deprotonation. For example, a fully deprotonated anion (such as CO_3^{2-}) will be basic. A partially deprotonated anion (such as HCO_3^-) is amphiprotic and is capable of undergoing both acid and base reactions with water. A solution may be acidic or basic depending on the relative strengths of the anion as an acid or as a base.
- Alkali metal and alkaline earth cations have no measurable effect on solution pH.
- Basic cations are conjugate bases of acidic cations such as $[Al(H_2O)_6]^{3+}$.
- Acidic cations fall into two categories: (a) metal cations with 2+ and 3+ charges and (b) ammonium ions (and its organic derivatives). All metal cations are hydrated in water, forming ions such as $[M(H_2O)_6]^{n+}$. However, only when M is a 2+ or 3+ ion does the ion act as an acid.

Hydrolysis Reactions and Hydrolysis Constants Chemists often say that, when ions interact with water to produce acidic or basic solutions, the ions "hydrolyze" in water, or they undergo "hydrolysis." Thus, some books refer to the K_a and K_b values of ions as "hydrolysis constants," K_h.

EXAMPLE 16.2

Acid–Base Properties of Salts

Problem Decide whether each of the following will give rise to an acidic, basic, or neutral solution in water.

(a) $NaNO_3$
(b) K_3PO_4
(c) $FeCl_2$
(d) $NaHCO_3$
(e) NH_4F

What Do You Know? You know the salt formulas and, from Tables 16.2 and 16.3, you know the effect of the constituent ions on pH.

Strategy First, identify the cation and anion in each salt. Next, use Tables 16.2 and 16.3 to describe the acid–base properties of each ion. Finally, decide on the overall acid–base properties of the salt.

Strategy Map 16.2

PROBLEM

Decide whether a salt is **acidic**, **basic**, or **neutral.**

DATA/INFORMATION KNOWN

- The formula of the salt: **K_3PO_4**

STEP 1. Identify the **cation** and **anion.**

Cation = **K^+**, anion = **PO_4^{3-}**

STEP 2. Identify the nature of the **cation.**

K^+ is a **neutral** cation.

STEP 3. Identify the nature of the **anion.**

PO_4^{3-} is a ***relatively strong*** **base.**

STEP 4. Decide on the acid–base properties of the salt.

K_3PO_4 is **basic.**

SOLUTION

(a) $NaNO_3$: This salt gives a neutral, aqueous solution (pH = 7). Neither the sodium ion, Na^+, nor the nitrate ion, NO_3^- (the very weak conjugate base of a strong acid), affects the solution pH.

(b) K_3PO_4: An aqueous solution of K_3PO_4 should be basic (pH > 7) because PO_4^{3-} is the fully deprotonated anion from the polyprotic acid H_3PO_4. The K^+ ion, like the Na^+ ion, does not affect the solution pH.

(c) $FeCl_2$: An aqueous solution of $FeCl_2$ should be weakly acidic (pH < 7). The Fe^{2+} ion in water, $[Fe(H_2O)_6]^{2+}$, is a Brønsted acid. In contrast, Cl^- is the very weak conjugate base of the strong acid HCl, so it does not contribute OH^- ions to the solution.

(d) $NaHCO_3$: Some additional information is needed concerning salts of amphiprotic anions such as HCO_3^-. Because they have an ionizable hydrogen, they can act as acids,

$$HCO_3^-(aq) + H_2O(\ell) \rightleftharpoons CO_3^{2-}(aq) + H_3O^+(aq) \qquad K_a = 4.8 \times 10^{-11}$$

but because they are anions, they can also act as bases and accept an H^+ ion from water.

$$HCO_3^-(aq) + H_2O(\ell) \rightleftharpoons H_2CO_3(aq) + OH^-(aq) \qquad K_b = 2.4 \times 10^{-8}$$

Whether the solution is acidic or basic will depend on the relative magnitudes of K_a and K_b. In the case of the hydrogen carbonate anion, K_b is larger than K_a, so $[OH^-]$ is larger than $[H_3O^+]$, and an aqueous solution of $NaHCO_3$ will be slightly basic.

(e) NH_4F: What happens if you have a salt based on an acidic cation and a basic anion? One example is ammonium fluoride. Here, the ammonium ion would decrease the pH, and the fluoride ion would increase the pH.

$$NH_4^+(aq) + H_2O(\ell) \rightleftharpoons H_3O^+(aq) + NH_3(aq) \qquad K_a\,(NH_4^+) = 5.6 \times 10^{-10}$$

$$F^-(aq) + H_2O(\ell) \rightleftharpoons HF(aq) + OH^-(aq) \qquad K_b\,(F^-) = 1.4 \times 10^{-11}$$

Because $K_a\,(NH_4^+) > K_b\,(F^-)$, the ammonium ion is a stronger acid than the fluoride ion is a base. The resulting solution should be slightly acidic.

Think about Your Answer

There are several important points here:

- Anions that are conjugate bases of strong acids—such as Cl^- and NO_3^-—have no effect on solution pH.
- To determine whether a salt is acidic, basic, or neutral, we must take into account both the cation and the anion. When a salt has an acidic cation and a basic anion, the pH of the solution will be determined by the ion that is the stronger acid or base.

Check Your Understanding

For each of the following salts in water, predict whether the pH will be greater than, less than, or equal to 7.

(a) KBr (b) NH_4NO_3 (c) $AlCl_3$ (d) Na_2HPO_4

16.5 Predicting the Direction of Acid–Base Reactions

Goal for Section 16.5

- Write equations for acid–base reactions, and decide whether they are product- or reactant-favored at equilibrium.

According to the Brønsted–Lowry theory, all acid–base reactions can be written as equilibria involving the acid and base and their conjugates.

$$\text{Acid} + \text{base} \rightleftharpoons \text{conjugate base of the acid} + \text{conjugate acid of the base}$$

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

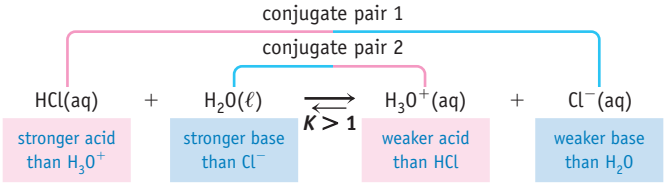
In Sections 16.3 and 16.4, we used equilibrium constants to provide information about the relative strengths of acids and bases. Now we want to show how these constants can be used to decide whether a particular acid–base reaction is product- or reactant-favored at equilibrium.



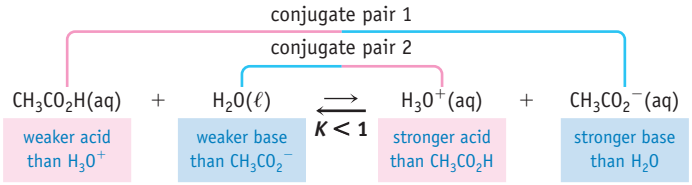
Hydrochloric acid is a strong acid. Its equilibrium constant for reaction with water is very large, with the equilibrium lying completely to the right.

$$HCl(aq) + H_2O(\ell) \rightleftharpoons H_3O^+(aq) + Cl^-(aq)$$

Strong acid (≈ 100% ionized), $K_a >> 1$

$[H_3O^+] \approx$ initial concentration of the acid

Of the two acids here, HCl is stronger than H_3O^+. Of the two bases, H_2O and Cl^-, water is the stronger base and wins out in the competition for the proton. *The equilibrium lies to the side of the chemical reaction having the weaker acid and base.*



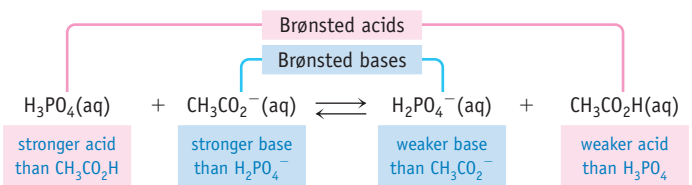
In contrast to HCl and other strong acids, acetic acid, a *weak* acid, ionizes to only a very small extent (Table 16.2).

$$CH_3CO_2H(aq) + H_2O(\ell) \rightleftharpoons H_3O^+(aq) + CH_3CO_2^-(aq)$$

Weak acid (< 100% ionized), $K_a = 1.8 \times 10^{-5}$

$[H_3O^+] <<$ initial concentration of the acid

When equilibrium is achieved in a 0.1 M aqueous solution of CH_3CO_2H, the concentrations of $H_3O^+(aq)$ and $CH_3CO_2^-(aq)$ are each only about 0.001 M. Approximately 99% of the acetic acid is not ionized.



Again, the equilibrium lies toward the side of the reaction having the weaker acid and base.

These two examples of the relative extent of acid–base reactions illustrate a general principle:

> All proton transfer reactions proceed from the stronger acid and base to the weaker acid and base.

General Principle of Reactivity
A general principle in chemistry is that more reactive substances react to form less reactive substances. Here you see the result of this for acid–base reactions: The stronger acid and stronger base always react to form the weaker acid and weaker base.

Using this principle and Table 16.2, you can predict which reactions are product-favored and which are reactant-favored at equilibrium. Consider the possible reaction of phosphoric acid and acetate ion to give acetic acid and the dihydrogen phosphate ion. Table 16.2 informs us that H_3PO_4 is a stronger acid ($K_a = 7.5 \times 10^{-3}$) than acetic acid ($K_a = 1.8 \times 10^{-5}$), and the acetate ion ($K_b = 5.6 \times 10^{-10}$) is a stronger base than the dihydrogen phosphate ion ($K_b = 1.3 \times 10^{-12}$).

Thus, mixing phosphoric acid with sodium acetate will produce a significant amount of dihydrogen phosphate ion and acetic acid. That is, the equilibrium is predicted to lie to the right.

EXAMPLE 16.3

Reactions of Acids and Bases

Problem Write a balanced, net ionic equation for the reaction that occurs between acetic acid and sodium bicarbonate. Decide whether the equilibrium lies predominantly to the left or to the right.

What Do You Know? You know the identity of the acid, and you know that the other reactant, $NaHCO_3$, is a water-soluble salt that forms Na^+ and HCO_3^- ions in water. You also know that the HCO_3^- ion is amphiprotic, but it must act as a base toward acetic acid in this reaction. You need to know the ionization constants for acetic acid and the HCO_3^- ion and for their conjugates.

Strategy

- Identify the products of the acid–base reaction (which arise by H^+ transfer from acetic acid to the base, HCO_3^-). That is, identify the conjugate base of acetic acid and the conjugate acid of HCO_3^-.
- Write a balanced chemical equation for the equilibrium between the acid and base and their conjugate base and acid.
- Use Table 16.2 to decide which is the weaker of the two acids (or the weaker of the two bases). The equilibrium will favor the weaker acid and base.

SOLUTION The conjugate base of acetic acid is the acetate ion, $CH_3CO_2^-$, and the conjugate acid of the base HCO_3^- is H_2CO_3. Hydrogen ion transfer from the acid to the base occurs by the following net ionic equation:

$$CH_3CO_2H(aq) + HCO_3^-(aq) \rightleftharpoons CH_3CO_2^-(aq) + H_2CO_3(aq)$$

$$K_a = 1.8 \times 10^{-5} \qquad K_b = 2.4 \times 10^{-8} \qquad K_b = 5.6 \times 10^{-10} \qquad K_a = 4.2 \times 10^{-7}$$

The value of K_a or K_b (from Table 16.2) is given for each reactant and product. The equilibrium constants show that H_2CO_3 is a weaker acid than CH_3CO_2H, and $CH_3CO_2^-$ is a weaker base than HCO_3^-. The reaction favors the side having the weaker acid and base—that is, the equilibrium lies to the right.

Think about Your Answer One product of the reaction of acetic acid and $NaHCO_3$ is H_2CO_3, which dissociates into CO_2 and H_2O. As you can see in the photograph in the margin, CO_2 bubbles out of the solution. The equilibrium for the dissociation of H_2CO_3 to form CO_2 and H_2O lies far to the right.

$$H_2CO_3(aq) \rightleftharpoons CO_2(g) + H_2O(\ell)$$

The loss of a product, CO_2, causes the equilibrium to shift farther to the right. See the discussion of gas-forming reactions in Section 3.7 and Le Chatelier's principle in Section 15.6.

Check Your Understanding

(a) Which is the stronger Brønsted acid, HCO_3^- or NH_4^+? Which has the stronger conjugate base?

(b) Is a reaction between HCO_3^- ions and NH_3 product- or reactant-favored at equilibrium?

$$HCO_3^-(aq) + NH_3(aq) \rightleftharpoons CO_3^{2-}(aq) + NH_4^+(aq)$$

© Cengage Learning/Charles D. Winters

Reaction of vinegar and baking soda. This reaction involves the weak acid acetic acid and the weak base HCO_3^- from sodium hydrogen carbonate. Based on the values of the equilibrium constants, the reaction is predicted to proceed to the right to produce acetate ion, CO_2, and water.

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

(c) You mix solutions of sodium hydrogen phosphate and ammonia. The net ionic equation for a possible reaction is

$$HPO_4^{2-}(aq) + NH_3(aq) \rightleftharpoons PO_4^{3-}(aq) + NH_4^+(aq)$$

Does the equilibrium lie to the left or to the right for this reaction?

16.6 Types of Acid–Base Reactions

Goal for Section 16.6

- Predict whether the solutions resulting from acid-base reactions are acidic, neutral, or basic.

The reaction of hydrochloric acid and sodium hydroxide is the classic example of a strong acid–strong base reaction, whereas the reaction of citric acid and bicarbonate ion represents the reaction of a weak acid and weak base (Figure 16.4). These are two of four general types of acid–base reactions (Table 16.4). Because acid–base reactions are among the most important classes of chemical reactions, it is useful for you to know the outcome of the various types of these reactions.

© Cengage Learning/Charles D. Winters

Figure 16.4 Reaction of a weak acid with a weak base. The bubbles coming from the tablet are carbon dioxide. This arises from the reaction of a weak Brønsted acid (citric acid) with a weak Brønsted base (HCO_3^-). The reaction is driven to completion by gas evolution.

The Reaction of a Strong Acid with a Strong Base

Strong acids and bases are effectively 100% ionized in solution. Therefore, the complete ionic equation for the reaction of HCl (strong acid) and NaOH (strong base) is

$$H_3O^+(aq) + Cl^-(aq) + Na^+(aq) + OH^-(aq) \rightleftharpoons 2\ H_2O(\ell) + Na^+(aq) + Cl^-(aq)$$

which leads to the following net ionic equation

$$H_3O^+(aq) + OH^-(aq) \rightleftharpoons 2\ H_2O(\ell) \qquad K = 1/K_w = 1.0 \times 10^{14}$$

The net ionic equation for the reaction of any strong acid with any strong base is always simply the reaction of hydronium ion and hydroxide ion to give water (Section 3.6). Because this reaction is the reverse of the autoionization of water, it has an equilibrium constant of $1/K_w$. This very large value of K shows that, for all practical purposes, the reactants are completely consumed to form products. Thus, if equal numbers of moles of NaOH and HCl are mixed, the result is just a solution of NaCl in water. The constituents of NaCl, Na^+ and Cl^- ions, which arise from a strong base and a strong acid, respectively, produce a neutral aqueous

TABLE 16.4 Characteristics of Acid–Base Reactions

Type	Example	Net Ionic Equation	Species Present after Equal Amounts Are Mixed; pH
Strong acid + strong base	HCl + NaOH	$H_3O^+(aq) + OH^-(aq) \rightleftharpoons 2\ H_2O(\ell)$	Cl^-, Na^+, pH = 7
Strong acid + weak base	HCl + NH_3	$H_3O^+(aq) + NH_3(aq) \rightleftharpoons NH_4^+(aq) + H_2O(\ell)$	Cl^-, NH_4^+, pH < 7
Weak acid + strong base	HCO_2H + NaOH	$HCO_2H(aq) + OH^-(aq) \rightleftharpoons HCO_2^-(aq) + H_2O(\ell)$	HCO_2^-, Na^+, pH > 7
Weak acid + weak base	HCO_2H + NH_3	$HCO_2H(aq) + NH_3(aq) \rightleftharpoons HCO_2^-(aq) + NH_4^+(aq)$	HCO_2^-, NH_4^+, pH dependent on K_a and K_b of conjugate acid and base

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

solution. For this reason, reactions of strong acids and bases are often called "neutralizations."

Mixing equal amounts (moles) of a strong monoprotic base and a strong monoprotic acid produces a neutral solution (pH = 7.00 at 25 °C).

The Reaction of a Weak Acid with a Strong Base

Formic Acid + NaOH The equilibrium constant for the reaction of formic acid and sodium hydroxide is 1.8×10^{10}. Can you confirm this?

Consider the reaction of the naturally occurring weak acid formic acid, HCO_2H, with sodium hydroxide. The net ionic equation is

$$HCO_2H(aq) + OH^-(aq) \rightleftharpoons H_2O(\ell) + HCO_2^-(aq)$$

In this reaction, OH^- is a much stronger base than HCO_2^- ($K_b = 5.6 \times 10^{-11}$), and the reaction is predicted to proceed to the right. If equal amounts of weak acid and base are mixed, the final solution will contain sodium formate ($NaHCO_2$), a salt that is 100% dissociated in water. The Na^+ ion is a Group IA cation and so gives a neutral solution. The formate ion, however, is the conjugate base of a weak acid (Table 16.2), so the solution is basic. This example leads to a useful general conclusion:

Mixing equal amounts (moles) of a strong base and a weak acid produces a salt whose anion is the conjugate base of the weak acid. The solution is basic, with the pH depending on both the K_b for the anion and its concentration.

The Reaction of a Strong Acid with a Weak Base

Ammonia + HCl The equilibrium constant for the reaction of a strong acid with aqueous ammonia is 1.8×10^9. Can you confirm this?

The net ionic equation for the reaction of the strong acid HCl and the weak base NH_3 is

$$H_3O^+(aq) + NH_3(aq) \rightleftharpoons H_2O(\ell) + NH_4^+(aq)$$

The hydronium ion, H_3O^+, is a much stronger acid than NH_4^+ ($K_a = 5.6 \times 10^{-10}$), and NH_3 is a stronger base ($K_b = 1.8 \times 10^{-5}$) than H_2O. Therefore, the reaction is predicted to proceed to the right and to reach completion. After mixing equal amounts of HCl and NH_3, the solution contains the salt ammonium chloride, NH_4Cl. The Cl^- ion has no effect on the solution pH (Tables 16.2 and 16.3). However, the NH_4^+ ion is the conjugate acid of the weak base NH_3, so the solution at the conclusion of the reaction is acidic. In general, we can conclude that

Mixing equal amounts (moles) of a strong acid and a weak base produces a salt whose cation is the conjugate acid of the weak base. The solution is acidic, with the pH depending on both the K_a for the cation and its concentration.

The Reaction of a Weak Acid with a Weak Base

***K* for Reaction of Weak Acid and Weak Base** The equilibrium constant for the reaction between a weak acid and a weak base is $K_{net} = (K_a \cdot K_b)/K_w$.

If acetic acid, a weak acid, is mixed with ammonia, a weak base, the following reaction occurs.

$$CH_3CO_2H(aq) + NH_3(aq) \rightleftharpoons NH_4^+(aq) + CH_3CO_2^-(aq)$$

The reaction is product-favored because CH_3CO_2H is a stronger acid than NH_4^+ and NH_3 is a stronger base than $CH_3CO_2^-$ (Table 16.2). Thus, if equal amounts of the acid and base are mixed, the resulting solution contains ammonium acetate, $NH_4CH_3CO_2$. Is this solution acidic or basic? In Example 16.2(e) you learned that this depends on the relative values of K_a for the conjugate acid (here, NH_4^+; $K_a = 5.6 \times 10^{-10}$) and K_b for the conjugate base (here, $CH_3CO_2^-$; $K_b = 5.6 \times 10^{-10}$). In this case, the values of K_a and K_b are the same, so the solution is predicted to be neutral.

Mixing equal amounts (moles) of a weak acid and a weak base produces a salt whose cation is the conjugate acid of the weak base and whose anion is the conjugate base of the weak acid. The solution pH depends on the relative K_a and K_b values.

16.7 Calculations with Equilibrium Constants

Goals for Section 16.7

- Calculate the equilibrium constant for a weak acid (K_a) or a weak base (K_b) from experimental information (such as pH, $[H_3O^+]$, or $[OH^-]$).
- Use the equilibrium constant and other information to calculate the pH of a solution of a weak acid or weak base.
- Calculate the pH after an acid–base reaction.

Determining *K* from Initial Concentrations and Measured pH

The K_a and K_b values found in Table 16.2 and in the more extensive tables in Appendices H and I were all determined by experiment. There are several experimental methods available, but one approach, illustrated by the following example, is to determine the pH of the solution.

EXAMPLE 16.4

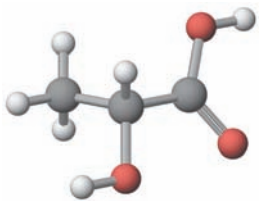
Calculating a K_a Value from a Measured pH

Problem A 0.10 M aqueous solution of lactic acid, $CH_3CHOHCO_2H$, has a pH of 2.43. What is the value of K_a for lactic acid?

What Do You Know? You need to know the equilibrium concentration of each species to calculate K_a. The pH of the solution allows you to calculate the equilibrium concentration of H_3O^+, and you can derive the other equilibrium concentrations from this.

Strategy

- Write the equilibrium constant expression, set up an ICE table, and convert pH to $[H_3O^+]$, the hydronium ion equilibrium concentration.
- Enter the initial concentration of $CH_3CHOHCO_2H$ on the initial (I) line of the ICE table.
- Assign the variable x to represent changes in concentration. Based on the reaction stoichiometry the change in $[CH_3CHOHCO_2H]$ is $-x$ and the change in $[CH_3CHOHCO_2^-]$ is $+x$. Enter these values in the change (C) line of the table.
- Recognize that the hydronium ion equilibrium concentration, $[H_3O^+]$, is equal to x.
- Enter the expressions for the final equilibrium concentrations of all three species on the E line of the ICE table. Using this, determine the values of the other equilibrium concentrations.
- Use the equilibrium concentrations to solve for K_a.



SOLUTION The equation for the reaction of lactic acid with water and its equilibrium constant expression are

$$\underset{\text{lactic acid}}{CH_3CHOHCO_2H(aq)} + H_2O(\ell) \rightleftharpoons \underset{\text{lactate ion}}{CH_3CHOHCO_2^-(aq)} + H_3O^+(aq)$$

$$K_a \text{ (lactic acid)} = \frac{[H_3O^+][CH_3CHOHCO_2^-]}{[CH_3CHOHCO_2H]}$$

Begin by converting the pH to $[H_3O^+]$:

$$[H_3O^+] = 10^{-pH} = 10^{-2.43} = 3.72 \times 10^{-3}\ M$$

lactic acid, $CH_3CHOHCO_2H$

Lactic acid, $CH_3CHOHCO_2H$. Lactic acid is a weak monoprotic acid that occurs naturally in sour milk and arises from metabolism in the human body.

Strategy Map 16.4

PROBLEM

Calculate K_a for the ionization of **lactic acid**, a weak acid.

↓

DATA/INFORMATION KNOWN

- Acid concentration
- Solution pH

↓

STEP 1. Write **balanced equation** and K_a **expression** and set up **ICE table.**

↓

K_a expression and ICE table

↓

STEP 2. Enter **equilibrium concentrations** in ICE table.

↓

At equilibrium:
$[H_3O^+]$ = [Conjugate base] = x
[Lactic acid] = original conc. − x

↓

STEP 3. Convert **pH** to **$[H_3O^+]$** and solve for x.

↓

Equilibrium concentrations of **lactic acid**, **hydronium ion**, and **lactate ion**

↓

STEP 4. Enter **equilibrium concentrations** into K_a **expression** and solve.

↓

Value of K_a

Enter in the ICE table the concentrations before equilibrium is established, the change that occurs as the reaction proceeds to equilibrium, and the concentrations when equilibrium has been achieved. (Examples 15.3–15.5.)

Equilibrium	$CH_3CHOHCO_2H + H_2O$	$\rightleftharpoons$	$CH_3CHOHCO_2^-$	+	H_3O^+
Initial (M)	0.10		0		0
Change (M)	$-x$		$+x$		$+x$
Equilibrium (M)	$(0.10 - x)$		x		x

The following points can be made concerning the ICE table.

- The quantity x represents the equilibrium concentrations of hydronium ion and lactate ion. That is, at equilibrium $x = [H_3O^+] = [CH_3CHOHCO_2^-] = 3.72 \times 10^{-3}$ M.
- By stoichiometry, x is also the concentration of acid that ionized on proceeding to equilibrium.

With these points in mind, we can calculate K_a for lactic acid.

$$K_a \text{ (lactic acid)} = \frac{[H_3O^+][CH_3CHOHCO_2^-]}{[CH_3CHOHCO_2H]}$$

$$= \frac{(3.72 \times 10^{-3})(3.72 \times 10^{-3})}{0.10 - 0.00372} = 1.4 \times 10^{-4}$$

Comparing this value of K_a with others in Table 16.2, we see lactic acid is similar to formic acid in its strength.

Think about Your Answer Hydronium ion, H_3O^+, is present in solution from lactic acid ionization and from water autoionization. Le Chatelier's principle informs us that the H_3O^+ from lactic acid will suppress the H_3O^+ coming from the water autoionization. Because $[H_3O^+]$ from water must be less than 10^{-7} M, the pH is almost completely from the ionization of lactic acid. (Example 16.1.)

Check Your Understanding

A solution prepared from 0.055 mol of butanoic acid and sufficient water to give 1.0 L of solution has a pH of 2.72. Determine K_a for butanoic acid. The acid ionizes according to the balanced equation

$$CH_3CH_2CH_2CO_2H(aq) + H_2O(\ell) \rightleftharpoons H_3O^+(aq) + CH_3CH_2CH_2CO_2^-(aq)$$

There is an important point to notice in Example 16.4. The lactic acid concentration at equilibrium was given by $(0.10 - x)$ where x was found from the solution pH to be 3.7×10^{-3} M. By the usual rules governing significant figures $(0.10 - 0.0037)$ is equal to 0.10. The acid is weak, so very little of it ionizes (approximately 4%), and the equilibrium concentration of lactic acid is essentially equal to the initial acid concentration. Neglecting to subtract 0.0037 from 0.10 has no effect on the answer, which is known only to two significant figures.

Like lactic acid, most weak acids (HA) are so weak that the equilibrium concentration of the acid, [HA], is effectively its initial concentration $(= [HA]_0)$. This leads to the useful conclusion that the denominator in the equilibrium constant expression for dilute solutions of most weak acids is simply $[HA]_0$, the original or initial concentration of the weak acid.

$$HA(aq) + H_2O(\ell) \rightleftharpoons H_3O^+(aq) + A^-(aq)$$

$$K_a = \frac{[H_3O^+][A^-]}{[HA]_0 - [H_3O^+]} \approx \frac{[H_3O^+][A^-]}{[HA]_0}$$

Analysis shows that

The approximation that

$$[HA]_{equilibrium} = [HA]_0 - [H_3O^+] \approx [HA]_0$$

is valid whenever $[HA]_0$ is greater than or equal to $100 \times K_a$.

This is the same approximation we used in Chapter 15 when deciding whether we needed to solve quadratic equations exactly (Problem Solving Tip 15.2).

What Is the pH of an Aqueous Solution of a Weak Acid or Base?

Knowing values of the equilibrium constants for weak acids and bases enables us to calculate the pH of a solution of a weak acid or base.

EXAMPLE 16.5

Calculating Equilibrium Concentrations and pH from K_a

Problem Calculate the concentration of H_3O^+ and the pH of a 0.020 M solution of benzoic acid ($C_6H_5CO_2H$) given that $K_a = 6.3 \times 10^{-5}$ for the acid.

$$C_6H_5CO_2H(aq) + H_2O(\ell) \rightleftharpoons H_3O^+(aq) + C_6H_5CO_2^-(aq)$$

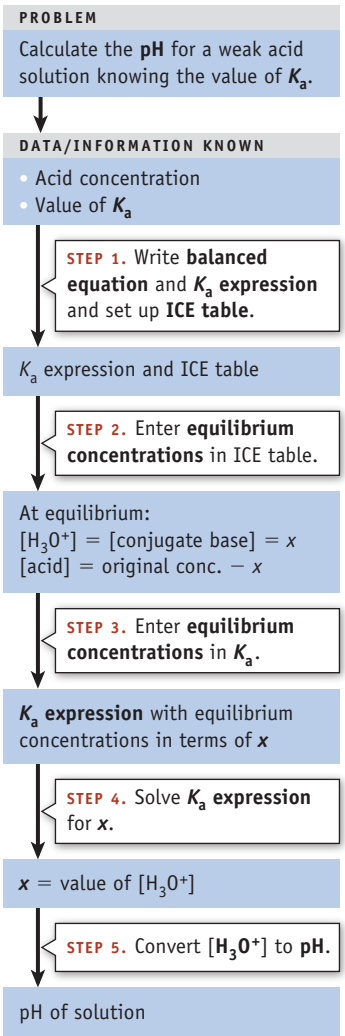
What Do You Know? You know the value of K_a for the acid and its initial concentration. You need to find the equilibrium concentration of H_3O^+ in order to calculate the pH.

Strategy This is similar to Examples 15.4 and 15.5, where you wanted to find the concentration of a reaction product. The strategy is the same:

- Write the equilibrium constant expression and set up an ICE table.
- Enter the initial concentration of $C_6H_5CO_2H$ on the Initial (I) line of the ICE table.
- The variable x represents changes in concentration, so the change in $[C_6H_5CO_2H]$ is $-x$ and the change in product concentrations is $+x$. Enter these values in the Change (C) line of the table.
- Enter the expressions for the final equilibrium concentrations of all three species on the Equilibrium (E) line of the ICE table, and then transfer these expressions to the equilibrium constant expression and solve for x.
- Convert $[H_3O^+]$ $(= x)$ to pH.

SOLUTION Organize the information in an ICE table.

Equilibrium	$C_6H_5CO_2H + H_2O$	$\rightleftharpoons$	$C_6H_5CO_2^-$	+	H_3O^+
Initial (M)	0.020		0		0
Change (M)	$-x$		$+x$		$+x$
Equilibrium (M)	$(0.020 - x)$		x		x



According to reaction stoichiometry,

$$[H_3O^+] = [C_6H_5CO_2^-] = x \text{ at equilibrium}$$

the concentration of acid ionized is x. Thus, the benzoic acid concentration at equilibrium is

$$[C_6H_5CO_2H] = \text{initial acid concentration} - \text{concentration of acid that ionized}$$
$$= 0.020 - x$$

Strategy Map 16.5

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Substituting these equilibrium concentrations into the K_a expression, we have

$$K_a = \frac{[H_3O^+][C_6H_5CO_2^-]}{[C_6H_5CO_2H]}$$

$$6.3 \times 10^{-5} = \frac{(x)(x)}{0.020 - x}$$

The value of x is small compared with 0.020 (because $[HA]_0 > 100 \times K_a$; $0.020\ M > 6.3 \times 10^{-3}$). Therefore, you can use the approximate expression.

$$K_a = 6.3 \times 10^{-5} = \frac{x^2}{0.020}$$

Solving for x, we have

$$x = \sqrt{K_a \times (0.020)} = 0.00112\ M$$

and we find that

$$[H_3O^+] = [C_6H_5CO_2^-] = 0.00112\ M = 0.0011\ M$$

Finally, the pH of the solution is found to be

$$pH = -\log\ (1.12 \times 10^{-3}) = 2.95$$

Think about Your Answer We made the approximation that $(0.020 - x) \approx 0.020$. If the approximation is not made and the exact expression is solved, $x = [H_3O^+] = 0.0011$ M. This is the same answer to two significant figures that we obtained from the "approximate" expression. Finally, notice that any H_3O^+ that arises from water ionization was again ignored.

Check Your Understanding

What are the equilibrium concentrations of acetic acid, the acetate ion, and H_3O^+ for a 0.10 M solution of acetic acid ($K_a = 1.8 \times 10^{-5}$)? What is the pH of the solution?

EXAMPLE 16.6

Calculating Equilibrium Concentrations and pH from K_a and Using the Method of Successive Approximations

Problem What is the concentration of H_3O^+ and the pH of a 0.0010 M solution of formic acid? What is the concentration of formic acid at equilibrium? The acid is moderately weak, with $K_a = 1.8 \times 10^{-4}$.

$$HCO_2H(aq) + H_2O(\ell) \rightleftharpoons HCO_2^-(aq) + H_3O^+(aq)$$

What Do You Know? You know the value of K_a for the acid and its initial concentration. You need to find the equilibrium concentration of H_3O^+ in order to calculate the pH.

Strategy This is similar to Example 16.5, where you wanted to find the concentration of a reaction product, except that an approximate solution will not be possible. The strategy is the same:

- Write the equilibrium constant expression and set up an ICE table.
- Enter the initial concentration of HCO_2H on the Initial (I) line of the ICE table.
- The variable x represents changes in concentration, so the change in $[HCO_2H]$ is $-x$ and the change in product concentrations is $+x$. Enter these values in the Change (C) line of the table.

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

- Enter the expressions for the final equilibrium concentrations of all three species on the Equilibrium (E) line of the ICE table, and then transfer these expressions to the equilibrium constant expression and solve for *x*.
- Convert $[H_3O^+]$ $(= x)$ to pH.

SOLUTION The ICE table is as follows.

Equilibrium	$HCO_2H + H_2O$	$\rightleftharpoons$	HCO_2^-	+	H_3O^+
Initial (M)	0.0010		0		0
Change (M)	$-x$		$+x$		$+x$
Equilibrium (M)	$(0.0010 - x)$		x		x

Substituting the values in the table into the K_a expression we have

$$K_a = \frac{[H_3O^+][HCO_2^-]}{[HCO_2H]} = 1.8 \times 10^{-4} = \frac{(x)(x)}{0.0010 - x}$$

In this example, $[HA]_0$ $(= 0.0010$ M) is *not* greater than $100 \times K_a$ $(= 1.8 \times 10^{-2})$, so the usual approximation is not reasonable. Thus, we have to find the equilibrium concentrations by solving the "exact" expression. This can be solved with the quadratic formula or by successive approximations (Appendix A). Let us use the successive approximation method here.

To use the **successive approximations approach**, begin by solving the approximate expression for *x*.

$$1.8 \times 10^{-4} = \frac{(x)(x)}{0.0010}$$

Solving this, we find $x = 4.24 \times 10^{-4}$. Put this value into the expression for *x* in the denominator of the exact expression.

$$1.8 \times 10^{-4} = \frac{(x)(x)}{0.0010 - x} = \frac{(x)(x)}{0.0010 - 4.24 \times 10^{-4}}$$

Solving this equation for *x*, we now find $x = 3.22 \times 10^{-4}$. Again, put this value into the denominator, and solve for *x*.

$$1.8 \times 10^{-4} = \frac{(x)(x)}{0.0010 - x} = \frac{(x)(x)}{0.0010 - 3.22 \times 10^{-4}}$$

Continue this procedure until the value of *x* does not change from one cycle to the next. In this case, several more cycles give us the result that

$$x = [H_3O^+] = [HCO_2^-] = 3.44 \times 10^{-4} \text{ M} = 3.4 \times 10^{-4} \text{ M}$$

Thus,

$$[HCO_2H] = 0.0010 - x \approx 0.0007 \text{ M}$$

and the pH of the formic acid solution is

$$\text{pH} = -\log (3.44 \times 10^{-4}) = 3.46$$

Think about Your Answer If we had used the approximate expression to find the H_3O^+ concentration, we would have obtained a value of $[H_3O^+] = 4.2 \times 10^{-4}$ M. The simplifying assumption led to a large error, about 24%. The approximate solution fails in this case because (a) the acid concentration is small and (b) the acid is not all that weak.

Check Your Understanding

What are the equilibrium concentrations of HF, F^- ion, and H_3O^+ ion in a 0.00150 M solution of HF? What is the pH of the solution?

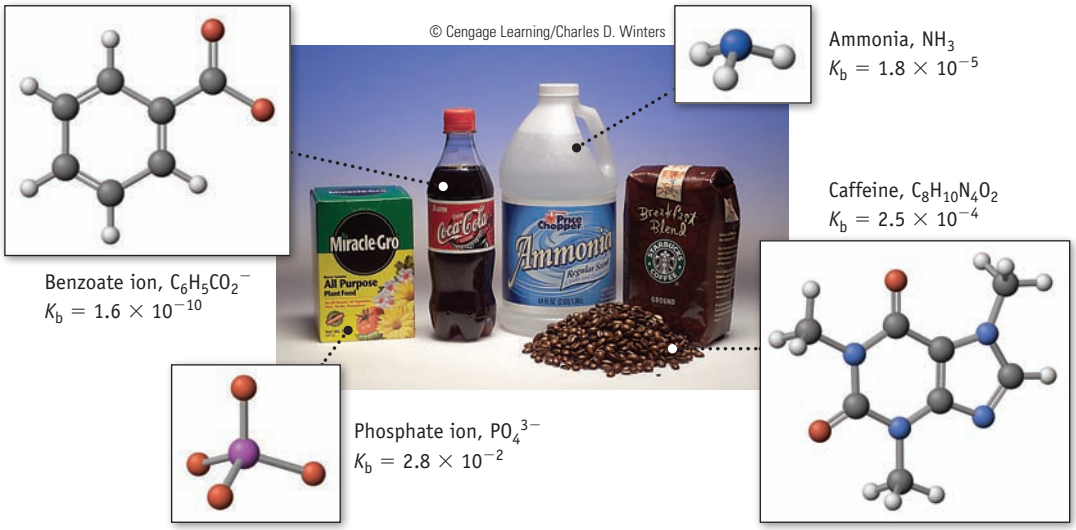

Figure 16.5 Examples of weak bases. Weak bases in water include molecules having one or more N atoms capable of accepting an H^+ ion and anions of weak acids such as benzoate and phosphate.

Just as acids can be molecular species or ions, bases can be ionic or molecular (Figures 16.3–16.5). Many molecular bases are based on nitrogen, with ammonia being the simplest. Many nitrogen-containing bases occur naturally, such as caffeine and nicotine. The anionic conjugate bases of weak acids make up another group of bases. The following example describes the calculation of the pH for a solution of sodium acetate.

Strategy Map 16.7

PROBLEM

Calculate the **pH** for a weak base knowing the value of K_b.

↓

DATA/INFORMATION KNOWN

- Base concentration
- Value of K_b

STEP 1. Write **balanced equation** and K_b **expression** and set up **ICE table**.

K_b expression and ICE table

STEP 2. Enter **equilibrium concentrations** in ICE table.

At equilibrium:
$[OH^-]$ = [conjugate acid] = x
[base] = original conc. − x

STEP 3. Enter **equilibrium concentrations** in K_b.

K_b **expression** with equilibrium concentrations in terms of x

STEP 4. Solve K_b **expression** for x.

x = value of $[OH^-]$

STEP 5. Using $[OH^-]$ and K_w, calculate $[H_3O^+]$ and then **pH**.

pH of solution

EXAMPLE 16.7

The pH of a Solution of a Weakly Basic Salt, Sodium Acetate

Problem What is the pH of a 0.015 M solution of sodium acetate, $NaCH_3CO_2$?

What Do You Know? You know sodium acetate is basic in water because the acetate ion, the conjugate base of a weak acid, acetic acid, reacts with water to form OH^- (Tables 16.2 and 16.3). (You also know that the sodium ion of sodium acetate does not affect the solution pH.) Finally, you know the value of K_b for the acetate ion (Table 16.2) and its initial concentration. You need to find the equilibrium concentration of H_3O^+ in order to calculate the pH.

Strategy This is similar to Examples 16.5 and 16.6, where you wanted to find the concentration of a reaction product.

- Write the balanced equation and the equilibrium constant expression, and set up an ICE table.
- Enter the initial concentration of $CH_3CO_2^-$ on the Initial (I) line of the ICE table.
- The variable x represents changes in concentration, so the change in $[CH_3CO_2^-]$ is $-x$ and the change in product concentrations is $+x$. Enter these values in the Change (C) line of the table.
- Enter the expressions for the equilibrium concentrations of all three species on the Equilibrium (E) line of the ICE table, and then transfer these to the equilibrium constant expression and solve for x.
- The value of $x = [OH^-]$. Determine $[H_3O^+]$ from this value using the expression $K_w = [H_3O^+][OH^-]$, then calculate pH from $[H_3O^+]$.

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

SOLUTION The value of K_b for the acetate ion is 5.6×10^{-10} (Table 16.2).

$$CH_3CO_2^-(aq) + H_2O(\ell) \rightleftharpoons CH_3CO_2H(aq) + OH^-(aq)$$

Set up an ICE table to summarize the initial and equilibrium concentrations of the species in solution.

Equilibrium	$CH_3CO_2^- + H_2O$	$\rightleftharpoons$	CH_3CO_2H	+	OH^-
Initial (M)	0.015		0		0
Change (M)	$-x$		$+x$		$+x$
Equilibrium (M)	$(0.015 - x)$		x		x

Next, substitute the values in the table into the K_b expression.

$$K_b = 5.6 \times 10^{-10} = \frac{[CH_3CO_2H][OH^-]}{[CH_3CO_2^-]} = \frac{x^2}{0.015 - x}$$

The acetate ion, a weak base, has a very small value of K_b. Therefore, we assume that x, the concentration of hydroxide ion generated by reaction of acetate ion with water, is very small, and we use the approximate expression to solve for x.

$$K_b = 5.6 \times 10^{-10} = \frac{x^2}{0.015}$$

$$x = [OH^-] = [CH_3CO_2H] = \sqrt{(5.6 \times 10^{-10})(0.015)} = 2.90 \times 10^{-6}\ M$$

To calculate the pH of the solution, we need the hydronium ion concentration. In aqueous solutions, it is always true that, at 25 °C,

$$K_w = 1.0 \times 10^{-14} = [H_3O^+][OH^-]$$

$$[H_3O^+] = \frac{K_w}{[OH^-]} = \frac{1.0 \times 10^{-14}}{2.90 \times 10^{-6}} = 3.45 \times 10^{-9}\ M$$

Therefore, $pH = -\log(3.45 \times 10^{-9}) = 8.46$

Think about Your Answer The hydroxide ion concentration (x) is indeed quite small relative to the initial acetate ion concentration so the approximate expression is appropriate. (Note that $100 \times K_b$ is less than the initial base concentration.)

Check Your Understanding

The weak base, ClO^- (hypochlorite ion), is used in the form of NaClO as a disinfectant in swimming pools and water treatment plants. What are the concentrations of HClO and OH^- and the pH of a 0.015 M solution of NaClO?

EXAMPLE 16.8

Calculating the pH after the Reaction of a Weak Base with a Strong Acid

Problem What is the pH of the solution that results from mixing 25 mL of 0.016 M NH_3 and 25 mL of 0.016 M HCl?

What Do You Know? You know this is an acid–base reaction ($HCl + NH_3$), and you know the amount of each reactant (calculated from the volume and concentration of each). Because equal volumes and concentrations are involved, neither the acid nor the base is in excess, and none will remain after the reaction. To find the pH of the solution after reaction, you need to know the amount of product, whether it is a weak acid or weak base, and its concentration. The final step then involves a weak acid or weak base equilibrium calculation (Examples 16.5–16.7). You will need to look up the equilibrium constant for the acid or base.

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Strategy This question involves three problems in one:

(a) *Writing a balanced equation:* First write a balanced equation for the reaction that occurs and then decide whether the reaction products are acids or bases. Here, the weak acid NH_4^+ is the product of interest.

(b) *Stoichiometry problem:* Finding the "initial" NH_4^+ concentration is a stoichiometry problem. The amount of NH_4^+ (in moles) produced in the HCl + NH_3 reaction is divided by the volume of the resulting solution.

(c) *Equilibrium problem:* Calculating the pH involves first solving an equilibrium problem. Needed for this calculation is the "initial" concentration of NH_4^+ from part (b) and the value of K_a for NH_4^+.

SOLUTION If equal amounts (moles) of base (NH_3) and acid (HCl) are mixed, the result should be an acidic solution because the significant species remaining in solution upon completion of the reaction is NH_4^+, the conjugate acid of the weak base ammonia (Tables 16.2 and 16.4).

(a) *Writing balanced equations*

The equation for the product-favored reaction of HCl (the supplier of hydronium ion) with NH_3 to give NH_4^+:

$$NH_3(aq) + H_3O^+(aq) \longrightarrow NH_4^+(aq) + H_2O(\ell)$$

The equation for the reactant-favored reaction of NH_4^+, the product, with water:

$$NH_4^+(aq) + H_2O(\ell) \rightleftharpoons H_3O^+(aq) + NH_3(aq)$$

(b) *Stoichiometry problem*

Amount of HCl and NH_3 consumed:

$$(0.025\ \text{L HCl})(0.016\ \text{mol/L}) = 4.00 \times 10^{-4}\ \text{mol HCl}$$

$$(0.025\ \text{L NH}_3)(0.016\ \text{mol/L}) = 4.00 \times 10^{-4}\ \text{mol NH}_3$$

Amount of NH_4^+ produced upon completion of the reaction:

$$4.00 \times 10^{-4}\ \text{mol NH}_3 \left(\frac{1\ \text{mol NH}_4^+}{1\ \text{mol NH}_3} \right) = 4.00 \times 10^{-4}\ \text{mol NH}_4^+$$

Concentration of NH_4^+: Combining 25 mL each of HCl and NH_3 gives a total solution volume of 50. mL. Therefore, the concentration of NH_4^+ is

$$[NH_4^+] = \frac{4.00 \times 10^{-4}\ \text{mol}}{0.050\ \text{L}} = 8.00 \times 10^{-3}\ \text{M}$$

(c) *Acid–base equilibrium problem*

With the initial concentration of ammonium ion known, set up an ICE table to find the equilibrium concentration of hydronium ion.

Equilibrium	$NH_4^+ + H_2O$	$\rightleftharpoons$	NH_3	+	H_3O^+
Initial (M)	0.00800		0		0
Change (M)	$-x$		$+x$		$+x$
Equilibrium (M)	$(0.00800 - x)$		x		x

Next, substitute the values in the table into the K_a expression for the ammonium ion.

$$K_a = 5.6 \times 10^{-10} = \frac{[H_3O^+][NH_3]}{[NH_4^+]} = \frac{(x)(x)}{0.00800 - x}$$

Strategy Map 16.8

PROBLEM

Calculate **pH** of solution after the reaction of a **weak base** and a **strong acid.**

DATA/INFORMATION KNOWN

- Reactant concentrations
- Reactant volumes

STEP 1. Write **balanced equation** and solve **stoichiometry problem.**

Know **amounts of reactants** and derive **amount of product.**

STEP 2. Decide if product is **weak acid** or **weak base.**

Product is a **weak acid** (NH_4^+)

STEP 3. Calculate concentration of NH_4^+.

Concentration of weak acid whose K_a is known.

STEP 4. Solve for $[H_3O^+]$ as in Examples 16.5–16.7.

Value of $[H_3O^+]$

STEP 5. Convert $[H_3O^+]$ to **pH.**

pH of solution

The ammonium ion is a very weak acid, as reflected by the very small value of K_a. Therefore, x, the concentration of hydronium ion generated by reaction of ammonium ion with water, is assumed to be very small, and the approximate expression is used to solve for x. (Here $100 \times K_a$ is much less than the original acid concentration.)

$$K_a = 5.6 \times 10^{-10} = \frac{x^2}{0.00800}$$

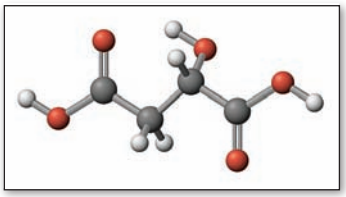
$$x = \sqrt{(5.6 \times 10^{-10})(0.00800)}$$

$$= [H_3O^+] = [NH_3] = 2.12 \times 10^{-6}\ M$$

$$pH = -\log(2.12 \times 10^{-6}) = 5.67$$

Think about Your Answer As predicted (Table 16.4), the solution after mixing equal amounts of a strong acid and weak base is weakly acidic.

Check Your Understanding



Calculate the pH after mixing 15 mL of 0.12 M acetic acid with 15 mL of 0.12 M NaOH. What are the major species in solution at equilibrium (besides water), and what are their concentrations?

16.8 Polyprotic Acids and Bases

Goal for Section 16.8

- Use the equilibrium constant, K_{a1} or K_{b1}, and other information to calculate the pH of a solution of a polyprotic acid or base.

Because polyprotic acids are capable of donating more than one proton, they present us with additional challenges when predicting the pH of their solutions. For many inorganic polyprotic acids, such as phosphoric acid, carbonic acid, and hydrosulfuric acid (H_2S), the ionization constant for each successive loss of a proton is about 10^4 to 10^6 smaller than the previous ionization step. This means that the first ionization step of a polyprotic acid produces up to about a million times more H_3O^+ ions than the second step. For this reason, *the pH of many inorganic polyprotic acids depends primarily on the hydronium ion generated in the first ionization step; the hydronium ion produced in the second step can be neglected.* The same principle applies to the fully deprotonated conjugate bases of polyprotic acids. This is illustrated by the calculation of the pH of a solution of carbonate ion, an important base in our environment.

© Cengage Learning/Charles D. Winters

A polyprotic acid. Malic acid, $C_4H_6O_5$, is a diprotic acid occurring in apples. It is also classified as an alpha-hydroxy acid because it has an OH group on the C atom next to the CO_2H (in the alpha position). It is one of a large group of natural alpha-hydroxy acids such as lactic acid, citric acid, and ascorbic acid. Alpha-hydroxy acids have been touted as an ingredient in "anti-aging" skin creams. They work by accelerating the natural process by which skin replaces the outer layer of cells with new cells.

Problem Solving Tip 16.2 What Is the pH After Mixing Equal Amounts (Moles) of an Acid and a Base?

Table 16.4 summarizes the outcome of mixing various types of acids and bases. But how do you calculate a numerical value for the pH, particularly in the case of mixing a weak acid with a strong base or a weak base with a strong acid? The strategy (Example 16.8) is to recognize that this involves two calculations: a stoichiometry calculation and an equilibrium calculation. The key is that you need to know the concentration of the weak acid or weak base produced when the acid and base are mixed. Answering the following questions will guide you to an answer:

(a) What amounts of acid and base are used (in moles)? (This is a stoichiometry problem.)
(b) What is the total volume of the solution after mixing the acid and base solutions?
(c) What is the concentration of the weak acid or base produced on mixing the acid and base solutions?
(d) Using the concentration found in Step (c), what is the hydronium ion concentration in the solution? (This is an equilibrium problem.) Determine the pH from the hydronium ion concentration.

EXAMPLE 16.9

Calculating the pH of the Solution of a Polyprotic Base

Problem The carbonate ion, CO_3^{2-}, is a base in water, forming the hydrogen carbonate ion, which in turn can form carbonic acid.

$$CO_3^{2-}(aq) + H_2O(\ell) \rightleftharpoons HCO_3^-(aq) + OH^-(aq) \qquad K_{b1} = 2.1 \times 10^{-4}$$

$$HCO_3^-(aq) + H_2O(\ell) \rightleftharpoons H_2CO_3(aq) + OH^-(aq) \qquad K_{b2} = 2.4 \times 10^{-8}$$

What is the pH of a 0.10 M solution of Na_2CO_3?

What Do You Know? You know the balanced equations and the values of K_b for the ions as well as the concentration of the carbonate ion.

Strategy The first ionization constant, K_{b1}, is much larger than the second, K_{b2}, so the hydroxide ion concentration in the solution results almost entirely from the first step. Therefore, you can calculate the OH^- concentration produced by considering only the first ionization step, but we will want to test the conclusion that OH^- produced in the second step is negligible.

© Cengage Learning/Charles D. Winters

Sodium carbonate, a polyprotic base. This common substance is a base in aqueous solution. Its primary use is in the glass industry. Although it used to be manufactured, it is now mined as the mineral trona, $Na_2CO_3 \cdot NaHCO_3 \cdot 2\,H_2O$.

SOLUTION Set up an ICE table for the reaction of the carbonate ion (Equilibrium Table 1).

Equilibrium Table 1—Reaction of CO_3^{2-} Ion

Equilibrium	$CO_3^{2-} + H_2O$	$\rightleftharpoons$	HCO_3^-	+	OH^-
Initial (M)	0.10		0		0
Change	$-x$		$+x$		$+x$
Equilibrium (M)	$(0.10 - x)$		x		x

Based on this table, the equilibrium concentration of OH^- ($= x$) can then be calculated.

$$K_{b1} = 2.1 \times 10^{-4} = \frac{[HCO_3^-][OH^-]}{[CO_3^{2-}]} = \frac{x^2}{0.10 - x}$$

Because K_{b1} is relatively small, it is reasonable to make the approximation that $(0.10 - x) \approx 0.10$. Therefore,

$$x = [HCO_3^-] = [OH^-] = \sqrt{(2.1 \times 10^{-4})(0.10)} = 4.58 \times 10^{-3}\ M$$

Using this value of $[OH^-]$, you can calculate the pOH of the solution,

$$pOH = -\log\,(4.58 \times 10^{-3}) = 2.34$$

and then use the relationship pH + pOH = 14.00 to calculate the pH.

$$pH = 14.00 - pOH = 11.66$$

Finally, you can conclude that the concentration of the carbonate ion is approximately 0.10 M.

$$[CO_3^{2-}] = 0.10 - 0.00458 \approx 0.10\ M$$

The HCO_3^- ion produced in the first step could acquire another proton to give H_2CO_3 and this could affect the pH. But does this occur to a meaningful extent? To test this, set up a second ICE Table.

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Equilibrium Table 2—Reaction of HCO_3^- Ion

Equilibrium	$HCO_3^- + H_2O$	$\rightleftharpoons$	H_2CO_3	+	OH^-
Initial (M)	4.58×10^{-3}		0		4.58×10^{-3}
Change (M)	$-y$		$+y$		$+y$
Equilibrium (M)	$(4.58 \times 10^{-3} - y)$		y		$(4.58 \times 10^{-3} + y)$

Because K_{b2} is so small, the second step occurs to a much smaller extent than the first step. This means the amount of H_2CO_3 and OH^- produced in the second step ($= y$) is much smaller than 4.58×10^{-3} M. Therefore, it is reasonable that both $[HCO_3^-]$ and $[OH^-]$ are very close to 4.58×10^{-3} M.

$$K_{b2} = 2.4 \times 10^{-8} = \frac{[H_2CO_3][OH^-]}{[HCO_3^-]} = \frac{(y)(4.58 \times 10^{-3})}{4.58 \times 10^{-3}}$$

Because $[HCO_3^-]$ and $[OH^-]$ have nearly identical values, they cancel from the expression, and we find that $[H_2CO_3]$ is simply equal to K_{b2}.

$$y = [H_2CO_3] = K_{b2} = 2.4 \times 10^{-8} \text{ M}$$

The amount of OH^- produced in this reaction is negligible. All of the hydroxide ion is essentially produced in the first equilibrium process.

Think about Your Answer It is almost always the case that the pH of a solution of an inorganic polyprotic acid is due to the hydronium ion generated in the first ionization step. Similarly, the pH of a polyprotic base is due to the OH^- ion produced in the first hydrolysis step.

Check Your Understanding

What is the pH of a 0.10 M solution of oxalic acid, $H_2C_2O_4$? What are the concentrations of H_3O^+, $HC_2O_4^-$, and the oxalate ion, $C_2O_4^{2-}$? (See Appendix H for K_a values.)

16.9 Molecular Structure, Bonding, and Acid–Base Behavior

Goal for Section 16.9

- Appreciate the connection between the structure of a compound and its acidity or basicity.

One of the most interesting aspects of chemistry is the correlation between a molecule's structure and bonding and its chemical properties. Because acids and bases play such a key role in chemistry, principles relating acid or base character to structure will be useful.

Acid Strength of the Hydrogen Halides, HX

Aqueous HF is a weak Brønsted acid in water, whereas the other hydrohalic acids—aqueous HCl, HBr, and HI—are all strong acids. Experiments show that the acid strength increases in the order HF << HCl < HBr < HI. A detailed analysis of the factors that lead to these differences in acid strength in this group is informative (*A Closer Look: Acid Strengths and Molecular Structure*, page 741).

Predictions about relative acid strength can be made based on the sum of two energy quantities, the energy required to break the H—X bond (the bond dissociation

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

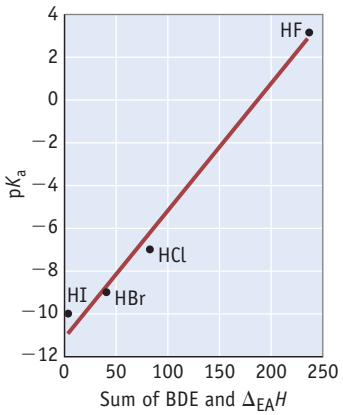

Figure 16.6 The effect of H—X bond enthalpy and X electron attachment enthalpy on acid strength. Stronger acids have weaker H—X bonds and X atoms with more negative electron attachment enthalpies. (BDE is the bond dissociation enthalpy of the H—X bond, and $\Delta_{EA}H$ is the electron attachment enthalpy of the halogen atom.) See M. Moran, *Journal of Chemical Education*, Vol. 83, pp. 800–803, 2006.

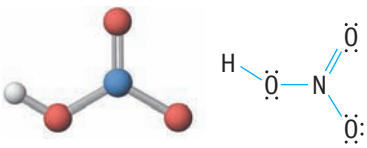
enthalpy) and the electron attachment enthalpy of the halogen. That is, when a hydrohalic acid HX ionizes in water,

$$HX(aq) + H_2O(\ell) \longrightarrow H_3O^+(aq) + X^-(aq)$$

the sum of the two energy terms

Change in energy $\propto$ HX bond dissociation enthalpy + electron attachment enthalpy of X

correlates with acid strength. Stronger acids should result when the H—X bond is more easily broken (as signaled by a smaller, positive value of ΔH for bond dissociation) and when there is a more negative value for the electron attachment enthalpy of X.



The bond dissociation enthalpy and electron attachment enthalpy effects can work together (a weak H—X bond and a large, negative electron attachment enthalpy of the X group) to produce a strong acid, but they can also work in opposite directions. The balance of the two effects is important. The table below has some data for the hydrogen halides.

	Increasing acid strength →			
	HF	HCl	HBr	HI
pK_a	+3.14	−7	−9	−10
H—X bond strength (kJ/mol)	565	432	366	299
Electron attachment enthalpy of *X* (kJ/mol)	−328	−349	−325	−295
Sum (kJ/mol)	237	83	41	4

In this series of acids, the bond enthalpy factor dominates: the weakest acid, HF, has the strongest H—X bond, and the strongest acid, HI, has the weakest H—X bond. However, the electron attachment enthalpy of X is most negative with Cl, less so with F and Br, and much less so with I. A less negative electron attachment enthalpy should lead to a weaker acid. The *sum* of the two effects leads to the observation that HI is the strongest acid. In Figure 16.6 you see there is a good correlation between an acid's pK_a and the *sum* of the enthalpies for bond dissociation and electron attachment enthalpy.

Comparing Oxoacids: HNO_2 and HNO_3

Nitrous acid (HNO_2) and nitric acid (HNO_3) are representative of several series of **oxoacids**. Oxoacids contain an atom (usually a nonmetal atom) bonded to one or more oxygen atoms, some with hydrogen atoms attached. Besides those based on N, you are familiar with the sulfur- and chlorine-based oxoacids (Table 16.5). In all these series of related compounds, the acid strength increases as the number of oxygen atoms bonded to the central element increases. Thus, nitric acid (HNO_3) is a stronger acid than nitrous acid (HNO_2).

HNO_3, strong acid, $pK_a = -1.4$

HNO_2, weak acid, $pK_a = +3.35$

Let's apply the bond enthalpy/electron attachment enthalpy analysis to HNO_3 and HNO_2.

	Increasing acid strength →	
	HNO_2	HNO_3
pK_a	+3.35	−1.4
H—O bond strength in these molecules (kJ/mol)	328	423
Electron attachment enthalpy of NO_2 or NO_3 (kJ/mol)	−219	−377
Sum (kJ/mol)	109	46

TABLE 16.5

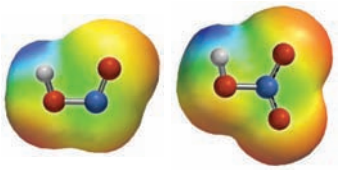
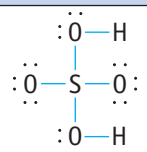
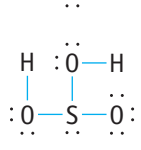
As in the case of the Group 7A acids, the acid strength correlates with the sum of the enthalpies of bond breaking and X group (NO_2 or NO_3) attachment enthalpy. (The larger the sum, the weaker the acid.)

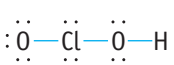


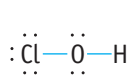
Analysis of the Group 7A acids showed that the H—X bond strength was the more important factor; as the H—X bond became weaker, the acid became stronger. However, the data for HNO_3 and HNO_2 show this is not true here. The O—H bond is stronger in the stronger acid HNO_3. Instead, the electron attachment term is the more important term in this correlation. These same effects are observed for other oxoacids such as the chlorine-based oxoacids HOCl < HOClO < $HOClO_2$ < $HOClO_3$ and the S-based oxoacids (Table 16.5). How is this to be interpreted?

In HNO_3, there are two other oxygen atoms bonded to the central nitrogen atom, whereas in HNO_2 only one other oxygen is bonded to the nitrogen atom. By attaching more electronegative O atoms to nitrogen, we are increasing the electron affinity of the group attached to hydrogen, and anything that increases the affinity of the X group for an electron should also make HX a stronger acid and X^- a weaker conjugate base. This is another way of saying that if X^- has a way to accommodate and stabilize a negative charge, it will be a weaker conjugate base. In the case of oxoacids, additional oxygen atoms have the effect of stabilizing the anion because the negative charge on the anion can be dispersed over more atoms. In the nitrate ion, for example, the negative charge is shared equally over the three oxygen atoms. This is represented symbolically by the three resonance structures for this ion.









In the nitrite ion, only two atoms share the negative charge. Therefore, NO_2^- is a stronger conjugate base than NO_3^-. *In general, greater stabilization of the products formed by ionizing the acid contributes to increased acidity.*

It is also found that in a series of related acids, the larger the formal charge on the central atom, the stronger the acid and the weaker the conjugate base. For example, the N atom formal charge in the weak acid HNO_2 is 0, whereas it is +1 in the strong acid HNO_3, and these are reflected by the results of theoretical calculations presented in Figure 16.7. In oxoacids, the formal charge on the central atom increases as the number of oxygen atom attached to the central atom increases. The results are shown below for two pairs of oxoacids.

nitrous acid, HNO_2 nitric acid, HNO_3

Figure 16.7 Electrostatic potential surfaces for the nitrogen oxoacids. Both surfaces show the O—H bond is quite polar. More importantly, calculations show that the OH bond becomes more polar as more O atoms are added to N.

	Central Atom Formal Charge	pK_a
	+2	−3
	+1	1.92
	+1	2
	0	7.46

Partial Charges			
Molecule	H Atom	O Atom of OH	N Atom
HNO_2	+0.39	−0.35	+0.14
HNO_3	+0.41	−0.47	+0.76

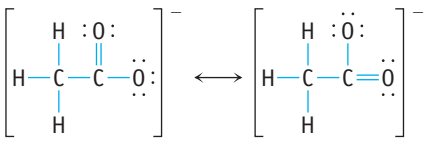
In summary, oxoacids can behave as stronger Brønsted acids when the anion created by loss of H^+ is better able to accommodate the negative charge. These conditions are promoted by



- the presence of electronegative atoms attached to the central atom.
- the possibility of resonance structures for the anion, which lead to delocalization of the negative charge over the anion and thus to a more stable ion.
- greater positive formal charge of the central atom.

Why Are Carboxylic Acids Brønsted Acids?

There is a large class of organic acids, typified by acetic acid (CH_3CO_2H) (Figure 16.8), called *carboxylic acids* because all have the carboxylic acid group, $—CO_2H$ (Section 23.4). The arguments used to explain the acidity of oxoacids can also be applied to carboxylic acids. The O—H bond in these compounds is polar, a prerequisite for ionization.

In addition, carboxylate anions are stabilized by delocalizing the negative charge over the two oxygen atoms.

Carboxylic acids, RCO_2H in which R is a hydrocarbon group, do not differ markedly in acid strength (compare acetic acid, $pK_a = 4.74$, and propanoic acid, $pK_a = 4.89$, Table 16.2). The acidity of carboxylic acids is enhanced, however, if electronegative atoms replace the hydrogen atoms in the alkyl ($—CH_3$ or $—C_2H_5$) group. Compare, for example, the pK_a values of a series of acetic acids in which hydrogen is replaced sequentially by the more electronegative element chlorine.

Acid		pK_a Value	
CH_3CO_2H	Acetic acid	4.74	
$ClCH_2CO_2H$	Chloroacetic acid	2.85	Increasing acid strength
Cl_2CHCO_2H	Dichloroacetic acid	1.49	
Cl_3CCO_2H	Trichloroacetic acid	0.7	

As in the nitrogen oxoacids, increasingly electronegative substituents lead to an increase in acid strength. One argument is that electronegative substituents stabilize the negative charge of the anion. That is, the $Cl_3CCO_2^-$ anion is more stable than the $H_3CCO_2^-$ anion, so the formation of $Cl_3CCO_2^-$ is more favored than the formation of $CH_3CO_2^-$. Thus, the $Cl_3CCO_2^-$ anion is a weaker base than the $CH_3CO_2^-$ anion.

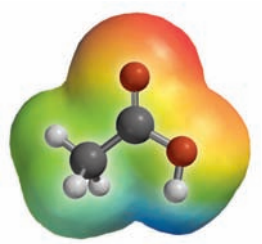


Figure 16.8 Electrostatic potential surface and partial charges for acetic acid. The H atoms of the molecule are all positively charged, but the H atom of the OH is much more highly charged. As expected, both of the electronegative O atoms have a partial negative charge.

Atom or Group	Calculated Partial Charge
H of OH	+0.43
O of OH	−0.62
H of CH_3	+0.23

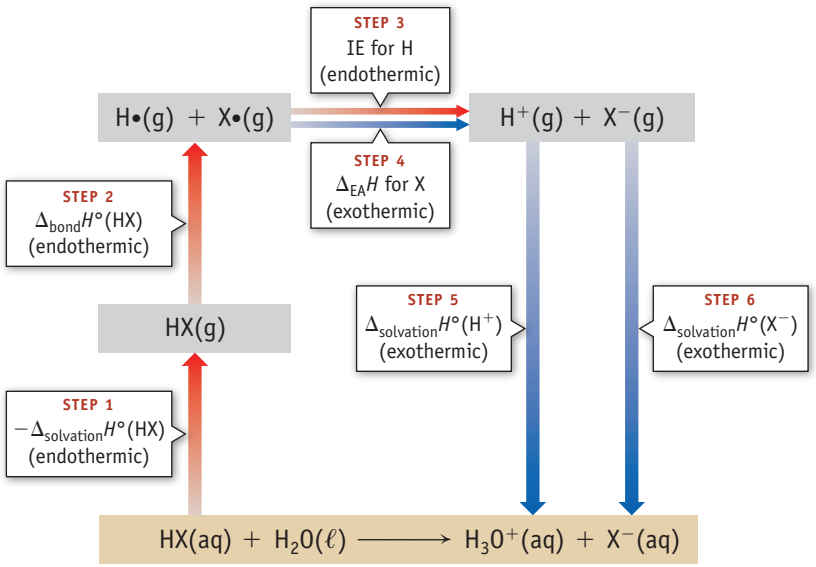
A CLOSER LOOK



Acid Strengths and Molecular Structure

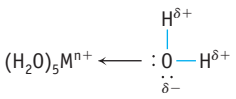
Although predictions about acid strength in aqueous solution are fairly simple to make, a complete explanation can be complicated. When evaluating the strength of an acid HX(aq), we are looking at the following reaction:

$$HX(aq) + H_2O(\ell) \rightleftharpoons H_3O^+(aq) + X^-(aq)$$

Acid strength is sometimes correlated with the strength and the polarity of the H—X bond, readily identifiable characteristics derived from the structure of the acid. To fully explain the extent of ionization, we must also consider characteristics of the conjugate base of the acid, X^-. The ability of the anion to spread out the negative charge across the ion and the solvation of the anion by the solvent are also relevant in an explanation of the strength of the acid.

How enthalpy changes contribute to acid strength can be assessed using a thermochemical cycle. The enthalpy change for the ionization of an acid such as a hydrogen halide in water can be related to other enthalpy changes as shown in the diagram. The ionization energy (Step 3) and the solvation of H^+ (Step 5) are common to all acids and therefore do not contribute to the differences among their enthalpies for ionization, but the four remaining terms are different. For the hydrogen halides, the bond dissociation enthalpy (Step 2) of HF is much larger than the bond dissociation enthalpies of the other hydrogen halides and contributes significantly to the reason why HF is a weak acid whereas the others are strong acids. However, it is compensated for significantly by the enthalpy of solvation of the anion (Step 6), which for the fluoride ion is much more exothermic than the solvation energies of the other halide ions. The electron attachment enthalpy (Step 4) is also a contributor to the differences in overall enthalpy changes; their values vary among the halogens, but to a smaller extent than the variation in bond energy and the enthalpy of solvation of the halide ion. Differences in solvation energy for the molecular species (Step 1) are minimal.

We noted earlier (Section 13.2) that entropy plays an important role in solution chemistry. It should not be surprising then that entropy also has a role in determining acid strength. Indeed, differences in entropy changes are significant in accounting for the differences in acid strength of the hydrogen halides. Entropy has yet to be discussed in this text in detail (Chapter 18) but a complete analysis of strengths of acids in aqueous solution will include consideration of both enthalpies and entropies.



Why Are Hydrated Metal Cations Brønsted Acids?

When a coordinate covalent bond is formed between a metal cation and a water molecule, the positive charge of the metal ion and its small size means that the electrons of the $H_2O \rightarrow M^{n+}$ bond are very strongly attracted to the metal (Section 16.10). As a result, the O—H bonds of the bound water molecules are polarized, just as in oxoacids and carboxylic acids. The net effect is that a hydrogen atom of a coordinated water molecule is removed as H^+ more readily than in an uncoordinated water molecule. Thus, a hydrated metal cation functions as a Brønsted acid or proton donor.

$$[Cu(H_2O)_6]^{2+} + H_2O(\ell) \rightleftharpoons [Cu(H_2O)_5(OH)]^+(aq) + H_3O^+(aq)$$

The acidity of the hydrated metal ion increases with increasing charge (Table 16.2). Acid dissociation constants of +3 ions (for example Al^{3+} and Fe^{3+}) are greater than for +2 cations (Cu^{2+}, Pb^{2+}, Co^{2+}, Fe^{2+}, Ni^{2+}). Ions with a single positive charge such as Na^+ and K^+ are not acidic. (This is similar to the effect of central atom formal charge in a series of related oxoacids.)

Polarization of O—H Bonds
Water molecules attached to a metal cation have strongly polarized O—H bonds.

TABLE 16.6

Basic Oxoanions

Anion	pK_b
PO_4^{3-}	1.55
HPO_4^{2-}	6.80
$H_2PO_4^-$	11.89
CO_3^{2-}	3.68
HCO_3^-	7.62
SO_3^{2-}	6.80
HSO_3^-	12.08

Why Are Anions Brønsted Bases?

Anions, particularly oxoanions such as PO_4^{3-}, are Brønsted bases. The negatively charged anion interacts with the positively charged H atom of a polar water molecule, and an H^+ ion is transferred to the anion.

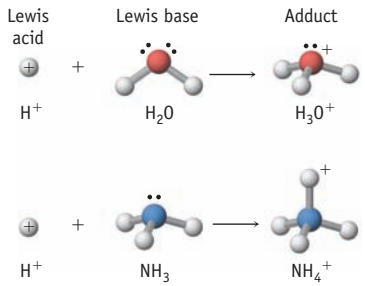
The data in Table 16.6 show that, in a series of related anions, the basicity of an anionic base increases as the negative charge of the anion increases.

16.10 The Lewis Concept of Acids and Bases

Goal for Section 16.10

- Characterize a compound as a Lewis base (an electron-pair donor) or a Lewis acid (an electron-pair acceptor).

The concept of acid–base behavior advanced by Brønsted and Lowry in the 1920s works well for reactions involving proton transfer. However, a more general acid–base concept was developed by Gilbert N. Lewis in the 1930s (Section 8.2). This concept is based on the sharing of an electron pair between an acid and a base.

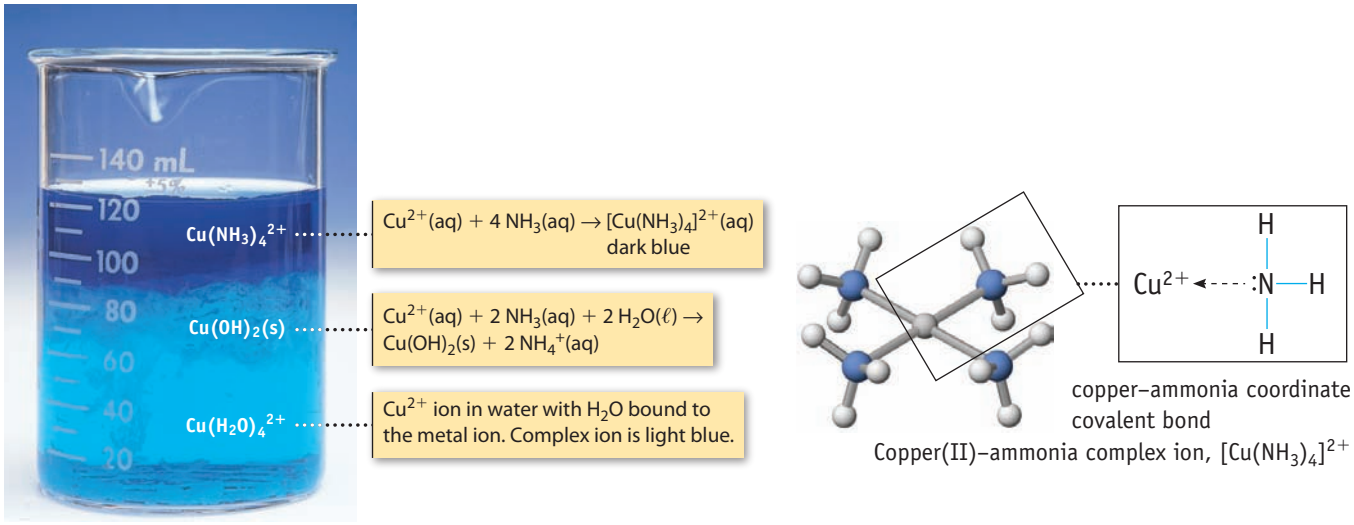


A **Lewis acid** is a substance that can accept a pair of electrons from another atom to form a new bond, and a **Lewis base** is a substance that can donate a pair of electrons to another atom to form a new bond.

The product of a Lewis acid–base reaction is called an **acid–base adduct.**

$$\underset{\text{acid}}{A} + \underset{\text{base}}{B:} \rightarrow \underset{\text{adduct}}{B{\rightarrow}A}$$

In Section 8.5, this type of chemical bond was called a *coordinate covalent bond.*



All Brønsted–Lowry acid–base reactions can be characterized as Lewis acid–base reactions. Formation of a hydronium ion from H^+ and water, and the formation of the ammonium ion from H^+ and ammonia, illustrate how a Brønsted–Lowry acid–base reaction can be described as a Lewis acid–base reaction.

The H^+ ion has no electrons in its valence (1*s*) shell, and the water molecule has two unshared pairs of electrons (located in sp^3 hybrid orbitals). One of the lone pairs of a water molecule oxygen atom can be shared with an H^+ ion, thus forming an O—H bond in an H_3O^+ ion. A similar interaction occurs between H^+ and the nitrogen lone pair on ammonia to form the ammonium ion.

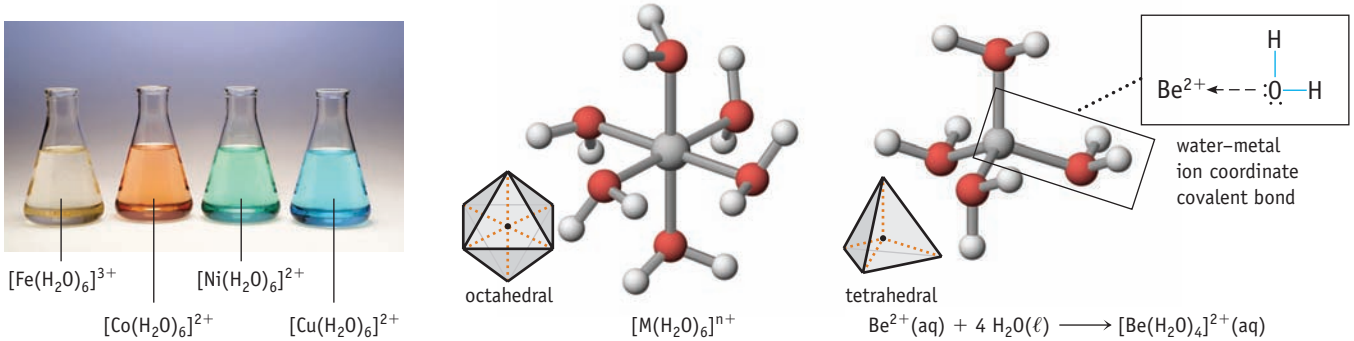
Figure 16.9 The Lewis acid–base complex ion $[Cu(NH_3)_4]^{2+}$. Aqueous ammonia was added to aqueous $CuSO_4$ in a beaker (the light blue solution at the bottom of the beaker). The small concentration of OH^- in $NH_3(aq)$ first led to the formation of insoluble blue-white $Cu(OH)_2$. With additional NH_3, however, the dark blue, soluble complex ion formed. Ammonia is bound to the Cu^{2+} ion by a coordinate-covalent bond. (The distribution of products in the beaker is a result of a decrease in NH_3 concentration from the top to the bottom of the solution.)



Coordination Complexes

Metal cations interact with water molecules to form hydrated cations. In these species, coordinate covalent bonds form between the metal cation and a lone pair of electrons on the O atom of each water. For example, an iron(II) ion, Fe^{2+}, forms six coordinate-covalent bonds to water.

$$Fe^{2+}(aq) + 6\ H_2O(\ell) \rightleftharpoons [Fe(H_2O)_6]^{2+}(aq)$$

Solutions of transition metal cations are generally very colorful (Figures 16.9 and 16.10 and Section 22.7). Chemists call the species formed by coordination of water to a metal ion **complex ions** or, because of the presence of coordinate covalent bonds, **coordination complexes**. Several are listed in Table 16.2 as acids, and their behavior is described further in Chapter 22.

Ammonia is a typical Lewis base and, like water, it also combines with metal cations to give coordination complexes, which are often very colorful. For example, copper(II) ions, light blue in aqueous solution (Figure 16.9), react with ammonia to give a deep blue adduct with four ammonia molecules surrounding each Cu^{2+} ion.

© Cengage Learning/Charles D. Winters

Solutions of the nitrate salts of iron(III), cobalt(II), nickel(II), and copper(II) all have characteristic colors.

Models of complex ions (Lewis acid–base adducts) formed between a metal cation and water molecules. Such complexes often have six or four water molecules arranged octahedrally or tetrahedrally around the metal cation.

Figure 16.10 Metal cations in water.

TABLE 16.7 Some Common Amphoteric Metal Hydroxides

Hydroxide	Reaction as a Base*	Reaction as an Acid
$Al(OH)_3$	$Al(OH)_3(s) + 3\ H_3O^+(aq) \rightleftharpoons Al^{3+}(aq) + 6\ H_2O(\ell)$	$Al(OH)_3(s) + OH^-(aq) \rightleftharpoons [Al(OH)_4]^-(aq)$
$Zn(OH)_2$	$Zn(OH)_2(s) + 2\ H_3O^+(aq) \rightleftharpoons Zn^{2+}(aq) + 4\ H_2O(\ell)$	$Zn(OH)_2(s) + 2\ OH^-(aq) \rightleftharpoons [Zn(OH)_4]^{2-}(aq)$
$Sn(OH)_4$	$Sn(OH)_4(s) + 4\ H_3O^+(aq) \rightleftharpoons Sn^{4+}(aq) + 8\ H_2O(\ell)$	$Sn(OH)_4(s) + 2\ OH^-(aq) \rightleftharpoons [Sn(OH)_6]^{2-}(aq)$
$Cr(OH)_3$	$Cr(OH)_3(s) + 3\ H_3O^+(aq) \rightleftharpoons Cr^{3+}(aq) + 6\ H_2O(\ell)$	$Cr(OH)_3(s) + OH^-(aq) \rightleftharpoons [Cr(OH)_4]^-(aq)$

*The aqueous metal cations are best described as $[M(H_2O)_x]^{n+}$ where x varies.

Hydroxide ion, OH^-, is an excellent Lewis base and binds readily to metal cations to give metal hydroxides. An important feature of the chemistry of some metal hydroxides is that they are **amphoteric**. An amphoteric metal hydroxide can behave as an acid or a base (Table 16.7), and the chemistry of aluminum hydroxide, $Al(OH)_3$, is one of the best examples of this behavior. Adding OH^- to a precipitate of $Al(OH)_3$ produces the water-soluble complex ion $[Al(OH)_4]^-$ (Figure 16.11). In this reaction, $Al(OH)_3$ is acting as a Lewis acid.

$$\underset{\text{acid}}{Al(OH)_3(s)} + \underset{\text{base}}{OH^-(aq)} \rightleftharpoons [Al(OH)_4]^-(aq)$$

Photos: © Cengage Learning/Charles D. Winters

Figure 16.11 The amphoteric nature of $Al(OH)_3$. Aluminum hydroxide is formed by the reaction of aqueous Al^{3+} and ammonia.

$$Al^{3+}(aq) + 3\ NH_3(aq) + 3\ H_2O(\ell) \rightleftharpoons Al(OH)_3(s) + 3\ NH_4^+(aq)$$

Reactions of solid $Al(OH)_3$ with aqueous NaOH and HCl demonstrate that aluminum hydroxide is amphoteric.

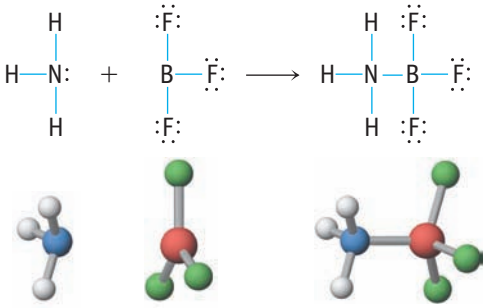
If acid is added to the $Al(OH)_3$ precipitate, it again dissolves. This time, however, aluminum hydroxide is acting as a Brønsted base.

$$\underset{\text{base}}{Al(OH)_3(s)} + 3\ \underset{\text{acid}}{H_3O^+(aq)} \longrightarrow Al^{3+}(aq) + 6\ H_2O(\ell)$$

Molecular Lewis Acids

Lewis's acid–base concept also accounts for the fact that oxides of nonmetals such as CO_2 and SO_2 behave as acids (Section 3.6). Because oxygen is more electronegative than C, the C—O bonding electrons in CO_2 are polarized away from carbon and toward oxygen. This causes the carbon atom to be slightly positive, and it is this atom that the negatively charged Lewis base OH^- can attack to give the bicarbonate ion.



CO_2 in Basic Solution This reaction of CO_2 with OH^- is the first step in the precipitation of $CaCO_3$ when CO_2 is bubbled into a solution of $Ca(OH)_2$ (Figure 3.5).

Similarly, SO_2 reacts with aqueous OH^- to form the HSO_3^- ion.

Molecular Lewis Bases

Ammonia is the parent compound of an enormous number of compounds that behave as Lewis and Brønsted bases (Figure 16.12). These molecules all have an electronegative N atom with a partial negative charge surrounded by three bonds and a lone pair of electrons. It is the lone pair of electrons that allows the molecules to function as Lewis bases in forming a coordinate covalent bond with an electron deficient atom, as NH_3 does with the Lewis acid BF_3.

In addition, the lone pair can be used to form a coordinate covalent bond to a metal cation in a Lewis acid–base reaction (Figure 16.9).

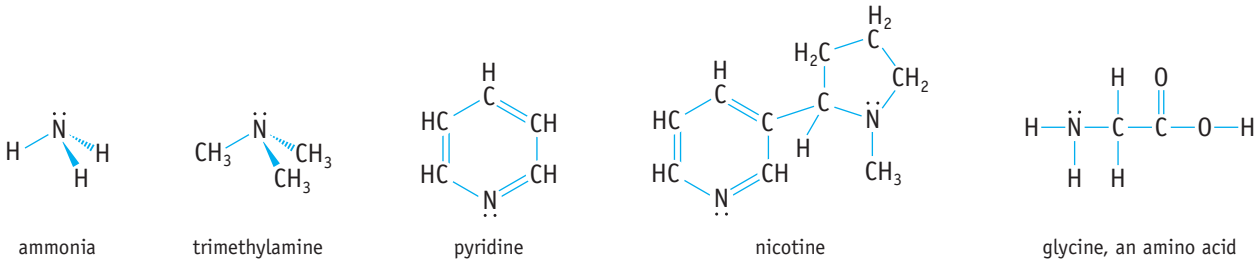


Figure 16.12 Nitrogen-based Lewis and Brønsted bases. Ammonia and hundreds of other compounds important in industry and in nature have an N atom surrounded by three bonds and a lone pair of electrons. This allows them to function as a Brønsted base and a Lewis base.

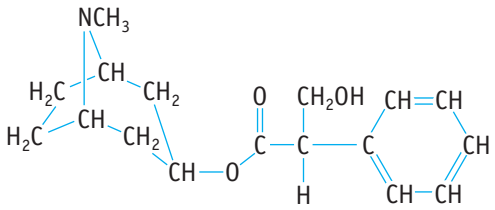
16.1 Would You Like Some Belladonna Juice in Your Drink?

The belladonna plant produces black, cherry-sized berries that look good enough to eat. But you should think twice because the plant is also called *deadly nightshade.* The berries contain atropine, a base, which is toxic and has been used by women and men for centuries to eliminate old lovers and political enemies.

The name for the plant, *belladonna*, comes from the Italian meaning "beautiful woman." Courtesans and actresses in Venice in the 16th century would put a drop or two of the juice in their eyes. It would dilate the pupils and give them a "fashionable, doe-like" appearance that could last several days.

Atropine was used for some years by physicians to dilate the eye, and it is used to treat such conditions as bradycardia, an extremely low heart rate. It is also an antidote for sarin, a nerve gas. In fact, victims of a sarin gas attack in Japan in the 1990s were treated with atropine, and soldiers in the first Gulf War in 1990–1991 carried atropine as an antidote in the event of a nerve gas attack.



But atropine is mostly remembered in history as a poison. A fatal dose is around 100 mg. One legend is that Cleopatra at first wanted to commit suicide by taking atropine. She had a slave try it first, but the slave's death was not pleasant, so she opted for the bite of an asp, a deadly snake.

At the height of the Roman Empire, atropine and other agents were so often used as poisons that a law was passed in 82 BC to "suppress domestic poisoning." It apparently had little effect.

WILDLIFE GmbH/Alamy Stock Photo

Berries of the belladonna plant, a source of atropine

Atropine, $C_{17}H_{23}NO_3$.

The symptoms of atropine poisoning are well known. Physicians say the patient is "red as a beet" because the blood vessels dilate. Or you can be "blind as a bat" because the pupils are so dilated that vision is blurred. "Dry as a bone" is another symptom arising from the suppression of the salivary glands. In addition, you can be "hot as a hare" because your body temperature goes up and stays up for some hours. Finally, you can be "mad as a hatter" (like the hatter in *Alice in Wonderland*) because you act like a drunk person.

Atropine is not very soluble in water. However, because atropine is a base it reacts with acids. For example, reaction with sulfuric acid forms the sulfate salt. This salt is so soluble that 1 mL of a saturated solution of this compound contains many times the amount needed for a fatal dose.

If you are interested in the history of atropine as a murder weapon, be sure to read the book *Molecules of Murder* where the author describes the attempted murder of Alexandra Agutter by her husband in Scotland in the 1990s.

Questions:

1. If a fatal does of atropine is 100. mg, what amount of compound (moles) is this?
2. When atropine is added to sulfuric acid, a proton attaches to the molecule. What is the site of attachment?
3. The pK_a of the conjugate acid of atropine is 4.35. How does this compare with the pK_a values for the conjugate acids of ammonia, methylamine, and aniline?

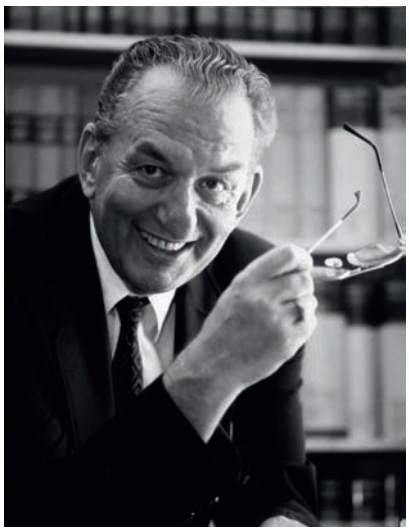
16.2 The Leveling Effect, Nonaqueous Solvents, and Superacids



What is the strongest Brønsted acid that can exist in water? The answer is the hydronium ion. Although the common strong acids (HCl, HBr, HI, HNO_3, $HClO_4$, and H_2SO_4) are all stronger acids than H_3O^+, these acids ionize completely in water. The result is that all Brønsted acids with acidities above a certain value are equally acidic in water and, thus, their acid strength is indistinguishable. This is referred to as the *leveling effect* of water.

Similarly, the strongest base that can exist in water is OH^-. Any base that is stronger than OH^- will react completely with water to give OH^-. The amide ion, NH_2^-, and the oxide ion, O^{2-}, both stronger bases than OH^-, react completely with water, giving OH^-.

Although strong acids behave identically in water, they are not equally strong. One means of differentiating the strengths of these acids is to measure the degree of their ionization in

George Olah (1927–2017). Much of the early research on superacids was done by Olah, who received the Nobel Prize in Chemistry for this work in 1994.

solvents other than water. These solvents, like water, must be Brønsted bases. Additionally, the solvents must be weaker bases than water so that they are not fully protonated by a strong acid. One such solvent is acetic acid. Pure acetic acid—known as *glacial acetic acid*—is similar to water in that it can both donate or accept protons. Dissolution of hydrochloric acid in acetic acid, for example, yields the following chemical reaction:

$$HCl + CH_3CO_2H \rightleftharpoons CH_3CO_2H_2^+ + Cl^-$$

Unlike the ionization of HCl in water, this reaction does not go to completion; the pK value of this reaction is 8.8. Two other important acids, $HClO_4$ and H_2SO_4 (first proton only), have pK values of 5.3 and 6.8, respectively.

Other strong acids are known and are often called *superacids.* One superacid is fluorosulfonic acid (HSO_3F), which is about 1000 times stronger than sulfuric acid. An even stronger acid is a mixture of HSO_3F and SbF_5, which is over 10^{16} times stronger than 100% sulfuric acid. It is sold under a suitable name, "Magic Acid."

Questions:

1. Convert the pK values to K values for the ionization of HCl, $HClO_4$, and H_2SO_4 in glacial acetic acid. Rank these acids in order from strongest to weakest.
2. Other solvents also undergo autoionization.
   a. Write a chemical equation for the autoionization of glacial acetic acid.
   b. The equilibrium constant for the autoionization of glacial acetic acid is 3.2×10^{-15} at 25°C. Determine the concentration of $[CH_3CO_2H_2]^+$ in acetic acid at 25°C.
3. Write an equation for the reaction of the amide ion (a stronger base than OH^-) and water. Does the equilibrium favor products or reactants?
4. Will a solution of $HClO_4$ in glacial acetic acid be a strong conductor of electricity, a weak conductor, or a nonconductor?
5. To measure the relative strengths of bases stronger than OH^-, it is necessary to choose a solvent that is a weaker acid than water. One such solvent is liquid ammonia.
   a. Write a chemical equation for the autoionization of ammonia.
   b. What is the strongest acid and base that can exist in liquid ammonia?
   c. Will a solution of HCl in liquid ammonia be a strong electrical conductor, a weak conductor, or a nonconductor?
   d. Oxide ion (O^{2-}) is a stronger base than the amide ion (NH_2^-). Write an equation for the reaction of O^{2-} with NH_3 in liquid ammonia. Will the equilibrium favor products or reactants?

CHAPTER GOALS REVISITED

The goals for this chapter are keyed to specific Study Questions to help you organize your review.

16.1 The Brønsted–Lowry Concept of Acids and Bases

- Recognize common monoprotic and polyprotic acids and bases, and write balanced equations for their ionization in water. **23, 24, 69, 70.**
- Recognize the Brønsted acid and base in a reaction, and identify the conjugate partner of each. **1–4, 7, 8.**
- Identify the acid and base reactions undergone by amphiprotic substances. **5, 6.**

16.2 Water and the pH Scale

- Use the water ionization constant, K_w. **33–36.**
- Use the pH concept. **9–14.**

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

16.3 Equilibrium Constants for Acids and Bases

- Write equilibrium constant expressions for acids and bases. 15, 16.
- Understand the relationship between K_a for an acid and K_b for its conjugate base. 19–22, 33–36.
- Calculate pK_a from K_a (or K_a from pK_a), and understand how pK_a is correlated with acid strength. 27–32, 112, 114.

16.4 Acid–Base Properties of Salts

- Describe the acid–base properties of salts. 92, 100, 101, 111.

16.5 Predicting the Direction of Acid–Base Reactions

- Write equations for acid–base reactions, and decide whether they are product- or reactant-favored at equilibrium. 37–44, 89, 90.

16.6 Types of Acid–Base Reactions

- Predict whether the solutions resulting from acid-base reactions are acidic, neutral, or basic. 67, 68.

16.7 Calculations with Equilibrium Constants

- Calculate the equilibrium constant for a weak acid (K_a) or a weak base (K_b) from experimental information (such as pH, $[H_3O^+]$, or $[OH^-]$). 45–48, 93, 115.
- Use the equilibrium constant and other information to calculate the pH of a solution of a weak acid or weak base. 51–60, 85, 95, 97, 99.
- Calculate the pH after an acid–base reaction. 65, 66.

16.8 Polyprotic Acids and Bases

- Use the equilibrium constant, K_{a1} or K_{b1}, and other information to calculate the pH of a solution of a polyprotic acid or base. 73–76, 102.

16.9 Molecular Structure, Bonding, and Acid–Base Behavior

- Appreciate the connection between the structure of a compound and its acidity or basicity. 77–80, 82, 122.

16.10 The Lewis Concept of Acids and Bases

- Characterize a compound as a Lewis base (an electron-pair donor) or a Lewis acid (an electron-pair acceptor). 81–84, 116.

KEY EQUATIONS

Equation 16.1 (page 712) Water ionization constant.

$$K_w = [H_3O^+][OH^-] = 1.0 \times 10^{-14} \text{ at } 25\ ^\circ\text{C}$$

Equation 16.2 (page 714) Definition of pH.

$$pH = -\log[H_3O^+]$$

Equation 16.3 (page 714) Definition of pOH.

$$pOH = -\log[OH^-]$$

Equation 16.4 (page 714) Definition of pK_w = pH + pOH (= 14.00 at 25 °C).

$$pK_w = 14.00 = pH + pOH$$

Equation 16.5 (page 716) Equilibrium expression for a general acid, HA, in water.

$$K_a = \frac{[H_3O^+][A^-]}{[HA]}$$

Equation 16.6 (page 716) Equilibrium expression for a general base, B, in water.

$$K_b = \frac{[BH^+][OH^-]}{[B]}$$

Equation 16.7 (page 719) Definition of pK_a.

$$pK_a = -\log K_a$$

Equation 16.8 (page 720) Relationship of K_a, K_b, and K_w, where K_a and K_b are for a conjugate acid–base pair.

$$K_a \times K_b = K_w$$

STUDY QUESTIONS

▲ denotes challenging questions. **Blue-numbered questions** have answers in Appendix N and fully worked solutions in the *Student Solutions Manual*.

Practicing Skills

The Brønsted Concept

(See Section 16.1.)

1. Write the formula and give the name of the conjugate base of each of the following acids.
   (a) HCN (b) HSO_4^- (c) HF
2. Write the formula and give the name of the conjugate acid of each of the following bases.
   (a) NH_3 (b) HCO_3^- (c) Br^-
3. What are the products of each of the following acid–base reactions? Indicate the acid and its conjugate base and the base and its conjugate acid.
   (a) $HNO_3 + H_2O \rightarrow$
   (b) $HSO_4^- + H_2O \rightarrow$
   (c) $H_3O^+ + F^- \rightarrow$
4. What are the products of each of the following acid–base reactions? Indicate the acid and its conjugate base and the base and its conjugate acid.
   (a) $HClO_4 + H_2O \rightarrow$
   (b) $NH_4^+ + H_2O \rightarrow$
   (c) $HCO_3^- + OH^- \rightarrow$
5. Write balanced equations showing how the hydrogen oxalate ion, $HC_2O_4^-$, can be both a Brønsted acid and a Brønsted base.
6. Write balanced equations showing how the HPO_4^{2-} ion of sodium hydrogen phosphate, Na_2HPO_4, can be a Brønsted acid or a Brønsted base.

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

7. In each of the following acid–base reactions, identify the Brønsted acid and base on the left and their conjugate partners on the right.
   (a) $HCO_2H(aq) + H_2O(\ell) \rightleftharpoons HCO_2^-(aq) + H_3O^+(aq)$
   (b) $NH_3(aq) + H_2S(aq) \rightleftharpoons NH_4^+(aq) + HS^-(aq)$
   (c) $HSO_4^-(aq) + OH^-(aq) \rightleftharpoons SO_4^{2-}(aq) + H_2O(\ell)$

8. In each of the following acid–base reactions, identify the Brønsted acid and base on the left and their conjugate partners on the right.
   (a) $C_5H_5N(aq) + CH_3CO_2H(aq) \rightleftharpoons C_5H_5NH^+(aq) + CH_3CO_2^-(aq)$
   (b) $N_2H_4(aq) + HSO_4^-(aq) \rightleftharpoons N_2H_5^+(aq) + SO_4^{2-}(aq)$
   (c) $[Al(H_2O)_6]^{3+}(aq) + OH^-(aq) \rightleftharpoons [Al(H_2O)_5OH]^{2+}(aq) + H_2O(\ell)$

pH Calculations

(See Section 16.2 and Examples 4.8 and 16.1.)

9. An aqueous solution has a pH of 3.75. What is the hydronium ion concentration of the solution? Is it acidic or basic?

10. A saturated solution of milk of magnesia, $Mg(OH)_2$, has a pH of 10.52. What is the hydronium ion concentration of the solution? What is the hydroxide ion concentration? Is the solution acidic or basic?

11. What is the pH of a 0.0075 M solution of HCl? What is the hydroxide ion concentration of the solution?

12. What is the pH of a 1.2×10^{-4} M solution of KOH? What is the hydronium ion concentration of the solution?

13. What is the pH of a 0.0015 M solution of $Ba(OH)_2$?

14. The pH of a solution of $Ba(OH)_2$ is 10.66 at 25 °C. What is the hydroxide ion concentration in the solution? If the solution volume is 125 mL, what mass of $Ba(OH)_2$ must have been dissolved?

Equilibrium Constants for Acids and Bases

(See Sections 16.3 and 16.4 and Example 16.2.)

15. Write an equilibrium constant expression for the reaction of ammonium ion, a weak acid, with water.

16. Write an equilibrium constant expression for the reaction of fluoride ion, a weak base, with water.

17. Several acids are listed here with their respective equilibrium constants:

$$C_6H_5OH(aq) + H_2O(\ell) \rightleftharpoons H_3O^+(aq) + C_6H_5O^-(aq) \qquad K_a = 1.3 \times 10^{-10}$$

$$HCO_2H(aq) + H_2O(\ell) \rightleftharpoons H_3O^+(aq) + HCO_2^-(aq) \qquad K_a = 1.8 \times 10^{-4}$$

$$HC_2O_4^-(aq) + H_2O(\ell) \rightleftharpoons H_3O^+(aq) + C_2O_4^{2-}(aq) \qquad K_a = 6.4 \times 10^{-5}$$

   (a) Which is the strongest acid? Which is the weakest acid?
   (b) Which acid has the weakest conjugate base?
   (c) Which acid has the strongest conjugate base?

18. Several acids are listed here with their respective equilibrium constants.

$$HF(aq) + H_2O(\ell) \rightleftharpoons H_3O^+(aq) + F^-(aq) \qquad K_a = 7.2 \times 10^{-4}$$

$$HPO_4^{2-}(aq) + H_2O(\ell) \rightleftharpoons H_3O^+(aq) + PO_4^{3-}(aq) \qquad K_a = 3.6 \times 10^{-13}$$

$$CH_3CO_2H(aq) + H_2O(\ell) \rightleftharpoons H_3O^+(aq) + CH_3CO_2^-(aq) \qquad K_a = 1.8 \times 10^{-5}$$

   (a) Which is the strongest acid? Which is the weakest acid?
   (b) What is the conjugate base of the acid HF?
   (c) Which acid has the weakest conjugate base?
   (d) Which acid has the strongest conjugate base?

19. Which of the following ions or compounds has the strongest conjugate base? Briefly explain your choice.
   (a) HSO_4^- (b) CH_3CO_2H (c) HOCl

20. Which of the following compounds or ions has the weakest conjugate base? Briefly explain your choice.
   (a) HCN (b) HClO (c) NH_4^+

21. Which of the following compounds or ions has the weakest conjugate acid? Briefly explain your choice.
   (a) HCO_3^- (b) F^- (c) NO_2^-

22. Which of the following compounds or ions has the strongest conjugate acid? Briefly explain your choice.
   (a) CN^- (b) NH_3 (c) SO_4^{2-}

23. Dissolving K_2CO_3 in water gives a basic solution. Write a balanced equation showing how this can occur.

24. Dissolving ammonium bromide in water gives an acidic solution. Write a balanced equation showing how this can occur.

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

25. If each of the salts listed here were dissolved in water to give a 0.10 M solution, which solution would have the highest pH? Which would have the lowest pH?
(a) Na_2S (d) NaF
(b) Na_3PO_4 (e) $NaCH_3CO_2$
(c) NaH_2PO_4 (f) $AlCl_3$

26. Which of the following common food additives would give a basic solution when dissolved in water?
(a) $NaNO_3$ (used as a meat preservative)
(b) $NaC_6H_5CO_2$ (sodium benzoate; used as a soft-drink preservative)
(c) Na_2HPO_4 (used as an emulsifier in the manufacture of pasteurized cheese)

pK_a: A Logarithmic Scale of Acid Strength
(See Section 16.3.)

27. A weak acid has a K_a of 6.5×10^{-5}. What is the value of pK_a for the acid?

28. If K_a for a weak acid is 2.4×10^{-11}, what is the value of pK_a?

29. Epinephrine hydrochloride has a pK_a value of 9.53. What is the value of K_a? Where does the acid fit in Table 16.2?

30. An organic acid has pK_a = 8.95. What is its K_a value? Where does the acid fit in Table 16.2?

31. Which is the stronger of the following two acids?
(a) benzoic acid, $C_6H_5CO_2H$, pK_a = 4.20
(b) 2-chlorobenzoic acid, $ClC_6H_4CO_2H$, pK_a = 2.90

32. Which is the stronger of the following two acids?
(a) acetic acid, CH_3CO_2H, $K_a = 1.8 \times 10^{-5}$
(b) chloroacetic acid, $ClCH_2CO_2H$, pK_a = 2.85

Ionization Constants for Weak Acids and Their Conjugate Bases
(See Section 16.3.)

33. Chloroacetic acid ($ClCH_2CO_2H$) has $K_a = 1.41 \times 10^{-3}$. What is the value of K_b for the chloroacetate ion ($ClCH_2CO_2^-$)?

34. A weak base has $K_b = 1.5 \times 10^{-9}$. What is the value of K_a for the conjugate acid?

35. The trimethylammonium ion, $(CH_3)_3NH^+$, is the conjugate acid of the weak base trimethylamine, $(CH_3)_3N$. A chemical handbook gives 9.80 as the pK_a value for $(CH_3)_3NH^+$. What is the value of K_b for $(CH_3)_3N$?

36. The chromium(III) ion in water, $[Cr(H_2O)_6]^{3+}$, is a weak acid with pK_a = 3.95. What is the value of K_b for its conjugate base, $[Cr(H_2O)_5OH]^{2+}$?

Predicting the Direction of Acid–Base Reactions
(See Section 16.5 and Example 16.3.)

37. Acetic acid and sodium hydrogen carbonate, $NaHCO_3$, are mixed in water. Write a balanced equation for the acid–base reaction that could, in principle, occur. Using Table 16.2, decide whether the equilibrium lies predominantly to the right or to the left.

38. Ammonium chloride and sodium dihydrogen phosphate, NaH_2PO_4, are mixed in water. Write a balanced equation for the acid–base reaction that could, in principle, occur. Using Table 16.2, decide whether the equilibrium lies predominantly to the right or to the left.

39. For each of the following reactions, predict whether the equilibrium lies predominantly to the left or to the right. Explain your predictions briefly.
(a) $NH_4^+(aq) + Br^-(aq) \rightleftharpoons NH_3(aq) + HBr(aq)$
(b) $HPO_4^{2-}(aq) + CH_3CO_2^-(aq) \rightleftharpoons PO_4^{3-}(aq) + CH_3CO_2H(aq)$
(c) $[Fe(H_2O)_6]^{3+}(aq) + HCO_3^-(aq) \rightleftharpoons [Fe(H_2O)_5(OH)]^{2+}(aq) + H_2CO_3(aq)$

40. For each of the following reactions, predict whether the equilibrium lies predominantly to the left or to the right. Explain your predictions briefly.
(a) $H_2S(aq) + CO_3^{2-}(aq) \rightleftharpoons HS^-(aq) + HCO_3^-(aq)$
(b) $HCN(aq) + SO_4^{2-}(aq) \rightleftharpoons CN^-(aq) + HSO_4^-(aq)$
(c) $SO_4^{2-}(aq) + CH_3CO_2H(aq) \rightleftharpoons HSO_4^-(aq) + CH_3CO_2^-(aq)$

Types of Acid–Base Reactions
(See Section 16.6.)

41. Equal molar quantities of sodium hydroxide and sodium hydrogen phosphate (Na_2HPO_4) are mixed.
(a) Write the balanced, net ionic equation for the acid–base reaction that can, in principle, occur.
(b) Does the equilibrium lie to the right or left?

42. Equal molar quantities of hydrochloric acid and sodium hypochlorite (NaClO) are mixed.
(a) Write the balanced, net ionic equation for the acid–base reaction that can, in principle, occur.
(b) Does the equilibrium lie to the right or left?

Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

43. Equal molar quantities of acetic acid and sodium hydrogen phosphate (Na_2HPO_4) are mixed.
   (a) Write a balanced, net ionic equation for the acid–base reaction that can, in principle, occur.
   (b) Does the equilibrium lie to the right or left?

44. Equal molar quantities of ammonia and sodium dihydrogen phosphate (NaH_2PO_4) are mixed.
   (a) Write a balanced, net ionic equation for the acid–base reaction that can, in principle, occur.
   (b) Does the equilibrium lie to the right or left?

Using pH to Calculate Ionization Constants

(See Section 16.7 and Example 16.4.)

45. A 0.015 M solution of hydrogen cyanate, HOCN, has a pH of 2.67.
   (a) What is the hydronium ion concentration in the solution?
   (b) What is the ionization constant, K_a, for the acid?

46. A 0.10 M solution of chloroacetic acid, $ClCH_2CO_2H$, has a pH of 1.95. Calculate K_a for the acid.

47. A 0.025 M solution of hydroxylamine has a pH of 9.11. What is the value of K_b for this weak base?

$$H_2NOH(aq) + H_2O(\ell) \rightleftharpoons H_3NOH^+(aq) + OH^-(aq)$$

48. Methylamine, CH_3NH_2, is a weak base.

$$CH_3NH_2(aq) + H_2O(\ell) \rightleftharpoons CH_3NH_3^+(aq) + OH^-(aq)$$

If the pH of a 0.065 M solution of the amine is 11.70, what is the value of K_b?

49. A 2.5×10^{-3} M solution of an unknown acid has a pH of 3.80 at 25 °C.
   (a) What is the hydronium ion concentration of the solution?
   (b) Is the acid a strong acid, a moderately weak acid (K_a of about 10^{-5}), or a very weak acid (K_a of about 10^{-10})?

50. A 0.015 M solution of a base has a pH of 10.09.
   (a) What are the hydronium and hydroxide ion concentrations of this solution?
   (b) Is the base a strong base, a moderately weak base (K_b of about 10^{-5}), or a very weak base (K_b of about 10^{-10})?

Using Ionization Constants

(See Section 16.7 and Examples 16.5–16.6.)

51. What are the equilibrium concentrations of hydronium ion, acetate ion, and acetic acid in a 0.20 M aqueous solution of acetic acid?

52. The ionization constant of a very weak acid, HA, is 4.0×10^{-9}. Calculate the equilibrium concentrations of H_3O^+, A^-, and HA in a 0.040 M solution of the acid.

53. What are the equilibrium concentrations of H_3O^+, CN^-, and HCN in a 0.025 M solution of HCN? What is the pH of the solution?

54. Phenol (C_6H_5OH), commonly called *carbolic acid*, is a weak organic acid.

$$C_6H_5OH(aq) + H_2O(\ell) \rightleftharpoons C_6H_5O^-(aq) + H_3O^+(aq) \qquad K_a = 1.3 \times 10^{-10}$$

If you dissolve 0.195 g of the acid in enough water to make 125 mL of solution, what is the equilibrium hydronium ion concentration? What is the pH of the solution?

55. What are the equilibrium concentrations of NH_3, NH_4^+, and OH^- in a 0.15 M solution of ammonia? What is the pH of the solution?

56. A hypothetical weak base has $K_b = 5.0 \times 10^{-4}$. Calculate the equilibrium concentrations of the base, its conjugate acid, and OH^- in a 0.15 M solution of the base.

57. The weak base methylamine, CH_3NH_2, has $K_b = 4.2 \times 10^{-4}$. It reacts with water according to the equation

$$CH_3NH_2(aq) + H_2O(\ell) \rightleftharpoons CH_3NH_3^+(aq) + OH^-(aq)$$

Calculate the equilibrium hydroxide ion concentration in a 0.25 M solution of the base. What are the pH and pOH of the solution?

58. Calculate the pH of a 0.12 M aqueous solution of the base aniline, $C_6H_5NH_2$ ($K_b = 4.0 \times 10^{-10}$).

$$C_6H_5NH_2(aq) + H_2O(\ell) \rightleftharpoons C_6H_5NH_3^+(aq) + OH^-(aq)$$

59. Calculate the pH of a 0.0010 M aqueous solution of HF.

60. A solution of hydrofluoric acid, HF, has a pH of 2.30. Calculate the equilibrium concentrations of HF, F^-, and H_3O^+, and calculate the amount of HF originally dissolved per liter.

Acid–Base Properties of Salts

(See Sections 16.4 and 16.7 and Example 16.7.)

61. Calculate the hydronium ion concentration and pH in a 0.20 M solution of ammonium chloride, NH_4Cl.

62. ▲ Calculate the hydronium ion concentration and pH for a 0.015 M solution of sodium formate, $NaHCO_2$.

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

63. Sodium cyanide is the salt of the weak acid HCN. Calculate the concentrations of H_3O^+, OH^-, HCN, and Na^+ in a solution prepared by dissolving 10.8 g of NaCN in enough water to make 5.00×10^2 mL of solution at 25 °C.

64. The sodium salt of propanoic acid, $NaCH_3CH_2CO_2$, is used as an antifungal agent by veterinarians. Calculate the equilibrium concentrations of H_3O^+ and OH^-, and the pH, for a solution of 0.10 M $NaCH_3CH_2CO_2$.

pH after an Acid–Base Reaction

(See Example 16.8.)

65. Calculate the hydronium ion concentration and pH of the solution that results when 22.0 mL of 0.15 M acetic acid, CH_3CO_2H, is mixed with 22.0 mL of 0.15 M NaOH.

66. Calculate the hydronium ion concentration and the pH when 50.0 mL of 0.40 M NH_3 is mixed with 50.0 mL of 0.40 M HCl.

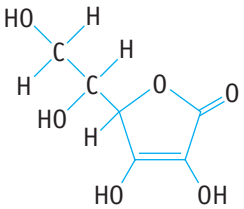
67. For each of the following cases, decide whether the pH is less than 7, equal to 7, or greater than 7.
   (a) Equal volumes of 0.10 M acetic acid, CH_3CO_2H, and 0.10 M KOH are mixed.
   (b) 25 mL of 0.015 M NH_3 is mixed with 25 mL of 0.015 M HCl.
   (c) 150 mL of 0.20 M HNO_3 is mixed with 75 mL of 0.40 M NaOH.

68. For each of the following cases, decide whether the pH is less than 7, equal to 7, or greater than 7.
   (a) 25 mL of 0.45 M H_2SO_4 is mixed with 25 mL of 0.90 M NaOH.
   (b) 15 mL of 0.050 M formic acid, HCO_2H, is mixed with 15 mL of 0.050 M NaOH.
   (c) 25 mL of 0.15 M $H_2C_2O_4$ (oxalic acid) is mixed with 25 mL of 0.30 M NaOH. (Both H^+ ions of oxalic acid are removed with NaOH.)

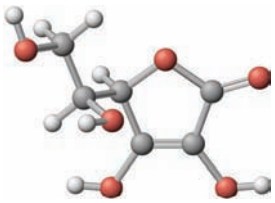
Polyprotic Acids and Bases

(See Section 16.8 and Example 16.9.)

69. Oxalic acid, $H_2C_2O_4$, is a diprotic acid. Write a chemical equilibrium expression for each ionization step in water.



70. Sodium carbonate is a diprotic base. Write a chemical equilibrium expression for each of the two successive base reactions with water.



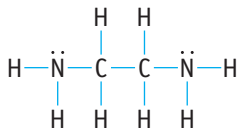
71. Prove that $K_{a1} \times K_{b2} = K_w$ for oxalic acid, $H_2C_2O_4$, by adding the chemical equilibrium expressions that correspond to first ionization step of the acid in water with the second step of the reaction of the fully deprotonated base, $C_2O_4^{2-}$, with water.

72. Prove that $K_{a3} \times K_{b1} = K_w$ for phosphoric acid, H_3PO_4, by adding the chemical equilibrium expressions that correspond to the third ionization step of the acid in water with the first of the three successive steps of the reaction of phosphate ion, PO_4^{3-}, with water.

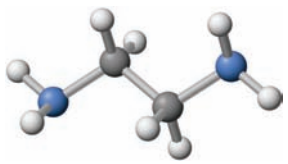
73. Sulfurous acid, H_2SO_3, is a weak acid capable of providing two H^+ ions.
   (a) What is the pH of a 0.45 M solution of H_2SO_3?
   (b) What is the equilibrium concentration of the sulfite ion, SO_3^{2-}, in the 0.45 M solution of H_2SO_3?

74. Ascorbic acid (vitamin C, $C_6H_8O_6$) is a diprotic acid ($K_{a1} = 6.8 \times 10^{-5}$ and $K_{a2} = 2.7 \times 10^{-12}$). What is the pH of a solution that contains 5.0 mg of acid per milliliter of solution?

Ascorbic acid



75. Hydrazine, N_2H_4, can interact with water in two steps.



$$N_2H_4(aq) + H_2O(\ell) \rightleftharpoons N_2H_5^+(aq) + OH^-(aq) \qquad K_{b1} = 8.5 \times 10^{-7}$$

$$N_2H_5^+(aq) + H_2O(\ell) \rightleftharpoons N_2H_6^{2+}(aq) + OH^-(aq) \qquad K_{b2} = 8.9 \times 10^{-16}$$

   (a) What is the concentration of OH^-, $N_2H_5^+$, and $N_2H_6^{2+}$ in a 0.010 M aqueous solution of hydrazine?
   (b) What is the pH of the 0.010 M solution of hydrazine?

76. Ethylenediamine, $H_2NCH_2CH_2NH_2$, can interact with water in two steps, forming OH^- in each step (Appendix I). If you have a 0.15 M aqueous solution of the amine, calculate the concentrations of $[H_3NCH_2CH_2NH_3]^{2+}$ and OH^-.

Ethylenediamine

Molecular Structure, Bonding, and Acid–Base Behavior

(See Section 16.9.)

77. Which should be the stronger acid, HOCN or HCN? Explain briefly. (In HOCN, the H^+ ion is attached to the O atom of the OCN^- ion.)

78. Which should be the stronger Brønsted acid, $[V(H_2O)_6]^{2+}$ or $[V(H_2O)_6]^{3+}$?

79. Explain why benzenesulfonic acid is a Brønsted acid.

benzenesulfonic acid

80. The structure of ethylenediamine is illustrated in Study Question 76. Is this compound a Brønsted acid, a Brønsted base, a Lewis acid, or a Lewis base, or some combination of these?

Lewis Acids and Bases

(See Section 16.10.)

81. Decide whether each of the following substances should be classified as a Lewis acid or a Lewis base.
    (a) H_2NOH in the reaction
    $$H_2NOH(aq) + HCl(aq) \longrightarrow [H_3NOH]Cl(aq)$$
    (b) Fe^{2+}
    (c) CH_3NH_2 (*Hint:* Draw the electron dot structure.)

82. Decide whether each of the following substances should be classified as a Lewis acid or a Lewis base.
    (a) BCl_3 (*Hint:* Draw the electron dot structure.)
    (b) H_2NNH_2, hydrazine (*Hint:* Draw the electron dot structure.)
    (c) the reactants in the reaction
    $$Ag^+(aq) + 2\ NH_3(aq) \rightleftharpoons [Ag(NH_3)_2]^+(aq)$$

83. Carbon monoxide forms complexes with low-valent metals. For example, $Ni(CO)_4$ and $Fe(CO)_5$ are well known. CO also forms complexes with the iron(II) ion in hemoglobin, which prevents the hemoglobin from acting in its normal way. Is CO a Lewis acid or a Lewis base?

84. Trimethylamine, $(CH_3)_3N$, is a common reagent. It interacts readily with diborane gas, B_2H_6. The latter dissociates to BH_3, and this forms a complex with the amine, $(CH_3)_3N{\rightarrow}BH_3$. Is the BH_3 fragment a Lewis acid or a Lewis base?

General Questions

These questions are not designated as to type or location in the chapter. They may combine several concepts.

85. About this time, you may be wishing you had an aspirin. Aspirin is an organic acid with a K_a of 3.27×10^{-4} for the reaction
    $$HC_9H_7O_4(aq) + H_2O(\ell) \rightleftharpoons C_9H_7O_4^-(aq) + H_3O^+(aq)$$
    If you have two tablets, each containing 0.325 g of aspirin (mixed with a neutral "binder" to hold the tablet together), and you dissolve them in a glass of water to give 225 mL of solution, what is the pH of the solution?

86. Consider the following ions: NH_4^+, CO_3^{2-}, Br^-, S^{2-}, and ClO_4^-.
    (a) Which of these ions in water gives an acidic solution and which gives a basic solution?
    (b) Which of these anions will have no effect on the pH of an aqueous solution?
    (c) Which ion is the strongest base?
    (d) Write a chemical equation for the reaction of each basic anion with water.

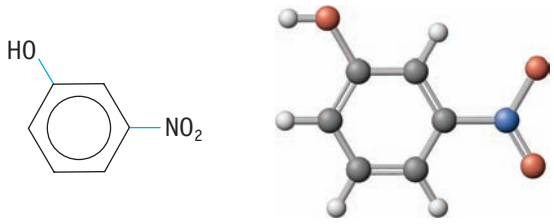
87. A 2.50-g sample of a solid that could be $Ba(OH)_2$ or $Sr(OH)_2$ was dissolved in enough water to make 1.00 L of solution. If the pH of the solution is 12.61, what is the identity of the solid?

88. ▲ In a particular solution, acetic acid is 11% ionized at 25 °C. Calculate the pH of the solution and the mass of acetic acid dissolved to yield 1.00 L of solution.

89. Hydrogen sulfide, H_2S, and sodium acetate, $NaCH_3CO_2$, are mixed in water. Using Table 16.2, write a balanced equation for the acid–base reaction that could, in principle, occur. Does the equilibrium lie toward the products or the reactants?

90. For each of the following reactions, predict whether the equilibrium lies predominantly to the left or to the right. Explain your prediction briefly.
    (a) $HCO_3^-(aq) + SO_4^{2-}(aq) \rightleftharpoons CO_3^{2-}(aq) + HSO_4^-(aq)$
    (b) $HSO_4^-(aq) + CH_3CO_2^-(aq) \rightleftharpoons SO_4^{2-}(aq) + CH_3CO_2H(aq)$
    (c) $[Co(H_2O)_6]^{2+}(aq) + CH_3CO_2^-(aq) \rightleftharpoons [Co(H_2O)_5(OH)]^+(aq) + CH_3CO_2H(aq)$

91. A monoprotic acid HX has $K_a = 1.3 \times 10^{-3}$. Calculate the equilibrium concentrations of HX and H_3O^+ and the pH for a 0.010 M solution of the acid.



Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

92. Arrange the following 0.10 M solutions in order of increasing pH.

(a) NaCl
(b) NH_4Cl
(c) HCl
(d) $NaCH_3CO_2$
(e) KOH

93. *m*-Nitrophenol, a weak acid, can be used as a pH indicator because it is yellow at a pH above 8.6 and colorless at a pH below 6.8. If the pH of a 0.010 M solution of the compound is 3.44, calculate its pK_a.

m-Nitrophenol

94. The butylammonium ion, $C_4H_9NH_3^+$, has a K_a of 2.3×10^{-11}.

$$C_4H_9NH_3^+(aq) + H_2O(\ell) \rightleftharpoons H_3O^+(aq) + C_4H_9NH_2(aq)$$

(a) Calculate K_b for the conjugate base, $C_4H_9NH_2$ (butylamine).
(b) Place the butylammonium ion and its conjugate base in Table 16.2. Name an acid weaker than $C_4H_9NH_3^+$ and a base stronger than $C_4H_9NH_2$.
(c) What is the pH of a 0.015 M solution of butylammonium chloride?

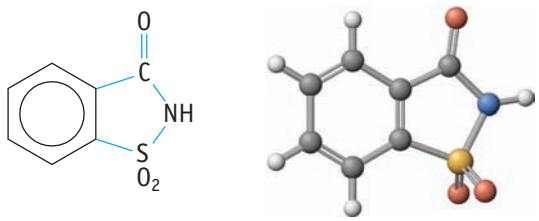
95. The local anesthetic novocaine is the hydrogen chloride salt of an organic base, procaine.

$$\underset{\text{procaine}}{C_{13}H_{20}N_2O_2(aq)} + HCl(aq) \longrightarrow \underset{\text{novocaine}}{[HC_{13}H_{20}N_2O_2]^+Cl^-(aq)}$$

The pK_a for novocaine is 8.85. What is the pH of a 0.0015 M solution of novocaine?

96. Pyridine is a weak organic base and readily forms a salt with hydrochloric acid.

$$\underset{\text{pyridine}}{C_5H_5N(aq)} + HCl(aq) \longrightarrow \underset{\text{pyridinium ion}}{C_5H_5NH^+(aq)} + Cl^-(aq)$$



What is the pH of a 0.025 M solution of pyridinium hydrochloride, $[C_5H_5NH^+]Cl^-$?

97. The base ethylamine ($CH_3CH_2NH_2$) has a K_b of 4.3×10^{-4}. A closely related base, ethanolamine ($HOCH_2CH_2NH_2$), has a K_b of 3.2×10^{-5}.

(a) Which of the two bases is stronger?
(b) Calculate the pH of a 0.10 M solution of the stronger base.

98. Chloroacetic acid, $ClCH_2CO_2H$, is a moderately weak acid ($K_a = 1.40 \times 10^{-3}$). If you dissolve 94.5 mg of the acid in water to give 125 mL of solution, what is the pH of the solution?

99. Saccharin ($HC_7H_4NO_3S$) is a weak acid with $pK_a = 2.32$ at 25 °C. It is used in the form of sodium saccharide, $NaC_7H_4NO_3S$. What is the pH of a 0.10 M solution of sodium saccharide at 25 °C?

Saccharin

100. Given the following solutions:

(a) 0.1 M NH_3
(b) 0.1 M Na_2CO_3
(c) 0.1 M NaCl
(d) 0.1 M CH_3CO_2H
(e) 0.1 M NH_4Cl
(f) 0.1 M $NaCH_3CO_2$
(g) 0.1 M $NH_4CH_3CO_2$
  (i) Which of the solutions are acidic?
  (ii) Which of the solutions are basic?
  (iii) Which of the solutions is most acidic?

101. For each of the following salts, predict whether a 0.10 M solution has a pH less than, equal to, or greater than 7.

(a) $NaHSO_4$
(b) NH_4Br
(c) $KClO_4$
(d) Na_2CO_3
(e) $(NH_4)_2S$
(f) $NaNO_3$
(g) Na_2HPO_4
(h) LiBr
(i) $FeCl_3$

Which solution has the highest pH? The lowest pH?

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

102. Nicotine, $C_{10}H_{14}N_2$, has two basic nitrogen atoms (Figure 16.12), and both can react with water.

$$Nic(aq) + H_2O(\ell) \rightleftharpoons NicH^+(aq) + OH^-(aq)$$

$$NicH^+(aq) + H_2O(\ell) \rightleftharpoons NicH_2^{2+}(aq) + OH^-(aq)$$

K_{b1} is 7.0×10^{-7} and K_{b2} is 1.1×10^{-10}. Calculate the approximate pH of a 0.020 M solution.

103. Oxalic acid is a relatively weak diprotic acid. Calculate the equilibrium constant for the reaction shown below from K_{a1} and K_{a2}. (See Appendix H for the required K_a values.)

$$H_2C_2O_4(aq) + 2\ H_2O(\ell) \rightleftharpoons C_2O_4^{2-}(aq) + 2\ H_3O^+(aq)$$

104. ▲ The equilibrium constant for the reaction of hydrochloric acid and ammonia is 1.8×10^9 (page 726). Confirm this value.

105. ▲ The equilibrium constant for the reaction of formic acid and sodium hydroxide is 1.8×10^{10} (page 726). Confirm this value.

106. ▲ Calculate the pH of the solution that results from mixing 25.0 mL of 0.14 M formic acid and 50.0 mL of 0.070 M sodium hydroxide.

107. ▲ To what volume should 1.00×10^2 mL of any weak acid, HA, with a concentration 0.20 M be diluted to double the percentage ionization?

108. ▲ The hydrogen phthalate ion, $C_8H_5O_4^-$, is a weak acid with $K_a = 3.91 \times 10^{-6}$.

$$C_8H_5O_4^-(aq) + H_2O(\ell) \rightleftharpoons C_8H_4O_4^{2-}(aq) + H_3O^+(aq)$$

What is the pH of a 0.050 M solution of potassium hydrogen phthalate, $KC_8H_5O_4$? *Note*: To find the pH for a solution of the anion, we must take into account that the ion is amphiprotic. It can be shown that, for most cases of amphiprotic ions, the H_3O^+ concentration is

$$[H_3O^+] = \sqrt{K_{a1} \times K_{a2}}$$

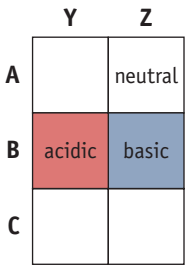
For phthalic acid, $C_8H_6O_4$, K_{a1} is 1.12×10^{-3}, and K_{a2} is 3.91×10^{-6}.

109. ▲ You prepare a 0.10 M solution of oxalic acid, $H_2C_2O_4$. What molecules and ions exist in this solution? List them in order of decreasing concentration.

110. ▲ You mix 30.0 mL of 0.15 M NaOH with 30.0 mL of 0.15 M acetic acid. What molecules and ions exist in this solution? List them in order of decreasing concentration.

In the Laboratory

111. Describe an experiment that will allow you to place the following three bases in order of increasing base strength: NaCN, CH_3NH_2, Na_2CO_3.

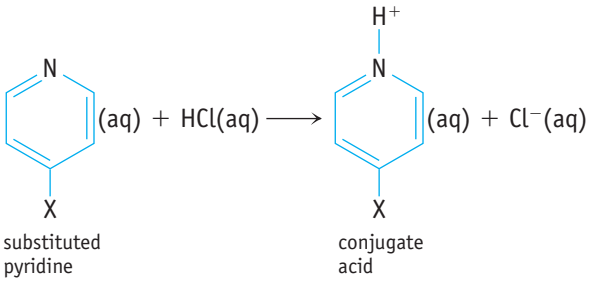


112. The data below compare the strength of acetic acid with a related series of acids, where the H atoms of the CH_3 group in acetic acid are successively replaced by Br.

Acid	pK_a
CH_3CO_2H	4.74
$BrCH_2CO_2H$	2.90
Br_2CHCO_2H	1.39
Br_3CCO_2H	−0.147

(a) What trend in acid strength do you observe as H is successively replaced by Br? Can you suggest a reason for this trend?

(b) Suppose each of the acids above was present as a 0.10 M aqueous solution. Which would have the highest pH? The lowest pH?



113. ▲ You have three solutions labeled A, B, and C. You know only that each contains a different cation—Na^+, NH_4^+, or H_3O^+. Each has an anion that does not contribute to the solution pH (e.g., Cl^-). You also have two other solutions, Y and Z, each containing a different anion, Cl^- or OH^-, with a cation that does not influence solution pH (e.g., K^+). If equal amounts of B and Y are mixed, the result is an acidic solution. Mixing A and Z gives a neutral solution, whereas B and Z give a basic solution. Identify the five unknown solutions. (Adapted from D. H. Barouch: *Voyages in Conceptual Chemistry*, Boston, Jones and Bartlett, 1997.)

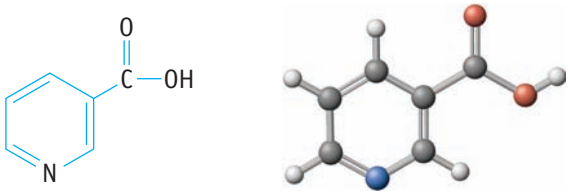
114. A hydrogen atom in the organic base pyridine, C_5H_5N, can be substituted by various atoms or groups to give XC_5H_4N, where X is an atom such as Cl or a group such as CH_3. The following table gives K_a values for the conjugate acids of a variety of substituted pyridines.



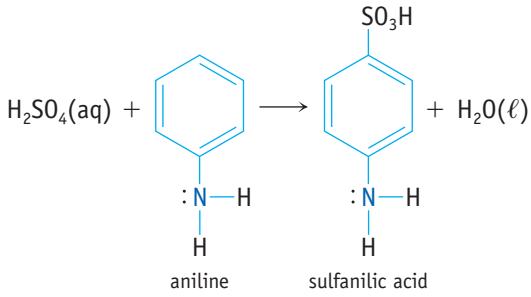
Atom or Group X	K_a of Conjugate Acid
NO_2	5.9×10^{-2}
Cl	1.5×10^{-4}
H	6.8×10^{-6}
CH_3	1.0×10^{-6}

(a) Suppose each conjugate acid is dissolved in sufficient water to give a 0.050 M solution. Which solution would have the highest pH? The lowest pH?

(b) Which of the substituted pyridines is the strongest Brønsted base? Which is the weakest Brønsted base?

115. Nicotinic acid, $C_6H_5NO_2$, is found in minute amounts in all living cells, but appreciable amounts occur in liver, yeast, milk, adrenal glands, white meat, and corn. Whole-wheat flour contains about 60. μg per gram of flour. One gram (1.00 g) of the acid dissolves in water to give 60. mL of solution having a pH of 2.70. What is the approximate value of K_a for the acid?

Nicotinic acid

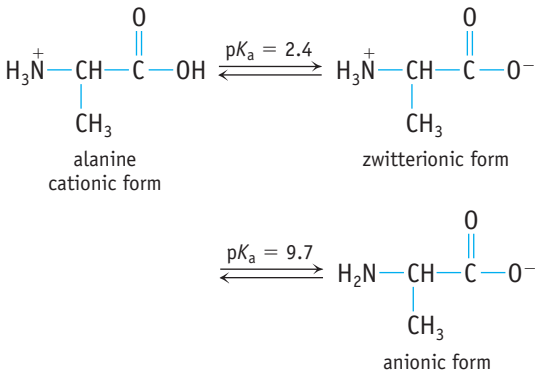


116. ▲ Equilibrium constants can be measured for the dissociation of Lewis acid–base complexes such as the dimethyl ether complex of BF_3, $(CH_3)_2O{\rightarrow}BF_3$. The value of K (here K_p) for the reaction is 0.17 at 125 °C.

$$(CH_3)_2O{\rightarrow}BF_3(g) \rightleftharpoons BF_3(g) + (CH_3)_2O(g)$$

(a) Describe each product as a Lewis acid or a Lewis base.

(b) If you place 1.00 g of the complex in a 565-mL flask at 125 °C, what is the total pressure in the flask when equilibrium is established? What are the equilibrium partial pressures of the Lewis acid, the Lewis base, and the complex?



117. ▲ Sulfanilic acid, which is used in making dyes, is made by reacting aniline with sulfuric acid.

(a) Is aniline a Brønsted base, a Lewis base, or both? Explain, using its possible reactions with HCl, BF_3, or other acid.

(b) Sulfanilic acid has a pK_a value of 3.23. The sodium salt of the acid, $Na(H_2NC_6H_4SO_3)$, is quite soluble in water. If you dissolve 1.25 g of the salt in water to give 125 mL of solution, what is the pH of the solution?

118. Amino acids are an important group of compounds. At low pH, both the carboxylic acid group (—CO_2H) and the amine group (—NHR) are protonated. However, as the pH of the solution increases (say, by adding base), the carboxylic acid proton is removed, usually at a pH between 2 and 3. In a middle range of pHs, therefore, the amine group is protonated, but the carboxylic acid group has lost the proton. (This is called a *zwitterion*.) At more basic pH values, the amine proton is dissociated.

What is the pH of a 0.20 M solution of alanine hydrochloride, $[NH_3CHCH_3CO_2H]Cl$?

Summary and Conceptual Questions

The following questions may use concepts from this and previous chapters.

119. How can water be both a Brønsted base and a Lewis base? Can water be a Brønsted acid? A Lewis acid?

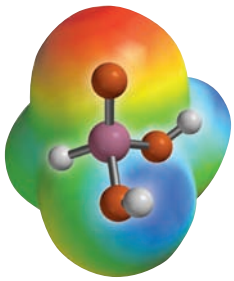
120. The nickel(II) ion exists as $[Ni(H_2O)_6]^{2+}$ in aqueous solution. Why is this solution acidic? As part of your answer, include a balanced equation depicting what happens when $[Ni(H_2O)_6]^{2+}$ interacts with water.

121. The halogens form three stable, weak acids, HOX.

Acid	pK_a
HOCl	7.46
HOBr	8.7
HOI	10.6

(a) Which is the strongest of these acids?

(b) Explain why the acid strength changes as the halogen atom is changed.



122. The acidity of the oxoacids was described in Section 16.9, and a larger number of acids are listed in the table below.

(a) What general trends do you see in these data?

(b) What has a greater effect on acidity, the number of O atoms bonded directly to the central atom E or the number of OH groups?

(c) Look at the acids based on Cl, N, and S. Is there a correlation of acidity with the formal charge on the central atom, E?

(d) The acid H_3PO_3 has a pK_a of 1.8, and this led to some insight into its structure. If the structure of the acid were $P(OH)_3$, what would be its predicted pK_a value? Given that this is a diprotic acid, which H atoms are lost as H^+ ions?

The acid H_3PO_3

123. Perchloric acid behaves as an acid, even when it is dissolved in sulfuric acid.

(a) Write a balanced equation showing how perchloric acid can transfer a proton to sulfuric acid.

(b) Draw a Lewis electron dot structure for sulfuric acid. How can sulfuric acid function as a base?

124. You purchase a bottle of water. On checking its pH, you find that it is not neutral, as you might have expected. Instead, it is slightly acidic. Why?

$E(OH)_m$	pK_a	$EO(OH)_m$	pK_a	$EO_2(OH)_m$	pK_a	$EO_3(OH)_m$	pK_a
Very weak		Weak		Strong		Very strong	
Cl(OH)	7.5	ClO(OH)	2	$ClO_2(OH)$	−3	$ClO_3(OH)$	−10
Br(OH)	8.7	NO(OH)	3.4	$NO_2(OH)$	−1.4		
I(OH)	10.6	IO(OH)	1.6	$IO_2(OH)$	0.8		
$Si(OH)_4$	9.7	$SO(OH)_2$	1.8	$SO_2(OH)_2$	−3		
$Sb(OH)_3$	11.0	$SeO(OH)_2$	2.5	$SeO_2(OH)_2$	−3		
$As(OH)_3$	9.2	$AsO(OH)_3$	2.3				
		$PO(OH)_3$	2.1				
		$HPO(OH)_2$	1.8				
		$H_2PO(OH)$	2.0

125. Iodine, I_2, is much more soluble in an aqueous solution of potassium iodide, KI, than it is in pure water. The anion found in solution is I_3^-.

(a) Draw an electron dot structure for I_3^-.

(b) Write an equation for this reaction, indicating the Lewis acid and the Lewis base.

126. ▲ Uracil is a base found in RNA. Indicate sites in the molecule where hydrogen bonding is possible or that are sites of Lewis basicity.

Uracil

127. Chemists often refer to the *degree of ionization* of a weak acid or base and give it the symbol α. The equilibrium constant in terms of α and C_o, the initial acid or base concentration, is given by the useful equation

$$K = \frac{\alpha^2 C_o}{(1-\alpha)}$$

As an example, the degree of ionization for 0.010 M acetic acid is 0.0103.

(a) Show how we can arrive at the general equation given above.

(b) Calculate the degree of ionization for the ammonium ion in 0.10 M NH_4Cl.

128. ▲ Exploring the degree of ionization equation in Study Question 127:

Calculate the degree of ionization, α, for formic acid at the following concentrations: 0.0100 M, 0.0200 M, 0.0400 M, 0.100 M, 0.200 M, 0.400 M, 1.00 M, 2.00 M, and 4.00 M.

(a) Plot the results of the calculation as α versus formic acid concentration. Is there a linear relationship? If not, try plotting the logarithm of C_o versus α.

(b) What can you conclude about the relationship of the degree of ionization and the initial acid or base concentration?

129. ▲ Consider a salt of a weak base and a weak acid such as ammonium cyanide. Both the NH_4^+ and CN^- ions interact with water in aqueous solution, but the net reaction can be considered as a proton transfer from NH_4^+ to CN^-.

$$NH_4^+(aq) + CN^-(aq) \rightleftharpoons NH_3(aq) + HCN(aq)$$

(a) Show that the equilibrium constant for this reaction, K_{net}, is

$$K_{net} = \frac{K_a K_b}{K_w}$$

where K_a is the ionization constant for the weak acid NH_4^+ and K_b is the constant for the weak base CN^-.

(b) Calculate K_{net} values for each of the following: NH_4CN, $NH_4CH_3CO_2$, and NH_4F. Which salt has the largest value of K_{net} and why?

(c) Predict whether a solution of each of the compounds in (b) is acidic or basic. Explain how you made this prediction. (You do not need a calculation to make this prediction.)

CHAPTER OUTLINE

17.1 The Common Ion Effect

17.2 Controlling pH: Buffer Solutions

17.3 Acid–Base Titrations

17.4 Solubility of Salts

17.5 Precipitation Reactions

17.6 Equilibria Involving Complex Ions

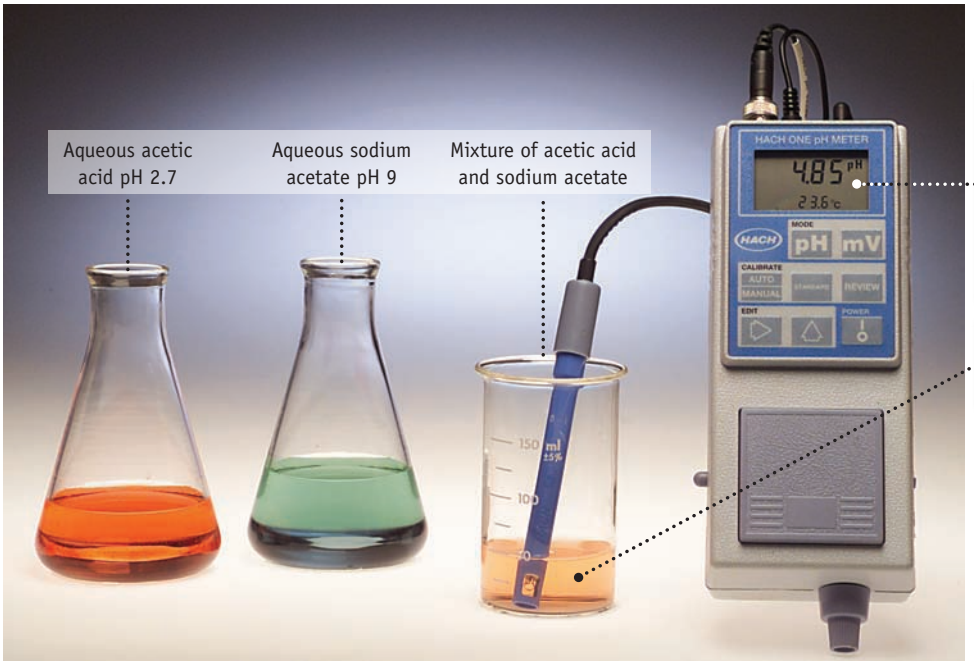
17.1 The Common Ion Effect

Goal for Section 17.1

- Predict the effect of the addition of a "common ion" on the pH of the solution of a weak acid or base.

What happens to the pH of an acetic acid solution if you add a significant amount of its conjugate base, the acetate ion? The answer is that the pH of such a solution—weak acid + conjugate base—is higher than the pH of a solution of the weak acid by itself. The effect on the pH produced by having a significant concentration of acetate ion in an acetic acid solution is an example of the **common ion effect**. The name comes from the fact that the added acetate ion is "common" to the ionization equilibrium reaction of acetic acid.

$$CH_3CO_2H(aq) + H_2O(\ell) \rightleftharpoons H_3O^+(aq) + CH_3CO_2^-(aq)$$



How does the common ion effect work? Without added $NaCH_3CO_2$, the ionization of 0.25 M acetic acid will produce H_3O^+ and $CH_3CO_2^-$ ions in a concentration of 0.0021 M (pH = 2.67). Le Chatelier's principle, however, predicts that the added common ion, $CH_3CO_2^-$, causes the reaction to proceed far less to the right. Hence, $[H_3O^+]$ is less than 0.0021 M in the presence of added acetate ion (Figure 17.1).

The pH of a solution containing a mixture of an acid and its conjugate base can be determined using the same strategies used for the determination of the pH of a weak acid. One strategy, employing ICE tables, is shown in Example 17.1.

◀ **Acids are responsible for the tart taste of grapes. The most abundant acids in grapes are tartaric ($C_4H_6O_6$) and malic ($C_4H_6O_5$) acids.**

The pH meter shows that the solution in the beaker has a lower hydronium ion concentration (a pH of about 5) than the acetic acid solution, owing to the presence of acetate ion, the conjugate base of the acid and an ion common to the ionization reaction of the acid.

Approximately equal amounts of acetic acid and sodium acetate, a base, were mixed in the beaker.

Figure 17.1 The common ion effect. The acetic acid and sodium acetate solutions each had about the same concentration. Each solution contains a universal indicator. This dye is red in low pH, yellow in slightly acidic media, and green in neutral to weakly basic media.

EXAMPLE 17.1

The Common Ion Effect: pH of a Solution of Acetic Acid and Acetate Ion

Problem What is the pH of the solution that contains 0.25 moles per liter of acetic acid and 0.10 moles per liter of sodium acetate? (K_a for acetic acid $= 1.8 \times 10^{-5}$)

$$CH_3CO_2H(aq) + H_2O(\ell) \rightleftharpoons H_3O^+(aq) + CH_3CO_2^-(aq)$$

What Do You Know? You know the initial concentrations of the acid (0.25 M CH_3CO_2H) and base (0.10 M $CH_3CO_2^-$) and the ionization constant for the weak acid.

Strategy Set up an ICE table where the initial acid and conjugate base concentrations are known and the changes in the concentration of acid consumed and concentration of conjugate base produced are defined as x. Insert the equilibrium concentrations in the K_a expression for acetic acid and solve for x, then calculate the pH from the equilibrium hydronium ion concentration ($= x$).

The Common Ion Effect In this ICE table, the first row (Initial) reflects the assumption that no ionization of the acid has yet occurred. Ionization of the acid in the presence of the conjugate base then produces x mol/L of hydronium ion and x mol/L *more* of the conjugate base.

SOLUTION

The concentrations are used as the initial concentrations in an ICE table.

Equilibrium	$CH_3CO_2H + H_2O$	$\rightleftharpoons$	H_3O^+	+	$CH_3CO_2^-$
Initial (M)	0.25		0		0.10
Change (M)	$-x$		$+x$		$+x$
Equilibrium (M)	$(0.25 - x)$		x		$(0.10 + x)$

Substitute the concentrations into the equilibrium constant expression.

$$K_a \text{ (acetic acid)} = 1.8 \times 10^{-5} = \frac{[H_3O^+][CH_3CO_2^-]}{[CH_3CO_2H]} = \frac{(x)(0.10 + x)}{0.25 - x}$$

Making the assumption that x is small with respect to 0.25 M and 0.10 M,

$$K_a = 1.8 \times 10^{-5} = \frac{(x)(0.10)}{0.25} = 0.400(x)$$

and,

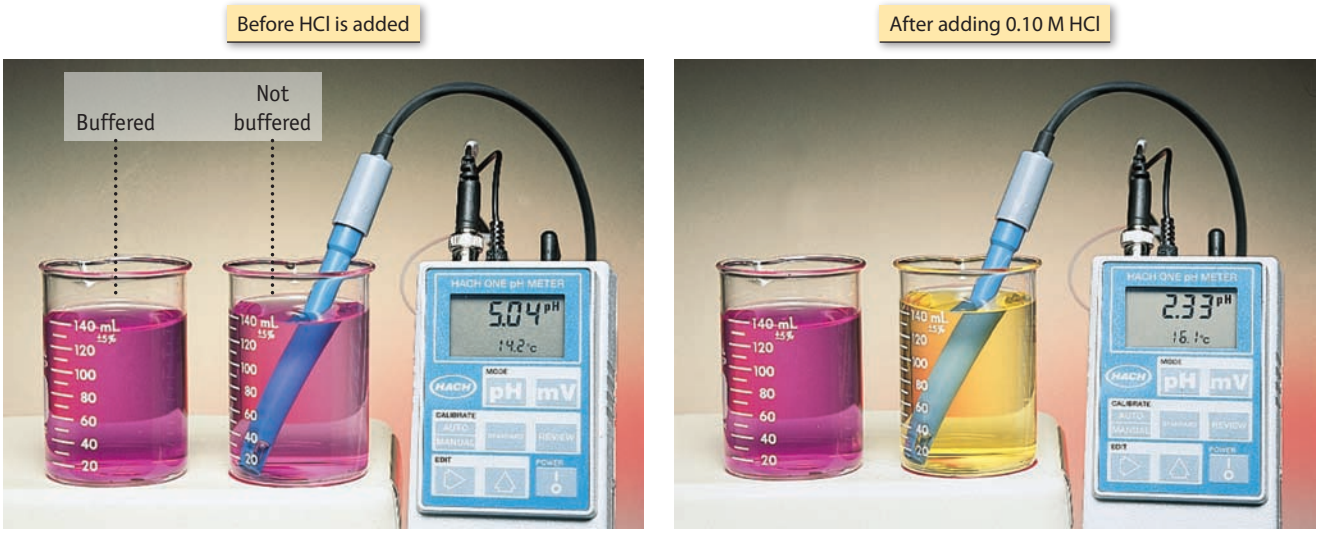
$$x = [H_3O^+] = 4.50 \times 10^{-5}\ M, \text{ which gives a pH of } 4.35.$$

Think about Your Answer Several observations:

- The assumption that $x << 0.25$ and 0.10 is valid.
- The presence of 0.10 M acetate ion (a Brønsted base) in this solution has resulted in an increase of the pH from 2.67 to 4.35.
- Here, a base (acetate ion) was added to the acidic solution. A useful observation is that *adding base to any solution will always result in an increase in pH.*

Check Your Understanding

You have a 0.30 M solution of formic acid (HCO_2H) and have added enough sodium formate ($NaHCO_2$) to make the solution 0.10 M in the salt. Calculate the pH of the formic acid solution before and after adding solid sodium formate.



Equilibrium Constants and Temperature Unless specified otherwise, all equilibrium constants and all calculations in this chapter are at 25 °C.

17.2 Controlling pH: Buffer Solutions

Goals for Section 17.2

- Recognize the composition of a buffer, know how to prepare a buffer solution of a given pH, and understand how a buffer solution works.
- Calculate the pH of a buffer solution of given composition using either the equation for the equilibrium for a weak acid or the Henderson–Hasselbalch equation.
- Calculate the pH of a buffered solution after the addition of acid or base.

The addition of a small quantity of strong acid or base, say 0.010 mol, to a liter of human blood leads to a change in pH of only about 0.1 pH units from the normal pH of about 7.4. In comparison, if you add 0.010 mol of HCl to 1.0 L of pure water, the pH drops from 7 to 2. Addition of 0.010 mol of NaOH to pure water increases the pH from 7 to 12. Blood, and many other body fluids, are said to be buffered. *A buffered solution is resistant to a change in pH when an acid or base is added* (Figure 17.2).

Photos: © Cengage Learning/Charles D. Winters

(a) The pH electrode is indicating the pH of water that contains a trace of acid (and bromphenol blue, an acid–base indicator). The solution at the left is a buffer solution with a pH of about 7. (It also contains bromphenol blue.)

(b) When 5 mL of 0.10 M HCl is added to each solution, the pH of the water drops several units, whereas the pH of the buffer stays essentially constant, as implied by the fact that the indicator color does not change.

TABLE 17.1 Some Commonly Used Buffer Systems

Weak Acid	Conjugate Base	Acid K_a (pK_a)	Useful pH Range
Phthalic acid, $C_6H_4(CO_2H)_2$	Hydrogen phthalate ion, $C_6H_4(CO_2H)(CO_2)^-$	1.3×10^{-3} (2.89)	1.9–3.9
Acetic acid, CH_3CO_2H	Acetate ion, $CH_3CO_2^-$	1.8×10^{-5} (4.74)	3.7–5.7
Dihydrogen phosphate ion, $H_2PO_4^-$	Hydrogen phosphate ion, HPO_4^{2-}	6.2×10^{-8} (7.21)	6.2–8.2
Hydrogen phosphate ion, HPO_4^{2-}	Phosphate ion, PO_4^{3-}	3.6×10^{-13} (12.44)	11.4–13.4

Buffers and the Common Ion Effect The common ion effect is observed for an acid (or base) ionizing in the presence of its conjugate base (or acid). A buffer is a solution of a weak acid and its conjugate base.

There are two requirements for a buffer:

- Two substances are needed: an acid capable of reacting with added OH^- ions and a base that can consume added H_3O^+ ions.
- The acid and base must not react with each another.

These requirements mean a buffer is usually prepared from a conjugate acid–base pair (such as acetic acid and acetate ion). Some buffers commonly used in the laboratory are given in Table 17.1.

To see how a buffer works, consider an acetic acid/acetate ion buffer. Acetic acid, a weak acid, is needed to consume any added hydroxide ions.

$$CH_3CO_2H(aq) + OH^-(aq) \rightleftharpoons CH_3CO_2^-(aq) + H_2O(\ell) \qquad K = 1.8 \times 10^9$$

The equilibrium constant for the reaction is very large because OH^- is a much stronger base than acetate ion, $CH_3CO_2^-$ (Section 16.5 and Table 16.2). This means that any OH^- added to the solution is consumed completely. In a similar way, any hydronium ion added to the solution reacts completely with the acetate ion present in the buffer.

$$H_3O^+(aq) + CH_3CO_2^-(aq) \rightleftharpoons H_2O(\ell) + CH_3CO_2H(aq) \qquad K = 5.6 \times 10^4$$

The equilibrium constant for this reaction is also quite large because H_3O^+ is a much stronger acid than CH_3CO_2H.

Buffers can be prepared by directly combining an acid with its conjugate base, combining a weak base with a strong acid, or, as shown in Example 17.2, by combining a weak acid with a strong base.

EXAMPLE 17.2

pH of a Buffer Solution

Problem A buffer solution can be prepared by adding a deficiency of NaOH to a solution of a weak acid. The reaction produces the conjugate base of the acid and leaves some acid in solution. What is the pH of an acetic acid/sodium acetate buffer that results from adding 25.0 mL of 0.050 M NaOH to 25.0 mL of 0.10 M CH_3CO_2H? (K_a for acetic acid $= 1.8 \times 10^{-5}$)

What Do You Know? You know the volumes and concentrations of the acid and base, and the ionization constant for the weak acid.

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Strategy There are two parts to this problem: a stoichiometry problem followed by an equilibrium problem.

Part 1: *Stoichiometry Problem*

- Determine the initial amounts of acid and base from their volumes and concentrations.
- Work a limiting reactant problem (in moles) to determine the amounts of acetic acid and acetate ion remaining in solution after the reaction between acetic acid and sodium hydroxide to produce sodium acetate.
- Calculate the concentrations of acetic acid and acetate ion that are present from the amounts of acetic acid and acetate ion calculated in step (b) and the total volume of solution.

Part 2: *Equilibrium Problem*

- Set up an ICE table where the initial acid and conjugate base concentrations are known and the changes in the concentration of acid consumed and concentration of conjugate base produced are defined as x.
- Insert the equilibrium concentrations in the K_a expression for acetic acid and solve for x, then calculate the pH from the equilibrium hydronium ion concentration ($= x$).

SOLUTION

Part 1: *Stoichiometry Problem*

First, calculate the amounts of NaOH and acetic acid used in the reaction.

$$(0.0250\ \text{L NaOH})(0.050\ \text{mol/L}) = 1.25 \times 10^{-3}\ \text{mol NaOH}$$

$$(0.0250\ \text{L } CH_3CO_2H)(0.10\ \text{mol/L}) = 2.50 \times 10^{-3}\ \text{mol } CH_3CO_2H$$

Use the principles of stoichiometry to calculate the amounts of reactants and products after reaction. The limiting reactant is NaOH, so some CH_3CO_2H remains along with the product, $CH_3CO_2^-$.

Equation	CH_3CO_2H	+	OH^-	$\rightleftharpoons$	$CH_3CO_2^-$	+	H_2O
Initial (mol)	0.00250		0.00125		0		
Change (mol)	−0.00125		−0.00125		+0.00125		
After rxn (mol)	0.00125		0		0.00125		

Determine the concentrations of acetic acid and acetate ion after reaction. Note that the total solution volume after reaction is 50.0 mL or 0.0500 L.

$$[CH_3CO_2H] = \frac{1.25 \times 10^{-3}\ \text{mol } CH_3CO_2H}{0.0500\ \text{L}} = 2.50 \times 10^{-2}\ \text{M}$$

Because the amount of acetic acid remaining is the same as the amount of acetate ion produced, you have

$$[CH_3CO_2H] = [CH_3CO_2^-] = 2.50 \times 10^{-2}\ \text{M}$$

Part 2: *Equilibrium Problem*

The concentrations just determined are used as the initial concentrations in an ICE table.

Equilibrium	CH_3CO_2H	+	H_2O	$\rightleftharpoons$	H_3O^+	+	$CH_3CO_2^-$
Initial (M)	0.0250				0		0.0250
Change (M)	$-x$				$+x$		$+x$
Equilibrium (M)	$(0.0250 - x)$				x		$(0.0250 + x)$

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Substituting the concentrations into the equilibrium constant expression, you have

$$K_a = 1.8 \times 10^{-5} = \frac{[H_3O^+][CH_3CO_2^-]}{[CH_3CO_2H]} = \frac{(x)(0.0250 + x)}{0.0250 - x}$$

The value of x will be very small with respect to 0.0250, so you can use the "approximate expression" to find x, the hydronium ion concentration.

$$K_a = 1.8 \times 10^{-5} = \frac{[H_3O^+][CH_3CO_2^-]}{[CH_3CO_2H]} = \frac{(x)(0.0.0250)}{0.0250}$$

$$x = 1.8 \times 10^{-5}\ \text{M}$$

$$\text{pH} = -\log\,(1.8 \times 10^{-5}) = 4.74$$

Think about Your Answer If a buffer is composed of equal amounts of a weak acid and its conjugate base, its pH will be equal to the pK_a for the weak acid.

Check Your Understanding

What is the pH of a buffer solution composed of 0.50 M formic acid (HCO_2H) and 0.70 M sodium formate ($NaHCO_2$)?

General Expressions for Buffer Solutions

In Example 17.2, the hydronium ion concentration of the acetic acid/acetate ion buffer solution was found by solving for x in the equation

$$K_a = 1.8 \times 10^{-5} = \frac{[H_3O^+][CH_3CO_2^-]}{[CH_3CO_2H]} = \frac{(x)(0.0.0250)}{0.0250}$$

Rearrangement results in a useful equation that can help you better understand how a buffer works.

$$[H_3O^+] = \frac{[CH_3CO_2H]}{[CH_3CO_2^-]} \times K_a$$

That is, the hydronium ion concentration in the acetic acid/acetate ion buffer is given by the ratio of the acid and conjugate base concentrations at equilibrium times the acid ionization constant. Indeed, this is true for all solutions of *a weak acid and its conjugate base*.

Buffer Solutions You will find it generally useful to consider all buffer solutions as composed of a weak acid and its conjugate base. Suppose, for example, you have a solution containing the weak base ammonia and its conjugate acid ammonium ion. The hydronium ion concentration can be found from Equation 17.1 or 17.2 by assuming the buffer is composed of the weak acid NH_4^+ and its conjugate base, NH_3.

$$[H_3O^+] = \frac{[\text{acid}]}{[\text{conjugate base}]} \times K_a \qquad (17.1)$$

It is often convenient to use Equation 17.1 in a different form. If you take the negative logarithm of each side of the equation, you have

$$-\log[H_3O^+] = \left\{-\log\frac{[\text{acid}]}{[\text{conjugate base}]}\right\} + (-\log K_a)$$

You know that $-\log[H_3O^+]$ is defined as pH, and $-\log K_a$ is defined as pK_a (Sections 16.2 and 16.3). Furthermore, because

$$-\log\frac{[\text{acid}]}{[\text{conjugate base}]} = +\log\frac{[\text{conjugate base}]}{[\text{acid}]}$$

the preceding equation can be rewritten as

$$\text{pH} = \text{p}K_a + \log\frac{[\text{conjugate base}]}{[\text{acid}]} \qquad (17.2)$$

This equation is known as the **Henderson–Hasselbalch equation**. The equation is simply a rearrangement of the equilibrium expression for the ionization of an acid. But, *to use the Henderson-Hasselbalch equation you assume that the acid and conjugate base concentrations at equilibrium are essentially unchanged from the concentrations used to prepare the buffer*. This criterion is met when:

- *the pH of the buffer falls within a pH range of 3 to 11*. The pH of a buffer will be close to the pK_a for the weak acid. If K_a for a weak acid is greater than 10^{-3} ($pK_a < 3$), a significant fraction of the acid will ionize in water and, thus, the equilibrium concentrations of the acid and the conjugate base will differ from the concentrations originally prepared. Likewise, for buffers with pH values above 11, K_b for the weak base is greater than 10^{-3} and the base reacts to a significant extent with water.
- *the concentrations of the acid and the conjugate base are large* so that a small amount of ionization of the acid (or the conjugate base) will not result in an appreciable change in concentration.

The Henderson-Hasselbalch equation shows that *the pH of a buffer solution is controlled by two factors:*

- the strength of the acid (as expressed by pK_a)
- and the relative amounts of acid and conjugate base

The solution pH is established primarily by the value of pK_a, and the pH can be fine-tuned by adjusting the acid-to-conjugate base ratio.

When the concentrations of conjugate base and acid are the same in a solution, the ratio [conjugate base]/[acid] is 1. The log of 1 is zero, so pH = pK_a under these circumstances. If there is more of the conjugate base in the solution than acid, for example, then pH > pK_a. Conversely, if there is more acid than conjugate base in solution, then pH < pK_a.

EXAMPLE 17.3

Using the Henderson–Hasselbalch Equation

Problem Benzoic acid ($C_6H_5CO_2H$, 2.00 g) and sodium benzoate ($NaC_6H_5CO_2$, 2.00 g) are dissolved in enough water to make 1.00 L of solution. Calculate the pH of the solution using the Henderson–Hasselbalch equation.

What Do You Know? You know the masses of weak acid and conjugate base and the volume of solution. You can look up the K_a for the weak acid (Table 16.2 or Appendix H), from which you can calculate the required pK_a for the acid.

Strategy Calculate the acid and conjugate base concentrations and substitute these into the Henderson–Hasselbalch equation along with the value of pK_a for the acid.

SOLUTION

K_a for benzoic acid is 6.3×10^{-5}. Therefore, $pK_a = -\log(6.3 \times 10^{-5}) = 4.201$

Next, you need the concentrations of the acid (benzoic acid) and its conjugate base (benzoate ion).

$$2.00 \text{ g benzoic acid} \left(\frac{1 \text{ mol}}{122.1 \text{ g}} \right) = 0.01638 \text{ mol benzoic acid}$$

$$2.00 \text{ g sodium benzoate} \left(\frac{1 \text{ mol}}{144.1 \text{ g}} \right) = 0.01388 \text{ mol sodium benzoate}$$

Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Because the solution volume is 1.00 L, the concentrations are [benzoic acid] = 0.01638 M and [benzoate ion] = 0.01388 M. Therefore, using Equation 17.2, you have

$$\text{pH} = 4.201 + \log\frac{0.01388}{0.01638} = 4.201 + \log(0.8473) = 4.13$$

Think about Your Answer Notice that the pH is less than the pK_a because the concentration of acid is greater than the concentration of the conjugate base (and so the ratio of conjugate base to acid concentration is less than 1).

Check Your Understanding

Use the Henderson–Hasselbalch equation to calculate the pH of 1.00 L of a buffer solution containing 15.0 g of $NaHCO_3$ and 18.0 g of Na_2CO_3. (Consider this buffer as a solution of the weak acid HCO_3^- and its conjugate base, CO_3^{2-}.)

Preparing Buffer Solutions

To be useful, a buffer solution must have two characteristics:

- *pH Control:* It should control the pH at the desired value. The Henderson–Hasselbalch equation shows us how this can be done.

$$\text{pH} = pK_a + \log\frac{[\text{conjugate base}]}{[\text{acid}]}$$

  First, an acid is chosen whose pK_a (or K_a) is near the intended value of pH (or $[H_3O^+]$). Second, the exact value of pH (or $[H_3O^+]$) is then achieved by adjusting the conjugate base-to-acid ratio.

Buffer Capacity If too much water is added, the acid and conjugate base concentrations will be too low, and the buffer capacity could be exceeded. Buffer solutions usually have solute concentrations around 0.10 M to 1.0 M.

- *Buffer capacity:* The buffer should have the ability to keep the pH approximately constant after the addition of reasonable amounts of acid and base. For example, the concentration of acetic acid in an acetic acid/acetate ion buffer must be sufficient to consume the hydroxide ion that may be added and still control the pH. Buffers are often prepared as 0.10 M to 1.0 M solutions of reagents. However, any buffer will lose its ability to moderate changes if too much strong acid or base is added.

EXAMPLE 17.4

Preparing a Buffer Solution

Problem You wish to prepare 1.0 L of a buffer solution with a pH of 4.30. A list of possible acids (and their conjugate bases) follows:

Acid	Conjugate Base	K_a	pK_a
CH_3CO_2H	$CH_3CO_2^-$	1.8×10^{-5}	4.74
$H_2PO_4^-$	HPO_4^{2-}	6.2×10^{-8}	7.21
HCO_3^-	CO_3^{2-}	4.8×10^{-11}	10.32

Which combination should be selected, and what should be the ratio of acid to conjugate base?

What Do You Know? You know the desired pH of the buffer, and you have a list of possible acid/conjugate base combinations.

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Strategy Use either the general equation for a buffer (Equation 17.1) or the Henderson–Hasselbalch equation (Equation 17.2). Equation 17.1 informs you that $[H_3O^+]$ should be close to the acid K_a value, and Equation 17.2 tells you that pH should be close to the acid pK_a value. Either will establish which acid you should use. Having decided which acid to use, convert pH to $[H_3O^+]$ to use Equation 17.1. If you use Equation 17.2, use the pK_a value in the table. Finally, calculate the ratio of acid to conjugate base.

SOLUTION The hydronium ion concentration for the buffer is found from the targeted pH.

$$\text{pH} = 4.30, \text{ so } [H_3O^+] = 10^{-\text{pH}} = 10^{-4.30} = 5.01 \times 10^{-5} \text{ M}$$

Of the acids given, only acetic acid (CH_3CO_2H) has a K_a value close to that of the desired $[H_3O^+]$ (or a pK_a close to a pH of 4.30). Now you need only to adjust the ratio $[CH_3CO_2H]/[CH_3CO_2^-]$ to achieve the desired hydronium ion concentration.

$$[H_3O^+] = 5.01 \times 10^{-5} \text{ M} = \frac{[CH_3CO_2H]}{[CH_3CO_2^-]}(1.8 \times 10^{-5})$$

Rearrange this equation to find the ratio $[CH_3CO_2H]/[CH_3CO_2^-]$.

$$\frac{[CH_3CO_2H]}{[CH_3CO_2^-]} = \frac{[H_3O^+]}{K_a} = \frac{5.01 \times 10^{-5} \text{ mol/L}}{1.8 \times 10^{-5}} = \frac{2.8 \text{ mol acid/L}}{1.0 \text{ mol base/L}}$$

Therefore, if you add 0.28 mol of acetic acid and 0.10 mol of sodium acetate (or any other pair of molar quantities in the ratio 2.8/1) to enough water to prepare 1.0 L of solution, the buffer solution will have a pH of 4.30.

Think about Your Answer If you use the Henderson–Hasselbalch equation, you would have

$$\text{pH} = 4.30 = 4.74 + \log \frac{[CH_3CO_2^-]}{[CH_3CO_2H]}$$

$$\log \frac{[CH_3CO_2^-]}{[CH_3CO_2H]} = 4.30 - 4.74 = -0.44$$

$$\frac{[CH_3CO_2^-]}{[CH_3CO_2H]} = 10^{-0.44} = 0.36$$

The ratio of conjugate base to acid, $[CH_3CO_2^-]/[CH_3CO_2H]$, is 0.36. The reciprocal of this ratio {$= [CH_3CO_2H]/[CH_3CO_2^-] = 1/0.36$} is 2.8/1. This is the same result obtained previously using Equation 17.1.

Check Your Understanding

Using an acetic acid/sodium acetate buffer solution, what ratio of conjugate base to acid will you need to maintain the pH at 5.00? Describe how you would prepare such a solution.

Example 17.4 illustrates several important points concerning buffer solutions. The hydronium ion concentration depends not only on the K_a value of the acid but also on the ratio of acid and conjugate base concentrations. However, even though the ratios are written in terms of reagent concentrations, it is *the relative number of moles of acid and conjugate base that is important in determining the pH of a buffer solution.* Because both reagents are dissolved in the same solution, their concentrations depend on the same solution volume. In Example 17.4, the ratio 2.8/1 for acetic acid and sodium acetate implies that 2.8 times as many moles of acid were dissolved per liter as moles of sodium acetate.

$$\frac{[CH_3CO_2H]}{[CH_3CO_2^-]} = \frac{2.8 \text{ mol } CH_3CO_2H/\text{L}}{1.0 \text{ mol } CH_3CO_2^-/\text{L}} = \frac{2.8 \text{ mol } CH_3CO_2H}{1.0 \text{ mol } CH_3CO_2^-}$$

Problem Solving Tip 17.1 Buffer Solutions

The following is a summary of important aspects of buffer solutions.

- A buffer resists changes in pH on adding small quantities of acid or base.
- A buffer consists of a weak acid and its conjugate base.
- The hydronium ion concentration of a buffer solution can be calculated from Equation 17.1,

$$[H_3O^+] = \frac{[\text{acid}]}{[\text{conjugate base}]} \times K_a$$

or the pH can be calculated from the Henderson–Hasselbalch equation (Equation 17.2).

$$\text{pH} = \text{p}K_a + \log \frac{[\text{conjugate base}]}{[\text{acid}]}$$

- The pH depends primarily on the K_a of the weak acid and secondarily on the relative amounts of acid and conjugate base.
- The function of the weak acid of a buffer is to consume added base, and the function of the conjugate base is to consume added acid. Such reactions change the relative amounts of weak acid and its conjugate base. Because this ratio of acid to its conjugate base has only a secondary effect on the pH, the pH can be maintained relatively constant.
- The buffer must have sufficient capacity to react with reasonable quantities of added acid or base.

© Cengage Learning/Charles D. Winters

Figure 17.3 A commercial buffer solution. The solid acid and conjugate base in the packet are mixed with water to give a solution with the indicated pH. The quantity of water used does not matter because the ratio [acid]/[conjugate base] does not depend on the solution volume.

Notice that on dividing one concentration by the other, the volumes "cancel." This means that you only need to ensure that the ratio of moles of acid to moles of conjugate base is 2.8 to 1 in this example. The acid and its conjugate base could have been dissolved in any reasonable amount of water. This also means that *diluting a buffer solution will not change its pH*. Commercially available buffer solutions are often sold as premixed, dry reagents. To use them, you only need to mix the reagents in some volume of pure water (Figure 17.3).

How Does a Buffer Maintain pH?

Now let us explore quantitatively how a given buffer solution can maintain the pH of a solution after a small amount of strong acid has been added.

EXAMPLE 17.5

How Does a Buffer Maintain a Constant pH?

Problem What is the change in pH when 1.0 mL of 1.00 M HCl is added to (1) 1.000 L of pure water and to (2) 1.000 L of acetic acid/sodium acetate buffer with $[CH_3CO_2H] = 0.700$ M and $[CH_3CO_2^-] = 0.600$ M? (The pH of this acetic acid/acetate ion buffer is 4.68.)

What Do You Know? You know HCl is a strong acid and ionizes completely in water. In the first problem, when HCl is added to pure water, the concentration of HCl in the solution determines the pH. In the second problem, the conjugate base of the weak acid will react with the added HCl forming more CH_3CO_2H and decreasing the amount of $CH_3CO_2^-$. To determine the pH of the resulting solution you need to perform a stoichiometry calculation to determine the new weak acid/conjugate base concentrations.

Strategy

Part 1: *involves two steps:*

- Find the H_3O^+ concentration when adding 1.0 mL of acid to 1.000 L of pure water.
- Convert the value of $[H_3O^+]$ for the dilute solution to pH.

Part 2: *involves three steps:*

- Calculate the concentrations of acid and conjugate base after adding H_3O^+.
- Find $[H_3O^+]$ for a buffer solution knowing the concentrations of CH_3CO_2H and $CH_3CO_2^-$.
- Convert the value of $[H_3O^+]$ for the solution to pH.

SOLUTION

Part 1: *Adding Acid to Pure Water*

1.0 mL of 1.00 M HCl represents 0.0010 mol of acid. If this is added to 1.000 L of pure water, the H_3O^+ concentration of the water changes from 10^{-7} to almost 10^{-3},

$$c_1 \times V_1 = c_2 \times V_2$$

$$(1.0\ \text{M})(0.00100\ \text{L}) = c_2 \times (1.001\ \text{L})$$

$$c_2 = [H_3O^+] \text{ in diluted solution} = 9.99 \times 10^{-4}\ \text{M}$$

and so the pH falls from 7.00 to 3.00.

Part 2: *Adding Acid to an Acetic Acid/Acetate Buffer Solution*

HCl is a strong acid that is 100% ionized in water and supplies H_3O^+, which reacts completely with the base (acetate ion) in the buffer solution according to the following equation:

$$H_3O^+(aq) + CH_3CO_2^-(aq) \longrightarrow H_2O(\ell) + CH_3CO_2H(aq)$$

	H_3O^+ from Added HCl	$CH_3CO_2^-$ from Buffer	CH_3CO_2H from Buffer
Initial amount of acid or base (mol = $c \times V$)	0.00100	0.600	0.700
Change (mol)	−0.00100	−0.00100	+0.00100
After reaction (mol)	0	0.599	0.701
Concentrations after reaction (c = mol/V)	0	0.598	0.700

Because the added HCl reacts completely with acetate ion to produce acetic acid, the solution after this reaction (with V = 1.001 L) is once again a buffer containing only the weak acid and its salt. Now you only need to use Equation 17.1 (or the Henderson–Hasselbalch equation) to find $[H_3O^+]$ and the pH in the buffer solution as in Examples 17.2 and 17.3.

Equilibrium	CH_3CO_2H	+	H_2O	⇌	H_3O^+	+	$CH_3CO_2^-$
Initial (M)	0.700				0		0.598
Change (M)	$-x$				$+x$		$+x$
Equilibrium (M)	$0.700 - x$				x		$0.598 + x$

You can make the approximation that x, the concentration of H_3O^+ formed by ionizing acetic acid in the presence of acetate ion, is very small compared with 0.700 M or 0.598 M. Using Equation 17.1, you should get a pH of 4.68, the same as the pH of the buffer before adding acid.

$$[H_3O^+] = x = \frac{[CH_3CO_2H]}{[CH_3CO_2^-]} \times K_a = \left(\frac{0.700\ \text{mol}}{0.598\ \text{mol}}\right)(1.8 \times 10^{-5}) = 2.11 \times 10^{-5}\ \text{M}$$

$$\text{pH} = 4.68$$

Think about Your Answer Within the number of significant figures allowed, the pH of the buffer solution does not change after adding this amount of HCl. The buffer solution contains the conjugate base of the weak acid, and the base consumed the added HCl. In contrast, the pH changed by 4 units when the same amount of HCl was added to 1.0 L of pure water. That is, $[H_3O^+]$ went up by 10^4.

Check Your Understanding

Calculate the pH of 0.500 L of a buffer solution composed of 0.50 M formic acid (HCO_2H) and 0.70 M sodium formate ($NaHCO_2$) before and after adding 10.0 mL of 1.0 M HCl.

17.3 Acid–Base Titrations

Goals for Section 17.3

- Recognize the differences between a titration curve for a strong acid–strong base titration and a titration curve in which one of the substances is weak.
- Calculate the pH at various points in acid-base titrations (initial pH, the pH prior to the equivalence point, at the equivalence point, and after the equivalence point).
- Describe how an indicator functions in an acid–base titration.

A titration is one of the most useful ways of determining accurately the quantity of an acid, a base, or some other substance in a mixture. You learned how to perform the stoichiometry calculations involved in titrations in Chapter 4 (Section 4.8). In Chapter 16, the following points were emphasized regarding acid–base reactions (Section 16.6):

- The pH at the equivalence point of a strong acid–strong base titration is 7. The solution at the equivalence point is truly "neutral" *only* when a strong acid is titrated with a strong base and vice versa.
- If the substance being titrated is a weak acid or base, then the pH at the equivalence point is not 7 (Table 16.4).
  (a) A weak acid titrated with a strong base leads to a pH $>$ 7 at the equivalence point due to the conjugate base of the weak acid.
  (b) A weak base titrated with a strong acid leads to a pH $<$ 7 at the equivalence point due to the conjugate acid of the weak base.

Equivalence Point The equivalence point for a reaction is the point at which one reactant has been completely consumed upon addition of another reactant (Section 4.8).

Titration of a Strong Acid with a Strong Base

Weak Acid–Weak Base Titrations Titrations combining a weak acid and weak base are generally not done because the equivalence point cannot be accurately judged.

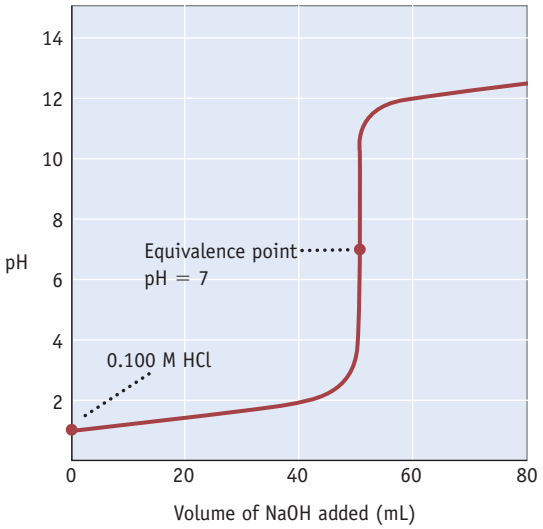
Figure 17.4 illustrates what happens to the pH as 0.100 M NaOH is slowly added to 50.0 mL of 0.100 M HCl.

$$HCl(aq) + NaOH(aq) \rightarrow NaCl(aq) + H_2O(\ell)$$

$$\text{Net ionic equation: } H_3O^+(aq) + OH^-(aq) \rightarrow 2\ H_2O(\ell)$$

Let us focus on four regions on this plot.

- pH of the initial solution
- pH just before the equivalence point
- pH at the equivalence point
- pH after the equivalence point



Before beginning the titration, the 0.100 M solution of HCl has a pH of 1.00. As NaOH is added to the acid solution, the amount of HCl declines, and the acid remaining is dissolved in an ever-increasing volume of solution. Thus, $[H_3O^+]$ decreases, and the pH slowly increases. Here, a table is created to list the amounts of acid and base before reaction, the changes in those amounts, and the amounts remaining after reaction. As an example, let us find the pH of the solution after 10.0 mL of 0.100 M NaOH has been added to 50.0 mL of 0.100 M HCl. Be sure to notice that the volume of the solution after reaction is the sum of the combined volumes of NaOH and HCl (60.0 mL or 0.0600 L in this example).

Titrations, Stoichiometry, and Limiting Reactants In the titration of an acid with a base (as in Figure 17.4) the limiting reactant is the base before the equivalence point. After the equivalence point the base is present in excess.

	$H_3O^+(aq)$	+	$OH^-(aq)$	$\rightarrow$	$2\ H_2O(\ell)$
Initial amount (mol = $c \times V$)	0.005000		0.001000		
Change (mol)	−0.001000		−0.001000		
After reaction (mol)	0.004000		0		
After reaction (c = mol/V)	0.004000 mol/0.0600 L = 0.0667 M		0

50.0 mL of 0.100 M HCl titrated with 0.100 M NaOH	
Volume of base added	pH
0.0	1.00
10.0	1.18
20.0	1.37
40.0	1.95
45.0	2.28
48.0	2.69
49.0	3.00
50.0	7.00
51.0	11.00
55.0	11.68
60.0	11.96
80.0	12.36
100.0	12.52
very large amount	13.00 (maximum)

Figure 17.4 The change in pH as a strong acid is titrated with a strong base. In this case, 50.0 mL of 0.100 M HCl is titrated with 0.100 M NaOH. The pH at the equivalence point is 7.0 for the reaction of a strong acid with a strong base.

After addition of 10.0 mL of NaOH, the final solution has a hydronium ion concentration of 0.0667 M, and so the pH is

$$\text{pH} = -\log[H_3O^+] = -\log(0.0667) = 1.176$$

After 49.5 mL of base has been added—that is, just before the equivalence point—the same approach can be used to show that the pH is 3.3. The solution being titrated is still quite acidic, even very close to the equivalence point.

The pH of the equivalence point in an acid–base titration is the value at the steepest point in the vertical portion of the pH versus volume of titrant curve. (The **titrant** is the substance being added during the titration.) In the HCl/NaOH titration illustrated in Figure 17.4, you see that the pH increases very rapidly near the equivalence point. In fact, in this case the pH rises 7 units as the H_3O^+ concentration decreases by a factor of 10 million when only a drop or two of the NaOH solution is added, and the steepest point of the vertical portion of the curve is at a pH of 7.00.

The pH of the solution at the equivalence point in a monoprotic strong acid–strong base reaction is always 7.00 (at 25 °C) because the solution contains a neutral salt.

After all of the HCl has been consumed and the slightest excess of NaOH has been added, the solution will be basic, and the pH will continue to increase as more NaOH is added. For example, if you calculate the pH of the solution after 55.0 mL of 0.100 M NaOH has been added to 50.0 mL of 0.100 M HCl, you find

	$H_3O^+(aq)$	+	$OH^-(aq)$	→	$2\ H_2O(\ell)$
Initial amount (mol = $c \times V$)	0.005000		0.005500		
Change (mol)	−0.005000		−0.005000		
After reaction (mol)	0		0.000500		
After reaction (c = mol/V)	0		0.000500 mol/0.1050 L = 0.00476 M		

At this point, the solution has a hydroxide ion concentration of 0.0048 M. Calculate the pOH from this value, then use this to calculate pH.

$$\text{pOH} = -\log[OH^-] = -\log(0.0048) = 2.32$$

$$\text{pH} = 14.00 - \text{pOH} = 11.68$$

Titration of a Weak Acid with a Strong Base

The titration of a weak acid with a strong base is somewhat different from the strong acid–strong base titration. Look carefully at the curve for the titration of 100.0 mL of 0.100 M acetic acid with 0.100 M NaOH (Figure 17.5),

$$CH_3CO_2H(aq) + NaOH(aq) \rightarrow NaCH_3CO_2(aq) + H_2O(\ell)$$

and focus on four points on this curve:

- *The pH before titration begins.* The pH before any base is added can be calculated from the weak acid K_a value and the acid concentration (Example 16.5).
- *The pH in the buffer region and, in particular, at the halfway point (half-equivalence point) of the titration.* At the halfway point, the pH is equal to the pK_a of the weak acid, a conclusion discussed in more detail in the following paragraphs.
- *The pH at the equivalence point.* At the equivalence point, the solution contains only sodium acetate, the acetic acid and sodium hydroxide having been consumed. The pH is controlled by the acetate ion, and is thus basic.
- *The pH after the equivalence point.* The pH can be calculated using the amount of NaOH added after the equivalence point and the total volume of solution.

As NaOH is added, acetic acid is consumed and sodium acetate is produced. Thus, at every point between the beginning of the titration (when only acetic acid is present) and the equivalence point (when only sodium acetate is present), the solution contains both acetic acid and its salt, sodium acetate. These are the components of a *buffer solution*, and the hydronium ion concentration can be calculated from Equation 17.3 or 17.4.

$$[H_3O^+] = \frac{[\text{weak acid remaining}]}{[\text{conjugate base produced}]} \times K_a \qquad (17.3)$$

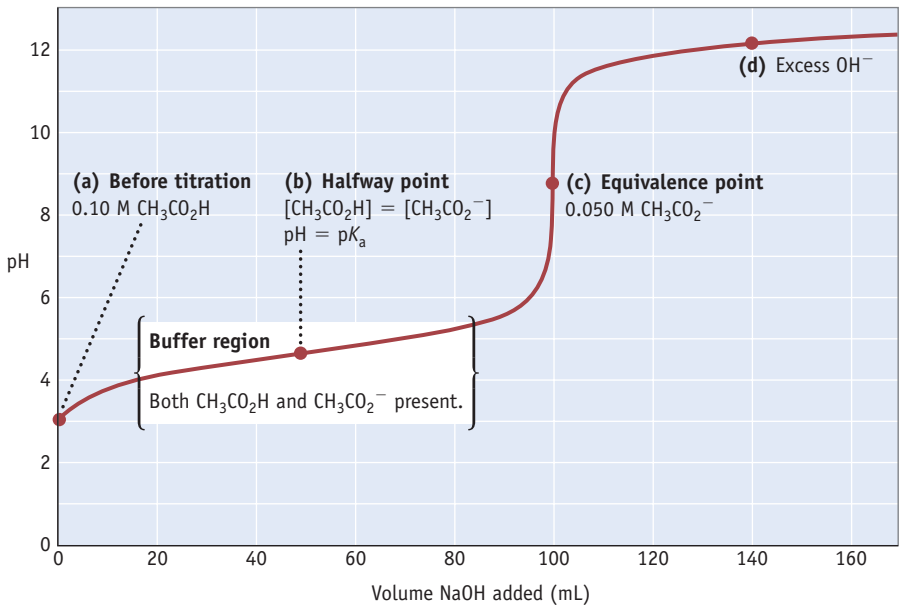

Figure 17.5 The change in pH during the titration of a weak acid with a strong base. Here, 100.0 mL of 0.100 M acetic acid is titrated with 0.100 M NaOH.

Photos: © Cengage Learning/ Charles D. Winters

(a) Before titration. A 0.100 M solution of acetic acid has a pH of 2.87.

(b) Halfway point. The pH at the point at which half the acid has reacted with base is equal to the pK_a for the acid (pH = pK_a = 4.74).

(c) Equivalence point. The solution contains the acetate ion, a weak base. Therefore, the solution is basic, with a pH of 8.72.

(d) After the equivalence point. The pH is determined from the moles of excess NaOH and total volume of solution.

or

$$\text{pH} = \text{p}K_a + \log\frac{[\text{conjugate base produced}]}{[\text{weak acid remaining}]} \qquad (17.4)$$

What happens to the pH when *exactly* half of the acid has been consumed by base? Half of the acid (CH_3CO_2H) has been converted to the conjugate base ($CH_3CO_2^-$), and half remains. Therefore, the concentration of weak acid remaining is equal to the concentration of conjugate base produced ($[CH_3CO_2H] = [CH_3CO_2^-]$). Using Equation 17.3 or 17.4, we see that

$$[H_3O^+] = (1) \times K_a \qquad \text{or} \qquad \text{pH} = \text{p}K_a + \log(1)$$

Because $\log(1) = 0$, we come to the following general conclusion:

At the halfway point in the titration of a weak acid with a strong base

$$[H_3O^+] = K_a \text{ and } \text{pH} = \text{p}K_a \qquad (17.5)$$

In the particular case of the titration of acetic acid with a strong base, $[H_3O^+] = 1.8 \times 10^{-5}$ M at the halfway point, and so the pH is 4.74. This is equal to the $\text{p}K_a$ of acetic acid.

EXAMPLE 17.6

Titration of Acetic Acid with Sodium Hydroxide

Problem Consider the titration of 100.0 mL of 0.100 M acetic acid ($K_a = 1.8 \times 10^{-5}$) with 0.100 M NaOH (Figure 17.5).

$$CH_3CO_2H(aq) + OH^-(aq) \rightarrow CH_3CO_2^-(aq) + H_2O(\ell)$$

(a) What is the pH of the solution when 90.0 mL of 0.100 M NaOH has been added to 100.0 mL of 0.100 M acetic acid?

(b) What is the pH at the equivalence point?

(c) What is the pH after 110.0 mL of NaOH has been added?

What Do You Know? You know the concentrations and volumes of the acid and base and the balanced equation for the reaction. For part (a) you know K_a of acetic acid and for part (b) you can calculate K_b for the acetate ion. You should also recognize that part (a) is similar to Example 17.2.

Strategy Each part of the problem has at least two steps:

(1) The first step in each part involves a limiting-reactant stoichiometry calculation to determine the amounts of acetic acid, sodium hydroxide, and acetate ion present after the acid–base reaction has gone to completion.

(2) **Part (a):** Before the equivalence point, do an equilibrium calculation to find $[H_3O^+]$ for a buffer solution where the amounts of CH_3CO_2H and $CH_3CO_2^-$ are known from the stoichiometry calculation.

Part (b): Only the acetate ion remains at the equivalence point. Determine the concentration of this ion after the acid–base reaction goes to completion. Using the balanced equation for the reaction of the acetate ion with water and its corresponding K_b, determine the equilibrium hydroxide ion concentration. Convert this to the equilibrium hydronium ion concentration and calculate the pH.

Part (c): After the equivalence point, the solution contains both the acetate ion and excess NaOH, but the latter controls the pH. Determine the concentration of excess NaOH (and $[OH^-]$), and then convert $[OH^-]$ to pH.

Acid–Base Titrations See Problem Solving Tip 17.2 (page 780): Calculating the pH at Various Stages in an Acid–Base Titration.

Strategy Map 17.6

PROBLEM — *Part (b)*

Calculate **pH** at the ***equivalence point*** for a titration of **acetic acid** with **NaOH.**

DATA/INFORMATION KNOWN

- Solution concentrations
- Solution volumes
- Value of conjugate base K_b

STEP 1. Stoichiometry problem

Concentration of **acetate ion** at ***equivalence point*** of acid–base titration

STEP 2. Enter **equilibrium concentrations** in ICE table.

At equilibrium:
$[OH^-] = [\text{Acetic acid}] = x$
$[\text{Acetate ion}] = \text{original conc.} - x$

STEP 3. Enter **equilibrium concentrations** in K_b.

K_b **expression** with equilibrium concentrations in terms of ***x***

STEP 4. Solve K_b **expression** for ***x***.

Value of $[OH^-]$

STEP 5. Convert $[OH^-]$ to **pH**.

pH of solution

SOLUTION

Part (a): *pH before the Equivalence Point*

First calculate the amounts of reactants before reaction (= concentration × volume) and then use the principles of stoichiometry to calculate the amounts of reactants and products after reaction. The limiting reactant is NaOH, so some CH_3CO_2H remains along with the product, $CH_3CO_2^-$.

Equation	CH_3CO_2H	+	OH^-	⇌	$CH_3CO_2^-$	+	H_2O
Initial (mol)	0.01000		0.009000		0		
Change (mol)	−0.009000		−0.009000		+0.009000		
After rxn (mol)	0.00100		0		0.009000		

The ratio of amounts (moles) of acid to conjugate base is the same as the ratio of their concentrations. Therefore, you can use the amounts of weak acid remaining and conjugate base formed to find the pH from Equation 17.3.

$$[H_3O^+] = \frac{\text{mol } CH_3CO_2H}{\text{mol } CH_3CO_2^-} \times K_a = \left(\frac{0.00100 \text{ mol}}{0.009000 \text{ mol}}\right)(1.8 \times 10^{-5}) = 2.00 \times 10^{-6} \text{ M}$$

$$\text{pH} = -\log(2.00 \times 10^{-6}) = 5.699 = 5.70$$

The pH is 5.70, in agreement with Figure 17.5. Notice that this pH is appropriate for a point after the halfway point (4.74) but before the equivalence point (8.72; see below).

Part (b): *pH at the Equivalence Point*

To reach the equivalence point, 0.0100 mol of NaOH has been added to 0.0100 mol of CH_3CO_2H and 0.0100 mol of $CH_3CO_2^-$ has been formed.

Equation	CH_3CO_2H	+	OH^-	→	$CH_3CO_2^-$	+	H_2O
Initial (mol)	0.01000		0.01000		0		
Change (mol)	−0.01000		−0.01000		+0.01000		
After rxn (mol)	0		0		0.01000		

Because two solutions, each with a volume of 100.0 mL, have been combined, the concentration of $CH_3CO_2^-$ at the equivalence point is (0.01000 mol/0.200 L) = 0.05000 M. Next, set up an ICE table for the reaction of this weak base with water,

Equation	$CH_3CO_2^-$	+	H_2O	⇌	CH_3CO_2H	+	OH^-
Initial (M)	0.05000				0		0
Change (M)	$-x$				$+x$		$+x$
Equilibrium (M)	$0.05000 - x$				x		x

and calculate the concentration of OH^- ion using K_b for the weak base.

$$K_b \text{ for } CH_3CO_2^- = \frac{K_w}{1.8 \times 10^{-5}} = 5.56 \times 10^{-10} = \frac{[CH_3CO_2H][OH^-]}{[CH_3CO_2^-]} = \frac{(x)(x)}{0.05000 - x}$$

Assume that x is small with respect to 0.05000 M,

$$x = [OH^-] = 5.27 \times 10^{-6} \text{ M and so the pOH} = 5.278$$

$$\text{pH} = 14.00 - 5.278 = 8.72$$

Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Part (c): *pH after the Equivalence Point*

The solution contains excess OH^- ion from the unused NaOH as well as from the hydrolysis of $CH_3CO_2^-$.

Equation	CH_3CO_2H	+	OH^-	→	$CH_3CO_2^-$	+	H_2O
Initial (mol)	0.01000		0.01100		0		
Change (mol)	−0.01000		−0.01000		+0.01000		
After rxn (mol)	0		0.00100		0.01000		

The amount of OH^- produced by $CH_3CO_2^-$ hydrolysis is very small [see part (b)], so the pH of the solution after the equivalence point is determined by the excess NaOH (in 210.0 mL of solution).

$$[OH^-] = 0.00100 \text{ mol}/0.2100 \text{ L} = 4.76 \times 10^{-3} \text{ M} \quad (\text{pOH} = 2.322)$$

$$\text{pH} = 14.00 - 2.322 = 11.68$$

Think about Your Answer The pH at the equivalence point (8.72) indicates the solution is mildly basic, as expected for a solution of the anion of a weak acid. As more NaOH is added past the equivalence point the solution becomes substantially more basic (pH = 11.68).

Check Your Understanding

The titration of 0.100 M acetic acid with 0.100 M NaOH is described in the text. What is the pH of the solution when 35.0 mL of the base has been added to 100.0 mL of 0.100 M acetic acid?

Titration of Weak Polyprotic Acids

The titrations illustrated thus far have been for the reaction of a monoprotic acid (HA) with a base such as NaOH. It is possible to extend the discussion of titrations to polyprotic acids such as oxalic acid, $H_2C_2O_4$.

$$H_2C_2O_4(aq) + H_2O(\ell) \rightleftharpoons HC_2O_4^-(aq) + H_3O^+(aq) \qquad K_{a1} = 5.9 \times 10^{-2}$$

$$HC_2O_4^-(aq) + H_2O(\ell) \rightleftharpoons C_2O_4^{2-}(aq) + H_3O^+(aq) \qquad K_{a2} = 6.4 \times 10^{-5}$$

Figure 17.6 illustrates the curve for the titration of 100 mL of 0.100 M oxalic acid with 0.100 M NaOH. The first significant rise in pH is experienced when 100 mL of base has been added, indicating that the first proton of the acid has been titrated.

$$H_2C_2O_4(aq) + OH^-(aq) \rightleftharpoons HC_2O_4^-(aq) + H_2O(\ell)$$

When the second proton of oxalic acid is titrated, the pH again rises significantly.

$$HC_2O_4^-(aq) + OH^-(aq) \rightleftharpoons C_2O_4^{2-}(aq) + H_2O(\ell)$$

The pH at this second equivalence point is controlled by the oxalate ion, $C_2O_4^{2-}$.

$$C_2O_4^{2-}(aq) + H_2O(\ell) \rightleftharpoons HC_2O_4^-(aq) + OH^-(aq)$$

$$K_{b1} = K_w/K_{a2} = 1.6 \times 10^{-10}$$

Calculation of the pH at the equivalence point indicates that it should be about 8.4, as observed.

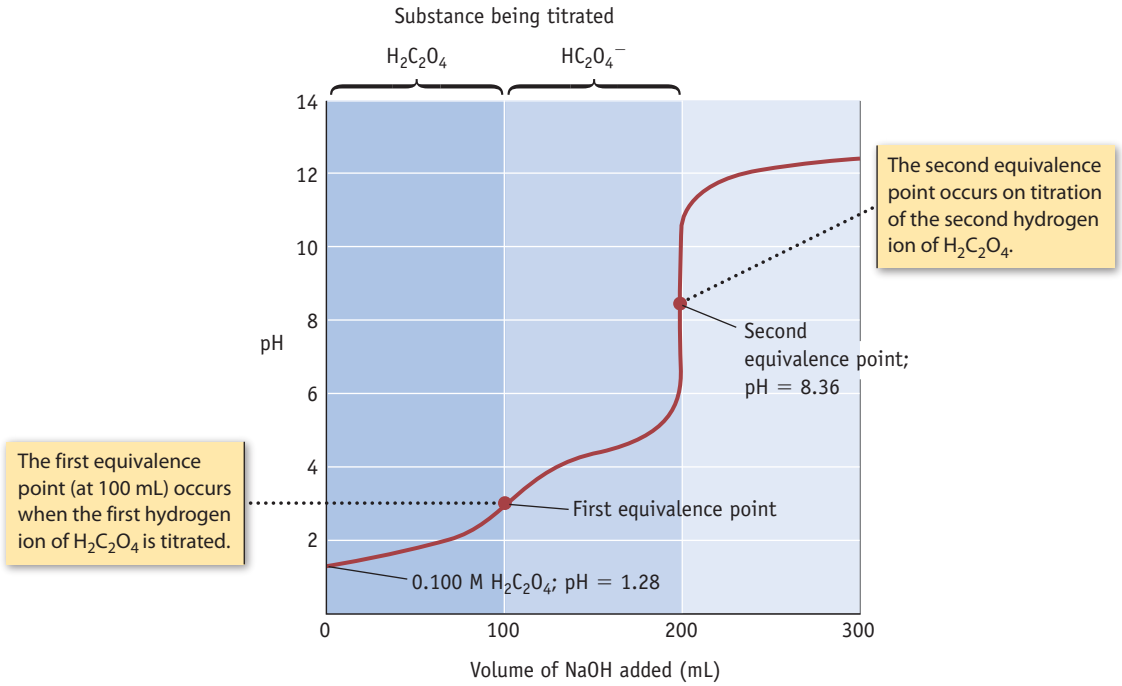

Figure 17.6 Titration curve for a diprotic acid. The curve for the titration of 100.0 mL of 0.100 M oxalic acid ($H_2C_2O_4$, a weak diprotic acid) with 0.100 M NaOH. The curve for pH versus volume of NaOH added shows an initial rise at the first equivalence point and then another rise at the second equivalence point.

Titration of a Weak Base with a Strong Acid

Finally, consider the titration of a weak base with a strong acid. Figure 17.7 illustrates the pH curve for the titration of 100.0 mL of 0.100 M NH_3 with 0.100 M HCl.

$$NH_3(aq) + H_3O^+(aq) \rightleftharpoons NH_4^+(aq) + H_2O(\ell)$$

The initial pH for a 0.100 M NH_3 solution is 11.13. As the titration progresses, the important species in solution are the weak acid NH_4^+ and its conjugate base, NH_3.

$$NH_4^+(aq) + H_2O(\ell) \rightleftharpoons NH_3(aq) + H_3O^+(aq) \qquad K_a = 5.6 \times 10^{-10}$$

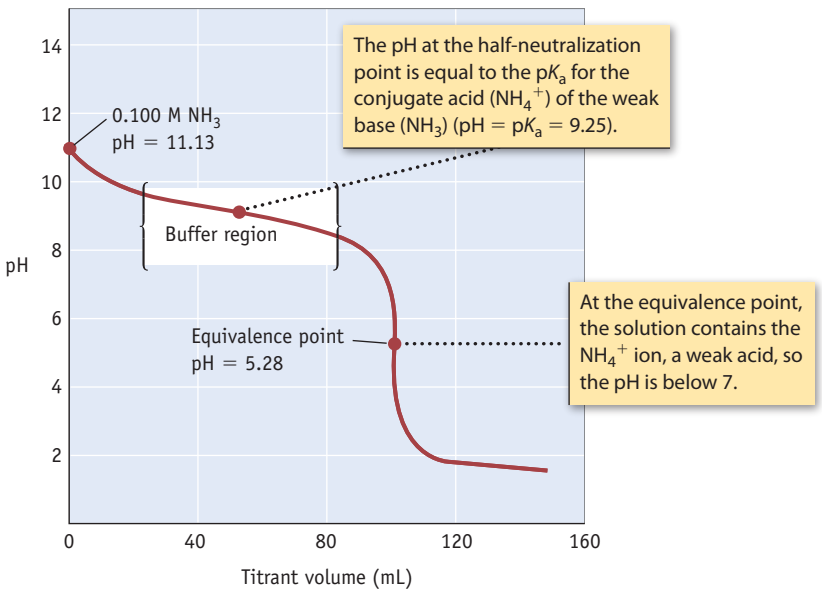

Figure 17.7 Titration of a weak base with a strong acid. The change in pH during the titration of a weak base (100.0 mL of 0.100 M NH_3) with a strong acid (0.100 M HCl).

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

At the halfway point, the concentrations of NH_4^+ and NH_3 are the same, so

$$[H_3O^+] = \frac{[NH_4^+]}{[NH_3]} \times K_a = 5.6 \times 10^{-10}$$

$$[H_3O^+] = K_a$$

$$pH = pK_a = -\log(5.6 \times 10^{-10}) = 9.25$$

As the addition of HCl to NH_3 continues, the pH declines slowly because of the buffering action of the NH_3/NH_4^+ combination. Near the equivalence point, however, the pH drops rapidly. At the equivalence point, the solution contains only ammonium chloride, a weak Brønsted acid, and the solution is weakly acidic.

EXAMPLE 17.7

Titration of Ammonia with HCl

Problem What is the pH of the solution at the equivalence point in the titration of 100.0 mL of 0.100 M ammonia with 0.100 M HCl (Figure 17.7)?

What Do You Know? This problem resembles part (b) of Example 17.6, although here you are titrating a weak base with a strong acid. In both examples you know the quantities of reagents and want to know the pH at the equivalence point. Here you need to know the K_a value for NH_4^+, the conjugate acid of the weak base, NH_3.

Strategy As in Example 17.6, this problem has two steps: (a) a stoichiometry calculation to find the concentration of NH_4^+ at the equivalence point, and (b) an equilibrium calculation to find $[H_3O^+]$ for a solution of the weak acid NH_4^+.

SOLUTION

Part 1: *Stoichiometry Problem*

Here, you are titrating 0.01000 mol of NH_3 ($= c \times V$), so 0.01000 mol of HCl is required. Thus, 100.0 mL of 0.100 M HCl (= 0.01000 mol HCl) must be used in the titration, and the solution volume at the equivalence point is 200.0 mL.

Equation	NH_3	+	H_3O^+	→	NH_4^+	+	H_2O
Initial (mol)	0.01000		0.01000		0		
Change on rxn (mol)	−0.01000		−0.01000		+0.01000		
After rxn (mol)	0		0		0.01000		
Concentration (M)	0		0		0.01000 mol/0.200L = 0.05000 M		

Part 2: *Equilibrium Problem*

When the equivalence point is reached, the solution consists of 0.0500 M NH_4^+. The pH is determined by the hydrolysis of this weak acid.

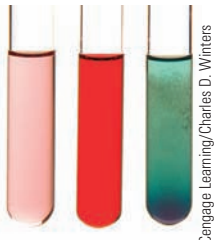
Equation	NH_4^+	+	H_2O	⇌	NH_3	+	H_3O^+
Initial (M)	0.05000				0		0
Change (M)	$-x$				$+x$		$+x$
Equilibrium (M)	$0.05000 - x$				x		x

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Using K_a for the weak acid NH_4^+, you have

$$K_a = 5.6 \times 10^{-10} = \frac{[NH_3][H_3O^+]}{[NH_4^+]} = \frac{x^2}{0.05000 - x}$$



$$\text{Simplifying, } x = [H_3O^+] = \sqrt{(5.6 \times 10^{-10})(0.05000)} = 5.29 \times 10^{-6}\ \text{M}$$

$$\text{pH} = 5.28$$

Think about Your Answer The pH at the equivalence point (5.28) indicates the solution is mildly acidic, as expected for a solution of the conjugate acid of a weak base.

Check Your Understanding

Calculate the pH after 75.0 mL of 0.100 M HCl has been added to 100.0 mL of 0.100 M NH_3 (Figure 17.7).

© Cengage Learning/Charles D. Winters

(a) (b) (c)

Figure 17.8 Roses are a natural indicator. (a) The pigment in rose petals, extracted with ethanol, is a faint red. (b) After adding one drop of 6 M HCl, the color changed to a vivid red. (c) Adding two drops of 6 M NH_3 produced a green color.

pH Indicators

Many organic compounds, both natural and synthetic, have a color that changes with pH (Figures 17.8 and 17.9). Not only does this add beauty and variety to our world, but it is also a useful property in chemistry.

You may have done an acid–base titration in the laboratory, and, before starting the titration, you added an **indicator**. The acid–base indicator is usually an organic compound that is itself a weak acid or weak base. In aqueous solution, the acid form is in equilibrium with its conjugate base. Abbreviating the indicator's acid formula as HInd and the formula of its conjugate base as Ind^-, you can write the equilibrium equation

$$HInd(aq) + H_2O(\ell) \rightleftharpoons H_3O^+(aq) + Ind^-(aq)$$

The important characteristic of acid–base indicators is that the acid form of the compound (HInd) has one color and the conjugate base (Ind^-) has another. To see how such compounds can be used as equivalence point indicators, let us write the equilibrium constant expressions for the dependence of hydronium ion concentration or pH on

Problem Solving Tip 17.2 Calculating the pH at Various Stages in an Acid–Base Titration

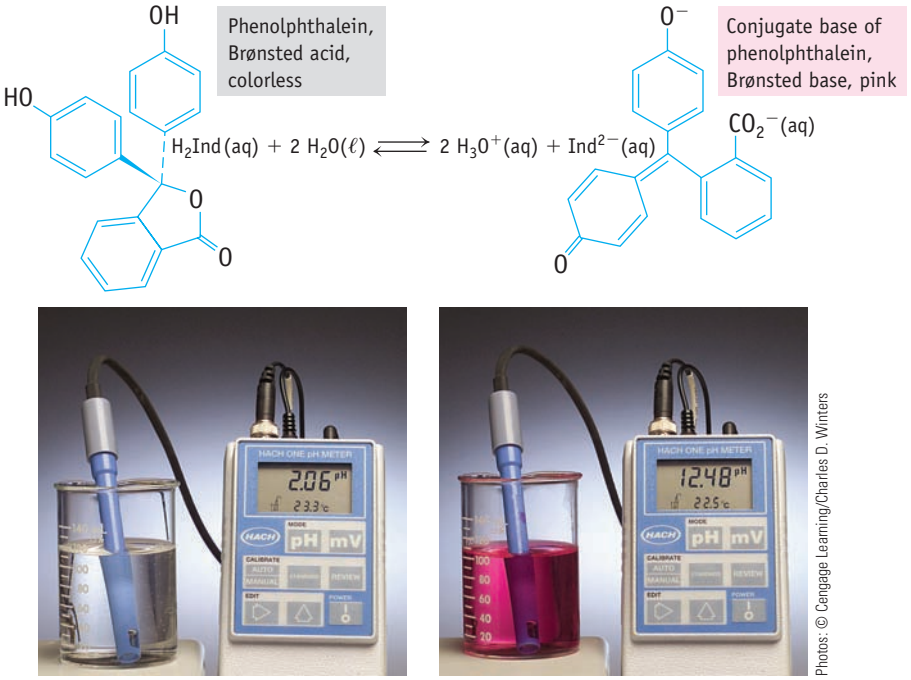
Finding the pH at or before the equivalence point for an acid–base reaction always involves several calculation steps. There are no shortcuts. Consider the *titration of a weak base, B, with a strong acid* as in Example 17.7. (The same principles apply to other acid–base reactions.)

$$H_3O^+(aq) + B(aq) \rightleftharpoons BH^+(aq) + H_2O(\ell)$$

A: Determining the pH before the equivalence point.

Step 1. *Solve the stoichiometry problem.* Up to the equivalence point, acid is consumed completely to leave a solution containing some base (B) and its conjugate acid (BH^+). Use the principles of stoichiometry to calculate (a) the amount of acid added, (b) the amount of base remaining, and (c) the amount of conjugate acid (BH^+) formed.

Step 2. Calculate the concentrations of B and BH^+. Recognize that the volume of the solution at any point is the sum of the original volume of base solution plus the volume of acid solution added.



Step 3. *Calculate the pH.* At any point before the equivalence point, the solution is a buffer solution because both B and BH^+ are present. Calculate $[H_3O^+]$ using the concentrations of Step 2 and the value of K_a for the conjugate acid of the weak base.

B: Determining the pH at the equivalence point.

Calculate the concentration of the conjugate acid using the procedure of Part A. Use the value of K_a for the conjugate acid of the weak base and the procedure outlined in Example 17.7. (For a titration of a weak acid with a strong base, use the value of K_b for the conjugate base of the acid and follow the procedure outlined in Example 17.6.)

Photos: © Cengage Learning/Charles D. Winters

Figure 17.9 Phenolphthalein, a common acid–base indicator. Phenolphthalein, a weak acid, is colorless. As the pH increases, the pink conjugate base form predominates, and the color of the solution changes. The change in color is most noticeable around pH 9. The dye is commonly used for strong acid + strong base or weak acid + strong base titrations because the pH changes from about 3 to about 10 in these cases. For other suitable indicator dyes, see Figure 17.11.

the indicator's ionization constant (K_a) and on the relative quantities of the acid and conjugate base.

$$[H_3O^+] = \frac{[HInd]}{[Ind^-]} \times K_a \quad \text{or} \quad pH = pK_a + \log \frac{[Ind^-]}{[HInd]}$$

These equations inform us that

- when the hydronium ion concentration is equivalent to the value of K_a (or when pH = pK_a), then [HInd] = [Ind^-]
- when [H_3O^+] > K_a (or pH < pK_a), then [HInd] > [Ind^-]
- when [H_3O^+] < K_a (or pH > pK_a), then [HInd] < [Ind^-]

Now apply these conclusions to, for example, the titration of an acid with a base using an indicator whose pK_a value is nearly the same as the pH at the equivalence point (Figure 17.10). At the beginning of the titration, the pH is low and [H_3O^+] is high; the acid form of the indicator (HInd) predominates, so its color is the one observed. As the titration progresses and the pH increases ([H_3O^+] decreases), less of the acid HInd and more of its conjugate base exist in solution. Finally, just after the equivalence point is reached, [Ind^-] is much larger than [HInd], and the color of [Ind^-] is observed.

Several questions remain to be answered. If you are trying to analyze for an acid and add an indicator that is a weak acid, won't this affect the analysis? Recall that you use only a tiny amount of an indicator in a titration. Although the acidic indicator molecules also react with the base as the titration progresses, so little indicator is present that any error is not significant.

Another question is whether you could accurately determine the pH by observing the color change of an indicator. In practice, your eyes are not quite that good. Assume, qualitatively, that you see the color of HInd when [HInd]/[Ind^-] is about 10/1, and the color of Ind^- when [HInd]/[Ind^-] is about 1/10. This means the color change is observed over a hydronium ion concentration interval of about 2 pH units. However, as you can see in Figures 17.4–17.7, on passing through the equivalence point of these titrations, the pH changes by as many as 7 units.

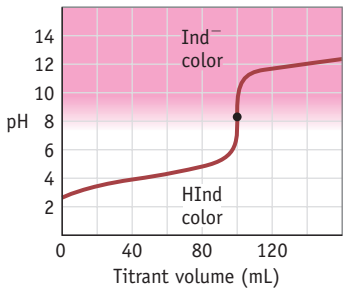

Figure 17.10 Indicator color changes in the course of a titration when the pK_a of the indicator HInd is about 8.

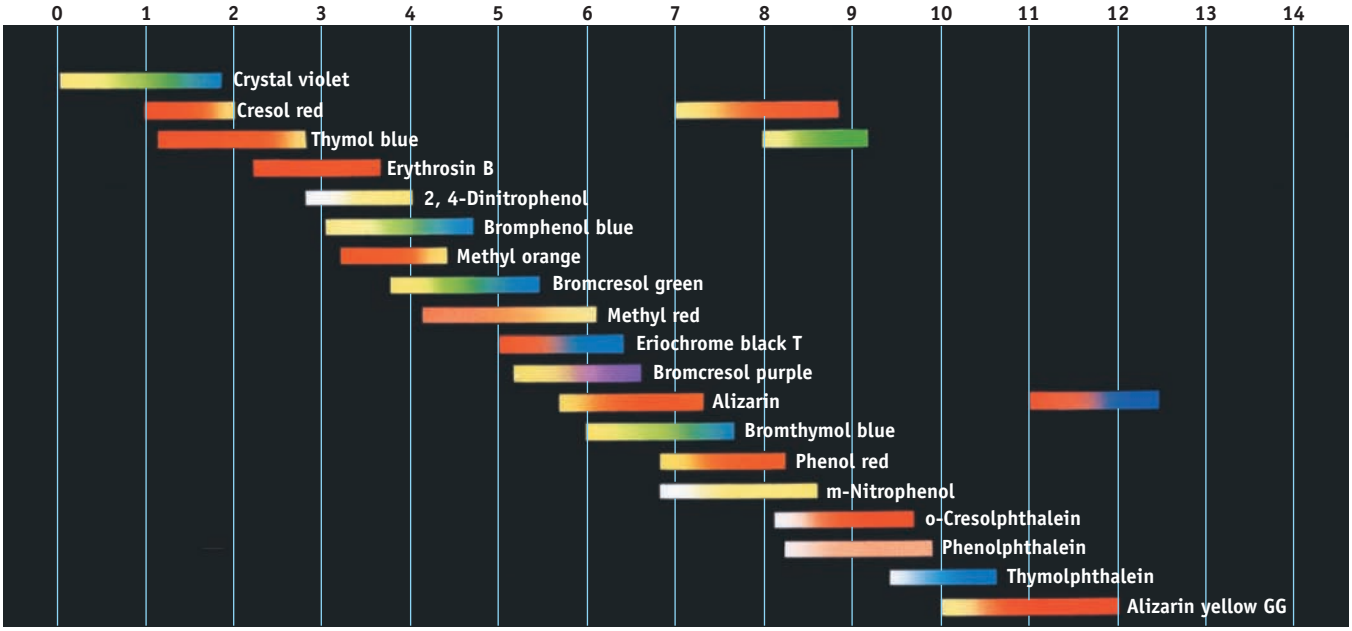

Figure 17.11 Common acid–base indicators. The color changes occur over a range of pH values. Notice that a few indicators have color changes over two different pH ranges.

As Figure 17.11 shows, a variety of indicators is available, each changing color in a different pH range. If you are analyzing an acid or base by titration, you must choose an indicator that changes color in a range that includes the pH to be observed at the equivalence point. For the titration of a strong acid with a strong base, an indicator that changes color in the pH range 7 ± 2 should be used. On the other hand, the pH at the equivalence point in the titration of a weak acid with a strong base is greater than 7, and you should choose an indicator that changes color at a pH near the anticipated equivalence point.

17.4 Solubility of Salts

Goals for Section 17.4

- Write the equilibrium constant expression relating concentrations of ions in solution to K_{sp} for any insoluble salt.
- Calculate the K_{sp} value for a salt from its solubility and calculate the solubility of a salt from its K_{sp}.
- Recognize how the presence of a common ion affects the solubility of a salt.
- Understand how hydrolysis of basic anions affects the solubility of a salt.
- Recognize that salts with anions derived from weak acids have increased solubility in acidic solutions.

Precipitation reactions (Section 3.5) are exchange reactions in which one of the products is a water-insoluble compound such as $CaCO_3$,

$$CaCl_2(aq) + Na_2CO_3(aq) \rightarrow CaCO_3(s) + 2\ NaCl(aq)$$

that is, a compound having a water solubility of less than about 0.01 mol of dissolved material per liter of solution (Figure 17.12).

How do you know when to predict an insoluble compound as the product of a reaction? In Chapter 3, some guidelines are listed for predicting solubility

Figure 17.12 **Some insoluble substances.**

(Figure 3.10). Now we want to make our estimates of solubility more quantitative and to explore conditions under which some compounds precipitate and others do not.

The Solubility Product Constant, K_{sp}

If some AgBr is placed in pure water, a tiny amount of the compound dissolves, and an equilibrium is established.

$$AgBr(s) \rightleftharpoons Ag^+(aq,\ 7.35 \times 10^{-7}\ M) + Br^-(aq,\ 7.35 \times 10^{-7}\ M)$$

When sufficient AgBr has dissolved and equilibrium is attained, the solution is said to be **saturated** (Section 13.2), and experiments show that the concentrations of the silver and bromide ions in the solution are each about 7.35×10^{-7} M at 25 °C. The extent to which an insoluble salt dissolves can be expressed in terms of the equilibrium constant for the dissolving process. In this case, the appropriate expression is

$$K_{sp} = [Ag^+][Br^-]$$

The equilibrium constant that reflects the solubility of a compound is referred to as its **solubility product constant**. Chemists frequently use the notation K_{sp} for such constants, the subscript "sp" denoting a "solubility product."

Writing Equilibrium Constant Expressions Solids are not included in these equations.

The water solubility of a compound, and thus its K_{sp} value, can be estimated by determining the concentration of the cation or anion when the compound dissolves. For example, if you find that AgBr dissolves to give a silver ion concentration of 7.35×10^{-7} mol/L, you know that 7.35×10^{-7} mol of AgBr must have dissolved per liter of solution (and that the bromide ion concentration also equals 7.35×10^{-7} M). Therefore, the value of the equilibrium constant for AgBr is

$$K_{sp} = [Ag^+][Br^-] = (7.35 \times 10^{-7})(7.35 \times 10^{-7}) = 5.40 \times 10^{-13}\ \text{(at 25 °C)}$$

Equilibrium constants for dissolving other insoluble salts can be calculated in the same manner.

The solubility product constant, K_{sp}, for any salt always has the form

$$A_xB_y(s) \rightleftharpoons x\ A^{y+}(aq) + y\ B^{x-}(aq) \qquad K_{sp} = [A^{y+}]^x[B^{x-}]^y \qquad (17.6)$$

For example,

$$CaF_2(s) \rightleftharpoons Ca^{2+}(aq) + 2\ F^-(aq) \qquad K_{sp} = [Ca^{2+}][F^-]^2 = 5.3 \times 10^{-11}$$

$$Ag_2SO_4(s) \rightleftharpoons 2\ Ag^+(aq) + SO_4^{2-}(aq) \qquad K_{sp} = [Ag^+]^2[SO_4^{2-}] = 1.2 \times 10^{-5}$$

The numerical values of K_{sp} for a few salts are given in Table 17.2, and more values are collected in Appendix J.

TABLE 17.2 Some Common Insoluble Compounds and Their K_{sp} Values*

Formula	Name	K_{sp} (25 °C)	Common Names/Uses
$CaCO_3$	Calcium carbonate	3.4×10^{-9}	Calcite, iceland spar
$MnCO_3$	Manganese(II) carbonate	2.3×10^{-11}	Rhodochrosite (forms rose-colored crystals)
$FeCO_3$	Iron(II) carbonate	3.1×10^{-11}	Siderite
CaF_2	Calcium fluoride	5.3×10^{-11}	Fluorite (source of HF and other inorganic fluorides)
AgCl	Silver chloride	1.8×10^{-10}	Chlorargyrite
AgBr	Silver bromide	5.4×10^{-13}	Used in photographic film
$CaSO_4$	Calcium sulfate	4.9×10^{-5}	Hydrated form is commonly called *gypsum*
$BaSO_4$	Barium sulfate	1.1×10^{-10}	Barite (used in "drilling mud" and as a component of paints)
$SrSO_4$	Strontium sulfate	3.4×10^{-7}	Celestite
$Ca(OH)_2$	Calcium hydroxide	5.5×10^{-5}	Slaked lime

*The values in this table were taken from *Lange's Handbook of Chemistry,* 15th edition, McGraw-Hill Publishers, New York, NY (1999). Additional K_{sp} values are given in Appendix J.

Do not confuse the *solubility* of a compound with its *solubility product constant.* The *solubility* of a salt is the quantity or amount present in some volume of a saturated solution, expressed in grams per 100 mL, moles per liter, or other units. The *solubility product constant* is an equilibrium constant. However, there is a connection between them: If one is known, the other can, in principle, be calculated.

Relating Solubility and K_{sp}

Solubility product constants are determined by careful laboratory measurements of the concentrations of ions in solution.

EXAMPLE 17.8

K_{sp} from Solubility Measurements

Problem Calcium fluoride, the main component of the mineral fluorite, dissolves to a slight extent in water.

$$CaF_2(s) \rightleftharpoons Ca^{2+}(aq) + 2\ F^-(aq) \qquad K_{sp} = [Ca^{2+}][F^-]^2$$

Calculate the K_{sp} value for CaF_2 if the calcium ion concentration has been found to be 2.3×10^{-4} mol/L.

What Do You Know? You know the balanced equation for the process, the Ca^{2+} concentration, and the K_{sp} expression.

Strategy

- Calculate the fluoride ion concentration from $[Ca^{2+}]$ and stoichiometry.
- Insert the values for $[F^-]$ and $[Ca^{2+}]$ into the K_{sp} expression and calculate the value of K_{sp}.

Strategy Map 17.8

PROBLEM
Calculate K_{sp} of CaF_2 from its **solubility.**

↓

DATA/INFORMATION KNOWN
- Concentration of Ca^{2+}
- Form of K_{sp}
- Balanced equation

↓

STEP 1. Calculate F^- **concentration.**

$[F^-] = 2 \times [Ca^{2+}]$

↓

STEP 2. Enter **equilibrium concentrations** in K_{sp} expression and calculate K_{sp}.

Value of K_{sp}

SOLUTION When CaF_2 dissolves in water, the balanced equation shows that the concentration of F^- ion must be twice the Ca^{2+} ion concentration.

$$\text{If } [Ca^{2+}] = 2.3 \times 10^{-4}\ \text{M, then } [F^-] = 2 \times [Ca^{2+}] = 4.6 \times 10^{-4}\ \text{M}$$

This means the solubility product constant is

$$K_{sp} = [Ca^{2+}][F^-]^2 = (2.3 \times 10^{-4})(4.6 \times 10^{-4})^2 = 4.9 \times 10^{-11}$$

Think about Your Answer A common student error is to forget the reaction stoichiometry. Be sure to notice that for every Ca^{2+} ion in solution there are two F^- ions.

Check Your Understanding

The barium ion concentration, $[Ba^{2+}]$, in a saturated solution of barium fluoride is 3.6×10^{-3} M. Calculate the value of the K_{sp} for BaF_2.

$$BaF_2(s) \rightleftharpoons Ba^{2+}(aq) + 2\ F^-(aq)$$

K_{sp} values for insoluble salts can be used to calculate the solubility of a solid salt or to determine whether a solid will precipitate when solutions of its anion and cation are mixed. Let us first look at an example of the calculation of the solubility of a salt from its K_{sp} value.

EXAMPLE 17.9

Solubility from K_{sp}

Problem The K_{sp} for the mineral barite ($BaSO_4$, Figure 17.13) is 1.1×10^{-10} at 25 °C. Calculate the solubility of barium sulfate in water in (a) moles per liter and (b) grams per liter.

What Do You Know? You know the formula for the mineral and its K_{sp} value.

Strategy When $BaSO_4$ dissolves, equimolar amounts of Ba^{2+} ions and SO_4^{2-} ions are produced. Thus, the solubility of $BaSO_4$ can be estimated by calculating the equilibrium concentration of either Ba^{2+} or SO_4^{2-} from the solubility product constant.

- Write the balanced equation and the K_{sp} expression.
- Set up an ICE table, designating the unknown concentrations of Ba^{2+} and SO_4^{2-} in solution as x.
- Using x for $[Ba^{2+}]$ and $[SO_4^{2-}]$ in the K_{sp} expression, solve for x.

SOLUTION The equation for the solubility of $BaSO_4$ and its K_{sp} expression are

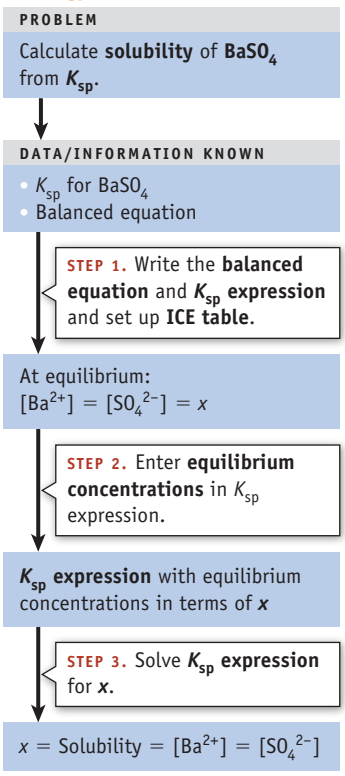
$$BaSO_4(s) \rightleftharpoons Ba^{2+}(aq) + SO_4^{2-}(aq) \qquad K_{sp} = [Ba^{2+}][SO_4^{2-}] = 1.1 \times 10^{-10}$$

Denote the solubility of $BaSO_4$ (in mol/L) by x; that is, x moles of $BaSO_4$ dissolve per liter. Therefore, both $[Ba^{2+}]$ and $[SO_4^{2-}]$ must also equal x at equilibrium.

Equation	$BaSO_4(s)$	$\rightleftharpoons$	$Ba^{2+}(aq)$	+	$SO_4^{2-}(aq)$
Initial (M)			0		0
Change (M)			$+x$		$+x$
Equilibrium (M)			x		x

Because K_{sp} is the product of the barium ion and sulfate ion concentrations, K_{sp} is the square of the solubility, x,

$$K_{sp} = [Ba^{2+}][SO_4^{2-}] = 1.1 \times 10^{-10} = (x)(x) = x^2$$



and so the value of x is

$$x = [Ba^{2+}] = [SO_4^{2-}] = \sqrt{K_{sp}} = \sqrt{1.1 \times 10^{-10}} = 1.05 \times 10^{-5}\ \text{M} = 1.0 \times 10^{-5}\ \text{M}$$

The solubility of $BaSO_4$ in pure water is 1.0×10^{-5} mol/L. To find its solubility in g/L, you only need to multiply by the molar mass of $BaSO_4$.

$$\text{Solubility in g/L} = (1.05 \times 10^{-5}\ \text{mol/L})(233\ \text{g/mol}) = 0.0024\ \text{g/L}$$

Strategy Map 17.9

(a) A sample of the mineral barite, which is mostly barium sulfate. "Drilling mud," used in drilling oil wells, consists of clay, barite, and calcium carbonate.

© Cengage Learning/Charles D. Winters

(b) Barium sulfate is opaque to x-rays, so it is used by physicians to examine the digestive tract. A patient drinks a "cocktail" containing $BaSO_4$, and the progress of the $BaSO_4$ through the digestive organs can be followed by x-ray analysis. This photo is an x-ray of the gastrointestinal tract after a person ingested barium sulfate.

CNRI/Science Source

Figure 17.13 Barium sulfate. Barium sulfate, a white solid, is quite insoluble in water ($K_{sp} = 1.1 \times 10^{-10}$) (Example 17.9).

Think about Your Answer As noted in Figure 17.13, $BaSO_4$ is used to investigate the digestive tract. It is fortunate the compound is so insoluble, because water- and acid-soluble barium salts are toxic.

Check Your Understanding

Calculate the solubility of AgCN in moles per liter and grams per liter. K_{sp} for AgCN is 6.0×10^{-17}.

EXAMPLE 17.10

Solubility from K_{sp}

Problem Knowing that the K_{sp} value for MgF_2 is 5.2×10^{-11}, calculate the solubility of the salt in (a) moles per liter and (b) grams per liter.

What Do You Know? You know the formula for magnesium fluoride and its K_{sp} value.

Strategy The solubility must be defined in terms that will allow you to solve the K_{sp} expression for the concentration of one ion. From stoichiometry, you can say that if x mol of MgF_2 dissolves, then x mol of Mg^{2+} and $2x$ mol of F^- appear in solution. This means the MgF_2 solubility (in moles dissolved per liter) is equivalent to the concentration of Mg^{2+} ions in the solution.

- Write the balanced equation and the K_{sp} expression.
- Set up an ICE table, designating the unknown concentrations of Mg^{2+} and F^- in solution as x and $2x$, respectively.
- Using x for $[Mg^{2+}]$ and $2x$ for $[F^-]$ in the K_{sp} expression, solve for x.

SOLUTION

$$MgF_2(s) \rightleftharpoons Mg^{2+}(aq) + 2\ F^-(aq) \qquad K_{sp} = [Mg^{2+}][F^-]^2 = 5.2 \times 10^{-11}$$

Equation	$MgF_2(s)$	$\rightleftharpoons$	$Mg^{2+}(aq)$	+	$2\ F^-(aq)$
Initial (M)			0		0
Change (M)			$+x$		$+2x$
Equilibrium (M)			x		$2x$

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Substituting the equilibrium concentrations for $[Mg^{2+}]$ and $[F^-]$ into the K_{sp} expression, you find

$$K_{sp} = [Mg^{2+}][F^-]^2 = (x)(2x)^2 = 4x^3$$

Solving the equation for x,

$$x = \sqrt[3]{\frac{K_{sp}}{4}} = \sqrt[3]{\frac{5.2 \times 10^{-11}}{4}} = 2.35 \times 10^{-4} = 2.4 \times 10^{-4}$$

you find that 2.4×10^{-4} moles of MgF_2 dissolve per liter. The solubility of MgF_2 in grams per liter is

$$(2.35 \times 10^{-4} \text{ mol/L})(62.3 \text{ g/mol}) = 0.015 \text{ g } MgF_2/L$$

Think about Your Answer Problems like this one might provoke our students to ask the question, "Aren't you counting things twice when you multiply x by 2 and then square it as well?" in the expression $K_{sp} = (x)(2x)^2$. The answer is no. The 2 in the $2x$ term is based on the stoichiometry of the compound. The exponent of 2 on the F^- ion concentration arises from the rules for writing equilibrium expressions.

Check Your Understanding

Calculate the solubility of $Ca(OH)_2$ in moles per liter and grams per liter ($K_{sp} = 5.5 \times 10^{-5}$).

The *relative* solubilities of salts can often be deduced by comparing values of solubility product constants, but you must be careful! For example, the K_{sp} value for silver chloride is

$$AgCl(s) \rightleftharpoons Ag^+(aq) + Cl^-(aq) \qquad K_{sp} = 1.8 \times 10^{-10}$$

whereas that for silver chromate is

$$Ag_2CrO_4(s) \rightleftharpoons 2\ Ag^+(aq) + CrO_4^{2-}(aq) \qquad K_{sp} = 9.0 \times 10^{-12}$$

In spite of the fact that Ag_2CrO_4 has a smaller numerical K_{sp} value than AgCl, the chromate salt is about 10 times *more* soluble than the chloride salt. If you determine

A CLOSER LOOK

Minerals and Gems—The Importance of Solubility

Minerals and gems are among nature's most beautiful creations. Many, such as rubies, are metal oxides, and the various types of quartz are based on silicon dioxide. Another large class of gemstones consists largely of metal silicates. These include emerald, topaz, aquamarine, and tourmaline.

Carbonates represent another large class of minerals and a few gemstones. Rhodochrosite, one of the most beautiful red stones, is manganese(II) carbonate. And one of the most abundant minerals on Earth is limestone, calcium carbonate, which is also a major component of sea shells and corals.

Hydroxides are represented by azurite, which is a mixed carbonate/hydroxide with the formula $Cu_3(OH)_2(CO_3)_2$. Turquoise is a mixed hydroxide/phosphate based on copper(II), the source of the blue color of turquoise.

Among the most common minerals are sulfides such as golden iron pyrite (FeS_2), black stibnite (Sb_2S_3), red cinnabar (HgS), and yellow orpiment (As_2S_3).

Other smaller classes of minerals exist; one of the smallest is the class based on the halides, and the best example is fluorite. Fluorite, CaF_2, exhibits a wide range of colors from purple to green to yellow.

What do all of these minerals and gems have in common? They are all insoluble or poorly soluble in water. If they were more soluble, they would be dissolved in the world's lakes and oceans.

© Cengage Learning/Charles D. Winters

Mineral samples (clockwise from the top center): red rhodochrosite, yellow orpiment, golden iron pyrite, green-blue turquoise, black stibnite, purple fluorite, and blue azurite. Formulas are in the text (see also Figure 17.12).

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

solubilities from K_{sp} values as in the examples above, you would find the solubility of AgCl is 1.3×10^{-5} mol/L, whereas that of Ag_2CrO_4 is 1.3×10^{-4} mol/L. From this we draw the following conclusion:

> Direct comparisons of the solubility of two salts on the basis of their K_{sp} values can be made only for salts having the same cation-to-anion ratio.

This means, for example, that you can directly compare solubilities of 1:1 salts such as the silver halides by comparing their K_{sp} values.

$$\underset{\longrightarrow \text{ increasing } K_{sp} \text{ and increasing solubility}}{\text{AgI } (K_{sp} = 8.5 \times 10^{-17}) < \text{AgBr } (K_{sp} = 5.4 \times 10^{-13}) < \text{AgCl } (K_{sp} = 1.8 \times 10^{-10})}$$

Similarly, you could compare 1:2 salts such as the lead halides,

$$\underset{\longrightarrow \text{ increasing } K_{sp} \text{ and increasing solubility}}{\text{PbI}_2 \, (K_{sp} = 9.8 \times 10^{-9}) < \text{PbBr}_2 \, (K_{sp} = 6.6 \times 10^{-6}) < \text{PbCl}_2 \, (K_{sp} = 1.7 \times 10^{-5})}$$

but you cannot directly compare the solubility of a 1:1 salt (AgCl) with a 2:1 salt (Ag_2CrO_4) by only comparing the K_{sp} values.

Solubility and the Common Ion Effect

The test tube on the left in Figure 17.14 contains a precipitate of silver acetate, $AgCH_3CO_2$, in water. The solution is saturated, and the silver ions and acetate ions in the solution are in equilibrium with solid silver acetate.

$$AgCH_3CO_2(s) \rightleftharpoons Ag^+(aq) + CH_3CO_2^-(aq)$$

But what would happen if the silver ion concentration is increased, say by adding silver nitrate? Le Chatelier's principle (Section 15.6) suggests—and observations confirm—that more silver acetate precipitate should form because silver ion has been added, causing the equilibrium to shift to form more silver acetate. The effect of adding silver ions to a saturated silver acetate solution is another example of the common ion effect. Adding a common ion to a saturated solution of a salt will lower the salt solubility (unless a complex ion can form; *A Closer Look*: *Solubility Calculations*).

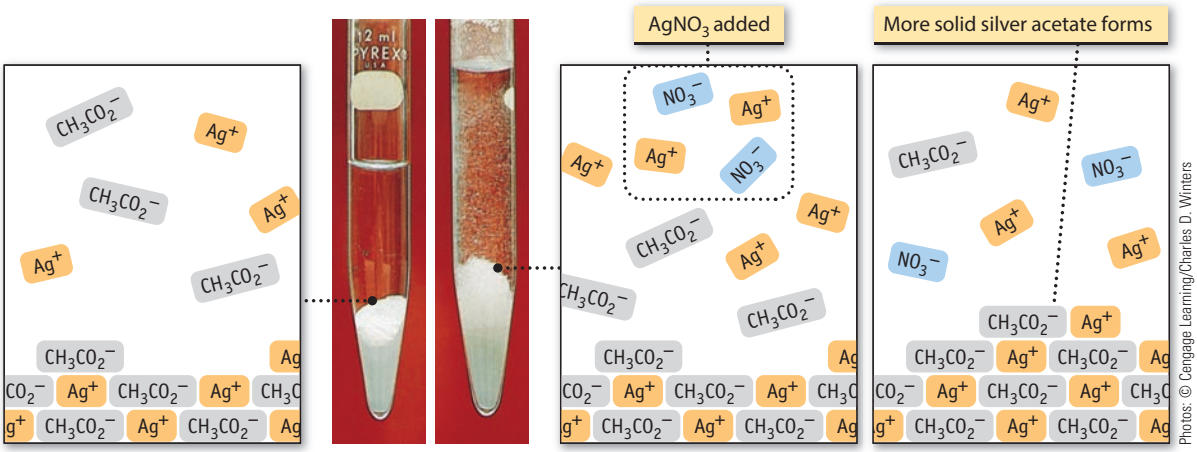

Figure 17.14 The common ion effect. The tube at the *left* contains a saturated solution of silver acetate, $AgCH_3CO_2$. When 1.0 M $AgNO_3$ is added to the tube *(right)*, more solid silver acetate forms.

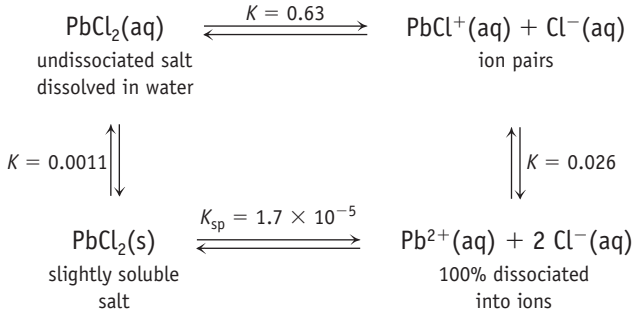
A CLOSER LOOK

Solubility Calculations

The K_{sp} value reported for lead(II) chloride, $PbCl_2$, is 1.7×10^{-5}. If we assume the appropriate equilibrium in solution is

$$PbCl_2(s) \rightleftharpoons Pb^{2+}(aq) + 2\ Cl^-(aq)$$



the calculated solubility of $PbCl_2$ is 0.016 M. The experimental value for the solubility of the salt, however, is 0.036 M, more than twice the calculated value! The problem is that the chemical behavior is often much more complicated than the equation defining K_{sp}.

The main problem in the lead(II) chloride case, and in many others, is that the compound dissolves but is not 100% dissociated into its constituent ions. Instead, it dissolves as the undissociated salt or forms ion pairs.

Other problems that lead to discrepancies between calculated and experimental solubilities are the reactions of ions (particularly anions) with water and complex ion formation. Complex ion formation is illustrated by the fact that lead chloride is more soluble in the presence of excess chloride ion, owing to the formation of the complex ion $PbCl_4^{2-}$.

$$PbCl_2(s) + 2\ Cl^-(aq) \rightleftharpoons PbCl_4^{2-}(aq)$$

Hydrolysis and complex ion formation are described in more detail later (page 791).

EXAMPLE 17.11

The Common Ion Effect and Salt Solubility

Problem If solid AgCl is placed in 1.00 L of 0.55 M NaCl, what mass of AgCl will dissolve?

What Do You Know? You know the formula of the insoluble compound, its K_{sp} (Table 17.2 and Appendix J), and its molar mass. You also know that the presence of an ion common to the equilibrium (Cl^-) suppresses the solubility of AgCl.

Strategy To determine the solubility of AgCl in the presence of excess Cl^-, calculate the concentration of the Ag^+ ion.

- Write the balanced equation and the K_{sp} expression for AgCl.
- Set up an ICE table, and enter 0.55 M as the initial concentration of the common ion, Cl^-.
- Define the solubility of AgCl as x. This is the increase in the concentration of Ag^+ and Cl^- in solution as AgCl dissolves. Enter this information on the change (C) line in the ICE table.
- Fill in the last line (E) of the ICE table with x for $[Ag^+]$ and $(0.55 + x)$ for $[Cl^-]$. Solve the K_{sp} expression for x.

SOLUTION Set up an ICE table to show the concentrations of Ag^+ and Cl^- when equilibrium is attained.

Equation	AgCl(s)	⇌	$Ag^+(aq)$	+	$Cl^-(aq)$
Initial (M)			0		0.55
Change (M)			$+x$		$+x$
Equilibrium (M)			x		$0.55 + x$

Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

The equilibrium concentrations from the table are substituted into the K_{sp} expression,

$$K_{sp} = 1.8 \times 10^{-10} = [Ag^+][Cl^-] = (x)(0.55 + x)$$

This is a quadratic equation and can be solved by the methods in Appendix A. An easier approach, however, is to make the approximation that x is very small with respect to 0.55 [and so $(0.55 + x) \approx 0.55$]. This is a reasonable assumption because you know that the solubility is very small without the common ion Cl^- and that it will be even smaller in the presence of added Cl^-. Therefore,

$$K_{sp} = 1.8 \times 10^{-10} = (x)(0.55)$$

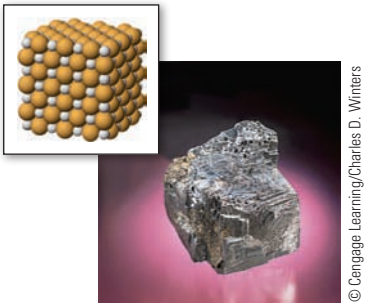
$$x = [Ag^+] = 3.27 \times 10^{-10}\ M$$

The solubility in grams per liter is then

$$(3.27 \times 10^{-10}\ mol/L)(143\ g/mol) = 4.7 \times 10^{-8}\ g/L$$

As predicted by Le Chatelier's principle, the solubility of AgCl in the presence of added Cl^- is much less (3.3×10^{-10} M) than in pure water (1.3×10^{-5} M).

Think about Your Answer The approximation you made here is similar to the approximations you make in acid–base equilibrium problems. As a final step, you should check its validity by substituting the calculated value of x into the exact expression $K_{sp} = (x)(0.55 + x)$. If the product $(x)(0.55 + x)$ is the same as the given value of K_{sp}, the approximation is valid.



$$K_{sp} = (x)(0.55 + x) = (3.3 \times 10^{-10})(0.55 + 3.3 \times 10^{-10}) = 1.8 \times 10^{-10}$$

Check Your Understanding

Calculate the solubility of $BaSO_4$ (a) in pure water and (b) in the presence of 0.010 M $Ba(NO_3)_2$. K_{sp} for $BaSO_4$ is 1.1×10^{-10}.

There are two important general ideas from Example 17.11:

- The solubility of a salt will be reduced by the presence of a common ion, in accordance with Le Chatelier's principle.
- We made the approximation that the amount of common ion added to the solution was very large in comparison with the amount of that ion coming from the insoluble salt, and this allowed us to simplify our calculations. This is almost always the case, but you should check to be sure.

© Cengage Learning/Charles D. Winters

Figure 17.15 Lead(II) sulfide (galena). This and other metal sulfides dissolve in water to a greater extent than expected because the sulfide ion reacts with water to form HS^- and OH^-.

$$PbS(s) + H_2O(\ell) \rightleftharpoons Pb^{2+}(aq) + HS^-(aq) + OH^-(aq)$$

The model of PbS shows that the unit cell is cubic, a feature reflected by the cubic crystals of the mineral galena.

The Effect of Basic Anions on Salt Solubility

The next time you are tempted to wash a supposedly insoluble salt down the kitchen or laboratory drain, stop and consider the consequences. Many metal ions such as lead, chromium, and mercury are toxic in the environment. Even if a so-called insoluble salt of one of these cations does not appear to dissolve, its solubility in water may be greater than you think, in part owing to the possibility that the anion of the salt is a weak base or the cation is a weak acid.

Lead(II) sulfide, PbS, which is found in nature as the mineral galena (Figure 17.15), is an example of the effect of the acid–base properties of an ion on salt solubility. When placed in water, a trace amount dissolves,

$$PbS(s) \rightleftharpoons Pb^{2+}(aq) + S^{2-}(aq)$$

and one product of the reaction is the sulfide ion, which is itself a strong base.

$$S^{2-}(aq) + H_2O(\ell) \rightleftharpoons HS^-(aq) + OH^-(aq) \qquad K_{b1} = 1 \times 10^5$$

The sulfide ion undergoes extensive hydrolysis (reaction with water) (Table 16.2), which decreases its concentration, and the equilibrium process for dissolving PbS

shifts to the right. Thus, the lead ion concentration in solution is greater than expected from the simple dissociation of the salt.

The lead(II) sulfide example leads to the following general observation:

> Any salt containing an anion that is the conjugate base of a weak acid will dissolve in water to a greater extent than given by K_{sp}.

This means that salts of phosphate, acetate, carbonate, and cyanide, as well as sulfide, can be affected, because all of these anions undergo the general hydrolysis reaction

$$X^-(aq) + H_2O(\ell) \rightleftharpoons HX(aq) + OH^-(aq)$$

The observation that ions from insoluble salts can undergo hydrolysis is related to another useful, general conclusion:

> Insoluble salts in which the anion is the conjugate base of a weak acid dissolve in strong acids.

Insoluble salts containing anions such as acetate, carbonate, hydroxide, phosphate, and sulfide dissolve in strong acids. For example, you know that if a strong acid is added to a water-insoluble metal carbonate such as $CaCO_3$, the salt dissolves (Section 3.7).

$$CaCO_3(s) + 2\ H_3O^+(aq) \rightarrow Ca^{2+}(aq) + 3\ H_2O(\ell) + CO_2(g)$$

You can think of this as the result of a series of reactions.

$$CaCO_3(s) \rightleftharpoons Ca^{2+}(aq) + CO_3^{2-}(aq) \qquad K_{sp} = 3.4 \times 10^{-9}$$

$$CO_3^{2-}(aq) + H_3O^+(aq) \rightleftharpoons HCO_3^-(aq) + H_2O(\ell) \qquad 1/K_{a2} = 1/4.8 \times 10^{-11} = 2.1 \times 10^{10}$$

$$HCO_3^-(aq) + H_3O^+(aq) \rightleftharpoons H_2CO_3(aq) + H_2O(\ell) \qquad 1/K_{a1} = 1/4.2 \times 10^{-7} = 2.4 \times 10^{6}$$

$$\text{Overall: } CaCO_3(s) + 2\ H_3O^+(aq) \rightleftharpoons Ca^{2+}(aq) + 2\ H_2O(\ell) + H_2CO_3(aq) \qquad K_{net} = (K_{sp})(1/K_{a2})(1/K_{a1}) = 1.7 \times 10^{8}$$

Carbonic acid, a product of this reaction, is not stable,

$$H_2CO_3(aq) \rightleftharpoons CO_2(g) + H_2O(\ell) \qquad K \approx 10^5$$

and you see CO_2 bubbling out of the solution, a process that moves the $CaCO_3 + H_3O^+$ equilibrium even further to the right. Calcium carbonate dissolves completely in strong acid!

Many metal sulfides are also soluble in strong acids

$$FeS(s) + 2\ H_3O^+(aq) \rightleftharpoons Fe^{2+}(aq) + H_2S(aq) + 2\ H_2O(\ell)$$

as are metal phosphates (Figure 17.16),

$$Ag_3PO_4(s) + 3\ H_3O^+(aq) \rightleftharpoons 3\ Ag^+(aq) + H_3PO_4(aq) + 3\ H_2O(\ell)$$

and metal hydroxides.

$$Mg(OH)_2(s) + 2\ H_3O^+(aq) \rightleftharpoons Mg^{2+}(aq) + 4\ H_2O(\ell)$$

In general, the solubility of a salt containing the conjugate base of a weak acid is increased by addition of a stronger acid to the solution. In contrast, salts are not soluble in strong acid if the anion is the conjugate base of a strong acid. For example, AgCl is not soluble in strong acid

$$AgCl(s) \rightleftharpoons Ag^+(aq) + Cl^-(aq) \qquad K_{sp} = 1.8 \times 10^{-10}$$

$$H_3O^+(aq) + Cl^-(aq) \rightleftharpoons HCl(aq) + H_2O(\ell) \qquad K << 1$$

because Cl^- is a very weak base (Table 16.2), and so its concentration is not lowered by a reaction with the strong acid H_3O^+ (Figure 17.16). This same conclusion would also apply to insoluble salts of Br^- and I^-.

Metal Sulfide Solubility The true solubility of a metal sulfide is better represented by a modified solubility product constant, K'_{sp}, which is defined as follows:

$$MS(s) \rightleftharpoons M^{2+}(aq) + S^{2-}(aq) \qquad K_{sp} = [M^{2+}][S^{2-}]$$

$$S^{2-}(aq) + H_2O(\ell) \rightleftharpoons HS^-(aq) + OH^-(aq) \qquad K_b = [HS^-][OH^-]/[S^{2-}]$$

Net reaction:

$$MS(s) + H_2O(\ell) \rightleftharpoons HS^-(aq) + M^{2+}(aq) + OH^-(aq) \qquad K'_{sp} = [M^{2+}][HS^-][OH^-] = K_{sp} \times K_b$$

Values for K'_{sp} for several metal sulfides are included in Appendix J (Table 18B).

Figure 17.16 The effect of the anion on salt solubility in acid. *(left)* A precipitate of AgCl (white) and Ag_3PO_4 (yellow). *(right)* Adding a strong acid (HNO_3) dissolves Ag_3PO_4 (and leaves insoluble AgCl). The basic anion PO_4^{3-} reacts with acid to give H_3PO_4, whereas Cl^- is too weakly basic to form HCl.

17.5 Precipitation Reactions

Goals for Section 17.5

- Evaluate the reaction quotient Q to determine if a precipitate will form when the ion concentrations are known.
- Calculate the ion concentrations required to begin the precipitation of an insoluble salt.

Figure 17.17 Minerals. Minerals are insoluble salts. The minerals shown here are light purple fluorite (calcium fluoride), black hematite [iron(III) oxide], and rust brown goethite, a mixture of iron(III) oxide and iron(III) hydroxide.

Metal-bearing ores contain the metal in the form of an insoluble salt (Figure 17.17), and, to complicate matters, ores often contain several such metal salts. Many industrial methods for separating metals from their ores involve dissolving metal salts to obtain the metal ion or ions in solution. The solution is then concentrated in some manner, and a precipitating agent is added to precipitate selectively only one type of metal ion as an insoluble salt. In the case of nickel, for example, the Ni^{2+} ion can be precipitated as insoluble nickel(II) sulfide or nickel(II) carbonate.

$$Ni^{2+}(aq) + HS^-(aq) + H_2O(\ell) \rightleftharpoons NiS(s) + H_3O^+(aq) \qquad K = 1.7 \times 10^{18}$$

$$Ni^{2+}(aq) + CO_3^{2-}(aq) \rightleftharpoons NiCO_3(s) \qquad K = 7.1 \times 10^{6}$$

After separating the insoluble salt, the final step in obtaining the metal itself is to reduce the metal cation to the metal either chemically or electrochemically (Chapters 19 and 22).

Our immediate goal in this section is to work out methods to determine whether a precipitate will form under a given set of conditions.

K_{sp} and the Reaction Quotient, Q

Silver chloride dissolves to a very small extent in water and has a correspondingly small value of K_{sp}.

$$AgCl(s) \rightleftharpoons Ag^+(aq) + Cl^-(aq) \qquad K_{sp} = [Ag^+][Cl^-] = 1.8 \times 10^{-10}$$

But look at the problem from the other direction: If a solution contains Ag^+ and Cl^- ions at some concentration, will AgCl precipitate from solution? This is the same question we asked in Section 15.2 when we wanted to know if a given mixture of reactants and products was an equilibrium mixture, if the reactants continued to form products, or if products would revert to reactants. The procedure was to calculate the reaction quotient, Q.

For silver chloride, the expression for the reaction quotient, Q, is

$$Q = [Ag^+][Cl^-]$$

Recall that *the difference between Q and K is that the concentrations in the reaction quotient expression, Q, may or may not be those at equilibrium*. For the case of a slightly soluble salt such as AgCl, we can reach the following conclusions (Section 15.2).

1. If $Q = K_{sp}$, the solution is saturated.

When $Q = K_{sp}$ the ion concentrations have reached their maximum value.

2. If $Q < K_{sp}$, the solution is not saturated.

This can mean either of two things: (i) If solid AgCl is present, more will dissolve until equilibrium is achieved (when $Q = K_{sp}$). (ii) If solid AgCl is not already present, more $Ag^+(aq)$ or more $Cl^-(aq)$ (or both) could be added to the solution until precipitation of solid AgCl begins (when $Q > K_{sp}$).

3. If $Q > K_{sp}$, the solution is oversaturated and precipitation will occur.

If $Q > K_{sp}$, then precipitation will occur until $Q = K_{sp}$.

EXAMPLE 17.12

Solubility and the Reaction Quotient

Problem Solid AgCl has been placed in a beaker of water. After some time, the concentrations of Ag^+ and Cl^- are each 1.2×10^{-5} mol/L. Has the system reached equilibrium? If not, will more AgCl dissolve?

What Do You Know? You know the balanced equation for dissolving the AgCl, its value of K_{sp}, and the Ag^+ and Cl^- concentrations.

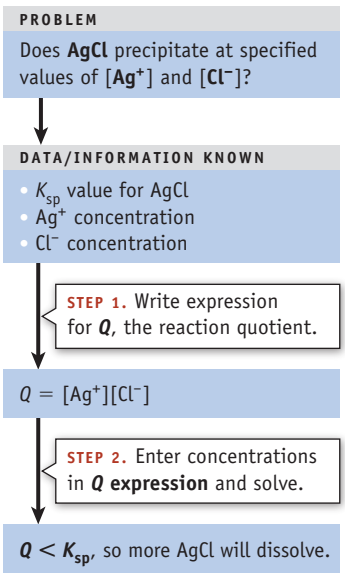
Strategy

- Write the balanced equation for dissolving the salt and then write the expression for the reaction quotient, *Q*.
- Use the experimental ion concentrations to calculate the reaction quotient *Q*. Compare *Q* and K_{sp} to decide if the system is at equilibrium (that is, if $Q = K_{sp}$).

SOLUTION

$$AgCl(s) \rightleftharpoons Ag^+(aq) + Cl^-(aq) \qquad K_{sp} = [Ag^+][Cl^-] = 1.8 \times 10^{-10}$$

$$Q = [Ag^+][Cl^-] = (1.2 \times 10^{-5})(1.2 \times 10^{-5}) = 1.4 \times 10^{-10}$$



Here, *Q* is less than K_{sp} (1.8×10^{-10}). The solution is not yet saturated, and AgCl will continue to dissolve until $Q = K_{sp}$, at which point $[Ag^+] = [Cl^-] = 1.3 \times 10^{-5}$ M. That is, an additional 0.1×10^{-5} mol of AgCl will dissolve per liter.

Think about Your Answer Dissolving is often a fairly slow process. If you measure the ion concentrations at a particular time, they may not have yet reached an equilibrium value, as is the case here.

Check Your Understanding

Solid PbI_2 ($K_{sp} = 9.8 \times 10^{-9}$) is placed in a beaker of water. After a period of time, the lead(II) concentration is measured and found to be 1.1×10^{-3} M. Has the system reached equilibrium? That is, is the solution saturated? If not, will more PbI_2 dissolve?

K_{sp}, the Reaction Quotient, and Precipitation Reactions

Using the reaction quotient and the solubility product constant, we can decide (1) if a precipitate will form when the ion concentrations are known or (2) what concentrations of ions are required to begin the precipitation of an insoluble salt.

Suppose the concentration of magnesium ion in an aqueous solution is 1.5×10^{-6} M. If enough NaOH is added to make the solution 1.0×10^{-4} M in hydroxide ion, OH^-, will precipitation of $Mg(OH)_2$ occur ($K_{sp} = 5.6 \times 10^{-12}$)? If not, will it occur if the concentration of OH^- is increased to 1.0×10^{-2} M?

Our strategy is similar to that in Example 17.12. That is, use the ion concentrations to calculate the value of Q and then compare Q with K_{sp} to decide if the system is at equilibrium. We begin with the equation for the dissolution of $Mg(OH)_2$.

$$Mg(OH)_2(s) \rightleftharpoons Mg^{2+}(aq) + 2\ OH^-(aq)$$

When the concentrations of magnesium and hydroxide ions are the first ones stated above, we find that Q is less than K_{sp}.

$$Q = [Mg^{2+}][OH^-]^2 = (1.5 \times 10^{-6})(1.0 \times 10^{-4})^2 = 1.5 \times 10^{-14}$$

$$Q\ (1.5 \times 10^{-14}) < K_{sp}\ (5.6 \times 10^{-12})$$

This means the solution is not yet saturated, and precipitation does not occur.

When $[OH^-]$ is increased to 1.0×10^{-2} M, the reaction quotient is 1.5×10^{-10},

$$Q = (1.5 \times 10^{-6})(1.0 \times 10^{-2})^2$$

$$Q = 1.5 \times 10^{-10} > K_{sp}\ (5.6 \times 10^{-12})$$

and the reaction quotient is now *larger* than K_{sp}. Precipitation of $Mg(OH)_2$ occurs and will continue until the Mg^{2+} and OH^- ion concentrations have decreased to the point where their product is equal to K_{sp}.

Now let us turn to a similar problem: deciding how much of the precipitating agent is required to begin the precipitation of an ion at a given concentration level.

Strategy Map 17.13

PROBLEM

What concentration of SO_4^{2-} is required to begin precipitation of $BaSO_4$?

DATA/INFORMATION KNOWN

- K_{sp} value for $BaSO_4$
- Initial $[Ba^{2+}]$

STEP 1. Write **expression** for K_{sp}.

$K_{sp} = [Ba^{2+}][SO_4^{2-}]$

STEP 2. Enter Ba^{2+} **concentration** and solve for $[SO_4^{2-}]$.

$BaSO_4$ begins to precipitate when $[SO_4^{2-}]$ exceeds calculated value.

EXAMPLE 17.13

Ion Concentrations Required to Begin Precipitation

Problem The concentration of barium ion, Ba^{2+}, in a solution is 0.010 M.

(a) What concentration of sulfate ion, SO_4^{2-}, is required to begin the precipitation of $BaSO_4$?

(b) When enough SO_4^{2-} has been added so that the concentration of sulfate ion in the solution reaches 0.015 M, what concentration of barium ion will remain in solution?

What Do You Know? There are three terms in the K_{sp} expression: K_{sp} and the anion and cation concentrations. Here, you know K_{sp} (1.1×10^{-10}) and one of the ion concentrations. You can calculate the other ion concentration.

Strategy

- Write the balanced equation for dissolving $BaSO_4$ and the K_{sp} expression.
- **Part (a):** Use the K_{sp} expression to calculate $[SO_4^{2-}]$ when $[Ba^{2+}] = 0.010$ M.
- **Part (b):** Use the K_{sp} expression to calculate $[Ba^{2+}]$ when $[SO_4^{2-}] = 0.015$ M.

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

SOLUTION

$$BaSO_4(s) \rightleftharpoons Ba^{2+}(aq) + SO_4^{2-}(aq) \qquad K_{sp} = [Ba^{2+}][SO_4^{2-}] = 1.1 \times 10^{-10}$$

(a) When the product of the ion concentrations exceeds the K_{sp} ($= 1.1 \times 10^{-10}$)—that is, when $Q > K_{sp}$—precipitation will occur. The Ba^{2+} ion concentration is known (0.010 M), so the SO_4^{2-} ion concentration necessary for precipitation can be calculated.

$$[SO_4^{2-}] = \frac{K_{sp}}{[Ba^{2+}]} = \frac{1.1 \times 10^{-10}}{0.010} = 1.1 \times 10^{-8}\ M$$

The result tells us that if the sulfate ion concentration is just slightly greater than 1.1×10^{-8} M, $BaSO_4$ will begin to precipitate.

(b) If the sulfate ion concentration is increased to 0.015 M, the maximum concentration of Ba^{2+} ion that can exist in solution (in equilibrium with $BaSO_4$) is

$$[Ba^{2+}] = \frac{K_{sp}}{[SO_4^{2-}]} = \frac{1.1 \times 10^{-10}}{0.015} = 7.3 \times 10^{-9}\ M$$

Think about Your Answer The fact that the barium ion concentration is so small when $[SO_4^{2-}] = 0.015$ M means that the Ba^{2+} ion has been essentially removed from solution. (It began at 0.010 M and has decreased by a factor of about 1 million.)

Check Your Understanding

What is the minimum concentration of I^- that can cause precipitation of PbI_2 from a 0.050 M solution of $Pb(NO_3)_2$? K_{sp} for PbI_2 is 9.8×10^{-9}. What concentration of Pb^{2+} ions remains in solution when the concentration of I^- is 0.0015 M?

EXAMPLE 17.14

K_{sp} and Precipitations

Problem Suppose you mix 100.0 mL of 0.0200 M $BaCl_2$ with 50.0 mL of 0.0300 M Na_2SO_4. Will $BaSO_4$ ($K_{sp} = 1.1 \times 10^{-10}$) precipitate?

What Do You Know? You know the concentration of two different compounds in solutions of differing volumes. You know that $BaCl_2$ and Na_2SO_4 will combine to give a precipitate, $BaSO_4$, if they are mixed in sufficient concentration. You also know the K_{sp} value for $BaSO_4$.

Strategy Here, you mix two solutions, one containing Ba^{2+} ions and the other SO_4^{2-} ions, both with known concentration and volume, and insoluble $BaSO_4$ may be formed.

- Find the concentration of each of these ions after mixing.
- Knowing the ion concentrations in the combined solution, calculate Q and compare it with the K_{sp} value for $BaSO_4$ to decide if $BaSO_4$ will precipitate under these circumstances.

SOLUTION First, use the equation $c_1V_1 = c_2V_2$ (Section 4.5) to calculate c_2, the concentration of the Ba^{2+} and SO_4^{2-} ions after mixing, to give a new solution with a volume of 150.0 mL ($= V_2$).

$$[Ba^{2+}] \text{ after mixing} = \frac{(0.0200\ mol/L)(0.1000\ L)}{0.1500\ L} = 0.01333\ M$$

$$[SO_4^{2-}] \text{ after mixing} = \frac{(0.0300\ mol/L)(0.0500\ L)}{0.1500\ L} = 0.01000\ M$$

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

The equilibrium governing the reaction that can occur is

$$BaSO_4(s) \rightleftharpoons Ba^{2+}(aq) + SO_4^{2-}(aq) \qquad K_{sp} = [Ba^{2+}][SO_4^{2-}] = 1.1 \times 10^{-10}$$

Now the reaction quotient can be calculated.

$$Q = [Ba^{2+}][SO_4^{2-}] = (0.01333)(0.01000) = 1.33 \times 10^{-4}$$

Q is much larger than K_{sp}, so $BaSO_4$ precipitates.

Think about Your Answer The K_{sp} value for $BaSO_4$ is very small, so mixing solutions with Ba^{2+} and SO_4^{2-} ions, even in very low concentration, can lead to the precipitation of $BaSO_4$.

Check Your Understanding

You have 100.0 mL of 0.0010 M silver nitrate. Will AgCl precipitate if you add 5.0 mL of 0.025 M HCl?

Complex Ions Complex ions are prevalent in chemistry and are the basis of such biologically important substances as hemoglobin and vitamin B_{12}. They are described in more detail in Chapter 22. See also Section 16.10.

17.6 Equilibria Involving Complex Ions

Goal for Section 17.6

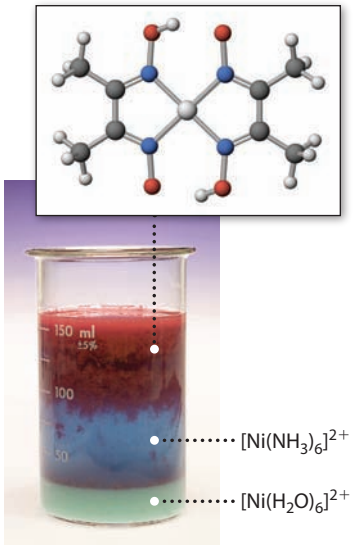
- Understand the formation of complex ions in solution and recognize how this can increase the solubility of an insoluble salt.

Metal ions exist in aqueous solution as complex ions (Section 16.10). Complex ions consist of the metal ion and other molecules or ions bound into a single entity. In water, metal ions are always surrounded by water molecules, with the negative end of the polar water molecule, the oxygen atom, attracted to the positive metal ion. In the case of Ni^{2+}, the ion exists as $[Ni(H_2O)_6]^{2+}$ in water. On adding ammonia, water molecules are displaced successively, and in the presence of a high enough concentration of ammonia, the complex ion $[Ni(NH_3)_6]^{2+}$ is formed. Many organic molecules also form complex ions with metal ions, one example being the complex with the dimethylglyoximate ion in Figure 17.18.

The molecules or ions that bind to metal ions are called **ligands** (Chapter 22). In aqueous solution, metal ions and ligands exist in equilibrium, and the equilibrium constants for these reactions are referred to as **formation constants**, K_f (Appendix K). For example,

$$Cu^{2+}(aq) + NH_3(aq) \rightleftharpoons [Cu(NH_3)]^{2+}(aq) \qquad K_{f1} = 2.0 \times 10^4$$

$$[Cu(NH_3)]^{2+}(aq) + NH_3(aq) \rightleftharpoons [Cu(NH_3)_2]^{2+}(aq) \qquad K_{f2} = 4.7 \times 10^3$$



$$[Cu(NH_3)_2]^{2+}(aq) + NH_3(aq) \rightleftharpoons [Cu(NH_3)_3]^{2+}(aq) \qquad K_{f3} = 1.1 \times 10^3$$

$$[Cu(NH_3)_3]^{2+}(aq) + NH_3(aq) \rightleftharpoons [Cu(NH_3)_4]^{2+}(aq) \qquad K_{f4} = 2.0 \times 10^2$$

In these reactions, Cu^{2+} begins as $[Cu(H_2O)_4]^{2+}$, but ammonia successively displaces the water molecules. Overall, the formation of the tetraammine copper(II) complex ion has an equilibrium constant of 2.1×10^{13} ($= K_{f1} \times K_{f2} \times K_{f3} \times K_{f4}$).

$$Cu^{2+}(aq) + 4\ NH_3(aq) \rightleftharpoons [Cu(NH_3)_4]^{2+}(aq) \qquad K_f = 2.1 \times 10^{13}$$

Dimethylglyoximate complex of Ni^{2+} ion

© Cengage Learning/Charles D. Winters

Figure 17.18 Complex ions. The green solution contains soluble $[Ni(H_2O)_6]^{2+}$ ions in which water molecules are bound to Ni^{2+} ions by ion–dipole forces. This complex ion gives the solution its green color. The Ni^{2+}-ammonia complex ion is purple. The red, insoluble solid is the dimethylglyoximate complex of the Ni^{2+} ion $[Ni(C_4H_7O_2N_2)_2]$ (model at top). Formation of this beautiful red insoluble compound is the classical test for the presence of the aqueous Ni^{2+} ion.

EXAMPLE 17.15

Complex Ion Equilibria

Problem What is the concentration of Cu^{2+} ions in a solution prepared by adding 0.00100 mol of $Cu(NO_3)_2$ to 1.00 L of 1.50 M NH_3? K_f for the copper-ammonia complex ion $[Cu(NH_3)_4]^{2+}$ is 2.1×10^{13}.

What Do You Know? Here you know the concentration of the species that form the complex ion (Cu^{2+} and NH_3), and you know the formation constant for the complex ion.

Strategy The formation constant for the complex ion is very large, so you start with the assumption that all of the Cu^{2+} ions react with NH_3 to form $[Cu(NH_3)_4]^{2+}$. That is, the initial concentration of the complex ion, $[Cu(NH_3)_4]^{2+}$ is 0.00100 M. This cation then dissociates to produce Cu^{2+} ions and additional NH_3 in solution. The equilibrium constant for the dissociation of $[Cu(NH_3)_4]^{2+}$ is the reciprocal of K_f because the dissociation of the ion is the reverse of its formation.

- Write a balanced equation for the dissociation of the complex ion that formed in solution and set up an ICE table.
- Assume that all of the Cu^{2+} ions in the solution are in the form of $[Cu(NH_3)_4]^{2+}$ (0.00100 M). This means that $[NH_3]$ = original concentration $- 4 \times 0.00100$ M.
- Assume the concentration of complex ion dissociated at equilibrium is x, so x mol/L of Cu^{2+} are released to solution as are $4x$ mol/L of NH_3.
- Use the equilibrium concentrations of the ions in the expression for $K_{dissociation}$ $(= 1/K_f)$ and solve for x (which is the concentration of Cu^{2+} at equilibrium).

SOLUTION Set up an ICE table for the dissociation of $[Cu(NH_3)_4]^{2+}$.

Equation	$[Cu(NH_3)_4]^{2+}(aq)$	$\rightleftharpoons$	$Cu^{2+}(aq)$	+	$4\ NH_3(aq)$
Initial (M)	0.00100		0		1.50 − 0.00400 M
Change (M)	$-x$		$+x$		$+4x$
Equilibrium (M)	$0.00100 - x \approx 0.00100$		x		$1.50 - 0.00400 + 4x \approx 1.50$

Here you assume that x is so small that the concentration of the complex ion is very nearly 0.00100 M and that the NH_3 concentration at equilibrium is essentially what was there originally.

$$K_{dissociation} = \frac{1}{K_f} = \frac{1}{2.1 \times 10^{13}} = \frac{[Cu^{2+}][NH_3]^4}{\{[Cu(NH_3)_4]^{2+}\}} = \frac{(x)(1.50)^4}{0.00100}$$

$$x = [Cu^{2+}] = 9.4 \times 10^{-18}\ M$$

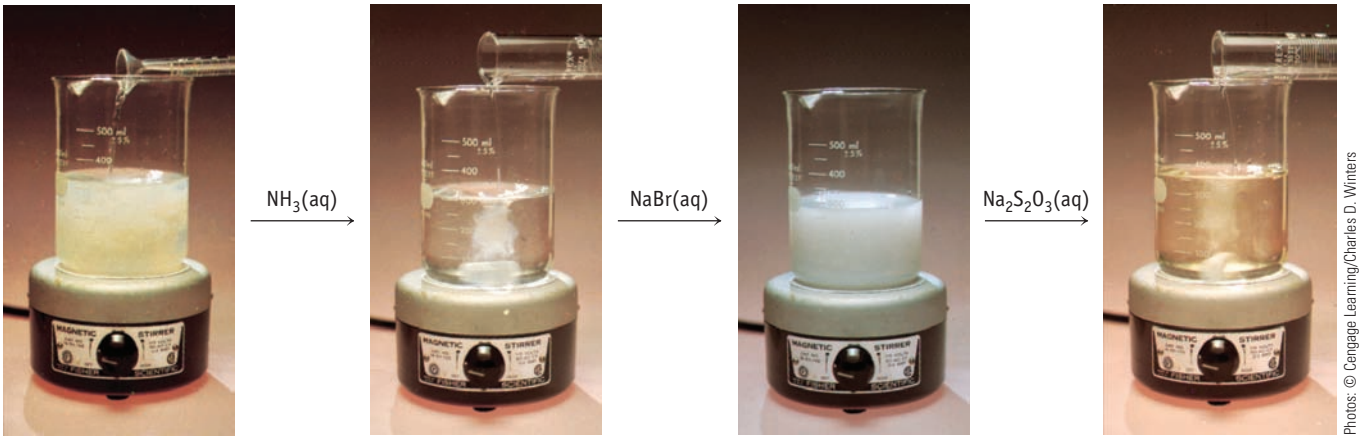
Think about Your Answer Make sure to test your assumption that x is so small it can be neglected in determining the equilibrium concentrations of $[Cu(NH_3)_4]^{2+}$ and NH_3. It certainly is in this case.

Check Your Understanding

Silver nitrate (0.0050 mol) is added to 1.00 L of 1.00 M NH_3. What is the concentration of Ag^+ ions at equilibrium?

$$Ag^+(aq) + 2\ NH_3(aq) \rightleftharpoons [Ag(NH_3)_2]^+(aq) \qquad K_f = 1.1 \times 10^7$$

Solubility and Complex Ions



Silver chloride does not dissolve either in water or in strong acid, but it does dissolve in ammonia because it forms a water-soluble complex ion, $[Ag(NH_3)_2]^+$ (Figure 17.19).

$$AgCl(s) + 2\ NH_3(aq) \rightleftharpoons [Ag(NH_3)_2]^+(aq) + Cl^-(aq)$$

Dissolving AgCl(s) can be viewed as a two-step process. First, AgCl dissolves minimally in water, giving $Ag^+(aq)$ and $Cl^-(aq)$ ion. Then, the $Ag^+(aq)$ ion combines

Figure 17.19 Forming and dissolving precipitates. Insoluble compounds often dissolve upon addition of a complexing agent.

with NH_3 to give the ammonia complex. Lowering the $Ag^+(aq)$ concentration through complexation with NH_3 shifts the solubility equilibrium to the right, and more solid AgCl dissolves.

$$AgCl(s) \rightleftharpoons Ag^+(aq) + Cl^-(aq) \qquad K_{sp} = 1.8 \times 10^{-10}$$

$$Ag^+(aq) + 2\ NH_3(aq) \rightleftharpoons [Ag(NH_3)_2]^+(aq) \qquad K_f = 1.1 \times 10^7$$

This is an example of combining or "coupling" two (or more) equilibria where one is a product-favored reaction and the other is reactant-favored.

The large value of the formation constant for $[Ag(NH_3)_2]^+$ means that the equilibrium lies well to the right, and AgCl can dissolve in the presence of NH_3. If you combine K_f with K_{sp}, you obtain the net equilibrium constant for the interaction of AgCl and aqueous ammonia.

$$K_{net} = K_{sp} \times K_f = (1.8 \times 10^{-10})(1.1 \times 10^7) = 2.0 \times 10^{-3}$$

$$K_{net} = 2.0 \times 10^{-3} = \frac{[[Ag(NH_3)_2]^+][Cl^-]}{[NH_3]^2}$$

Even though the value of K_{net} seems small, if you use a large concentration of NH_3, the concentration of $[Ag(NH_3)_2]^+$ in solution can be appreciable. Silver chloride is thus much more soluble in the presence of ammonia than in pure water.

The stabilities of various complex ions involving silver(I) can be compared by comparing values of their formation constants.

Formation Equilibrium	K_f
$Ag^+(aq) + 2\ Cl^-(aq) \rightleftharpoons [AgCl_2]^-(aq)$	1.1×10^5
$Ag^+(aq) + 2\ S_2O_3^{2-}(aq) \rightleftharpoons [Ag(S_2O_3)_2]^{3-}(aq)$	2.9×10^{13}
$Ag^+(aq) + 2\ CN^-(aq) \rightleftharpoons [Ag(CN)_2]^-(aq)$	1.3×10^{21}

The formation of all three silver complexes is strongly product-favored, and the cyanide complex ion $[Ag(CN)_2]^-$ is the most stable of the three.

Figure 17.19 shows what happens as complex ions are formed. Beginning with a precipitate of AgCl, adding aqueous ammonia dissolves the precipitate to give the soluble complex ion $[Ag(NH_3)_2]^+$. Silver bromide is even more stable than $[Ag(NH_3)_2]^+$, so AgBr ($K_{sp} = 5.4 \times 10^{-13}$) forms in preference to the complex ion on adding bromide ion. If thiosulfate ion, $S_2O_3^{2-}$, is then added, AgBr dissolves due to the formation of $[Ag(S_2O_3)_2]^{3-}$, a complex ion with a large formation constant (2.9×10^{13}).

EXAMPLE 17.16

Complex Ions and Solubility

Problem What is the value of the equilibrium constant, K_{net}, for dissolving AgBr in a solution containing the thiosulfate ion, $S_2O_3^{2-}$ (Figure 17.19)? Does AgBr dissolve readily on adding aqueous sodium thiosulfate to the solid?

What Do You Know? There are two equilibria here. One is for dissolving AgBr in water to give Ag^+ and Br^- ions, and its equilibrium constant is K_{sp}. The other is the formation of $[Ag(S_2O_3)_2]^{3-}$ ions from Ag^+ and $S_2O_3^{2-}$ ions; its equilibrium constant is K_f.

Strategy Summing several equilibrium processes gives the net chemical equation. K_{net} is the product of the values of K of the summed chemical equations (Section 15.5).

SOLUTION The overall reaction for dissolving AgBr in the presence of the thiosulfate anion is the sum of two equilibrium processes.

$$AgBr(s) \rightleftharpoons Ag^+(aq) + Br^-(aq) \qquad K_{sp} = 5.0 \times 10^{-13}$$

$$Ag^+(aq) + 2\ S_2O_3^{2-}(aq) \rightleftharpoons [Ag(S_2O_3)_2]^{3-}(aq) \qquad K_f = 2.9 \times 10^{13}$$

Net chemical equation:

$$AgBr(s) + 2\ S_2O_3^{2-}(aq) \rightleftharpoons [Ag(S_2O_3)_2]^{3-}(aq) + Br^-(aq) \qquad K_{net} = K_{sp} \times K_f = 15$$

AgBr is predicted to dissolve readily in aqueous $Na_2S_2O_3$, as observed (Figure 17.19).

Think about Your Answer The value of K_{net} is greater than 1, indicating a product-favored reaction at equilibrium.

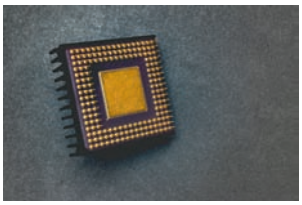
Check Your Understanding

Calculate the value of the equilibrium constant, K_{net}, for dissolving $Cu(OH)_2$ in aqueous ammonia (to form the complex ion $[Cu(NH_3)_4]^{2+}$) (Figure 16.9).

APPLYING CHEMICAL PRINCIPLES

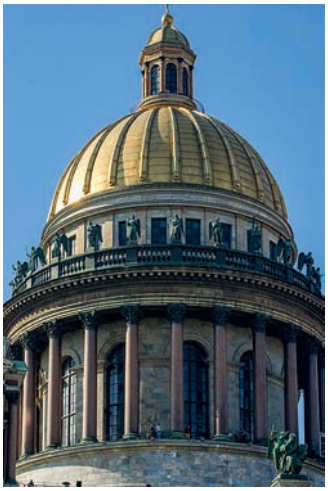
17.1 Everything that Glitters . . .

For thousands of years gold has been used in jewelry and for currency. Gold does not tarnish, and it can be drawn into wires or hammered into sheets. In modern society, the most important application of this element may be in electronics, where its high conductivity and resistance to corrosion make it invaluable for wires and connectors.



Gold mining evokes images of miners panning for gold in mountain streams or chopping rocks with pick axes. However, the percentage of gold in most deposits is too low for these extraction methods to be feasible. Today's miners blast and crush enormous quantities of gold-bearing ore and then dissolve gold from the ore using a chemical process involving cyanide ion and oxygen.

$$4\ Au(s) + 8\ NaCN(aq) + O_2(g) + 2\ H_2O(\ell) \rightarrow 4\ NaAu(CN)_2(aq) + 4\ NaOH(aq)$$



The solution containing the complex ion $[Au(CN)_2]^-$ is filtered to separate it from the solids. Metallic gold is then recovered

John C. Kotz

Using gold. *(left)* Much of current gold use today is in electronic devices. The microprocessor connector pins are coated with a thin film of gold. *(right)* The dome of St. Isaac's Cathedral in St. Petersburg, Russia, is covered with 100 kg of pure gold. (It was completed in 1858.)

by reacting the cyanide complex with zinc. The zinc reduces the gold(I) complex to elemental gold and then joins with cyanide ions to form $[Zn(CN)_4]^{2-}$.

Large volumes of 0.035% aqueous sodium cyanide are used for gold extraction. Unfortunately, unsafe disposal and accidental discharges have resulted in environmental disasters. In 2000, the collapse of dams in Baia Mare, Romania, resulted in millions of liters of cyanide waste entering the Tisza and Danube rivers. All aquatic life for miles downstream was killed. Although research into safer extraction methods is ongoing, extraction by cyanide ion is still the primary means of obtaining gold.

Questions:

1. Approximately 0.10 g of sodium cyanide is fatal to humans. What volume (in mL) of 0.035 mass percent NaCN solution contains a fatal dose of sodium cyanide? Assume the density of the solution is 1.0 g/mL.
2. What is the minimum volume of 0.0071 M NaCN(aq) necessary to dissolve the gold from 1.0 metric ton (1000 kg) of ore if the ore contains 0.012% gold?
3. Use the formation constant of $[Au(CN)_2]^-$ in Appendix K to determine the equilibrium concentration of $Au^+(aq)$ in a solution that is 0.0071 M CN^- and 1.1×10^{-4} M $[Au(CN)_2]^-$. Is it reasonable to conclude that 100% of the gold in solution is present as the $[Au(CN)_2]^-$ complex ion? Explain.
4. Silver undergoes similar reactions as those shown for gold. Both metals react with cyanide ion in the presence of oxygen to form soluble complexes, and both are reduced by zinc. The reaction of Ag^+ with cyanide ion may be viewed as two sequential steps:

$$(1)\quad Ag^+(aq) + CN^-(aq) \rightleftharpoons AgCN(s)$$

$$(2)\quad AgCN(s) + CN^-(aq) \rightleftharpoons [Ag(CN)_2]^-(aq)$$

$$\overline{Ag^+(aq) + 2\ CN^-(aq) \rightleftharpoons [Ag(CN)_2]^-(aq)} \qquad K_f = 1.3 \times 10^{21}$$

   a. Use the solubility product equilibrium constant (Appendix J) of AgCN(s) to determine the equilibrium constant for Step 1.
   b. Use the equilibrium constants from Step 1 and the overall reaction to determine the equilibrium constant for Step 2.
   c. Excess AgCN(s) is combined with 1.0 L of 0.0071 M $CN^-(aq)$ and allowed to equilibrate. Calculate the equilibrium concentrations of CN^- and $[Ag(CN)_2]^-$ using the equilibrium constant for Step 2. Assume no change in volume occurs.
5. Write a balanced chemical equation for the reaction of $NaAu(CN)_2(aq)$ and Zn(s).

17.2 Take a Deep Breath

Maintenance of pH is vital to the cells of all living organisms because enzyme activity is influenced by pH. The primary protection against harmful pH changes in cells is provided by buffer systems, which maintain the intracellular pH of most cells between 6.9 and 7.4. Two important biological buffer systems control pH in this range: the bicarbonate/carbonic acid system (HCO_3^-/H_2CO_3) and the phosphate system ($HPO_4^{2-}/H_2PO_4^-$).

The bicarbonate/carbonic acid buffer is important in blood plasma, where three equilibria are important.

$$CO_2(g) \rightleftharpoons CO_2(\text{dissolved})$$

$$CO_2(\text{dissolved}) + H_2O(\ell) \rightleftharpoons H_2CO_3(aq)$$

$$H_2CO_3(aq) + H_2O(\ell) \rightleftharpoons H_3O^+(aq) + HCO_3^-(aq)$$

The overall equilibrium for the second and third steps has $pK_{overall} = 6.3$ at 37 °C, the temperature of the human body. Thus,

$$7.4 = 6.3 + \log \frac{[HCO_3^-]}{[CO_2(\text{dissolved})]}$$

Although the value of $pK_{overall}$ is about 1 pH unit away from the blood pH, the natural partial pressure of CO_2 in the alveoli of the lungs (about 40 mm Hg) is sufficient to keep $[CO_2(\text{dissolved})]$ at about 1.2×10^{-3} M and $[HCO_3^-]$ at about 1.5×10^{-2} M as required to maintain this pH.

If blood pH rises above about 7.45, you can suffer from a condition called *alkalosis*. *Respiratory alkalosis* can arise from hyperventilation when a person breathes quickly to expel CO_2 from the lungs. This has the effect of lowering the CO_2 concentration, which in turn leads to a lower H_3O^+ concentration and a higher pH. This same condition can also arise from severe anxiety or from an oxygen deficiency at high altitude. It can ultimately lead to overexcitability of the central nervous system, muscle spasms, convulsions, and death. One way to treat acute respiratory alkalosis is to breathe into a paper bag. The CO_2 you exhale is recycled. This raises the blood CO_2 level and causes the equilibria above to shift to the right, thus raising the hydronium ion concentration and lowering the pH.

Metabolic alkalosis can occur if you take large amounts of sodium bicarbonate to treat stomach acid (which is mostly HCl

© Cengage Learning/Charles D. Winters

at a pH of about 1 to 2). It also commonly occurs when a person vomits profusely. This depletes the body of hydronium ions, which leads to an increase in bicarbonate ion concentration.

Athletes can use the H_2CO_3/HCO_3^- equilibrium to enhance their performance. Strenuous activity produces high levels of lactic acid, and this can lower blood pH and cause muscle cramps. To counteract this, athletes will prepare before a race by hyperventilating for some seconds to raise blood pH, thereby helping to neutralize the acidity from the lactic acid.

Acidosis is the opposite of alkalosis. There was a case of a toddler who came to the hospital with viral gastroenteritis and *metabolic acidosis*. He had severe diarrhea, was dehydrated, and had a high rate of respiration. One function of the bicarbonate ion is to neutralize stomach acid in the intestines. However, because of his diarrhea, the toddler was losing bicarbonate ions in his stool, and his blood pH was too low. To compensate, the toddler was breathing rapidly and blowing off CO_2 through the lungs (the effect of which is to lower $[H_3O^+]$ and raise the pH).

Respiratory acidosis results from a build-up of CO_2 in the body. This can be caused by pulmonary problems, by head injuries, or by drugs such as anesthetics and sedatives. It can be reversed by breathing rapidly and deeply. Doubling the breathing rate increases the blood pH by about 0.23 units.

Questions:

Phosphate ions are abundant in cells, both as the ions themselves and as important substituents on organic molecules. Most importantly, the pK_a for the $H_2PO_4^-$ ion is 7.20, which is very close to the normal pH in the body.

$$H_2PO_4^-(aq) + H_2O(\ell) \rightleftharpoons H_3O^+(aq) + HPO_4^{2-}(aq)$$

1. What should the ratio $[HPO_4^{2-}]/[H_2PO_4^-]$ be to control the pH at 7.40?
2. A typical total phosphate concentration in a cell, $[HPO_4^{2-}] + [H_2PO_4^-]$, is 2.0×10^{-2} M. What are the concentrations of HPO_4^{2-} and $H_2PO_4^-$ at pH 7.40?

CHAPTER GOALS REVISITED

The goals for this chapter are keyed to specific Study Questions to help you organize your review.

17.1 The Common Ion Effect

- Predict the effect of the addition of a "common ion" on the pH of the solution of a weak acid or base. 1–6.

17.2 Controlling pH: Buffer Solutions

- Recognize the composition of a buffer, know how to prepare a buffer solution of a given pH, and understand how a buffer solution works. 7–10, 17–20.
- Calculate the pH of a buffer solution of given composition using either the equation for the equilibrium for a weak acid or the Henderson–Hasselbalch equation. 11–16.
- Calculate the pH of a buffered solution after the addition of acid or base. 23–26.

17.3 Acid–Base Titrations

- Recognize the differences between a titration curve for a strong acid–strong base titration and a titration curve in which one of the substances is weak. 31, 32.

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

- Calculate the pH at various points in acid-base titrations (initial pH, the pH prior to the equivalence point, at the equivalence point, and after the equivalence point). 27–30, 33, 34, 106, 107.
- Describe how an indicator functions in an acid–base titration. 35, 36, 105–107.

17.4 Solubility of Salts

- Write the equilibrium constant expression relating concentrations of ions in solution to K_{sp} for any insoluble salt. 41, 42.
- Calculate the K_{sp} value for a salt from its solubility and calculate the solubility of a salt from its K_{sp}. 43–46, 51–56.
- Recognize how the presence of a common ion affects the solubility of a salt. 57–60.
- Understand how hydrolysis of basic anions affects the solubility of a salt. 64.
- Recognize that salts with anions derived from weak acids have increased solubility in acidic solutions. 61–63, 114.

17.5 Precipitation Reactions

- Evaluate the reaction quotient Q to determine if a precipitate will form when the ion concentrations are known. 65–68, 70.
- Calculate the ion concentrations required to begin the precipitation of an insoluble salt. 69, 84, 95.

17.6 Equilibria Involving Complex Ions

- Understand the formation of complex ions in solution and recognize how this can increase the solubility of an insoluble salt. 71–76.

KEY EQUATIONS

Equation 17.1 (page 766) Hydronium ion concentration in a buffer solution composed of a weak acid and its conjugate base.

$$[H_3O^+] = \frac{[\text{acid}]}{[\text{conjugate base}]} \times K_a$$

Equation 17.2 (page 766) Henderson–Hasselbalch equation. To calculate the pH of a buffer solution composed of a weak acid and its conjugate base.

$$\text{pH} = \text{p}K_a + \log \frac{[\text{conjugate base}]}{[\text{acid}]}$$

Equation 17.3 (page 774) Equation to calculate the hydronium ion concentration before the equivalence point in the titration of a weak acid with a strong base.

$$[H_3O^+] = \frac{[\text{weak acid remaining}]}{[\text{conjugate base produced}]} \times K_a$$

Equation 17.4 (page 775) Equation to calculate the pH before the equivalence point in the titration of a weak acid with a strong base based on the Henderson–Hasselbalch equation.

$$\text{pH} = \text{p}K_a + \log \frac{[\text{conjugate base produced}]}{[\text{weak acid remaining}]}$$

Equation 17.5 (page 775) The relationship between the pH of the solution and the pK_a of the weak acid (or $[H_3O^+]$ and K_a) at the halfway or half-neutralization point in the titration of a weak acid with a strong base (or of a weak base with a strong acid).

$$[H_3O^+] = K_a \text{ and } \text{pH} = \text{p}K_a$$

Equation 17.6 (page 783) The general equilibrium constant expression, K_{sp} (solubility constant) for dissolving a poorly soluble salt, A_xB_y.

$$A_xB_y(s) \rightleftharpoons x\ A^{y+}(aq) + y\ B^{x-}(aq) \qquad K_{sp} = [A^{y+}]^x[B^{x-}]^y$$

STUDY QUESTIONS

▲ denotes challenging questions. **Blue-numbered questions** have answers in Appendix N and fully worked solutions in the *Student Solutions Manual*.

Practicing Skills

The Common Ion Effect and Buffer Solutions

(See Sections 17.1 and 17.2 and Examples 17.1 and 17.2.)

1. Does the pH of the solution increase, decrease, or stay the same when you
   (a) add solid ammonium chloride to a dilute aqueous solution of NH_3?
   (b) add solid sodium acetate to a dilute aqueous solution of acetic acid?
   (c) add solid NaCl to a dilute aqueous solution of NaOH?
2. Does the pH of the solution increase, decrease, or stay the same when you
   (a) add solid sodium oxalate, $Na_2C_2O_4$, to 50.0 mL of 0.015 M oxalic acid, $H_2C_2O_4$?
   (b) add solid ammonium chloride to 75 mL of 0.016 M HCl?
   (c) add 20.0 g of NaCl to 1.0 L of 0.10 M sodium acetate, $NaCH_3CO_2$?
3. What is the pH of a solution that consists of 0.20 M ammonia, NH_3, and 0.20 M ammonium chloride, NH_4Cl?
4. What is the pH of 0.15 M acetic acid to which 1.56 g of sodium acetate, $NaCH_3CO_2$, has been added?
5. What is the pH of the solution that results from adding 30.0 mL of 0.015 M KOH to 50.0 mL of 0.015 M benzoic acid?
6. What is the pH of the solution that results from adding 25.0 mL of 0.12 M HCl to 25.0 mL of 0.43 M NH_3?
7. What is the pH of the buffer solution that contains 2.2 g of NH_4Cl in 250 mL of 0.12 M NH_3? Is the final pH lower or higher than the pH of the 0.12 M ammonia solution?
8. Lactic acid ($CH_3CHOHCO_2H$) is found in sour milk, in sauerkraut, and in muscles after activity. (K_a for lactic acid $= 1.4 \times 10^{-4}$.)
   (a) If 2.75 g of $NaCH_3CHOHCO_2$, sodium lactate, is added to 5.00×10^2 mL of 0.100 M lactic acid, what is the pH of the resulting buffer solution?
   (b) Is the pH of the buffered solution lower or higher than the pH of the lactic acid solution?
9. What mass of sodium acetate, $NaCH_3CO_2$, must be added to 1.00 L of 0.10 M acetic acid to give a solution with a pH of 4.50?
10. What mass of ammonium chloride, NH_4Cl, must be added to exactly 5.00×10^2 mL of 0.10 M NH_3 solution to give a solution with a pH of 9.00?

Using the Henderson–Hasselbalch Equation

(See Section 17.2 and Example 17.3.)

11. Calculate the pH of a solution that has an acetic acid concentration of 0.050 M and a sodium acetate concentration of 0.075 M.

12. Calculate the pH of a solution that has an ammonium chloride concentration of 0.050 M and an ammonia concentration of 0.045 M.

13. What must the ratio of acetic acid to acetate ion be to have a buffer with a pH value of 5.00?

14. What must the ratio of $H_2PO_4^-$ to HPO_4^{2-} be to have a buffer with a pH value of 7.00?

15. A buffer is composed of formic acid and its conjugate base, the formate ion.
    (a) What is the pH of a solution that has a formic acid concentration of 0.050 M and a sodium formate concentration of 0.035 M?
    (b) What must the ratio of acid to conjugate base be to have a pH value 0.50 units higher than the value calculated in part (a)?

16. A buffer solution is composed of 1.360 g of KH_2PO_4 and 5.677 g of Na_2HPO_4.
    (a) What is the pH of the buffer solution?
    (b) What mass of KH_2PO_4 must be added to decrease the buffer solution pH by 0.50 unit from the value calculated in part (a)?

Preparing a Buffer Solution

(See Section 17.2 and Example 17.4.)

17. Which of the following combinations would be the best to buffer the pH of a solution at approximately 9?
    (a) HCl and NaCl
    (b) NH_3 and NH_4Cl
    (c) CH_3CO_2H and $NaCH_3CO_2$

18. Which of the following combinations would be the best to buffer the pH of a solution at approximately 7?
    (a) H_3PO_4 and NaH_2PO_4
    (b) NaH_2PO_4 and Na_2HPO_4
    (c) Na_2HPO_4 and Na_3PO_4

19. Describe how to prepare a buffer solution from NaH_2PO_4 and Na_2HPO_4 to have a pH of 7.5.

20. Describe how to prepare a buffer solution from NH_3 and NH_4Cl to have a pH of 9.5.

21. Determine the volume (in mL) of 1.00 M NaOH that must be added to 250 mL of 0.50 M CH_3CO_2H to produce a buffer with a pH of 4.50.

22. Determine the volume (in mL) of 1.00 M HCl that must be added to 750 mL of 0.50 M HPO_4^{2-} to produce a buffer with a pH of 7.00.

Adding an Acid or a Base to a Buffer Solution

(See Section 17.2 and Example 17.5.)

23. A buffer solution was prepared by adding 4.95 g of sodium acetate, $NaCH_3CO_2$, to 2.50×10^2 mL of 0.150 M acetic acid, CH_3CO_2H.
    (a) What is the pH of the buffer?
    (b) What is the pH of 1.00×10^2 mL of the buffer solution if you add 82 mg of NaOH to the solution?

24. You dissolve 0.425 g of NaOH in 2.00 L of a buffer solution that has $[H_2PO_4^-] = [HPO_4^{2-}] = 0.132$ M. What is the pH of the solution before adding NaOH? After adding NaOH?

25. A buffer solution is prepared by adding 0.125 mol of ammonium chloride to 5.00×10^2 mL of 0.500 M solution of ammonia.
    (a) What is the pH of the buffer?
    (b) If 0.0100 mol of HCl gas is bubbled into 5.00×10^2 mL of the buffer, what is the new pH of the solution?

26. What is the pH change when 20.0 mL of 0.100 M NaOH is added to 80.0 mL of a buffer solution consisting of 0.169 M NH_3 and 0.183 M NH_4Cl?

More about Acid–Base Reactions: Titrations

(See Section 17.3 and Examples 17.6 and 17.7.)

27. Phenol, C_6H_5OH, is a weak organic acid. Suppose 0.515 g of the compound is dissolved in enough water to make 125 mL of solution. The resulting solution is titrated with 0.123 M NaOH.

$$C_6H_5OH(aq) + OH^-(aq) \rightleftharpoons C_6H_5O^-(aq) + H_2O(\ell)$$

    (a) What is the pH of the original solution of phenol?
    (b) What are the concentrations of all of the following ions at the equivalence point: Na^+, H_3O^+, OH^-, and $C_6H_5O^-$?
    (c) What is the pH of the solution at the equivalence point?

28. Assume you dissolve 0.235 g of the weak acid benzoic acid, $C_6H_5CO_2H$, in enough water to make 1.00×10^2 mL of solution and then titrate the solution with 0.108 M NaOH.

$$C_6H_5CO_2H(aq) + OH^-(aq) \rightleftharpoons C_6H_5CO_2^-(aq) + H_2O(\ell)$$

(a) What was the pH of the original benzoic acid solution?

(b) What are the concentrations of all of the following ions at the equivalence point: Na^+, H_3O^+, OH^-, and $C_6H_5CO_2^-$?

(c) What is the pH of the solution at the equivalence point?

29. You require 36.78 mL of 0.0105 M HCl to reach the equivalence point in the titration of 25.0 mL of aqueous ammonia.

(a) What was the concentration of NH_3 in the original ammonia solution?

(b) What are the concentrations of H_3O^+, OH^-, and NH_4^+ at the equivalence point?

(c) What is the pH of the solution at the equivalence point?

30. A titration of 25.0 mL of a solution of the weak base aniline, $C_6H_5NH_2$, requires 25.67 mL of 0.175 M HCl to reach the equivalence point.

$$C_6H_5NH_2(aq) + H_3O^+(aq) \rightleftharpoons C_6H_5NH_3^+(aq) + H_2O(\ell)$$

(a) What was the concentration of aniline in the original solution?

(b) What are the concentrations of H_3O^+, OH^-, and $C_6H_5NH_3^+$ at the equivalence point?

(c) What is the pH of the solution at the equivalence point?

Titration Curves and Indicators

(See Section 17.3 and Figures 17.4–17.11.)

31. Without doing detailed calculations, sketch the curve for the titration of 30.0 mL of 0.10 M NaOH with 0.10 M HCl. Indicate the approximate pH at the beginning of the titration and at the equivalence point. What is the total solution volume at the equivalence point?

32. Without doing detailed calculations, sketch the curve for the titration of 50 mL of 0.050 M pyridine, C_5H_5N (a weak base), with 0.10 M HCl. Indicate the approximate pH at the beginning of the titration and at the equivalence point. What is the total solution volume at the equivalence point?

33. You titrate 25.0 mL of 0.10 M NH_3 with 0.10 M HCl.

(a) What is the pH of the NH_3 solution before the titration begins?

(b) What is the pH at the equivalence point?

(c) What is the pH at the halfway point of the titration?

(d) What indicator in Figure 17.11 could be used to detect the equivalence point?

(e) Calculate the pH of the solution after adding 5.00, 15.0, 20.0, 22.0, and 30.0 mL of the acid. Combine this information with that in parts (a)–(c) and plot the titration curve.

34. Construct a rough plot of pH versus volume of base for the titration of 25.0 mL of 0.050 M HCN with 0.075 M NaOH.

(a) What is the pH before any NaOH is added?

(b) What is the pH at the halfway point of the titration?

(c) What is the pH when 95% of the required NaOH has been added?

(d) What volume of base, in milliliters, is required to reach the equivalence point?

(e) What is the pH at the equivalence point?

(f) What indicator would be most suitable for this titration? (Figure 17.11.)

(g) What is the pH when 105% of the required base has been added?

35. Using Figure 17.11, suggest an indicator to use in each of the following titrations:

(a) The weak base pyridine is titrated with HCl.

(b) Formic acid is titrated with NaOH.

(c) Ethylenediamine, a weak diprotic base, is titrated with HCl.

36. Using Figure 17.11, suggest an indicator to use in each of the following titrations.

(a) $NaHCO_3$ is titrated to CO_3^{2-} with NaOH.

(b) Hypochlorous acid is titrated with NaOH.

(c) Trimethylamine is titrated with HCl.

Solubility Guidelines

(See Sections 3.4 and 3.5, Figure 3.10, and Example 3.2.)

37. Name two insoluble salts of each of the following ions.

(a) Cl^- (b) Zn^{2+} (c) Fe^{2+}

38. Name two insoluble salts of each of the following ions.

(a) SO_4^{2-} (b) Ni^{2+} (c) Br^-

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

39. Using the solubility guidelines (Figure 3.10), predict whether each of the following is insoluble or soluble in water.
(a) $(NH_4)_2CO_3$ (c) NiS
(b) $ZnSO_4$ (d) $BaSO_4$

40. Predict whether each of the following is insoluble or soluble in water.
(a) $Pb(NO_3)_2$ (c) $ZnCl_2$
(b) $Fe(OH)_3$ (d) CuS

Writing Solubility Product Constant Expressions

(See Section 17.4.)

41. For each of the following insoluble salts, (1) write a balanced equation showing the equilibrium occurring when the salt is added to water, and (2) write the K_{sp} expression.
(a) AgCN (b) $NiCO_3$ (c) $AuBr_3$

42. For each of the following insoluble salts, (1) write a balanced equation showing the equilibrium occurring when the salt is added to water, and (2) write the K_{sp} expression.
(a) $PbSO_4$ (b) BaF_2 (c) Ag_3PO_4

Calculating K_{sp}

(See Section 17.4 and Example 17.8.)

43. When 1.55 g of solid thallium(I) bromide is added to 1.00 L of water, the salt dissolves to a small extent.

$$TlBr(s) \rightleftharpoons Tl^+(aq) + Br^-(aq)$$

The thallium(I) and bromide ions in equilibrium with TlBr each have a concentration of 1.9×10^{-3} M. What is the value of K_{sp} for TlBr?

44. At 20 °C, a saturated aqueous solution of silver acetate, $AgCH_3CO_2$, contains 1.0 g of the silver compound dissolved in 100.0 mL of solution. Calculate K_{sp} for silver acetate.

$$AgCH_3CO_2(s) \rightleftharpoons Ag^+(aq) + CH_3CO_2^-(aq)$$

45. When 250 mg of SrF_2, strontium fluoride, is added to 1.00 L of water, the salt dissolves to a very small extent.

$$SrF_2(s) \rightleftharpoons Sr^{2+}(aq) + 2\ F^-(aq)$$

At equilibrium, the concentration of Sr^{2+} is found to be 1.03×10^{-3} M. What is the value of K_{sp} for SrF_2?

46. Calcium hydroxide, $Ca(OH)_2$, dissolves in water to the extent of 1.78 g per liter. What is the value of K_{sp} for $Ca(OH)_2$?

$$Ca(OH)_2(s) \rightleftharpoons Ca^{2+}(aq) + 2\ OH^-(aq)$$

47. You add 0.979 g of $Pb(OH)_2$ to 1.00 L of pure water at 25 °C. The pH is 9.15. Estimate the value of K_{sp} for $Pb(OH)_2$.

48. You place 1.234 g of solid $Ca(OH)_2$ in 1.00 L of pure water at 25 °C. The pH of the solution is found to be 12.68. Estimate the value of K_{sp} for $Ca(OH)_2$.

Estimating Salt Solubility from K_{sp}

(See Section 17.4 and Examples 17.9 and 17.10.)

49. Estimate the solubility of silver iodide in pure water at 25 °C (a) in moles per liter and (b) in grams per liter.

$$AgI(s) \rightleftharpoons Ag^+(aq) + I^-(aq)$$

50. What is the molar concentration of $Au^+(aq)$ in a saturated solution of AuCl in pure water at 25 °C?

$$AuCl(s) \rightleftharpoons Au^+(aq) + Cl^-(aq)$$

51. Estimate the solubility of calcium fluoride, CaF_2, (a) in moles per liter and (b) in grams per liter of pure water.

$$CaF_2(s) \rightleftharpoons Ca^{2+}(aq) + 2\ F^-(aq)$$

52. Estimate the solubility of lead(II) bromide (a) in moles per liter and (b) in grams per liter of pure water.

53. The K_{sp} value for radium sulfate, $RaSO_4$, is 4.2×10^{-11}. If 25 mg of radium sulfate is placed in 1.00×10^2 mL of water, does all of it dissolve? If not, how much dissolves?

54. If 55 mg of lead(II) sulfate is placed in 250 mL of pure water, does all of it dissolve? If not, how much dissolves?

55. Use K_{sp} values to decide which compound in each of the following pairs is more soluble. (Appendix J.)
(a) $PbCl_2$ or $PbBr_2$
(b) HgS or FeS
(c) $Fe(OH)_2$ or $Zn(OH)_2$

56. Use K_{sp} values to decide which compound in each of the following pairs is more soluble. (Appendix J.)
(a) AgBr or AgSCN
(b) $SrCO_3$ or $SrSO_4$
(c) AgI or PbI_2
(d) MgF_2 or CaF_2

The Common Ion Effect and Salt Solubility

(See Section 17.4 and Example 17.11.)

57. Calculate the molar solubility of silver thiocyanate, AgSCN, in pure water and in water containing 0.010 M NaSCN.

58. Calculate the solubility of silver bromide, AgBr, in moles per liter, in pure water. Compare this value with the molar solubility of AgBr in 225 mL of water to which 0.15 g of NaBr has been added.

59. Compare the solubility, in milligrams per milliliter, of silver iodide, AgI, (a) in pure water and (b) in water that is 0.020 M in $AgNO_3$.

60. What is the solubility, in milligrams per milliliter, of BaF_2, (a) in pure water and (b) in water containing 5.0 mg/mL KF?

61. Calculate the solubility, in moles per liter, of iron(II) hydroxide, $Fe(OH)_2$, in a solution buffered to a pH of 7.00.

62. Calculate the solubility, in moles per liter, of calcium hydroxide, $Ca(OH)_2$, in a solution buffered to a pH of 12.60.

The Effect of Basic Anions on Salt Solubility

63. Which insoluble compound in each pair should be more soluble in nitric acid than in pure water?
    (a) $PbCl_2$ or PbS
    (b) Ag_2CO_3 or AgI
    (c) $Al(OH)_3$ or AgCl

64. Which compound in each pair is more soluble in water than is predicted by a calculation from K_{sp}?
    (a) AgI or Ag_2CO_3
    (b) $PbCO_3$ or $PbCl_2$
    (c) AgCl or AgCN

Precipitation Reactions

(See Section 17.5 and Examples 17.12–17.14.)

65. You have a solution that has a lead(II) ion concentration of 0.0012 M. If enough soluble chloride-containing salt is added so that the Cl^- concentration is 0.010 M, will $PbCl_2$ precipitate?

66. Sodium carbonate is added to a solution in which the concentration of Ni^{2+} ion is 0.0024 M. Will precipitation of $NiCO_3$ occur (a) when the concentration of the carbonate ion is 1.0×10^{-6} M or (b) when it is 100 times greater (1.0×10^{-4} M)?

67. If the concentration of Zn^{2+} in 10.0 mL of water is 1.63×10^{-4} M, will zinc hydroxide, $Zn(OH)_2$, precipitate when 4.0 mg of NaOH is added?

68. You have 95 mL of a solution that has a lead(II) concentration of 0.0012 M. Will $PbCl_2$ precipitate when 1.20 g of solid NaCl is added?

69. If the concentration of Mg^{2+} ion in seawater is 1350 mg/L, what OH^- concentration is required to precipitate $Mg(OH)_2$?

70. Will a precipitate of $Mg(OH)_2$ form when 25.0 mL of 0.010 M NaOH is combined with 75.0 mL of a 0.10 M solution of magnesium chloride?

Equilibria Involving Complex Ions

(See Section 17.6 and Examples 17.15 and 17.16.)

71. Zinc hydroxide is amphoteric (Section 16.10). Use equilibrium constants to show that, given sufficient OH^-, $Zn(OH)_2$ can dissolve in NaOH.

72. Solid silver iodide, AgI, can be dissolved by adding aqueous sodium cyanide. Calculate K_{net} for the following reaction.

$$AgI(s) + 2\ CN^-(aq) \rightleftharpoons [Ag(CN)_2]^-(aq) + I^-(aq)$$

73. ▲ What amount of ammonia (moles) must be added to dissolve 0.050 mol of AgCl suspended in 1.0 L of water?

74. Can you dissolve 15.0 mg of AuCl in 100.0 mL of water if you add 15.0 mL of 6.00 M NaCN?

75. What is the solubility of AgCl (a) in pure water and (b) in 1.0 M NH_3?

76. The chemistry of silver(I) cyanide:
    (a) Calculate the solubility of AgCN(s) in water from the K_{sp} value.
    (b) Calculate the value of the equilibrium constant for the reaction

$$AgCN(s) + CN^-(aq) \rightleftharpoons [Ag(CN)_2]^-(aq)$$

    from K_{sp} and K_f values and predict from this value whether AgCN(s) would dissolve in KCN(aq).
    (c) Determine the equilibrium constant for the reaction

$$AgCN(s) + 2\ S_2O_3^{2-}(aq) \rightleftharpoons [Ag(S_2O_3)_2]^{3-}(aq) + CN^-(aq)$$

    Calculate the solubility of AgCN in a solution containing 0.10 M $S_2O_3^{2-}$ and compare the value to the solubility in water [part (a)].

General Questions

These questions are not designated as to type or location in the chapter. They may combine several concepts.

77. In each of the following cases, decide whether a precipitate will form when mixing the indicated reagents, and write a balanced equation for the reaction.
    (a) $NaBr(aq) + AgNO_3(aq)$
    (b) $KCl(aq) + Pb(NO_3)_2(aq)$

78. In each of the following cases, decide whether a precipitate will form when mixing the indicated reagents, and write a balanced equation for the reaction.
    (a) $Na_2SO_4(aq) + Mg(NO_3)_2(aq)$
    (b) $K_3PO_4(aq) + FeCl_3(aq)$

79. If you mix 48 mL of 0.0012 M $BaCl_2$ with 24 mL of 1.0×10^{-6} M Na_2SO_4, will a precipitate of $BaSO_4$ form?

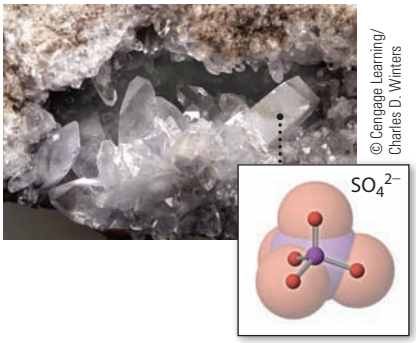
80. Calculate the hydronium ion concentration and the pH of the solution that results when 20.0 mL of 0.15 M acetic acid, CH_3CO_2H, is mixed with 5.0 mL of 0.17 M NaOH.

81. Calculate the hydronium ion concentration and the pH of the solution that results when 50.0 mL of 0.40 M NH_3 is mixed with 25.0 mL of 0.20 M HCl.

82. For each of the following cases, decide whether the pH is less than 7, equal to 7, or greater than 7.
    (a) Equal volumes of 0.10 M acetic acid, CH_3CO_2H, and 0.10 M KOH are mixed.
    (b) 25 mL of 0.015 M NH_3 is mixed with 12 mL of 0.015 M HCl.
    (c) 150 mL of 0.20 M HNO_3 is mixed with 75 mL of 0.40 M NaOH.
    (d) 25 mL of 0.45 M H_2SO_4 is mixed with 25 mL of 0.90 M NaOH.

83. Rank the following compounds in order of increasing solubility in water: Na_2CO_3, $BaCO_3$, Ag_2CO_3.

84. A sample of hard water contains about 2.0×10^{-3} M Ca^{2+}. A soluble fluoride-containing salt such as NaF is added to "fluoridate" the water (to aid in the prevention of dental cavities). What is the maximum concentration of F^- that can be present without precipitating CaF_2?



© Cengage Learning/Charles D. Winters

Dietary sources of fluoride ion. Adding fluoride ion to drinking water (or toothpaste) prevents the formation of dental cavities.

85. What is the pH of a buffer solution prepared from 5.15 g of NH_4NO_3 and 0.10 L of 0.15 M NH_3? What is the new pH if the solution is diluted with pure water to a volume of 5.00×10^2 mL?

86. If you place 5.0 mg of $SrSO_4$ in 1.0 L of pure water, will all of the salt dissolve before equilibrium is established, or will some salt remain undissolved?

© Cengage Learning/ Charles D. Winters

Celestite, $SrSO_4$
Strontium sulfate

Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

87. Describe the effect on the pH of the following actions or explain why there is not an effect:
   (a) Adding sodium acetate, $NaCH_3CO_2$, to 0.100 M CH_3CO_2H
   (b) Adding $NaNO_3$ to 0.100 M HNO_3

88. What volume of 0.120 M NaOH must be added to 100. mL of 0.100 M $NaHC_2O_4$ to reach a pH of 4.70?

89. ▲ A buffer solution is prepared by dissolving 1.50 g each of benzoic acid, $C_6H_5CO_2H$, and sodium benzoate, $NaC_6H_5CO_2$, in 150.0 mL of solution.
   (a) What is the pH of this buffer solution?
   (b) Which buffer component must be added, and in what quantity, to change the pH to 4.00?
   (c) What quantity of 2.0 M NaOH or 2.0 M HCl must be added to the buffer to change the pH to 4.00?

90. What volume of 0.200 M HCl must be added to 500.0 mL of 0.250 M NH_3 to have a buffer with a pH of 9.00?

91. What is the equilibrium constant for the following reaction?

$$AgCl(s) + I^-(aq) \rightleftharpoons AgI(s) + Cl^-(aq)$$

Does the equilibrium lie predominantly to the left or to the right? Will AgI form if iodide ion, I^-, is added to a saturated solution of AgCl?

92. Calculate the equilibrium constant for the following reaction.

$$Zn(OH)_2(s) + 2\ CN^-(aq) \rightleftharpoons Zn(CN)_2(s) + 2\ OH^-(aq)$$

Does the equilibrium lie predominantly to the left or to the right?

93. Suppose you eat 28 grams of rhubarb leaves with an oxalic acid content of 1.2% by weight.
   (a) What volume of 0.25 M NaOH is required to titrate completely the oxalic acid in the leaves?
   (b) What mass of calcium oxalate could be formed from the oxalic acid in these leaves?

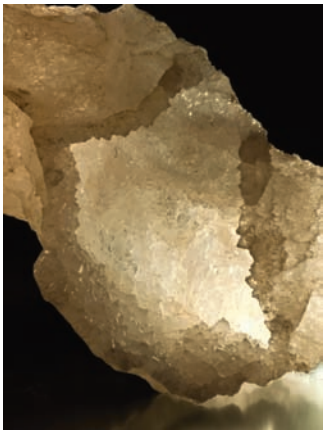
94. The solubility product constant for calcium oxalate is estimated to be 4×10^{-9}. What is its solubility in grams per liter?

95. ▲ In principle, the ions Ba^{2+} and Ca^{2+} can be separated by the difference in solubility of their fluorides, BaF_2 and CaF_2. If you have a solution that is 0.10 M in both Ba^{2+} and Ca^{2+}, CaF_2 will begin to precipitate first as fluoride ion is added slowly to the solution.
   (a) What concentration of fluoride ion will precipitate the maximum amount of Ca^{2+} ion without precipitating BaF_2?
   (b) What concentration of Ca^{2+} remains in solution when BaF_2 just begins to precipitate?

96. ▲ A solution contains 0.10 M iodide ion, I^-, and 0.10 M carbonate ion, CO_3^{2-}.
   (a) If solid $Pb(NO_3)_2$ is slowly added to the solution, which salt will precipitate first, PbI_2 or $PbCO_3$?
   (b) What will be the concentration of the first ion that precipitates (CO_3^{2-} or I^-) when the second, more soluble salt begins to precipitate?

© Cengage Learning/Charles D. Winters

Lead(II) iodide ($K_{sp} = 9.8 \times 10^{-9}$) is a bright yellow solid.



97. ▲ A solution contains Ca^{2+} and Pb^{2+} ions, both at a concentration of 0.010 M. You wish to separate the two ions from each other as completely as possible by precipitating one but not the other using aqueous Na_2SO_4 as the precipitating agent.
   (a) Which will precipitate first as sodium sulfate is added, $CaSO_4$ or $PbSO_4$?
   (b) What will be the concentration of the first ion that precipitates (Ca^{2+} or Pb^{2+}) when the second, more soluble salt begins to precipitate?

98. Buffer capacity is defined as the number of moles of a strong acid or strong base that is required to change the pH of 1 L of the buffer solution by one unit. What is the buffer capacity of a solution that is 0.10 M in acetic acid and 0.10 M in sodium acetate?

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

99. The Ca^{2+} ion in hard water can be precipitated as $CaCO_3$ by adding soda ash, Na_2CO_3. If the calcium ion concentration in hard water is 0.010 M and if the Na_2CO_3 is added until the carbonate ion concentration is 0.050 M, what percentage of the calcium ions has been removed from the water? (You may neglect carbonate ion hydrolysis.)

© Cengage Learning/Charles D. Winters

This sample of calcium carbonate ($K_{sp} = 3.4 \times 10^{-9}$) was deposited in a cave formation.

100. Some photographic film is coated with crystals of AgBr suspended in gelatin. Some of the silver ions are reduced to silver metal on exposure to light. Unexposed AgBr is then dissolved with sodium thiosulfate in the "fixing" step.

$$AgBr(s) + 2\ S_2O_3^{2-}(aq) \rightleftharpoons [Ag(S_2O_3)_2]^{3-}(aq) + Br^-(aq)$$

(a) What is the equilibrium constant for this reaction?

(b) What mass of $Na_2S_2O_3$ must be added to dissolve 1.00 g of AgBr suspended in 1.00 L of water?

In the Laboratory

101. Each pair of ions below is found together in aqueous solution. Using the table of solubility product constants in Appendix J, devise a way to separate these ions by adding a reagent to precipitate one of the ions as an insoluble salt and leaving the other in solution.

(a) Ba^{2+} and Na^+ (b) Ni^{2+} and Pb^{2+}

102. Each pair of ions below is found together in aqueous solution. Using the table of solubility product constants in Appendix J, devise a way to separate these ions by adding a reagent to precipitate one of the ions as an insoluble salt and leave the other in solution.

(a) Cu^{2+} and Ag^+

(b) Al^{3+} and Fe^{3+}

103. ▲ The cations Ba^{2+} and Sr^{2+} can be precipitated as very insoluble sulfates.

(a) If you add sodium sulfate to a solution containing these metal cations, each with a concentration of 0.10 M, which is precipitated first, $BaSO_4$ or $SrSO_4$?

(b) What will be the concentration of the first ion that precipitates (Ba^{2+} or Sr^{2+}) when the second, more soluble salt begins to precipitate?

104. ▲ You will often work with salts of Fe^{3+}, Pb^{2+}, and Al^{3+} in the laboratory. (All are found in nature, and all are important economically.) If you have a solution containing these three ions, each at a concentration of 0.10 M, what is the order in which their hydroxides precipitate as aqueous NaOH is slowly added to the solution?

105. Aniline hydrochloride, $(C_6H_5NH_3)Cl$, is a weak acid. (Its conjugate base is the weak base aniline, $C_6H_5NH_2$.) The acid can be titrated with a strong base such as NaOH.

$$C_6H_5NH_3^+(aq) + OH^-(aq) \rightleftharpoons C_6H_5NH_2(aq) + H_2O(\ell)$$

Assume 50.0 mL of 0.100 M aniline hydrochloride is titrated with 0.185 M NaOH. (K_a for aniline hydrochloride is 2.4×10^{-5}.)

(a) What is the pH of the $(C_6H_5NH_3)Cl$ solution before the titration begins?

(b) What is the pH at the equivalence point?

(c) What is the pH at the halfway point of the titration?

(d) Which indicator in Figure 17.11 could be used to detect the equivalence point?

(e) Calculate the pH of the solution after adding 10.0, 20.0, and 30.0 mL of base.

(f) Combine the information in parts (a), (b), (c), and (e), and plot an approximate titration curve.

106. The weak base ethanolamine, $HOCH_2CH_2NH_2$, can be titrated with HCl.

$$HOCH_2CH_2NH_2(aq) + H_3O^+(aq) \rightleftharpoons HOCH_2CH_2NH_3^+(aq) + H_2O(\ell)$$

Assume you have 25.0 mL of a 0.010 M solution of ethanolamine and titrate it with 0.0095 M HCl. (K_b for ethanolamine is 3.2×10^{-5}.)

(a) What is the pH of the ethanolamine solution before the titration begins?

(b) What is the pH at the equivalence point?

(c) What is the pH at the halfway point of the titration?

(d) Which indicator in Figure 17.11 would be the best choice to detect the equivalence point?

(e) Calculate the pH of the solution after adding 5.00, 10.0, 20.0, and 30.0 mL of the acid.

(f) Combine the information in parts (a), (b), (c), and (e), and plot an approximate titration curve.

107. For the titration of 50.0 mL of 0.150 M ethylamine, $C_2H_5NH_2$, with 0.100 M HCl, find the pH at each of the following points, and then use that information to sketch the titration curve and decide on an appropriate indicator.

(a) At the beginning, before HCl is added

(b) At the halfway point in the titration

(c) When 75% of the required acid has been added

(d) At the equivalence point

(e) When 10.0 mL more HCl has been added than is required

(f) Sketch the titration curve.

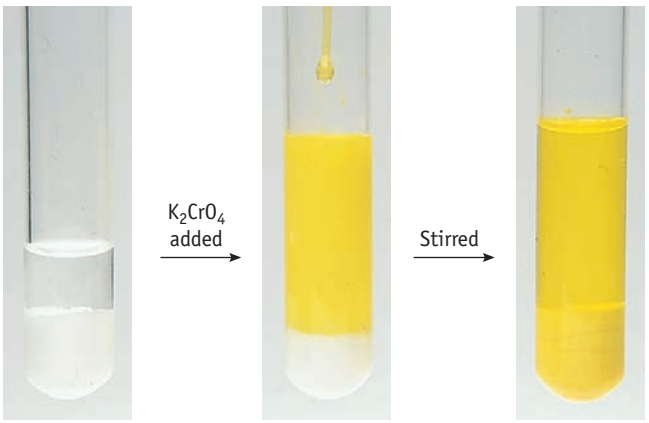
(g) Suggest an appropriate indicator for this titration.

108. A buffer solution with a pH of 12.00 consists of Na_3PO_4 and Na_2HPO_4. The volume of solution is 200.0 mL.

(a) Which component of the buffer is present in a larger amount?

(b) If the concentration of Na_3PO_4 is 0.400 M, what mass of Na_2HPO_4 is present?

(c) Which component of the buffer must be added to change the pH to 12.25? What mass of that component is required?



109. To have a buffer with a pH of 2.50, what volume of 0.150 M NaOH must be added to 100. mL of 0.230 M H_3PO_4?

110. ▲ What mass of Na_3PO_4 must be added to 80.0 mL of 0.200 M HCl to obtain a buffer with a pH of 7.75?

111. You have a solution that contains $AgNO_3$, $Pb(NO_3)_2$, and $Cu(NO_3)_2$. Devise a separation method that results in having Ag^+ in one test tube, Pb^{2+} in another, and Cu^{2+} in a third test tube. Use solubility guidelines and K_{sp} and K_f values.

112. Once you have separated the three salts in Study Question 111 into three test tubes, you now need to confirm their presence.

(a) For Pb^{2+} ion, one way to do this is to treat a precipitate of $PbCl_2$ with K_2CrO_4 to produce the bright yellow insoluble solid, $PbCrO_4$. Using K_{sp} values, confirm that the chloride salt should be converted to the chromate salt.

White $PbCl_2$ is converted to yellow $PbCrO_4$ on adding K_2CrO_4.

© Cengage Learning/Charles D. Winters

(b) Suggest a method for confirming the presence of Ag^+ and Cu^{2+} ions using complex ions.

Summary and Conceptual Questions

The following questions may use concepts from this and previous chapters.

113. Suggest a method for separating a precipitate consisting of a mixture of solid CuS and solid $Cu(OH)_2$.

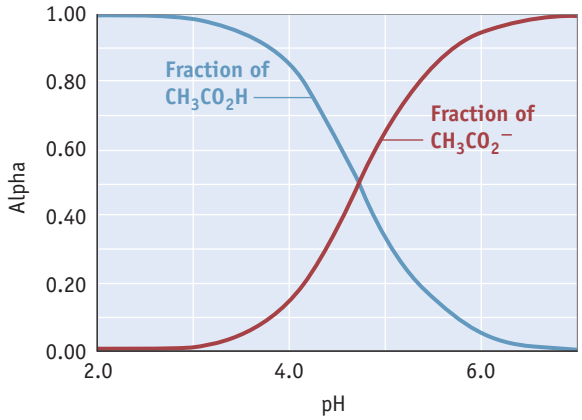
114. Which of the following barium salts should dissolve in a strong acid such as HCl: $Ba(OH)_2$, $BaSO_4$, or $BaCO_3$?



115. Explain why the solubility of Ag_3PO_4 can be greater in water than is calculated from the K_{sp} value of the salt.

116. Two acids, each approximately 0.01 M in concentration, are titrated separately with a strong base. The acids show the following pH values at the equivalence point: HA, pH = 9.5, and HB, pH = 8.5.

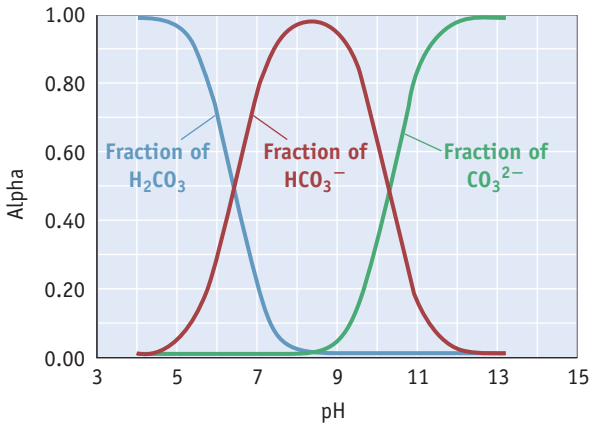
(a) Which is the stronger acid, HA or HB?

(b) Which of the conjugate bases, A^- or B^-, is the stronger base?

117. Composition diagrams, commonly known as "alpha plots," are often used to visualize the species in a solution of an acid or base as the pH is varied. The diagram for 0.100 M acetic acid is shown here.

The plot shows how the fraction [alpha (α)] of acetic acid in solution,

$$\alpha = \frac{[CH_3CO_2H]}{[CH_3CO_2H] + [CH_3CO_2^-]}$$



changes as the pH increases (blue curve). (The red curve shows how the fraction of acetate ion, $CH_3CO_2^-$, changes as the pH increases.) Alpha plots are another way of viewing the relative concentrations of acetic acid and acetate ion as a strong base is added to a solution of acetic acid in the course of a titration.

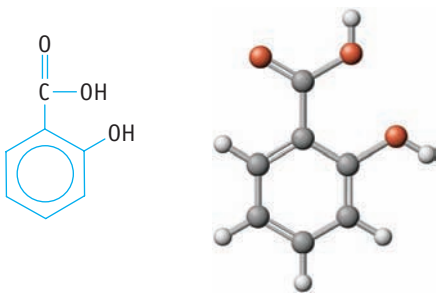
(a) Explain why the fraction of acetic acid declines and that of acetate ion increases as the pH increases.

(b) Which species predominates at a pH of 4, acetic acid or acetate ion? What is the situation at a pH of 6?

(c) Consider the point where the two lines cross. The fraction of acetic acid in the solution is 0.5, and so is that of acetate ion. That is, the solution is half acid and half conjugate base; their concentrations are equal. At this point, the graph shows the pH is 4.74. Explain why the pH at this point is 4.74.

118. The composition diagram, or alpha plot, for the important acid–base system of carbonic acid, H_2CO_3, is illustrated. (See Study Question 117 for more information on such diagrams.)

(a) Explain why the fraction of bicarbonate ion, HCO_3^-, rises and then falls as the pH increases.



(b) What is the composition of the solution when the pH is 6.0? When the pH is 10.0?

(c) If you wanted to buffer a solution at a pH of 11.0, what should be the ratio of HCO_3^- to CO_3^{2-}?

119. The chemical name for aspirin is acetylsalicylic acid. It is believed that the analgesic and other desirable properties of aspirin are due not to the aspirin itself but rather to the simpler compound salicylic acid, $C_6H_4(OH)CO_2H$, which results from the breakdown of aspirin in the stomach.

Salicylic acid

(a) Give approximate values for the following bond angles in the acid: (i) C—C—C in the ring; (ii) O—C═O; (iii) either of the C—O—H angles; and (iv) C—C—H.

(b) What is the hybridization of the C atoms of the ring? Of the C atom in the $—CO_2H$ group?

(c) Experiment shows that 1.00 g of the acid will dissolve in 460 mL of water. If the pH of this solution is 2.4, what is K_a for the acid?

(d) If you have salicylic acid in your stomach and if the pH of gastric juice is 2.0, calculate the percentage of salicylic acid that will be present in the stomach in the form of the salicylate ion, $C_6H_4(OH)CO_2^-$.

(e) Assume you have 25.0 mL of a 0.014 M solution of salicylic acid and titrate it with 0.010 M NaOH. What is the pH at the halfway point of the titration? What is the pH at the equivalence point?

120. Aluminum hydroxide reacts with phosphoric acid to give $AlPO_4$. The substance is used industrially in adhesives, binders, and cements.

(a) Write the balanced equation for the preparation of $AlPO_4$ from aluminum hydroxide and phosphoric acid.

(b) If you begin with 152 g of aluminum hydroxide and 3.00 L of 0.750 M phosphoric acid, what is the theoretical yield of $AlPO_4$?

(c) If you place 25.0 g of $AlPO_4$ in 1.00 L of water, what are the concentrations of Al^{3+} and PO_4^{3-} at equilibrium? (Neglect hydrolysis of aqueous Al^{3+} and PO_4^{3-} ions.) K_{sp} for $AlPO_4$ is 1.3×10^{-20}.

(d) Does the solubility of $AlPO_4$ increase or decrease on adding HCl? Explain.

18.7 The Interplay of Kinetics and Thermodynamics

18.1 Spontaneity and Dispersal of Energy: Entropy

Goals for Section 18.1

- Understand the concept of spontaneity: spontaneous processes occur without outside intervention and proceed to equilibrium, a result of energy dispersal.
- Know the second law of thermodynamics: a spontaneous process is one that leads to an increase in entropy in the universe.
- Recognize that an entropy change is the energy transferred as heat for a reversible process divided by the kelvin temperature.

In chemistry, we encounter many examples of chemical changes (chemical reactions) and physical changes (the formation of mixtures, expansion of gases, and changes of state, to name a few). Change is central to chemistry, so it is important to understand the factors that determine whether a change will occur. Chemists use the term *spontaneous* to represent a change that occurs without outside intervention. There is an important observation to be made: Spontaneous changes occur only in the direction that leads to equilibrium.

We can readily recognize many chemical reactions that are spontaneous, such as hydrogen and oxygen combining to form water, methane burning to give CO_2 and H_2O, Na and Cl_2 reacting to form NaCl, and HCl(aq) and NaOH(aq) reacting to form H_2O and NaCl(aq). A common feature of these reactions is that they are exothermic, so it would be tempting to conclude that evolution of energy as heat is the criterion that determines whether a reaction or process is spontaneous. Further inspection, however, reveals significant flaws in this reasoning. This is especially evident when we consider some common spontaneous changes that are endothermic or energy neutral:

- *Dissolving NH_4NO_3.* The ionic compound NH_4NO_3 dissolves spontaneously in water. The process is endothermic ($\Delta_r H° = +25.7$ kJ/mol).

◀ **The Combustion of Hydrogen Gas.** The exothermic reaction of hydrogen gas with oxygen to form water. (A hydrogen-filled balloon was ignited with a candle.)

Problem Solving Tip 18.1 A Review of Concepts of Thermodynamics

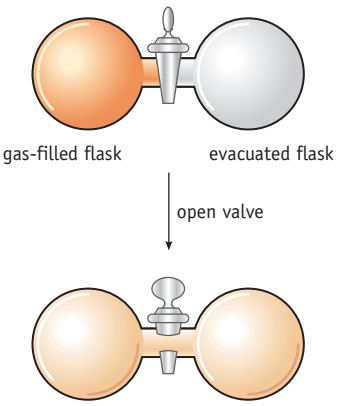
To understand the thermodynamic concepts introduced in this chapter, be sure to review the following ideas from Chapter 5.

System: The part of the universe under study.

Surroundings: The rest of the universe exclusive of the system, capable of exchanging energy and/or matter with the system.

Exothermic: Energy transfers as heat from the system to the surroundings.

Endothermic: Energy transfers as heat from the surroundings to the system.



First law of thermodynamics: The law of conservation of energy; energy cannot be created or destroyed. The change in internal energy of a system is the sum of energy transferred into or out of the system as heat and/or as work, $\Delta U = q + w$.

Enthalpy change: The energy transferred as heat under conditions of constant pressure.

State function: A quantity whose value depends only on the state of the system; changes in a state function can be calculated based on the initial and final states of a system.

Standard conditions: Pressure of 1 bar (1 bar = 0.98692 atm) and solution concentration of 1 *m*.

Standard enthalpy of formation, $\Delta_f H°$: The enthalpy change occurring when 1 mol of a compound is formed from its elements in their standard states.

When the valve is opened, the gas expands irreversibly to fill both flasks.

Figure 18.1 Spontaneous expansion of a gas.

© Cengage Learning/Charles D. Winters

Figure 18.2 A spontaneous process. The heated metal cylinder is placed in water. Energy transfers as heat spontaneously from the metal to water, that is, from the hotter object to the cooler object.

- *Expansion of a gas into a vacuum.* A system is set up with two flasks connected by a valve (Figure 18.1). One flask is filled with a gas, and the other is evacuated. When the valve is opened, the gas flows spontaneously from one flask to the other until the pressure is the same throughout. The expansion of an ideal gas is energy neutral (although expansion of most real gases is endothermic).
- *Phase changes.* Melting of ice is an endothermic process. Above 0 °C, ice melts spontaneously. Below 0 °C, melting is not spontaneous. At 0 °C, no net change will occur; liquid water and ice coexist at equilibrium. This example illustrates that temperature can have a role in determining spontaneity and that equilibrium is somehow an important aspect of the problem.
- *Energy transfer as heat.* The temperature of cold water sitting in a warm environment will rise until it reaches the ambient temperature. The energy required for this endothermic process comes from the surroundings. Energy transfer as heat from a hotter object (the surroundings) to a cooler object (the water) is spontaneous.
- *Chemical Reactions.* The reaction of H_2 and I_2 to form HI is endothermic, and the reverse reaction, the decomposition of HI to form H_2 and I_2, is exothermic. If $H_2(g)$ and $I_2(g)$ are mixed, a reaction forming HI will occur [$H_2(g) + I_2(g) \rightleftharpoons 2\ HI(g)$] until equilibrium is reached. Furthermore, if HI(g) is placed in a container, there will also be a reaction, but in the reverse direction, until equilibrium is achieved. Approach to equilibrium occurs spontaneously from either direction.

On further reflection, it is logical to conclude that evolution of heat cannot be a sufficient criterion in determining spontaneity. The first law of thermodynamics tells us that in any process energy must be conserved. If energy is transferred out of a system, then the same amount of energy must be transferred to the surroundings. Exothermicity of the system is always accompanied by an endothermic change in the surroundings. If energy evolution were the only factor determining whether a change is spontaneous, then for every spontaneous process there would be a corresponding nonspontaneous change in the surroundings. We must search further than the first law of thermodynamics to determine whether a change is spontaneous.

If energy alone is not sufficient to determine spontaneity, what further information do we need? Consider the following experiment: a piece of hot metal is placed in a beaker of water (Figure 18.2). Energy transfers as heat spontaneously from the metal to the water until the temperature of the metal and the water is the same. In accord with the first law of thermodynamics, the total amount of energy in the combination of the piece of metal and the water is conserved, but there is directionality to this process. Energy transfers as heat from a hotter object to a colder object; you

will never see a net flow of energy in the opposite direction, from a colder object to a hotter object. Is there a way to explain the directionality of this energy transfer?

Let us consider the initial and final states for the process of adding the hot metal to the cold water. Initially, energy is concentrated in the piece of metal. At the end of the process, this energy has been dispersed between the metal and the water. This is the indicator for which we have been searching. *In a spontaneous process, energy goes from being more concentrated to being more dispersed.*

There is a state function called **entropy (*S*)** that allows us to quantify the dispersal of energy. The **second law of thermodynamics** states that *a spontaneous process is one that results in an increase of the entropy of the universe. In a spontaneous process* ΔS*(universe) is greater than zero; this is a measure of the dispersal of energy in the process.*

Entropy For a more complete discussion of entropy, see the papers by F. L. Lambert, such as "Entropy Is Simple, Qualitatively," *Journal of Chemical Education*, Vol. 79, pp. 1241–1246, 2002, and references therein. See also Lambert's website: entropysite.oxy.edu

Because thermal energy is the result of the random motion of particles, potential energy is dispersed when it is converted to thermal energy. This conversion occurs when energy is transferred as heat, q. It is therefore not surprising that q is a part of the mathematical definition of ΔS. In addition, the effect of a given quantity of energy transferred as heat on energy dispersal is different at different temperatures. It turns out that a given q has a greater effect on ΔS at a lower temperature than at a higher temperature; that is, the extent of energy dispersal is inversely proportional to the temperature.

Second Law of Thermodynamics For a spontaneous process, ΔS(universe) > 0.

Our proposed definition for ΔS is thus related to the quotient q/T, but we must be a little more specific about q. The value of q used in the calculation of an entropy change must be the energy transferred as heat under what are called *reversible conditions,* which we symbolize as q_{rev}. (This is described more fully in *A Closer Look: Reversible and Irreversible Processes.*) The mathematical definition of ΔS is therefore q_{rev} divided by the absolute (Kelvin) temperature:

$$\Delta S = \frac{q_{rev}}{T} \qquad (18.1)$$

As expected from this equation, the units for ΔS are J/K.

18.2 Entropy: A Microscopic Understanding

Goal for Section 18.2

- Understand the statistical basis of entropy, that entropy is proportional to the number of ways that energy can be dispersed, that is, to the number of microstates available to a system.

Entropy is a measure of the extent of energy dispersal. In all spontaneous physical and chemical processes, energy changes from being localized or concentrated to being more dispersed or spread out. *In a spontaneous process, the change in entropy,* ΔS*, of the universe indicates the extent to which energy is dispersed.* So far, however, we have not explained why dispersal of energy occurs. In order to do this, we need to consider energy in its quantized form and matter on the atomic level.

Dispersal of Energy

We can explore the dispersal of energy using a simple example: energy being transferred as heat between hot and cold gaseous atoms. Consider an experiment involving two containers, one holding hot atoms and the other with cold atoms. The atoms move randomly in each container and collide with the walls. When the containers are in contact, energy is transferred through the container walls. Eventually, both containers will be at the same temperature; the energy originally localized in the hotter atoms is distributed over a greater number of atoms; and the atoms in each container will have the same distribution of energies.

A CLOSER LOOK

Reversible and Irreversible Processes

To determine entropy changes experimentally, the energy transferred by heating and cooling must be measured for a reversible process. But what is a reversible process?

The test for reversibility is that after carrying out a change along a given path (for example, energy added as heat), it must be possible to return to the starting point by the same path (energy taken away as heat) without altering the surroundings. Melting of ice and freezing of water at 0 °C are examples of reversible processes. Given a mixture of ice and water at equilibrium, adding energy as heat in small increments will convert ice to water; removing energy as heat in small increments will convert water back to ice.

Reversibility is closely associated with equilibrium. Assume we have a system at equilibrium. Reversible changes can be made by very slightly perturbing the equilibrium and letting the system readjust.

Spontaneous processes are not reversible. Suppose a gas is allowed to expand into a vacuum. No work is done in this process because there is no force to resist expansion. To return the system to its original state, it is necessary to compress the gas. Doing so means doing work on the system, however, because the system will not return to its original state on its own. In this process, the energy of the surroundings decreases by the amount of work expended by the surroundings. The system can be restored to its original state, but the surroundings will be altered in the process.

In summary, there are two important points concerning reversibility:

- At every step along a reversible pathway between two states, the system remains at equilibrium.
- Spontaneous processes follow irreversible pathways and involve nonequilibrium conditions.

To determine the entropy change for a process, it is necessary to identify a reversible pathway. Only then can an entropy change for the process be calculated from q_{rev} and the Kelvin temperature.

Quantization of Matter and Energy
In the examples that follow dealing with the submicroscopic nature of matter, we picture that matter is made up of atoms and that energy is also quantized, coming in packets of energy called quanta.

We can use a statistical explanation to show why energy is dispersed in a system. With statistical arguments, systems must include large numbers of particles for the arguments to be accurate. It will be easiest, however, if we look first at simple examples with only a few particles to understand the underlying concepts and then extrapolate our conclusions to larger systems.

Consider the system in Figure 18.3 in which, initially, there is one atom (1) with two discrete packets, or quanta, of energy and three other atoms (2, 3, and 4) with no energy. Collisions among the atoms allow energy to be transferred so that, over time, all distributions of the two packets of energy over the four atoms are seen. There are 10 different ways to distribute these 2 quanta of energy over the four atoms. Each of these 10 different ways to distribute the energy is called a **microstate**. In only one of these microstates do the 2 quanta remain on atom 1. In fact, only in 4 of the 10 microstates [1,1; 2,2; 3,3; and 4,4] is the energy concentrated on a single atom. In the majority of cases, 6 out of 10, the energy is distributed to two different atoms. Even in this small sample (four atoms) with only two packets of energy, it is more likely that at any given time the energy will be distributed to two atoms rather than concentrated on a single atom. There is a distinct preference that the energy will be dispersed over a greater number of atoms.

Let us now add more atoms to our system. We again begin with one atom (1) having 2 quanta of energy but now have five other atoms (2, 3, 4, 5, and 6) with no energy. Collisions let the energy be transferred between the atoms, and we now

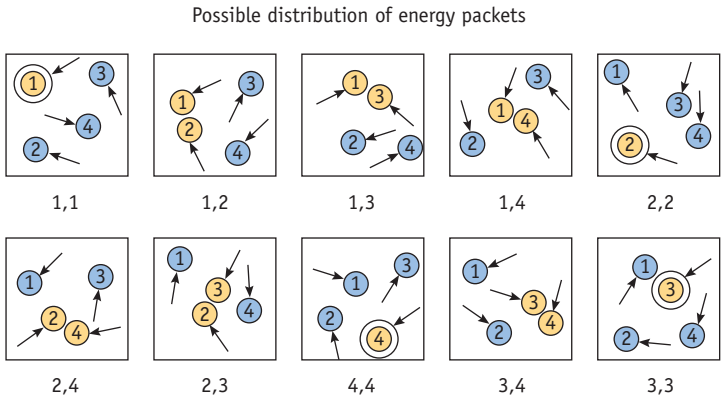

Figure 18.3 Energy dispersal. Possible ways of distributing two packets of energy among four atoms. To keep our analysis simple, we assume that initially there is one atom with two quanta of energy (1) and three atoms (2, 3, and 4) with no energy. There are 10 different ways to distribute the two quanta of energy among the four atoms.

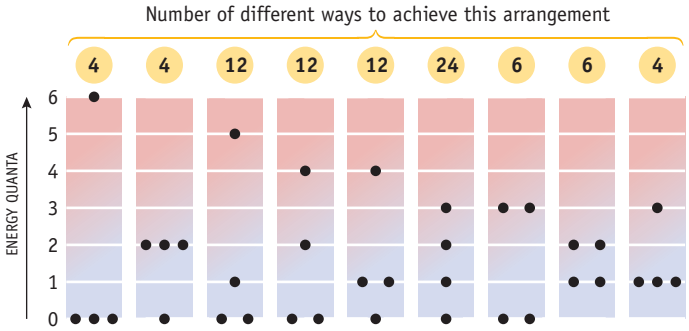
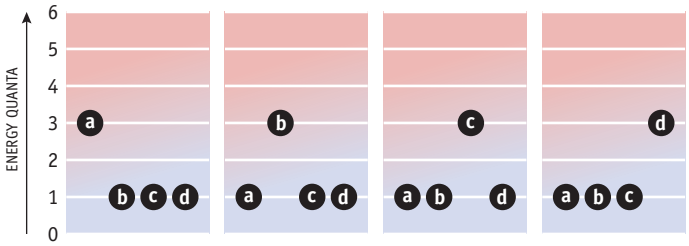
Number of Microstates	Distribution of 2 Quanta of Energy Among Six Atoms					
6	1:1	2:2	3:3	4:4	5:5	6:6
5	1:2	2:3	3:4	4:5	5:6	
4	1:3	2:4	3:5	4:6		
3	1:4	2:5	3:6			
2	1:5	2:6				
1	1:6					

Figure 18.4 Distributing 2 quanta of energy among six atoms. (Atoms are labeled 1 to 6.) There are 21 ways—21 microstates—of distributing 2 quanta of energy among six atoms.



find there are 21 possible microstates (Figure 18.4). There are six microstates in which the energy is concentrated on one atom, including one in which the energy is still on atom 1, but there are now 15 out of 21 microstates (or 71.4%) in which the energy is present on two different atoms. As the number of particles increases, the number of microstates available increases dramatically, and the fraction of microstates in which the energy is concentrated rather than dispersed goes down dramatically. It is much more likely that the energy will be dispersed rather than concentrated.

Now let us return to an example using a total of four atoms but increase the quantity of energy from 2 quanta to 6 quanta. Assume that we start with two atoms having 3 quanta of energy each. The other two atoms initially have zero energy (Figure 18.5). Through collisions, energy can be transferred to achieve different distributions of energy among the four atoms. In all, there are 84 microstates, falling into nine basic patterns. For example, one possible arrangement has one atom with 3 quanta of energy, and three atoms with 1 quantum each. There are four microstates in which this is true (Figure 18.5c). Increasing the number of quanta from 2 to 6 with the same number of atoms increased the number of possible microstates from 10 to 84. Increasing the amount of energy that is dispersed resulted in an increase in the number of microstates.



Statistical analyses for larger aggregates of atoms and energy quanta become increasingly complex, and the conclusions are even more compelling. As the

(a) Initially, two particles each have 3 quanta of energy, and the other two have none. A total of 6 quanta of energy will be distributed once the four particles interact.

(b) Once the particles begin to interact, there are nine ways to distribute the 6 available quanta. Each of these arrangements will have multiple ways of distributing the energy among the four atoms. Part (c) shows how the arrangement on the right can be achieved four ways.

(c) There are four different ways to have four particles (a, b, c, and d) such that one particle has 3 quanta of energy and the other three each have 1 quantum of energy.

Figure 18.5 Energy dispersal. Possible ways of distributing 6 quanta of energy among four atoms. A total of 84 microstates is possible.

Oesper Collection in the History of Chemistry/University of Cincinnati

Ludwig Boltzmann (1844–1906). Engraved on his tombstone in Vienna, Austria, is his equation defining entropy. The constant k is now known as Boltzmann's constant.

number of particles and/or quanta increases, the number of energy microstates grows rapidly. This larger number of microstates allows the energy to be dispersed to a greater extent. Ludwig Boltzmann proposed that the entropy of a system (the dispersal of energy at a given temperature) results from the number of microstates available. *As the number of microstates increases, so does the entropy of the system.* He expressed this idea in the equation

$$S = k \ln W \qquad (18.2)$$

which states that the entropy of a system, S, is proportional to the natural logarithm of the number of accessible microstates, W, that belong to a given energy of a system or substance. (The proportionality constant, k, is now known as **Boltzmann's constant** and has a value of 1.381×10^{-23} J/K.) Within these microstates, it turns out that those states that disperse energy over the largest number of atoms are vastly more probable than the others.

How Many Microstates? To give you a sense of the number of microstates available to a substance, consider a mole of ice at 273 K, where $S° = 41.3$ J/K · mol. Using Boltzmann's equation, we find that $W = 10^{1,299,000,000,000,000,000,000,000}$. That is, there are many, many more microstates for 1 mol of ice than there are atoms in the universe (about 10^{80}).

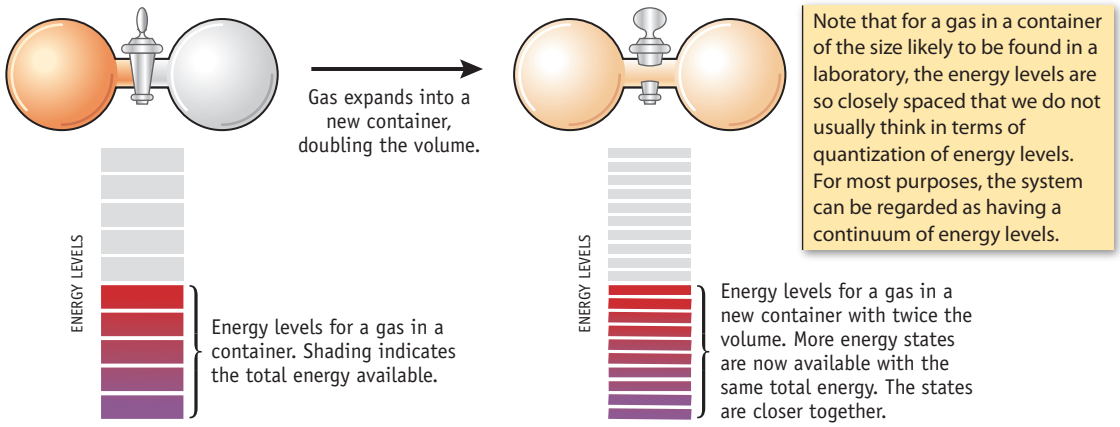
Dispersal of Matter: Dispersal of Energy Revisited

In many processes, it appears that the dispersal of matter also contributes to spontaneity. We shall see, however, that these effects can also be explained in terms of energy dispersal. Let us examine a specific case, the expansion of a gas into a vacuum (Figure 18.1). How is this spontaneous expansion of a gas related to energy dispersal and entropy?

We begin with the premise that all energy is quantized and that this applies to any system, including gas molecules in a room or in a reaction flask. You know from the previous discussion of kinetic-molecular theory that the molecules in a gas sample have a distribution of energies (Figure 10.11) (often referred to as *a Boltzmann distribution*). The molecules are assigned to (or "occupy") quantized microstates. Some molecules are in states of high or low energy, but most are in states near the average energy of the system. (For a gas in a laboratory-sized container, the energy levels are so closely spaced that, for most purposes, there is a continuum of energy states.)

Statistical Thermodynamics The arguments presented here come from a branch of chemistry called *statistical thermodynamics*. See H. Jungermann, *Journal of Chemical Education*, Vol. 83, pp. 1686–1694, 2006.

When the gas expands to fill a larger container, the average energy of the sample and the energy for the particles in a given energy range are constant. However, quantum mechanics show (for now, you will have to take our word for it) that as a consequence of having a larger volume in which the molecules can move in the expanded state, there is an increase in the number of microstates and that those microstates are even more closely spaced than before (Figure 18.6). The result of this greater density of microstates is that the number of microstates available to the gas particles increases when the gas expands. Gas expansion, a dispersal of matter, leads



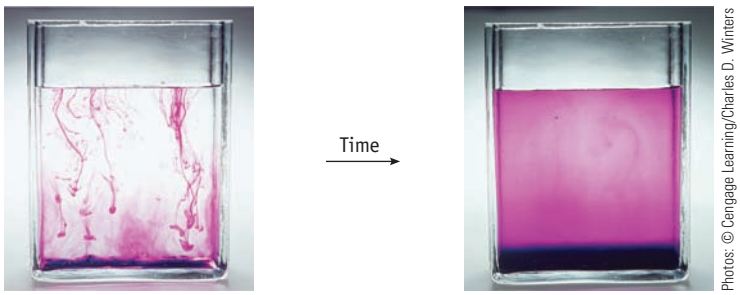


Figure 18.6 Energy (and matter) dispersal. As the size of the container for the chemical or physical change increases, the number of microstates accessible to the atoms or molecules of the system increases, and the density of states increases. A consequence of the distribution of molecules over a greater number of microstates is an increase in entropy.

Figure 18.7 Dissolving $KMnO_4$ in water. A small quantity of solid, purple $KMnO_4$ is added to water *(left)*. With time, the solid dissolves, and the highly colored MnO_4^- ions (and the K^+ ions) become dispersed throughout the solution. Entropy makes a large contribution to the mixing of liquids and solutions (Section 13.2).

to the dispersal of energy over a larger number of microstates and thus to an increase in entropy.

The logic applied to the expansion of a gas into a vacuum can be used to rationalize the mixing of two gases, the mixing of two liquids, or the dissolution of a solid in a liquid (Figure 18.7). For example, if flasks containing O_2 and N_2 are connected (in an experimental setup like that in Figure 18.6), the two gases diffuse together, eventually leading to a mixture in which O_2 and N_2 molecules are evenly distributed throughout the total volume. A mixture of O_2 and N_2 will never separate into samples of each component of its own accord. The gases spontaneously move toward a situation in which each gas and its energy are maximally dispersed. The energy of the system is dispersed over a larger number of microstates, and the entropy of the system increases. Indeed, this is a large part of the explanation for the fact that similar liquids (such as oil and gasoline or water and ethanol) will readily form homogeneous solutions. Recall the rule of thumb that "like dissolves like" (Section 13.2).

A Summary: Entropy, Entropy Change, and Energy Dispersal

According to Boltzmann's equation (Equation 18.2), entropy is proportional to the number of ways energy can be dispersed in a substance, that is, to the number of microstates available to the system *(W)*. The number of microstates increases with an increased number of particles, with an increase in energy, and with an increase in volume. There will be an increase in entropy, ΔS, if there is an increase in the number of microstates over which energy can be dispersed.

$$\Delta S = S_{final} - S_{initial} = k\,(\ln W_{final} - \ln W_{initial}) = k\,\ln(W_{final}/W_{initial})$$

Our focus as chemists is on ΔS, and we shall be concerned mainly with the dispersion of energy in systems and surroundings during a physical or chemical change.

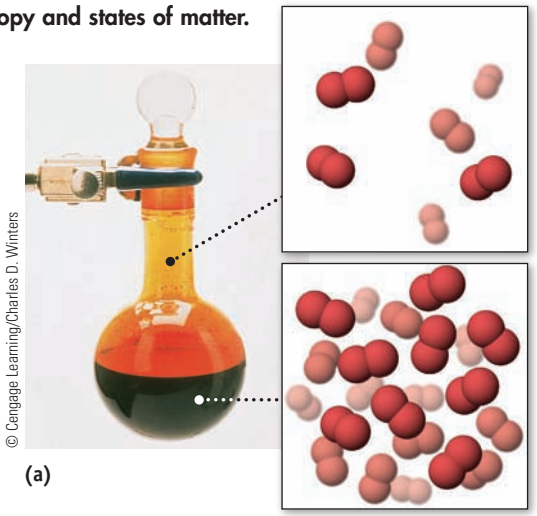
Entropy Change on Gas Expansion
The entropy change for a gas expansion can be calculated from

$$\Delta S = nR\ln(V_{final}/V_{initial})$$

At a given temperature, V is proportional to the number of microstates, so the equation is directly related to $k\,\ln(W_{final}/W_{initial})$.

18.3 Entropy Measurement and Values

Goals for Section 18.3



- Recognize that assigning a perfect crystal at 0 K to have zero entropy (the third law of thermodynamics) establishes a means of evaluating the entropy of a substance.
- Define standard molar entropies, $S°$, and evaluate and compare factors affecting $S°$ values (temperature, volume, molecular structure, states of matter).
- Use values of standard molar entropies to calculate changes in entropy, $\Delta S°$, for a chemical reaction.

A numerical value for entropy can be determined for any substance under a given set of conditions. The greater the dispersal of energy, the greater the entropy and the larger the value of S. The point of reference for entropy values is established by the **third law of thermodynamics**. Defined by Ludwig Boltzmann, the third law states

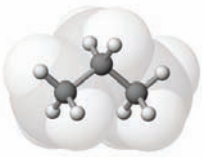
Figure 18.8 Entropy and states of matter.

The entropy of liquid bromine, $Br_2(\ell)$, is 152.2 J/K · mol, and that for bromine vapor is 245.47 J/K · mol.

The entropy of ice, which has a highly ordered molecular arrangement, is smaller than the entropy of liquid water.

that *a perfect crystal at 0 K has zero entropy; that is, $S = 0$*. The entropy of an element or compound under any other set of conditions is the entropy gained by converting the substance from 0 K to those conditions. To determine the value of S, it is necessary to measure the energy transferred as heat under reversible conditions for the conversion from 0 K to the defined conditions and then to use Equation 18.1 ($\Delta S = q_{rev}/T$). Because it is necessary to add energy as heat to raise the temperature, *all substances have positive entropy values at temperatures above 0 K*. Negative values of entropy cannot occur. Recognizing that entropy is directly related to energy added as heat allows us to predict several general features of entropy values:



- Raising the temperature of a substance corresponds to adding energy as heat. Thus, the entropy of a substance will increase with an increase in temperature.
- Conversions from solid to liquid and from liquid to gas typically require large inputs of energy as heat. Consequently, there is a large increase in entropy in conversions involving changes of state (Figure 18.8).

Negative Entropy Values A glance at thermodynamic tables indicates that ions in aqueous solution can and do have negative entropy values listed. However, these are not absolute entropies. For ions, the entropy of $H^+(aq)$ is arbitrarily assigned a standard entropy of zero, and the entropy values for other ions are assigned relative to this value.

Standard Entropy Values, $S°$

We introduced the concept of standard states into the earlier discussion of enthalpy (Section 5.5), and we can similarly define the entropy of any substance in its standard state. The **standard molar entropy**, $S°$, of a substance is the entropy gained by converting 1 mol of it from a perfect crystal at 0 K to standard state conditions (1 bar, 1 molal for a solution) at the specified temperature. The units for standard molar entropy values are J/K · mol. Generally, values of $S°$ found in tables of data refer to a temperature of 298 K. Appendix L lists many standard molar entropies at 298 K. More extensive lists of $S°$ values can be found in standard reference sources such as the NIST tables (**webbook.nist.gov**).

Scanning a list of standard entropies (such as those in Appendix L) will show that *large molecules generally have larger entropies than small molecules.* With a larger molecule, there are more ways for the molecule to rotate and vibrate, which provides a larger number of energy microstates over which energy can be distributed. As an example, consider the standard entropies for methane (CH_4), ethane (C_2H_6), and propane (C_3H_8), whose values are 186.3, 229.2, and 270.3 J/K · mol, respectively. Also, *molecules with more complex structures have larger entropies than molecules with simpler structures*. The effect of molecular structure can also be seen when comparing atoms or molecules of similar molar mass: Gaseous argon, CO_2, and C_3H_8 have entropies of 154.9, 213.7, and 270.3 J/K · mol, respectively.

	$S°$ (J/K · mol)
 methane	186.3
 ethane	229.2
 propane	270.3

Problem Solving Tip 18.2 A List of Common Entropy-Favored Processes

The discussion to this point allows the listing of several generalizations involving entropy changes:

- The entropy of a substance will increase in going from a solid to a liquid to a gas.
- The entropy of any substance increases as the temperature is raised. Energy must be transferred to a system to increase its temperature (that is, $q > 0$), so q_{rev}/T is necessarily positive.
- The entropy of a gas increases with an increase in volume. A larger volume provides a larger number of energy states over which to disperse energy.
- Reactions that increase the number of moles of gases in a system are accompanied by an increase in entropy.

Tables of entropy values also show that *entropies of gases are larger than those for liquids, and entropies of liquids are larger than those for solids.* In a solid, the particles have fixed positions in the solid lattice. When a solid melts, these particles have more freedom to assume different positions, resulting in an increase in the number of microstates available and an increase in entropy. When a liquid evaporates, constraints due to forces between the particles nearly disappear, the volume increases greatly, and a large entropy increase occurs. For example, the standard entropies of $I_2(s)$, $Br_2(\ell)$, and $Cl_2(g)$ are 116.1, 152.2, and 223.1 J/K · mol, respectively.

Finally, as illustrated in Figure 18.8, *for a given substance, a large increase in entropy accompanies changes of state,* reflecting the relatively large energy transfer as heat required to carry out these processes (as well as the dispersion of energy over a larger number of available microstates). For example, the entropies of liquid and gaseous water are 69.95 and 188.84 J/K · mol, respectively.

EXAMPLE 18.1

Entropy Comparisons

Problem Which substance has the higher entropy under standard conditions at 25 °C? Explain your reasoning.

(a) $NO_2(g)$ or $N_2O_4(g)$ (b) $I_2(g)$ or $I_2(s)$

What Do You Know? Larger molecules of related substances have greater entropies than smaller molecules, and entropy decreases in the order gas > liquid > solid.

Strategy For each part, identify the difference between the two substances and relate this to the general rules for entropy given above.

SOLUTION

(a) Both NO_2 and N_2O_4 are gases. N_2O_4 is a larger molecule than NO_2 and so is expected to have the higher standard entropy.

(b) For a given substance, gases have higher entropies than solids, so $I_2(g)$ is expected to have the greater standard entropy.

Think about Your Answer $S°$ values in Appendix L confirm these predictions. At 25 °C, $S°$ for $NO_2(g)$ is 240.04 J/K · mol, and $S°$ for $N_2O_4(g)$ is 304.38 J/K · mol. $S°$ for $I_2(g)$ is 260.69 J/K · mol; $S°$ for $I_2(s)$ is 116.135 J/K · mol.

Check Your Understanding

Predict which substance in each pair has the higher entropy and explain your reasoning.

(a) $O_2(g)$ or $O_3(g)$ (b) $SnCl_4(\ell)$ or $SnCl_4(g)$

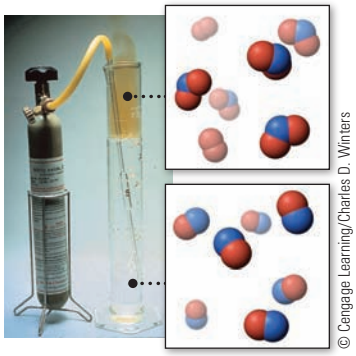
Determining Entropy Changes in Physical and Chemical Processes

It is possible to use standard molar entropy values quantitatively to calculate the change in entropy that occurs in various processes under standard conditions. The standard entropy change for a reaction ($\Delta_r S°$) is the sum of the standard molar entropies of the products, each multiplied by its stoichiometric coefficient, minus the sum of the standard molar entropies of the reactants, each multiplied by its stoichiometric coefficient.



$$\Delta_r S° = \Sigma nS°(\text{products}) - \Sigma nS°(\text{reactants}) \qquad (18.3)$$

This equation allows us to calculate entropy changes for a system in which reactants are completely converted to products, under standard conditions. To illustrate, let us calculate $\Delta_r S°$ for the oxidation of NO with O_2.

$$2\ NO(g) + O_2(g) \rightarrow 2\ NO_2(g)$$

$$\begin{aligned}\Delta_r S° &= (2\ \text{mol}\ NO_2/\text{mol-rxn})\ S°[NO_2(g)] - \\ &\qquad \{(2\ \text{mol}\ NO(g)/\text{mol-rxn})\ S°[NO(g)] + (1\ \text{mol}\ O_2/\text{mol-rxn})\ S°[O_2(g)]\} \\ &= (2\ \text{mol}\ NO_2/\text{mol-rxn})(240.0\ \text{J/K} \cdot \text{mol}) - \\ &\qquad [(2\ \text{mol}\ NO(g)/\text{mol-rxn})(210.8\ \text{J/K} \cdot \text{mol}) + (1\ \text{mol}\ O_2/\text{mol-rxn})(205.1\ \text{J/K} \cdot \text{mol})] \\ &= -146.7\ \text{J/K} \cdot \text{mol-rxn}\end{aligned}$$

The entropy of the system decreases, as is generally observed when some number of gaseous reactants has been converted to fewer molecules of gaseous products.

© Cengage Learning/Charles D. Winters

The reaction of NO with O_2. The entropy of the system decreases when two molecules of gas are produced from three molecules of gaseous reactants.

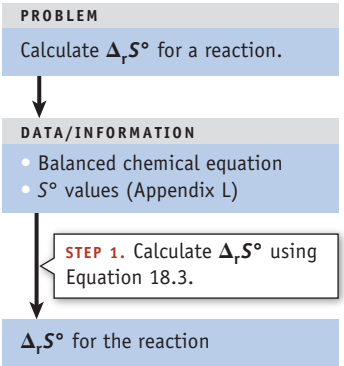
EXAMPLE 18.2

Predicting and Calculating $\Delta_r S°$ for a Reaction

Problem Using standard molar entropies, calculate the standard entropy changes for the following processes.

(a) Evaporation of 1.00 mol of liquid ethanol to ethanol vapor:

$$C_2H_5OH(\ell) \rightarrow C_2H_5OH(g)$$



(b) Formation of ammonia from hydrogen and nitrogen based on the following equation:

$$N_2(g) + 3\ H_2(g) \rightarrow 2\ NH_3(g)$$

What Do You Know? For each part, you are given a balanced chemical equation and asked to determine the standard entropy change for the reaction ($\Delta_r S°$). Values of standard molar entropies for the substances can be found in Appendix L.

Strategy Entropy changes for each system can be calculated from values of standard entropies (Appendix L) using Equation 18.3.

Strategy Map 18.2

SOLUTION

(a) Evaporation of ethanol

$$\begin{aligned}\Delta_r S° &= \Sigma nS°(\text{products}) - \Sigma nS°(\text{reactants}) \\ &= (1\ \text{mol}\ C_2H_5OH(g)/\text{mol-rxn})\ S°[C_2H_5OH(g)] - \\ &\qquad (1\ \text{mol}\ C_2H_5OH(\ell)/\text{mol-rxn})\ S°[C_2H_5OH(\ell)] \\ &= (1\ \text{mol}\ C_2H_5OH(g)/\text{mol-rxn})(282.7\ \text{J/K} \cdot \text{mol}) - \\ &\qquad (1\ \text{mol}\ C_2H_5OH(\ell)/\text{mol-rxn})(160.7\ \text{J/K} \cdot \text{mol}) \\ &= +122.0\ \text{J/K} \cdot \text{mol-rxn}\end{aligned}$$

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

(b) Formation of ammonia

$$\Delta_r S° = \Sigma nS°(\text{products}) - \Sigma nS°(\text{reactants})$$

$$= (2 \text{ mol } NH_3(g)/\text{mol-rxn})\, S°[NH_3(g)] - \{(1 \text{ mol } N_2(g)/\text{mol-rxn})\, S°[N_2(g)] + (3 \text{ mol } H_2(g)/\text{mol-rxn})\, S°[H_2(g)]\}$$

$$= (2 \text{ mol } NH_3(g)/\text{mol-rxn})(192.77 \text{ J/K} \cdot \text{mol}) - [(1 \text{ mol } N_2(g)/\text{mol-rxn})(191.56 \text{ J/K} \cdot \text{mol}) + (3 \text{ mol } H_2(g)/\text{mol-rxn})(130.7 \text{ J/K} \cdot \text{mol})]$$

$$= -198.1 \text{ J/K} \cdot \text{mol-rxn}$$

Think about Your Answer Predictions for the signs of these entropy changes can be made using the guidelines given in the text. In part (a), a large positive value for the entropy change is expected because the process converts ethanol from a liquid to a vapor. In part (b), a decrease in entropy is predicted because the number of moles of gases decreases from four to two.

Check Your Understanding

Calculate the standard entropy changes for the following processes using the entropy values in Appendix L. Are the signs of the calculated values of $\Delta_r S°$ in accord with predictions?

(a) Dissolving 1 mol of $NH_4Cl(s)$ in water: $NH_4Cl(s) \longrightarrow NH_4Cl(aq)$

(b) Oxidation of ethanol: $C_2H_5OH(g) + 3\ O_2(g) \longrightarrow 2\ CO_2(g) + 3\ H_2O(g)$

Amount of Substance and Thermodynamic Calculations In the calculation here and in all others in this chapter, when we write, for example,

$$282.70 \text{ J/K} \cdot \text{mol}$$

for the standard entropy of ethanol at 298 K, we mean

$$282.70 \text{ J/[K} \cdot \text{mol } C_2H_5OH(\ell)]$$

The identifying formula has been left off for the sake of simplicity.

18.4 Entropy Changes and Spontaneity

Goals for Section 18.4

- Calculate the change in entropy for a system, its surroundings, and the universe to determine whether a process is spontaneous under standard conditions.
- Recognize how reaction conditions influence whether a reaction is spontaneous.

As illustrated by Example 18.2, the standard entropy change *for the system* in a physical or chemical change can be either positive (evaporation of ethanol) or negative (synthesis of ammonia from nitrogen and hydrogen). How does this information contribute to determining the spontaneity of the process?

As discussed previously (Section 18.1), spontaneity is determined by the *second law of thermodynamics,* which states that *a spontaneous process is one that results in an increase of entropy in the universe*. The universe has two parts: the system and its surroundings (Section 5.1), and so the entropy change for the universe is the sum of the entropy changes for the system and the surroundings. Under standard conditions, the entropy change for the universe, $\Delta S°(\text{universe})$ is

$$\Delta S°(\text{universe}) = \Delta S°(\text{system}) + \Delta S°(\text{surroundings}) \qquad (18.4)$$

The calculation in Example 18.2 gave us the entropy change under standard conditions for a system, only half of the information needed. We will also have to determine how the change being studied affects the entropy of the surroundings.

The value of $\Delta S°(\text{universe})$ calculated from Equation 18.4 is the entropy change when reactants are converted *completely* to products, with all species at standard conditions. *A process is spontaneous under standard conditions if $\Delta S°$(universe) is greater than zero.* As an example of the determination of reaction spontaneity, let us calculate $\Delta S°(\text{universe})$ for the reaction currently used to manufacture methanol, CH_3OH.

$$CO(g) + 2\ H_2(g) \longrightarrow CH_3OH(\ell)$$

If $\Delta S°(\text{universe})$ is positive, the conversion of 1 mol of CO(g) and 2 mol of $H_2(g)$ to 1 mol of $CH_3OH(\ell)$ will be spontaneous under standard conditions.

Using $\Delta S°$(universe) For a process that is spontaneous under standard conditions:

$$\Delta S°(\text{universe}) > 0$$

For a process at equilibrium under standard conditions:

$$\Delta S°(\text{universe}) = 0$$

For a process that is not spontaneous under standard conditions:

$$\Delta S°(\text{universe}) < 0$$

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Calculating $\Delta S°$(system) To calculate $\Delta S°$(system), we start by defining the system to include the reactants and products. This means that $\Delta S°$(system) corresponds to the entropy change for the reaction, $\Delta_r S°$. Calculation of this entropy change follows the procedure given in Example 18.2.

$$\begin{aligned}\Delta S°(\text{system}) &= \Delta_r S° = \Sigma n S°(\text{products}) - \Sigma n S°(\text{reactants})\\ &= (1\ \text{mol}\ CH_3OH(\ell)/\text{mol-rxn})\ S°[CH_3OH(\ell)] -\\ &\quad \{(1\ \text{mol}\ CO(g)/\text{mol-rxn})\ S°[CO(g)] + (2\ \text{mol}\ H_2(g)/\text{mol-rxn})\ S°[H_2(g)]\}\\ &= (1\ \text{mol}\ CH_3OH(\ell)/\text{mol-rxn})(127.2\ \text{J/K} \cdot \text{mol}) -\\ &\quad [(1\ \text{mol}\ CO(g)/\text{mol-rxn})(197.7\ \text{J/K} \cdot \text{mol}) +\\ &\quad (2\ \text{mol}\ H_2(g)/\text{mol-rxn})(130.7\ \text{J/K} \cdot \text{mol})]\\ &= -331.9\ \text{J/K} \cdot \text{mol-rxn}\end{aligned}$$

A decrease in entropy for the system is expected because three moles of gaseous reactants are converted to one mole of a liquid product.

Calculating $\Delta S°$(surroundings) We now need to calculate the entropy change for the surroundings. Recall from Equation 18.1 that for a reversible change, ΔS is equal to q_{rev}/T. Under constant pressure conditions and assuming a reversible process, the entropy change in the surroundings results from the fact that the enthalpy change for the reaction ($q_{rev} = \Delta_r H$) affects the surroundings. For example, the energy associated with an exothermic chemical reaction is dispersed into the surroundings. Recognizing that $\Delta H°(\text{surroundings}) = -\Delta H°(\text{system}) = -\Delta_r H°$, the entropy change for the surroundings can be calculated by the equation

$$\Delta S°(\text{surroundings}) = -\Delta_r H°/T$$

For the synthesis of methanol by the reaction given, the enthalpy change can be calculated from enthalpy of formation data using Equation 5.6.

$$\begin{aligned}\Delta_r H° &= \Sigma n \Delta_f H°(\text{products}) - \Sigma n \Delta_f H°(\text{reactants})\\ &= (1\ \text{mol}\ CH_3OH(\ell)/\text{mol-rxn})\ \Delta_f H°[CH_3OH(\ell)] -\\ &\quad \{(1\ \text{mol}\ CO(g)/\text{mol-rxn})\ \Delta_f H°[CO(g)] + (2\ \text{mol}\ H_2(g)/\text{mol-rxn})\ \Delta_f H°[H_2(g)]\}\\ &= (1\ \text{mol}\ CH_3OH(\ell)/\text{mol-rxn})(-238.4\ \text{kJ/mol}) -\\ &\quad [(1\ \text{mol}\ CO(g)/\text{mol-rxn})(-110.5\ \text{kJ/mol}) + (2\ \text{mol}\ H_2(g)/\text{mol-rxn})(0\ \text{kJ/ mol})]\\ &= -127.9\ \text{kJ/mol-rxn}\end{aligned}$$

The entropy change for the surroundings in the methanol synthesis is $+429.2\ \text{J/K} \cdot$ mol-rxn, calculated as follows.

$$\begin{aligned}\Delta S°(\text{surroundings}) &= -\Delta_r H°/T\\ &= -[(-127.9\ \text{kJ/mol-rxn})/298\ \text{K})](1000\ \text{J/kJ})\\ &= +429.2\ \text{J/K} \cdot \text{mol-rxn}\end{aligned}$$

Calculating $\Delta S°$(universe) from the Entropy Change for the System and Surroundings The pieces are now in place to calculate the entropy change in the universe. For the formation of $CH_3OH(\ell)$ from CO(g) and H_2(g), $\Delta S°$(universe) is

$$\begin{aligned}\Delta S°(\text{universe}) &= \Delta S°(\text{system}) + \Delta S°(\text{surroundings})\\ &= -331.9\ \text{J/K} \cdot \text{mol-rxn} + 429.2\ \text{J/K} \cdot \text{mol-rxn}\\ &= +97.3\ \text{J/K} \cdot \text{mol-rxn}\end{aligned}$$

The positive value indicates an increase in the entropy of the universe. It follows from the second law of thermodynamics that this reaction is spontaneous under standard conditions.

A CLOSER LOOK

Entropy and Spontaneity?

In the text we calculated $\Delta S°$(universe) for the reaction

$$CO(g) + 2\ H_2(g) \rightarrow CH_3OH(\ell)$$

This calculation was for the *complete* conversion of reactants in their standard states into products in their standard states. We found that $\Delta S°$(universe) is positive for this transformation, and thus we concluded that this reaction is spontaneous. Does this mean that the reaction will proceed spontaneously all the way from reactants to products? The answer is no. The reaction will be spontaneous only to the point at which it is at equilibrium, where there will be a mixture of reactants and products. When $\Delta S°$(universe) is positive, this equilibrium position will be closer to the products than to the reactants—the reaction will be product-favored at equilibrium.

Let us now consider a reaction that has a negative value for $\Delta S°$(universe). The conclusion would be that the reaction completely converting reactants in their standard states into products in their standard states is not spontaneous. Does this mean that the reaction does not proceed at all? Again, the answer is no. If we start with pure reactants, the reaction will proceed spontaneously until it reaches equilibrium, but the equilibrium position now will occur closer to the reactants than to the products—the reaction will be reactant-favored at equilibrium.

EXAMPLE 18.3

Determining Whether a Process Is Spontaneous

Problem Calculate $\Delta S°$(universe) for the process of dissolving NaCl in water at 298 K.

What Do You Know? The process occurring is NaCl(s) $\rightarrow$ NaCl(aq). $\Delta S°$(universe) is equal to the sum of $\Delta S°$(system) and $\Delta S°$(surroundings). Values of $S°$ and $\Delta_f H°$ for NaCl(s) and NaCl(aq) are given in Appendix L.

Strategy The entropy change for the system, $\Delta S°$(system), can be calculated from values of $S°$ for the two species using Equation 18.3. $\Delta_r H°$ can be calculated from values of $\Delta_f H°$ for the two species using Equation 5.6. $\Delta S°$(surroundings) is determined by dividing $-\Delta_r H°$ for the process by the Kelvin temperature. The sum of $\Delta S°$(system) and $\Delta S°$(surroundings) is $\Delta S°$(universe). If this value is positive, then the process is spontaneous under standard conditions.

SOLUTION

Calculate $\Delta S°$(system)

$$\Delta_r S° = \Sigma nS°(\text{products}) - \Sigma nS°(\text{reactants})$$

$$= (1\ \text{mol NaCl(aq)/mol-rxn})\ S°[\text{NaCl(aq)}] - (1\ \text{mol NaCl(s)/mol-rxn})\ S°[\text{NaCl(s)}]$$

$$= (1\ \text{mol NaCl(aq)/mol-rxn})(115.5\ \text{J/K} \cdot \text{mol}) - (1\ \text{mol NaCl(s)/mol-rxn})(72.11\ \text{J/K} \cdot \text{mol})$$

$$= +43.39\ \text{J/K} \cdot \text{mol-rxn}$$

Calculate $\Delta S°$(surroundings)

$$\Delta_r H° = \Sigma n\Delta_f H°(\text{products}) - \Sigma n\Delta_f H°(\text{reactants})$$

$$= (1\ \text{mol NaCl(aq)/mol-rxn})\ \Delta_f H°[\text{NaCl(aq)}] - (1\ \text{mol NaCl(s)/mol-rxn})\ \Delta_f H°[\text{NaCl(s)}]$$

$$= (1\ \text{mol NaCl(aq)/mol-rxn})(-407.27\ \text{kJ/mol}) - (1\ \text{mol NaCl(s)/mol-rxn})(-411.12\ \text{kJ/mol})$$

$$= +3.85\ \text{kJ/mol-rxn}$$

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

The entropy change of the surroundings is determined by dividing $-\Delta_r H°$ by the Kelvin temperature.

$$\begin{aligned}\Delta S°(\text{surroundings}) &= -\Delta_r H°/T \\ &= -[3.85\ \text{kJ/mol-rxn}/298\ \text{K}](1000\ \text{J/kJ}) \\ &= -12.92\ \text{J/K} \cdot \text{mol-rxn}\end{aligned}$$

Calculate $\Delta S°$(universe)

The overall entropy change—the change of entropy in the universe—is the sum of the values for the system and the surroundings.

$$\begin{aligned}\Delta S°(\text{universe}) &= \Delta S°(\text{system}) + \Delta S°(\text{surroundings}) \\ &= (+43.39\ \text{J/K} \cdot \text{mol-rxn}) + (-12.92\ \text{J/K} \cdot \text{mol-rxn}) \\ &= +30.5\ \text{J/K} \cdot \text{mol-rxn}\end{aligned}$$

Think about Your Answer The sum of the two entropy quantities is positive, indicating that the entropy in the universe increases; thus, the process is spontaneous under standard conditions. Notice that the spontaneity of the process results from $\Delta S°$(system) and not from $\Delta S°$(surroundings).

Check Your Understanding

Based on $\Delta_r H°$ and $\Delta_r S°$, predict the spontaneity of the reaction of hydrogen and chlorine to give hydrogen chloride gas under standard conditions (at 298 K). Calculate $\Delta S°$(universe) to verify your prediction.

$$H_2(g) + Cl_2(g) \rightarrow 2\ HCl(g)$$

Spontaneous or Not?

$\Delta S°$(universe), Spontaneity, and Standard Conditions It is important to reiterate that $\Delta H°$ and $\Delta S°$ values for a reaction are for the *complete* conversion of reactants to products under standard conditions. If $\Delta S°$(universe) is > 0, the reaction as written is spontaneous *under standard conditions*. However, one can calculate values for ΔS(universe) (without the superscript zero) for *nonstandard* conditions. If ΔS(universe) is > 0, the reaction is spontaneous under those conditions.

In the preceding examples, predictions about the spontaneity of a process under standard conditions were made using values of $\Delta S°$(system) and $\Delta H°$(system) calculated from tables of thermodynamic data. It will be useful to look at all possibilities that result from the interplay of these two quantities. There are four possible outcomes when these two quantities are paired (Table 18.1). In two, $\Delta H°$(system) and $\Delta S°$(system) work in concert (Types 1 and 4 in Table 18.1). In the other two, the two quantities are opposed (Types 2 and 3).

TABLE 18.1 Predicting Whether a Reaction Will Be Spontaneous Under Standard Conditions

Reaction Type	$\Delta H°$(system)	$\Delta S°$(system)	Spontaneous Process? (Standard Conditions)
1	Exothermic, < 0	Positive, > 0	Spontaneous at all temperatures. $\Delta S°$(universe) > 0.
2	Exothermic, < 0	Negative, < 0	Depends on relative magnitudes of $\Delta H°$ and $\Delta S°$. Spontaneous at lower temperatures.
3	Endothermic, > 0	Positive, > 0	Depends on relative magnitudes of $\Delta H°$ and $\Delta S°$. Spontaneous at higher temperatures.
4	Endothermic, > 0	Negative, < 0	Not spontaneous at any temperature. $\Delta S°$(universe) < 0.

Processes in which both the standard enthalpy and entropy changes favor energy dispersal (Type 1) are always spontaneous under standard conditions. Processes disfavored by both their standard enthalpy and entropy changes in the system (Type 4) can *never* be spontaneous under standard conditions. Let us consider examples that illustrate each situation.

Combustion reactions are always exothermic and often produce a larger number of gaseous product molecules from a few reactant molecules. They are Type 1 reactions. The combustion of butane is an example.

$$2\ C_4H_{10}(g) + 13\ O_2(g) \rightarrow 8\ CO_2(g) + 10\ H_2O(g)$$

For this reaction, $\Delta H°(\text{system}) = \Delta_r H° = -5315.1$ kJ/mol-rxn, and $\Delta S°(\text{system}) = \Delta_r S° = 312.4$ J/K · mol-rxn. Both contribute to this reaction being spontaneous under standard conditions.

Hydrazine, N_2H_4, is used as a high-energy rocket fuel. Synthesis of N_2H_4 from gaseous N_2 and H_2 would be attractive because these reactants are inexpensive.

$$N_2(g) + 2\ H_2(g) \rightarrow N_2H_4(\ell)$$

However, this reaction fits into the Type 4 category. The reaction is endothermic ($\Delta H°(\text{system}) = \Delta_r H° = +50.63$ kJ/mol-rxn), and the entropy change is negative ($\Delta S°(\text{system}) = \Delta_r S° = -331.4$ J/K · mol-rxn) (1 mol of liquid is produced from 3 mol of gases), so the reaction is not spontaneous under standard conditions, and complete conversion of reactants to products will not occur without outside intervention.

In the two other possible outcomes, entropy and enthalpy changes oppose each other. A process could be favored by the enthalpy change but disfavored by the entropy change (Type 2), or vice versa (Type 3). In either instance, whether a process is spontaneous depends on which factor is more important.

How Temperature Affects $\Delta S°$(universe)

Temperature also influences the value of $\Delta S°$(universe). Because the enthalpy change for the surroundings is divided by the temperature to obtain $\Delta S°$(surroundings), the numerical value of $\Delta S°$(surroundings) will be smaller (either less positive or less negative) at higher temperatures. In contrast, $\Delta S°$(system) and $\Delta H°$(system) do not vary much with temperature. Thus, the effect of $\Delta S°$(surroundings) relative to $\Delta S°$(system) is diminished at higher temperature. Stated another way, at higher temperature, the enthalpy change becomes a less important factor in determining the overall entropy change. Consider the two cases where $\Delta H°$(system) and $\Delta S°$(system) are in opposition (Table 18.1):

- Type 2: Exothermic processes with $\Delta S°(\text{system}) < 0$. Such processes become less favorable with an increase in temperature.
- Type 3: Endothermic processes with $\Delta S°(\text{system}) > 0$. These processes become more favorable as the temperature increases.

The effect of temperature is illustrated by two examples. The first (Type 2) is the reaction of N_2 and H_2 to form NH_3. The reaction is exothermic, and thus it is favored by energy dispersal to the surroundings. The entropy change for the system is unfavorable, however, because the reaction, $N_2(g) + 3\ H_2(g) \rightarrow 2\ NH_3(g)$, converts four moles of gaseous reactants to two moles of gaseous products. The favorable enthalpy effect [$\Delta_r S°(\text{surroundings}) = -\Delta H°(\text{system})/T$] becomes less important at higher temperatures. It is therefore reasonable to expect that the reaction will not be spontaneous if the temperature is too high.

The second example (Type 3) considers the thermal decomposition of NH_4Cl (Figure 18.9). At room temperature, NH_4Cl is a stable, white, crystalline salt. When heated strongly, it decomposes to $NH_3(g)$ and $HCl(g)$. The reaction is endothermic (enthalpy-disfavored) but entropy-favored because of the formation of two moles of gas from one mole of a solid reactant. The reaction is increasingly favored at higher temperatures.

© Cengage Learning/Charles D. Winters

Figure 18.9 Thermal decomposition of $NH_4Cl(s)$. White, solid ammonium chloride, $NH_4Cl(s)$, is heated in a spoon. At high temperatures, decomposition to form $NH_3(g)$ and $HCl(g)$ is spontaneous. At lower temperatures, the reverse reaction, forming $NH_4Cl(s)$, is spontaneous. As gaseous $HCl(g)$ and $NH_3(g)$ cool, they recombine to form solid NH_4Cl, the white "smoke" seen in this photo.

18.5 Gibbs Free Energy

Goals for Section 18.5

- Define the Gibbs free energy change, ΔG, and relate $\Delta_r G°$ to $\Delta_r H°$ and $\Delta_r S°$.
- Relate $\Delta_r G°$, Q, and K to reaction spontaneity and product- and reactant-favorability.

The method used so far to determine whether a process is spontaneous requires evaluation of two quantities, $\Delta S°$(system) and $\Delta S°$(surroundings). Wouldn't it be convenient to have a single thermodynamic function that serves the same purpose? A function associated with the system only—one that does not require assessment of the surroundings—would be even better. Such a function exists. It is called the **Gibbs free energy**, with the name honoring J. Willard Gibbs (1839–1903). Gibbs free energy, G, often referred to simply as "free energy," is defined mathematically as

$$G = H - TS$$

where H is enthalpy, T is the Kelvin temperature, and S is entropy. In this equation, G, H, and S all refer to the system. Because enthalpy and entropy are state functions (Section 5.4), free energy is also a state function.

Every substance possesses free energy, but the actual quantity is seldom known. Instead, just as with enthalpy (H) and internal energy (U), we are concerned with *changes* in free energy, ΔG, that occur in chemical and physical processes.

Let us first see how to use free energy as a way to determine whether a reaction is spontaneous. We can then ask further questions about the meaning of the term "free energy" and its use in deciding whether a reaction is product- or reactant-favored.

INTERFOTO/Alamy Stock Photo

J. Willard Gibbs (1839–1903) Gibbs received a Ph.D. from Yale University in 1863. His was the first Ph.D. in science awarded from an American university.

The Change in the Gibbs Free Energy, ΔG

Recall the equation defining the entropy change for the universe:

$$\Delta S(\text{universe}) = \Delta S(\text{surroundings}) + \Delta S(\text{system})$$

The entropy change of the surroundings equals the negative of the change in enthalpy of the system divided by T. Thus,

$$\Delta S(\text{universe}) = -\Delta H(\text{system})/T + \Delta S(\text{system})$$

Multiplying through this equation by $-T$, gives the equation

$$-T\Delta S(\text{universe}) = \Delta H(\text{system}) - T\Delta S(\text{system})$$

Gibbs defined the free energy function so that $\Delta G(\text{system}) = -T\Delta S(\text{universe})$. Thus, the general expression relating changes in free energy to the enthalpy and entropy changes in the system is the following:

$$\Delta G = \Delta H - T\Delta S$$

Under standard conditions, we can rewrite this, the Gibbs free energy equation, as

$$\Delta G° = \Delta H° - T\Delta S° \qquad (18.5)$$

Gibbs Free Energy, Spontaneity, and Chemical Equilibrium

Because ΔG is related directly to ΔS(universe), the Gibbs free energy can be used as a criterion of spontaneity for physical and chemical changes. To better understand the Gibbs function, let us examine the diagrams in Figure 18.10, diagrams that will form the basis for our understanding of free energy and its relation to reaction spontaneity and the criterion of equilibrium.

In Figure 18.10 the free energy of pure, unmixed reactants is indicated on the left, and the free energy of the pure, unmixed products is indicated on the right.

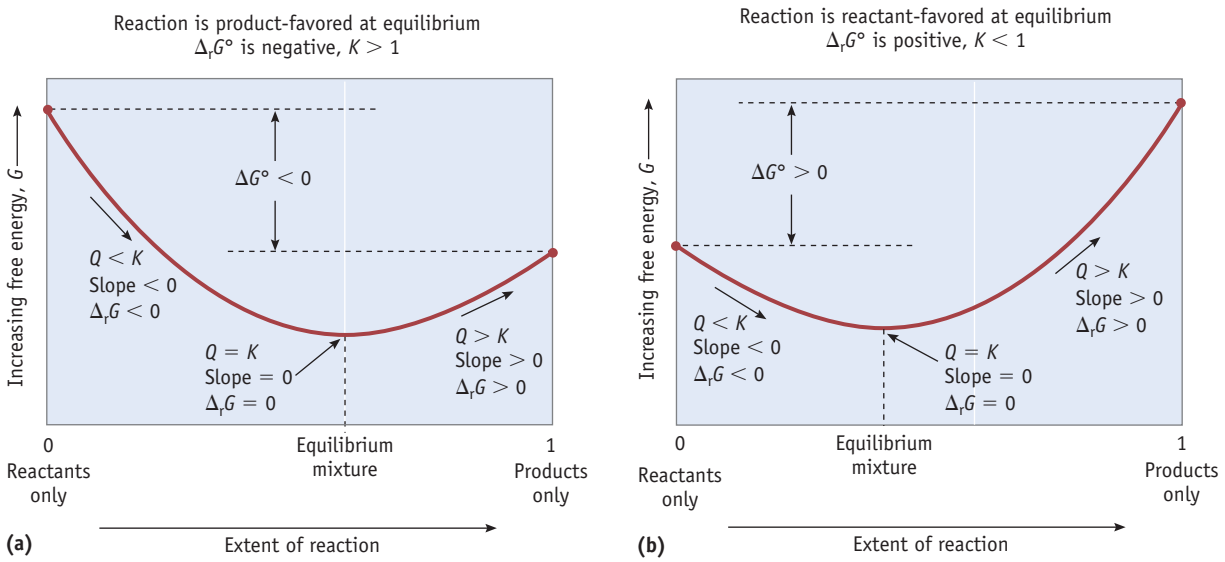

Figure 18.10 Free energy changes in the course of a reaction. The difference in free energy between the pure reactants in their standard states and the pure products in their standard states is $\Delta G°$. Here, Q is the reaction quotient, and K is the equilibrium constant.

The extent of reaction, plotted on the x-axis, goes from zero to one. $\Delta G°$ *is the change in free energy accompanying the complete conversion of reactants into products under standard conditions* ($\Delta G° = G°_{\text{products}} - G°_{\text{reactants}}$). It has units of kJ.

A closely related parameter, $\Delta_r G°$, is the *change of* $G°$ *as a function of the reaction composition on going from reactants to products*. This corresponds to the slope of a line connecting reactants and products on this graph and has units of kJ/mol-rxn. As you shall see below, $\Delta_r G°$ is related to the equilibrium constant, K.

As the reaction proceeds, the free energy of the system (now a mixture of reactants and products) changes. The red lines in Figures 18.10a and 18.10b indicate the value of G for the system at each point during two different reactions. At any one point along the way from reactants to products the difference between the free energy of the system at that point and another is ΔG.

In both cases in Figure 18.10, the free energy initially declines as reactants begin to form products; it reaches a minimum at equilibrium and then increases again as we move from the equilibrium position to pure products. *The free energy at equilibrium, where there is a mixture of reactants and products, is always lower than the free energy of the pure reactants and of the pure products. A reaction proceeds spontaneously toward the minimum in free energy.*

Now let us consider what happens to the instantaneous slope of the curve in Figure 18.10 as the reaction proceeds spontaneously toward equilibrium. Initially, this slope is negative. That is, the *change* in G per extent of reaction, $\Delta_r G$, has a negative value. *For all spontaneous reactions* $\Delta_r G < 0$.

Eventually the free energy reaches a minimum. At this point, the instantaneous slope of the graph is zero and $\Delta_r G = 0$; the reaction has reached equilibrium.

If we move past the equilibrium point, the instantaneous slope is positive ($\Delta_r G > 0$). Proceeding further toward products is *not* spontaneous. In fact, the reverse reaction will occur spontaneously (because $\Delta_r G$ will be negative in the reverse direction), and the reaction will once again proceed toward equilibrium.

An important observation in Figure 18.10a is that the equilibrium position occurs closer to the product side than to the reactant side. This is a product-favored reaction at equilibrium, and there is a connection between this observation and the quantity $\Delta_r G°$. That is, *a reaction with* $\Delta_r G° < 0$ *is product-favored at equilibrium.*

In Figure 18.10b, we find the opposite. The reaction is reactant-favored at equilibrium. A reaction with $\Delta_r G° > 0$ is reactant-favored at equilibrium.

Free Energy, Spontaneity, and Equilibrium $\Delta_r G°$ is an intensive quantity that describes how $G°$ changes per mole of reaction. For more on these relationships, see J. Quilez, *Journal of Chemical Education,* Vol. 89, pages 87–93, 2012.

© Cengage Learning/Charles D. Winters

A reactant-favored process. If a sample of yellow lead(II) iodide is placed in pure water, a small amount of the compound will dissolve spontaneously ($\Delta_r G < 0$ and $Q < K$) until equilibrium is reached. Because PbI_2 is quite insoluble ($K_{sp} = 9.8 \times 10^{-9}$), however, the process of dissolving the compound is reactant-favored at equilibrium. We may conclude, therefore, that the value of $\Delta_r G°$ is positive for the dissolving process.

We have introduced terms for the change in free energy per extent of reaction under standard conditions ($\Delta_r G°$) and nonstandard conditions ($\Delta_r G$). It turns out there is a very useful relationship between them (Equation 18.6).

$$\Delta_r G = \Delta_r G° + RT \ln Q \tag{18.6}$$

where R is the universal gas constant, T is the temperature in kelvins, and Q is the reaction quotient (Section 15.2). For a general reaction, $aA + bB \rightarrow cC + dD$:

$$Q = \frac{[C]^c[D]^d}{[A]^a[B]^b}$$

Equation 18.6 informs us that, at a given temperature, $\Delta_r G$ is determined by the values of $\Delta_r G°$ and Q. When the system reaches equilibrium, no further net change in concentration of reactants and products will occur; at this point $\Delta_r G = 0$ and $Q = K$. Substituting these values into Equation 18.6 gives

$$0 = \Delta_r G° + RT \ln K \text{ (at equilibrium)}$$

Rearranging this equation leads to a useful relationship between the standard free energy change for a reaction and the equilibrium constant, K, Equation 18.7:

$$\Delta_r G° = -RT \ln K \tag{18.7}$$

From this equation, we learn that, when $\Delta_r G°$ is negative, K is greater than 1, and we say the reaction is *product-favored at equilibrium*. The more negative the value of $\Delta_r G°$, the larger the equilibrium constant. This makes sense because, as described in Chapter 15, large equilibrium constants are associated with product-favored reactions. The converse is also true: For *reactant-favored* reactions, $\Delta_r G°$ is positive, and K is less than 1. Finally, if $K = 1$ (a special set of conditions), then $\Delta_r G° = 0$.

Let us now see that Equation 18.6 can yield the relationships between Q and K that we introduced in Chapter 15.

$$\Delta_r G = \Delta_r G° + RT \ln Q$$

Substituting $-RT \ln K$ for $\Delta_r G°$ (Equation 18.7) gives

$$\Delta_r G = -RT \ln K + RT \ln Q$$

This equation can be rearranged as follows:

$$\Delta_r G = RT (\ln Q - \ln K)$$

$$\Delta_r G = RT \ln (Q/K)$$

This means that for a spontaneous reaction where $\Delta_r G$ is negative, Q must be less than K ($Q < K$), just as has been stated earlier. A similar analysis shows that if $\Delta_r G$ is positive, then $Q > K$.

A Summary: Gibbs Free Energy ($\Delta_r G$ and $\Delta_r G°$), the Reaction Quotient (Q) and Equilibrium Constant (K), and Reaction Favorability

Let us summarize the relationships among $\Delta_r G°$, $\Delta_r G$, Q, and K.

- In Figure 18.10, you see that free energy decreases to a minimum as a system approaches equilibrium.
- When $\Delta_r G < 0$, the reaction is proceeding spontaneously toward equilibrium and $Q < K$.
- When $\Delta_r G > 0$, the reaction is not spontaneous and $Q > K$. It will be spontaneous in the reverse direction.
- When $\Delta_r G = 0$, the reaction is at equilibrium; $Q = K$.

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

- A reaction for which $\Delta_r G° < 0$ will proceed to an equilibrium position at which point the products will dominate in the reaction mixture because $K > 1$. That is, the reaction is *product-favored* at equilibrium.
- A reaction for which $\Delta_r G° > 0$ will proceed to an equilibrium position at which point the reactants will dominate in the equilibrium mixture because $K < 1$. That is, the reaction is *reactant-favored* at equilibrium.
- For the special condition where a reaction has $\Delta_r G° = 0$, the reaction is at equilibrium at standard conditions, with $K = 1$.

What Is "Free" Energy?

The term *free energy* was not arbitrarily chosen. In any given process, the free energy represents the maximum energy available to do useful work (mathematically, ΔG calculated starting from the reactants and proceeding to the equilibrium position corresponds to w_{max}). In this context, the word *free* means "available."

To illustrate the reasoning behind this relationship, consider a reaction carried out under standard conditions and in which energy is evolved as heat ($\Delta_r H° < 0$) and entropy decreases ($\Delta_r S° < 0$), such as the combustion of H_2 gas. At first glance, it might seem reasonable that all the energy released as heat would be available to do work. This is not the case, however. A negative entropy change in this reaction means that energy is less dispersed in the products than in the reactants. A portion of the energy released from the reaction must be used to reverse energy dispersal in the system; that is, to concentrate energy in the product. The energy left over is "free," or available to perform work.

18.6 Calculating and Using Standard Free Energies, $\Delta_r G°$

Goals for Section 18.6

- Use free energies of formation, $\Delta_f G°$, to calculate the standard free energy change for a reaction.
- Use the equation $\Delta_r G° = \Delta_r H° - T\Delta_r S°$ to assess the effect of changes in temperature on the favorability of a reaction.
- Relate $\Delta_r G°$ and the equilibrium constant for a reaction.

Standard Free Energy of Formation

The standard free energy of formation of a compound, $\Delta_f G°$, is the free energy change that occurs when forming one mole of the compound from the component elements, with products and reactants in their standard states. By defining $\Delta_f G°$ in this way, *the free energy of formation of an element in its standard state is zero.*

Just as the standard enthalpy or entropy change for a reaction can be calculated using values of $\Delta_f H°$ (Equation 5.6) or $S°$ (Equation 18.3), the standard free energy change for a reaction can be calculated from values of $\Delta_f G°$ using a similar equation, where n represents the stoichiometric coefficient of the material in the balanced chemical equation under consideration:

$$\Delta_r G° = \Sigma n \Delta_f G°(\text{products}) - \Sigma n \Delta_f G°(\text{reactants}) \qquad (18.8)$$

Calculating $\Delta_r G°$, the Free Energy Change for a Reaction Under Standard Conditions

The free energy change for a reaction under standard conditions can be calculated from thermodynamic data in two ways, either from standard enthalpy and entropy changes using values of $\Delta_r H°$ and $\Delta_r S°$ or directly from values of $\Delta_f G°$ found in tables. These calculations are illustrated in the following two examples.

EXAMPLE 18.4

Calculating $\Delta_r G°$ from $\Delta_r H°$ and $\Delta_r S°$

Problem Calculate the standard free energy change, $\Delta_r G°$, for the formation of methane from carbon and hydrogen at 298 K, using tabulated values of $\Delta_f H°$ and $S°$. Is the reaction product-favored or reactant-favored at equilibrium?

$$C(\text{graphite}) + 2\ H_2(g) \longrightarrow CH_4(g)$$

What Do You Know? You are given a balanced chemical equation. Standard molar enthalpies of formation and standard molar entropies can be found in Appendix L.

Strategy The values of $\Delta_f H°$ *and* $S°$ are first combined to find $\Delta_r H°$ and $\Delta_r S°$. With these values known, $\Delta_r G°$ can be calculated using Equation 18.5. (Remember that $S°$ values are given in units of J/K · mol, whereas $\Delta_f H°$ values are given in units of kJ/mol.)

SOLUTION

	C(graphite)	+	2 H_2(g)	→	CH_4(g)
$\Delta_f H°$ (kJ/mol)	0		0		−74.9
$S°$ (J/K·mol)	+5.6		+130.7		+186.3

From these values, we can find both $\Delta_r H°$ and $\Delta_r S°$ for the reaction:

$$\begin{aligned}
\Delta_r H° &= \Sigma n\Delta_f H°(\text{products}) - \Sigma n\Delta_f H°(\text{reactants}) \\
&= (1\ \text{mol}\ CH_4(g)/\text{mol-rxn})\ \Delta_f H°[CH_4(g)] - \\
&\qquad \{(1\ \text{mol C(graphite)/mol-rxn})\ \Delta_f H°[\text{C(graphite)}] + \\
&\qquad\qquad (2\ \text{mol}\ H_2(g)/\text{mol-rxn})\ \Delta_f H°[H_2(g)]\} \\
&= (1\ \text{mol}\ CH_4(g)/\text{mol-rxn})(-74.9\ \text{kJ/mol}) - \\
&\qquad [(1\ \text{mol C(graphite)/mol-rxn})(0\ \text{kJ/mol}) + (2\ \text{mol}\ H_2(g)/\text{mol-rxn})(0\ \text{kJ/mol})] \\
&= -74.9\ \text{kJ/mol-rxn}
\end{aligned}$$

$$\begin{aligned}
\Delta_r S° &= \Sigma nS°(\text{products}) - \Sigma nS°(\text{reactants}) \\
&= (1\ \text{mol}\ CH_4(g)/\text{mol-rxn})\ S°[CH_4(g)] - \\
&\qquad \{(1\ \text{mol C(graphite)/mol-rxn})\ S°[\text{C(graphite)}] + \\
&\qquad\qquad (2\ \text{mol}\ H_2(g)/\text{mol-rxn})\ S°[H_2(g)]\} \\
&= (1\ \text{mol}\ CH_4(g)/\text{mol-rxn})(186.3\ \text{J/K} \cdot \text{mol}) - \\
&\qquad [1\ \text{mol C(graphite)/mol-rxn}](5.6\ \text{J/K} \cdot \text{mol}) + \\
&\qquad\qquad (2\ \text{mol}\ H_2(g)/\text{mol-rxn})(130.7\ \text{J/K} \cdot \text{mol})] \\
&= -80.7\ \text{J/K} \cdot \text{mol-rxn}
\end{aligned}$$

Combining the values of $\Delta_r H°$ and $\Delta_r S°$ using Equation 18.5 gives $\Delta_r G°$.

$$\begin{aligned}
\Delta_r G° &= \Delta_r H° - T\Delta_r S° \\
&= -74.9\ \text{kJ/mol-rxn} - [(298\ \text{K})(-80.7\ \text{J/K} \cdot \text{mol-rxn})](1\ \text{kJ}/1000\ \text{J}) \\
&= -50.9\ \text{kJ/mol-rxn}
\end{aligned}$$

$\Delta_r G°$ is negative at 298 K, so the reaction is predicted to be product-favored at equilibrium.

Think about Your Answer In this example, the product $T\Delta_r S°$ is negative (−24.0 kJ/mol-rxn) and disfavors the reaction. However, the entropy change is relatively small, and $\Delta_r H° = -74.9$ kJ/mol-rxn is the dominant term. Chemists call this an *enthalpy-driven reaction.*

Check Your Understanding

Using values of $\Delta_f H°$ and $S°$ to find $\Delta_r H°$ and $\Delta_r S°$, calculate the free energy change, $\Delta_r G°$, for the formation of 2 mol of $NH_3(g)$ from the elements at standard conditions and 25 °C.

$$N_2(g) + 3\ H_2(g) \rightarrow 2\ NH_3(g)$$

EXAMPLE 18.5

Calculating $\Delta_r G°$ Using Free Energies of Formation

Problem Calculate the standard free energy change for the combustion of one mole of methane using values for standard free energies of formation of the products and reactants. Is the reaction product-favored or reactant-favored at equilibrium?

What Do You Know? You are asked to determine the standard free energy change for a reaction ($\Delta_r G°$). Values of standard molar free energies of formation for the substances involved in the reaction can be found in Appendix L.

Strategy Write a balanced equation for the reaction. Then, use Equation 18.8 with values of $\Delta_f G°$ obtained from Appendix L.

SOLUTION The balanced equation and values of $\Delta_f G°$ for each reactant and product are

	$CH_4(g)$	+	$2\ O_2(g)$	→	$2\ H_2O(g)$	+	$CO_2(g)$
$\Delta_f G°$(kJ/mol)	−50.8		0		−228.6		−394.4

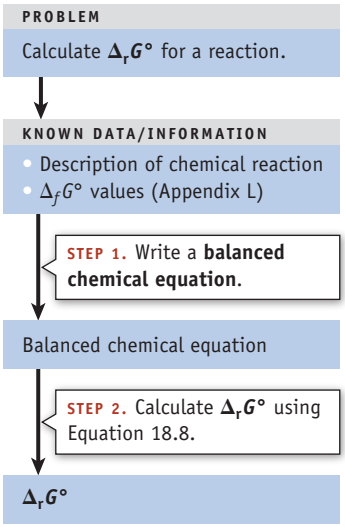
These values can then be substituted into Equation 18.8.

$$\Delta_r G° = \Sigma n \Delta_f G°(\text{products}) - \Sigma n \Delta_f G°(\text{reactants})$$

$$= \{(2\ \text{mol}\ H_2O(g)/\text{mol-rxn})\ \Delta_f G°[H_2O(g)] + (1\ \text{mol}\ CO_2(g)/\text{mol-rxn})\ \Delta_f G°[CO_2(g)]\} - \{(1\ \text{mol}\ CH_4(g)/\text{mol-rxn})\ \Delta_f G°[CH_4(g)] + (2\ \text{mol}\ O_2(g)/\text{mol-rxn})\ \Delta_f G°[O_2(g)]\}$$

$$= [(2\ \text{mol}\ H_2O(g)/\text{mol-rxn})(-228.6\ \text{kJ/mol}) + (1\ \text{mol}\ CO_2(g)/\text{mol-rxn})(-394.4\ \text{kJ/mol})] - [(1\ \text{mol}\ CH_4(g)/\text{mol-rxn})(-50.8\ \text{kJ/mol}) + (2\ \text{mol}\ O_2(g)/\text{mol-rxn})(0\ \text{kJ/mol})]$$

$$= -800.8\ \text{kJ/mol-rxn}$$



The large negative value of $\Delta_r G°$ indicates that the reaction is product-favored at equilibrium.

Think about Your Answer Common errors made by students in this calculation are (1) overlooking the stoichiometric coefficients in the equation and (2) confusing the signs for the terms when using Equation 18.8.

Check Your Understanding

Calculate the standard free energy change for the oxidation of 1.00 mol of $SO_2(g)$ to form $SO_3(g)$ using values of $\Delta_f G°$.

Strategy Map 18.5

Free Energy and Temperature

The definition of free energy, $G = H - TS$, informs us that free energy is a function of temperature, so $\Delta_r G°$ will change as the temperature changes (Figure 18.11). A

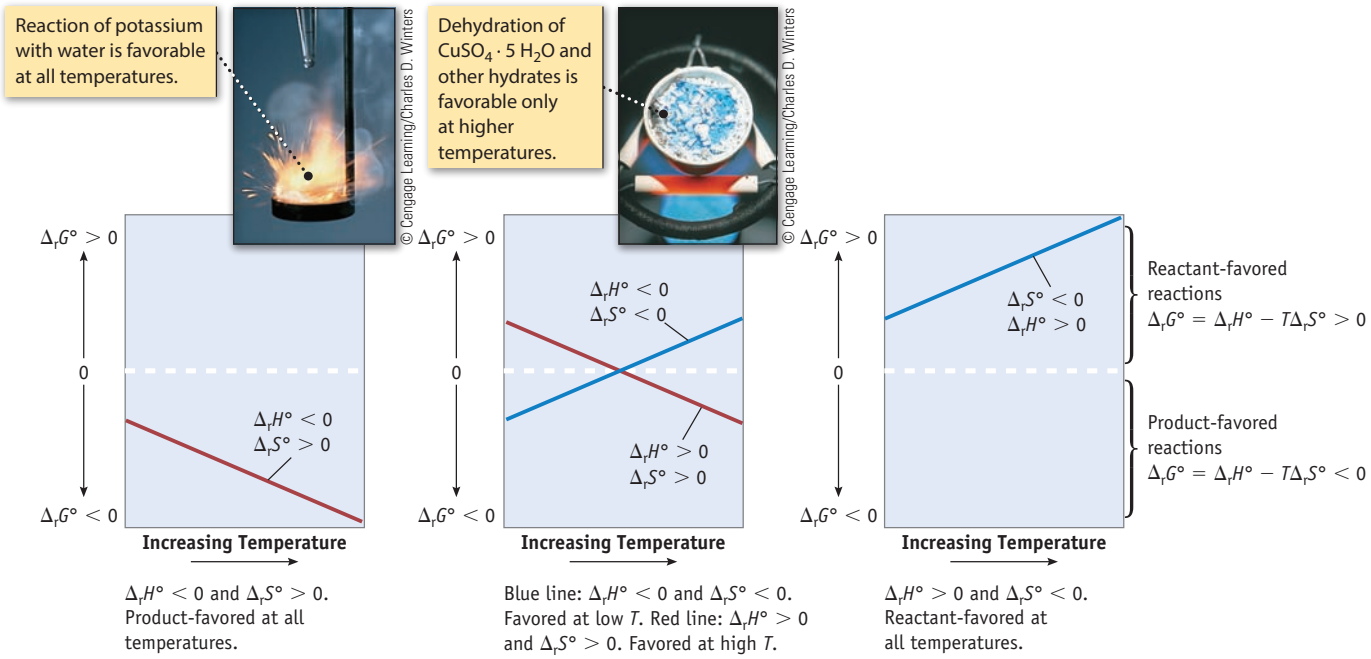

Figure 18.11 **The variation in $\Delta_r G°$ with temperature.**

consequence of this dependence on temperature is that, in certain instances, reactions can be product-favored at equilibrium at one temperature and reactant-favored at another. Those instances arise when the $\Delta_r H°$ and $T\Delta_r S°$ terms work in opposite directions:

- Processes that are entropy-favored ($\Delta_r S° > 0$) and enthalpy-disfavored ($\Delta_r H° > 0$)
- Processes that are enthalpy-favored ($\Delta_r H° < 0$) and entropy-disfavored ($\Delta_r S° < 0$)

Let us explore the relationship of $\Delta_r G°$ and T further and illustrate how it can be used to advantage.

Calcium carbonate is the primary component of limestone, marble, and seashells. Heating $CaCO_3$ produces lime, CaO, an important chemical, along with gaseous CO_2. The data below from Appendix L are at 298 K (25 °C).

	$CaCO_3(s)$	→	CaO(s)	+	$CO_2(g)$
$\Delta_f G°$ (kJ/mol)	−1129.16		−603.42		−394.36
$\Delta_f H°$ (kJ/mol)	−1207.6		−635.09		−393.51
$S°$ (J/K · mol)	91.7		38.2		213.74

For the conversion of 1 mol of $CaCO_3(s)$ to 1 mol of CaO(s) under standard conditions, $\Delta_r G° = +131.38$ kJ, $\Delta_r H° = +179.0$ kJ, and $\Delta_r S° = +160.2$ J/K. Although the reaction is entropy-favored, the large positive and unfavorable enthalpy change dominates at 298 K. Thus, the standard free energy change is positive at 298 K and 1 bar, indicating that the reaction is reactant-favored at equilibrium.

The temperature dependence of $\Delta_r G°$ provides a means to turn the $CaCO_3$ decomposition into a product-favored reaction. Notice that the entropy change in the reaction is positive as a result of the formation of CO_2 gas in the reaction. Thus, raising the temperature results in the value of $T\Delta_r S°$ becoming increasingly large. At a high enough temperature, $T\Delta_r S°$ will outweigh the enthalpy effect, and the process (shown by the red line in the middle diagram in Figure 18.11) will become product-favored at equilibrium.

How high must the temperature be for this reaction to become product-favored? An estimate of the temperature can be obtained using Equation 18.5, by calculating

Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

the temperature at which $\Delta_r G° = 0$. Above that temperature, $\Delta_r G°$ will have a negative value.

$$\Delta_r G° = \Delta_r H° - T\Delta_r S°$$

$$0 = (179.0 \text{ kJ/mol-rxn})(1000 \text{ J/kJ}) - T(160.2 \text{ J/K} \cdot \text{mol-rxn})$$

$$T = 1117 \text{ K (or } 844 \text{ °C)}$$

How accurate is this result? As noted earlier, this answer is only an estimate of the temperature needed. One source of error is the assumption that $\Delta_r H°$ and $\Delta_r S°$ do not vary with temperature, an assumption that is not strictly true. There is always a small variation in these values when the temperature changes—not large enough to be important if the temperature range is narrow, but potentially a problem over wider temperature ranges such as seen in this example. As an estimate, however, a temperature in the range of 850 °C for this reaction is reasonable.

$CaCO_3$ Decomposition Experiments show that the pressure of CO_2 in an equilibrium system [$CaCO_3(s) \rightleftharpoons CaO(s) + CO_2(g)$] is 1 bar at about 900 °C ($K = 1$ and $\Delta_r G° = 0$), close to our estimated temperature.

EXAMPLE 18.6

Effect of Temperature on $\Delta_r G°$

Problem The decomposition of liquid $Ni(CO)_4$ to produce nickel metal and carbon monoxide has a $\Delta_r G°$ value of 40 kJ/mol-rxn at 25 °C.

$$Ni(CO)_4(\ell) \rightarrow Ni(s) + 4\ CO(g)$$

Use values of $\Delta_f H°$ and $S°$ for the reactant and products to estimate the temperature at which the reaction becomes product-favored at equilibrium.

What Do You Know? You are given a balanced chemical equation. Values of standard molar enthalpies of formation and standard molar entropies can be found in the chemical literature. You also know that the key temperature to determine is that at which $\Delta_r G°$ is zero.

Strategy The reaction is reactant-favored at equilibrium at 298 K. However, if the entropy change is positive for the reaction and the reaction is endothermic (with a positive value of $\Delta_r H°$), then a higher temperature may allow the reaction to become product-favored at equilibrium. Therefore, first find $\Delta_r H°$ and $\Delta_r S°$ to see if their values meet these criteria, and if so, then calculate the temperature at which the following condition is met: $0 = \Delta_r H° - T\Delta_r S°$.

SOLUTION Values for $\Delta_f H°$ and $S°$ are obtained from the chemical literature for the substances involved.

	$Ni(CO)_4(\ell)$	→	Ni(s)	+	4 CO(g)
$\Delta_f H°$(kJ/mol)	−632.0		0		−110.525
$S°$(J/K · mol)	320.1		29.87		197.67

For a process in which 1 mol of liquid $Ni(CO)_4$ is converted to 1 mol of Ni(s) and 4 mol of CO(g), we find

$$\Delta_r H° = +189.90 \text{ kJ/mol-rxn}$$

$$\Delta_r S° = +500.45 \text{ J/K mol-rxn}$$

We use these values of $\Delta_r H°$ and $\Delta_r S°$ to find the temperature at which $\Delta_r G° = 0$.

$$\Delta_r G° = \Delta_r H° - T\Delta_r S°$$

$$0 = (189.90 \text{ kJ/mol-rxn})(1000 \text{ J/kJ}) - T(500.45 \text{ J/K} \cdot \text{mol-rxn})$$

$$T = 379.5 \text{ K (or } 106.3 \text{ °C)}$$

Strategy Map 18.6

PROBLEM

Determine the **temperature** above which a chemical reaction is ***product-favored*** at **equilibrium.**

KNOWN DATA/INFORMATION

- Balanced chemical equation
- Temperature
- Values of $\Delta_f H°$ and $S°$

STEP 1. Calculate $\Delta_r H°$ using Equation 5.6.

$\Delta_r H°$

STEP 2. Calculate $\Delta_r S°$ using Equation 18.3.

$\Delta_r S°$

STEP 3. Use the equation $\Delta_r G° = \Delta_r H° - T\Delta_r S°$ to determine the temperature at which $\Delta_r G° = 0$.

Temperature above which the reaction is ***product-favored*** at **equilibrium.**

Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Think about Your Answer At 298 K, the reaction is reactant-favored at equilibrium largely because it is quite endothermic. However, the positive entropy change allows the reaction to be product-favored at equilibrium at a slightly higher temperature.

Check Your Understanding

Oxygen was first prepared by Joseph Priestley (1733–1804) by heating HgO. Use data in Appendix L to estimate the temperature required to decompose HgO(s) into Hg(ℓ) and O_2(g).

Using the Relationship between $\Delta_r G°$ and K

Equation 18.7 provides a direct route to determine the standard free energy change from experimentally determined equilibrium constants.

EXAMPLE 18.7

Calculating $\Delta_r G°$ from K_{sp} for an Insoluble Solid

Problem The value of K_{sp} for AgCl(s) at 25 °C is 1.8×10^{-10}. Determine $\Delta_r G°$ for the process $Ag^+(aq) + Cl^-(aq) \rightleftharpoons AgCl(s)$ at 298.15 K.

What Do You Know You are given the value of K_{sp}. The process of interest is the reverse of the chemical equation for K_{sp}. You also know the temperature.

Strategy The chemical equation given is the opposite of the equation used to define K_{sp}; therefore, the equilibrium constant for this reaction is $1/K_{sp}$. This value is used in Equation 18.7 to calculate $\Delta_r G°$.

SOLUTION

For $Ag^+(aq) + Cl^-(aq) \rightleftharpoons AgCl(s)$,

$$K = 1/K_{sp} = 1/\ 1.8 \times 10^{-10} = 5.56 \times 10^9$$

$$\Delta_r G° = -RT\ \ln K = -(8.3145\ \text{J/K} \cdot \text{mol-rxn})(298.15\ \text{K})\ \ln(5.56 \times 10^9)$$

$$= -55{,}600\ \text{J/mol-rxn} = -55.6\ \text{kJ/mol-rxn}$$

Think about Your Answer The negative value of $\Delta_r G°$ indicates that the precipitation of AgCl from $Ag^+(aq)$ and $Cl^-(aq)$ is product-favored at equilibrium.

Check Your Understanding

Determine the value of $\Delta_r G°$ for the reaction $C(s) + CO_2(g) \rightleftharpoons 2\ CO(g)$ from data in Appendix L. Use this result to calculate the equilibrium constant.

We can solve Equation 18.7 for K by the following steps. We first divide both sides of the equation by $-RT$

$$-\frac{\Delta_r G°}{RT} = \ln K$$

and then take the antilog of both sides of the equation. Because e and ln are inverse functions of each other, their effects cancel, leaving just K on one side of the equation.

$$K = e^{-\frac{\Delta_r G°}{RT}} \qquad (18.9)$$

This equation can be used to calculate the value of K if the value of $\Delta_r G°$ is known.

Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

EXAMPLE 18.8

Calculating K_p from $\Delta_r G°$

Problem Determine the standard free energy change, $\Delta_r G°$, for the environmentally important reaction of nitrogen monoxide and oxygen to form nitrogen dioxide, according to the following chemical equation at 25.0 °C.

$$2\ NO(g) + O_2(g) \rightleftharpoons 2\ NO_2(g)$$

Use this value to calculate the equilibrium constant for this reaction at this temperature.

What Do You Know Values of $\Delta_f G°$ are given in Appendix L.

Strategy Free energy of formation values are used to calculate $\Delta_r G°$ for the reaction using Equation 18.8. The equilibrium constant for this reaction is calculated from $\Delta_r G°$ using Equation 18.9. Because the reactants and products are gases, the calculated value will be K_p.

SOLUTION

	2 NO(g)	+	O_2(g)	$\rightleftharpoons$	2 NO_2(g)
$\Delta_f G°$ (kJ/mol)	86.58		0		51.23

These values can be substituted into Equation 18.8.

$$\Delta_r G° = \Sigma n \Delta_f G°(\text{products}) - \Sigma n \Delta_f G°(\text{reactants})$$

$$= \{(2\ \text{mol}\ NO_2(g)/\text{mol-rxn})\ \Delta_f G°[NO_2(g)] - \{(2\ \text{mol}\ NO(g)/\text{mol-rxn})\ \Delta_f G°[NO(g)] + (1\ \text{mol}\ O_2(g)/\text{mol-rxn})\ \Delta_f G°[O_2(g)]\}$$

$$= \{(2\ \text{mol}\ NO_2(g)/\text{mol-rxn})(51.23\ \text{kJ/mol})] - \{(2\ \text{mol}\ NO(g)/\text{mol-rxn})(86.58\ \text{kJ/mol}) + (1\ \text{mol}\ O_2(g)/\text{mol-rxn})(0\ \text{kJ/mol})\}$$

$$= -70.70\ \text{kJ/mol-rxn}$$

This value is then used in Equation 18.9 to solve for K_p.

$$K_p = e^{-\frac{\Delta_r G°}{RT}}$$

$$= e^{-\frac{-70.70\ \text{kJ/mol-rxn}}{(0.0083145\ \text{kJ/K • mol})(298.2\ \text{K})}}$$

$$K_p = 2.4 \times 10^{12}$$

Think about Your Answer The value of $\Delta_r G°$ is less than zero, indicating that this reaction is product-favored at equilibrium. The value of K_p calculated is greater than 1 as it should be for such a process.

Check Your Understanding

Determine the value of the equilibrium constant, K_p, for the decomposition of liquid water according to the following equation at 25.0 °C.

$$2\ H_2O(\ell) \rightleftharpoons 2\ H_2(g) + O_2(g)$$

Calculating $\Delta_r G$, the Free Energy Change for a Reaction Using $\Delta_r G°$ and the Reaction Quotient

Equation 18.6 allows you to calculate the value of $\Delta_r G$, the free energy change for a reaction at nonstandard conditions, given the values of $\Delta_r G°$ and the reaction quotient, Q.

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

EXAMPLE 18.9

Calculating $\Delta_r G$ from $\Delta_r G°$ and Q

Problem Gaseous iodine monochloride can be decomposed into iodine and chlorine gases according to the following chemical equation

$$2\ ICl(g) \rightarrow I_2(g) + Cl_2(g)$$

(a) Calculate $\Delta_r G°$ for this reaction at 298 K using values for the standard free energies of formation of the products and reactant. Is this reaction reactant-favored or product-favored at equilibrium?

(b) Calculate the value of $\Delta_r G$ at 298 K for this reaction if the reactant and products are mixed with the following partial pressures: 1.0 atm ICl, 1.0×10^{-3} atm I_2, and 1.0×10^{-3} atm Cl_2. Is the reaction spontaneous under these conditions?

What Do You Know? You are given a balanced chemical equation. Standard free energies of formation are listed in Appendix L.

Strategy For part (a), use Equation 18.8 with values of $\Delta_f G°$ to obtain the value of $\Delta_r G°$. For part (b), use Equation 18.6 to obtain the value of $\Delta_r G$ under the conditions given.

SOLUTION

(a)

	2 ICl(g)	→	I_2(g)	+	Cl_2(g)
$\Delta_f G°$ (kJ/mol)	−5.73		19.33		0

These values can be substituted into Equation 18.8.

$$\Delta_r G° = \Sigma n\Delta_f G°(\text{products}) - \Sigma n\Delta_f G°(\text{reactants})$$

$$= \{(1\ \text{mol}\ I_2(g)/\text{mol-rxn})\ \Delta_f G°[I_2(g)] + (1\ \text{mol}\ Cl_2(g)/\text{mol-rxn})\ \Delta_f G°[Cl_2(g)]\} - (2\ \text{mol ICl(g)/mol-rxn})\ \Delta_f G°[ICl(g)]$$

$$= [(1\ \text{mol}\ I_2(g)/\text{mol-rxn})(19.33\ \text{kJ/mol}) + (1\ \text{mol}\ Cl_2(g)/\text{mol-rxn})(0\ \text{kJ/mol})] - (2\ \text{mol ICl(g)/mol-rxn})(-5.73\ \text{kJ/mol})$$

$$= 30.79\ \text{kJ/mol-rxn}$$

$\Delta_r G°$ is positive at 298 K, so the reaction is predicted to be reactant-favored at equilibrium.

(b) Equation 18.6 can be used to calculate $\Delta_r G$ for this reaction under the given conditions.

$$\Delta_r G = \Delta_r G° + RT\ln Q$$

$$= \Delta_r G° + RT\ln(P_{I_2}P_{Cl_2}/P_{ICl}^2)$$

$$= 30.79\ \text{kJ/mol-rxn} + (0.0083145\ \text{kJ/K}\cdot\text{mol-rxn})(298\ \text{K})\ln[(1.0 \times 10^{-3})(1.0 \times 10^{-3})/(1.0)^2]$$

$$= -3.44\ \text{kJ/mol-rxn}$$

$\Delta_r G$ is negative at 298 K, so the reaction will proceed spontaneously until the reactant-favored equilibrium position is reached.

Think about Your Answer Even though the equilibrium position for this reaction favors the reactants, the reaction is spontaneous under the conditions presented in part (b) of the question. Even a reactant-favored reaction is spontaneous until equilibrium is attained.

Check Your Understanding

Nitrogen and oxygen can react to form nitrogen monoxide according to the following chemical equation

$$N_2(g) + O_2(g) \rightarrow 2\ NO(g)$$

(a) Calculate $\Delta_r G°$ for this reaction at 298 K using values for the standard free energies of formation of the product and reactants. Is this reaction reactant-favored or product-favored at equilibrium?

(b) Calculate the value of $\Delta_r G$ at 298 K for this reaction if the reactants and product are mixed with the following partial pressures: 0.10 atm N_2, 0.10 atm O_2, and 0.010 atm NO. Is this reaction spontaneous under these conditions?

18.7 The Interplay of Kinetics and Thermodynamics

Goal for Section 18.7

- Understand how both thermodynamics and kinetics affect chemical reactions.

You have learned about both thermodynamics and kinetics in this text. Thermodynamics tells you *whether* a chemical reaction can occur on its own. Kinetics tells you how *fast* a reaction occurs. Just because a reaction is product-favored at equilibrium, that is, thermodynamically favored, does not mean that it will necessarily proceed quickly. For example, at 25°C and atmospheric pressure, $\Delta_r G°$ for the conversion of diamond to graphite has a value of −2.9 kJ/mol-rxn. Thermodynamics favors the transformation. Because it has a lower free energy, graphite is more **thermodynamically stable** than diamond under these conditions, but the activation energy for this process, a kinetics parameter, is very large. This causes the reaction to be so slow that we do not have to worry about it on an ordinary timescale. A diamond's long existence under normal conditions is due to the slow kinetics of the process, rather than to its thermodynamics. While diamond is thermodynamically unstable compared to graphite, diamond is said to be **kinetically stable** due to the large activation energy for the process.

Likewise the transformation of hydrogen gas and oxygen gas to water

$$2\ H_2(g) + O_2(g) \rightarrow 2\ H_2O(g)$$

is thermodynamically very favored with a $\Delta_r G°$ value of −457 kJ/mol-rxn at 25 °C. Yet a balloon can be filled with a mixture of hydrogen and oxygen and float in a room for a long time until some external source of energy, such as a lighted candle, is provided (page 814). Hydrogen and oxygen are thermodynamically unstable with respect to water at this temperature but are kinetically stable because the activation energy for the reaction is large enough that ambient conditions do not provide enough energy to overcome this barrier to reaction. Once some energy is provided, however, the reaction of some molecules proceeds; the energy released in the reaction of this small number of molecules then provides the energy needed for more of the reaction to occur, and the reaction proceeds explosively.

Yet another example of the interplay of thermodynamics and kinetics is the addition of hydrogen bromide to 1,3-butadiene. Two products are possible: 3-bromo-1-butene and 1-bromo-2-butene.

$$H_2C{=}CHCH{=}CH_2 + HBr \rightarrow H_2C{=}CHCHBrCH_3 + BrCH_2CH{=}CHCH_3$$

	3-bromo-1-butene	1-bromo-2-butene
Yield at −80 °C	81%	19%
Yield at 45 °C	15%	85%

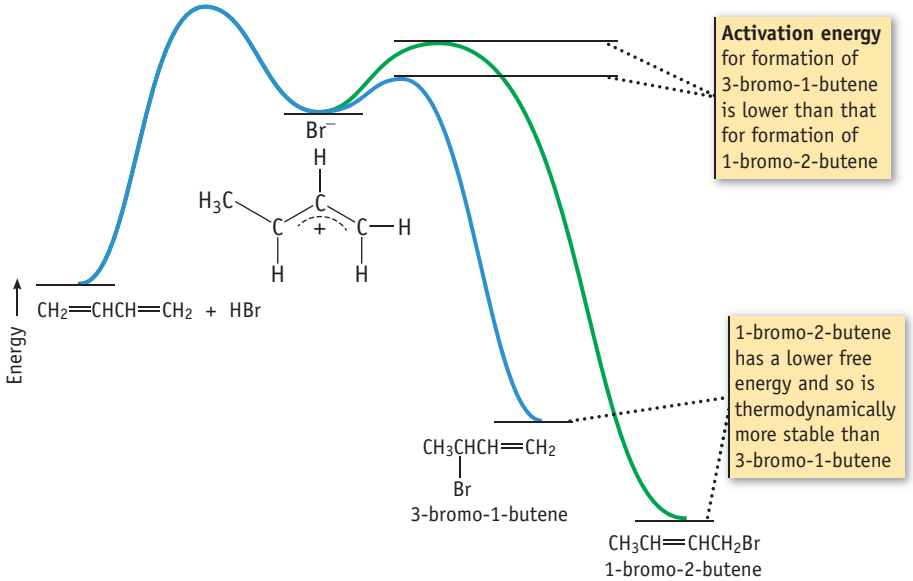

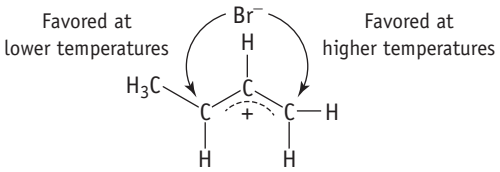

Figure 18.12 **Reaction coordinate diagram for the addition of HBr to 1,3-butadiene.**

Depending on the temperature, different ratios of these two products are obtained. At a low temperature, such as –80 °C, 3-bromo-1-butene predominates, whereas at a higher temperature, such as 45 °C, 1-bromo-2-butene is the major product. Why is this so?

The reaction coordinate diagram for this reaction is shown in Figure 18.12. Butadiene first forms an intermediate (called an allylic carbocation) by the addition of a hydrogen ion from the hydrogen bromide. This intermediate can then form either of the two products by addition of the bromide ion.

The point of attack of Br^- on the allylic carbocation depends on temperature.

At –80 °C, the product ratio is influenced by the rates of the chemical reactions and is said to be under **kinetic control**. The activation energy for the formation of 3-bromo-1-butene is smaller, so this product forms faster and is thus present in a larger amount.

As the temperature is raised, the number of molecules following the two paths is increased and the ratio of products changes. More molecules have sufficient energy to form both products. In addition, reformation of the intermediate and Br^- from the two product molecules (the reverse of the second step of this reaction) also occurs. This provides a mechanism allowing the two products to reach equilibrium.

$$\text{3-bromo-1-butene} \rightleftharpoons \text{1-bromo-2-butene}$$

At 45 °C, the ratio of the two products is established by this equilibrium. A reaction run under these conditions, in which the ratio of products is defined by the equilibrium between these two species, is said to be under **thermodynamic control**, that is, thermodynamics is controlling the ratio of products. In studying chemical reactions, therefore, both kinetics and thermodynamics play important roles.

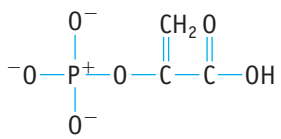
18.1 Thermodynamics and Living Things

The laws of thermodynamics apply to all chemical reactions. It should come as no surprise, therefore, that issues of spontaneity and calculations involving $\Delta_r G$ also arise in studies of biochemical reactions. For biochemical processes, however, a different standard state is often used. Most of the usual definition is retained: 1 bar pressure for gases and 1 *m* concentration for aqueous solutes with the exception of one very important solute. Rather than using a standard state of 1 molal for hydronium ions (corresponding to a pH of about 0), biochemists use a hydronium concentration of 1×10^{-7} M, corresponding to a pH of 7. This pH is more useful for biochemical reactions. When biochemists use this as the standard state, they write the symbol ′ next to the thermodynamic function. For example, they would write $\Delta G°'$ (pronounced *delta G zero prime*).

Living things require energy to perform their many functions. One of the main reactions providing this energy is that of adenosine triphosphate (ATP) with water, a reaction for which $\Delta_r G°' = -30.5$ kJ/mol-rxn.



ATP, adenosine triphosphate

One of the key functions of the process of respiration is to produce molecules of ATP for our bodies to use. ATP is produced in the reaction of adenosine diphosphate (ADP) with hydrogen phosphate ($HP_i = HPO_4^{2-}$),

$$ADP + HP_i + H^+ \longrightarrow ATP + H_2O \qquad \Delta_r G°' = +30.5 \text{ kJ/mol-rxn}$$

a reaction that is reactant-favored at equilibrium. How then do our bodies get this reaction to occur? The answer is to couple the production of ATP with another reaction that is even more product-favored than ATP production is reactant-favored. For example, organisms carry out the oxidation of carbohydrates in a multistep process, producing energy. One of the compounds produced in the process called *glycolysis* is phosphoenolpyruvate (PEP).

PEP, phosphoenolpyruvate

John C. Katz

Its reaction with water is product-favored at equilibrium

$$PEP + H_2O \longrightarrow Pyruvate + HP_i \qquad \Delta_r G°' = -61.9 \text{ kJ/mol-rxn}$$

This reaction and ATP formation are linked through the HP_i that is produced in the PEP reaction. If both reactions are carried out, we obtain the following:

$$PEP + H_2O \longrightarrow Pyruvate + HP_i \qquad \Delta_r G°' = -61.9 \text{ kJ/mol-rxn}$$

$$ADP + HP_i + H^+ \longrightarrow ATP + H_2O \qquad \Delta_r G°' = +30.5 \text{ kJ/mol-rxn}$$

$$PEP + ADP + H^+ \longrightarrow Pyruvate + ATP \qquad \Delta_r G°' = -31.4 \text{ kJ/mol-rxn}$$

The overall reaction has a negative value for $\Delta_r G°'$ and thus is product-favored at equilibrium. ATP is formed in this process.

The coupling of reactions to produce a system that is product-favored is used in a multitude of reactions that occur in our bodies.

Questions:

1. Consider the hydrolysis reactions of creatine phosphate and adenosine-5′-monophosphate.

$$\text{Creatine Phosphate} + H_2O \longrightarrow \text{Creatine} + HP_i$$

$$\Delta_r G°' = -43.3 \text{ kJ/mol-rxn}$$

$$\text{Adenosine-5′-Monophosphate} + H_2O \longrightarrow \text{Adenosine} + HP_i$$

$$\Delta_r G°' = -9.2 \text{ kJ/mol-rxn}$$

   Which of the following combinations produces a reaction that is product-favored at equilibrium: for creatine phosphate to transfer phosphate to adenosine or for adenosine-5′-monophosphate to transfer phosphate to creatine?

2. Assume the reaction A(aq) + B(aq) → C(aq) + H_3O^+(aq) produces one hydronium ion. What is the mathematical relationship between $\Delta_r G°'$ and $\Delta_r G°$ at 25 °C? (*Hint:* Use the equation $\Delta_r G = \Delta_r G° + RT \ln Q$ and substitute $\Delta_r G°'$ for $\Delta_r G$.)

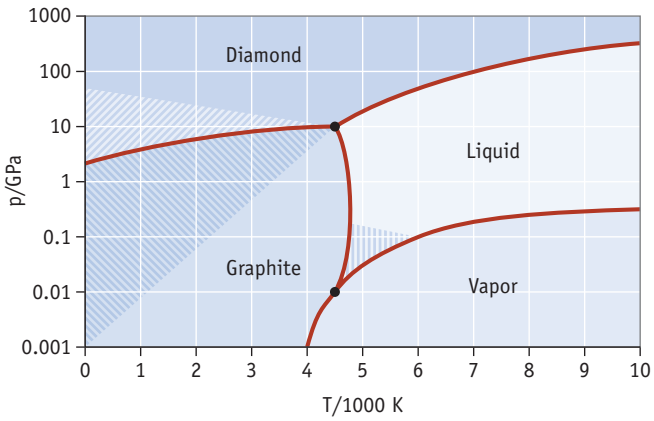
18.2 Are Diamonds Forever?

Natural diamonds are created over 150 kilometers beneath the Earth's surface. At these depths, enormous pressures and high temperatures convert graphite, the more stable allotrope of carbon at lower pressure, into diamond. It is believed that volcanic eruptions then push diamonds to the Earth's surface. If a diamond is pushed to the surface quickly, it will cool before it has a chance to revert to graphite. Although diamonds are thermodynamically unstable at room temperature, the activation barrier for conversion is too high for the process to occur.

Diamonds have been synthesized in laboratories since the 1950s by duplicating the conditions that exist deep underground. To produce a synthetic diamond, a seed crystal of diamond is combined with graphite and nickel (or chromium), then subjected to pressures greater than 50,000 atmospheres and temperatures around 1500 °C. The nickel, now molten, simultaneously acts as a solvent for carbon and a catalyst for the formation of diamond. If conditions are maintained near the equilibrium line between diamond and graphite (Figure 1), single crystals of synthetic diamonds may be grown to sizes larger than one carat in approximately three days. Synthetic diamonds may be produced in a variety of colors. One of the most common colors is yellow, which results from a small amount of nitrogen replacing carbon in diamond's lattice. Is this a problem? Probably not. Natural yellow diamonds are extremely rare and sell for high prices.

Currently, a technique known as *chemical vapor deposition* (CVD) is being used to grow diamonds in a vacuum and at lower temperatures (800 °C). In CVD, methane and hydrogen gases are atomized above a diamond seed crystal. Hydrogen atoms bond with carbon atoms on the diamond's surface, preventing the carbon atoms from forming double bonds with its neighbors. Carbon radicals, from the decomposed methane, slowly replace the hydrogen atoms on the diamond's surface, building a larger diamond, one atomic layer at a time. In addition to gemstones, the CVD method may be used to create diamond windows or thin diamond films over a variety of substrates (Figure 2).



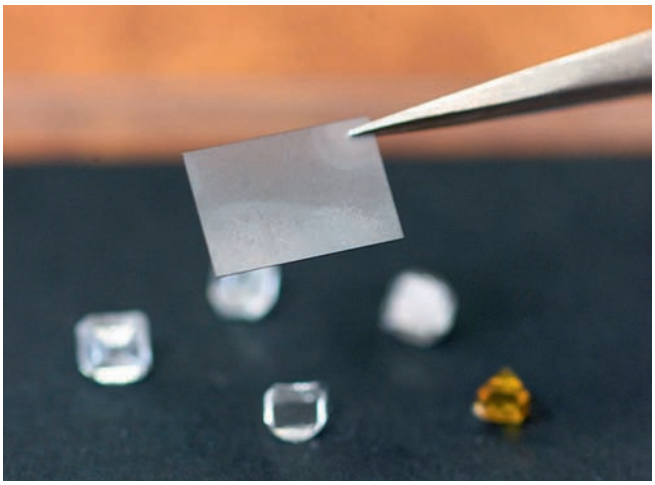


Figure 1 Phase diagram for carbon. The hatched areas are regions where the two phases can coexist. Pressures are in gigapascals (where 1 GPa is about 9900 atm).

TOSHIFUMI KITAMURA/AFP/Getty Images

Figure 2 Diamond wafers. The chemical vapor deposition (CVD) technique allows the synthesis of diamond in the shape of extended disks or wafers. Under optimized growth conditions the properties of these disks approach those of perfect diamond single crystals.

Questions:

1. The decomposition of diamond to graphite [C(diamond) → C(graphite)] is thermodynamically favored, but occurs slowly at room temperature.
   a. Use $\Delta_f G°$ values from Appendix L to calculate $\Delta_r G°$ and K_{eq} for the reaction under standard conditions and 298.15 K.
   b. Use $\Delta_f H°$ and $S°$ values from Appendix L to estimate $\Delta_r G°$ and K_{eq} for the reaction at 1000 K. Assume that enthalpy and entropy values are valid at these temperatures. Does heating shift the equilibrium toward the formation of diamond or graphite?
   c. Why is the formation of diamond favored at high pressures?
   d. The phase diagram shows that diamond is thermodynamically favored over graphite at 20,000 atmospheres pressure (about 2 GPa) at room temperature. Why is this conversion actually done at much higher temperatures and pressures?
2. It has been demonstrated that buckminsterfullerene (C_{60}), another allotrope of carbon (Section 2.3), may be converted into diamond at room temperature and 20,000 atmospheres pressure (about 2 GPa). The standard enthalpy of formation, $\Delta_f H°$, for buckminsterfullerene is 2320 kJ/mol at 298.2 K.
   a. Calculate $\Delta_r H°$ for the conversion of C_{60} to diamond at standard state conditions and 298.2 K.
   b. Assuming that the standard entropy per mole of carbon in both C_{60} and diamond is comparable (both about 2.3 J/K mol), is the conversion of C_{60} to diamond product-favored at room temperature?

CHAPTER GOALS REVISITED

The goals for this chapter are keyed to specific Study Questions to help you organize your review:

18.1 Spontaneity and Dispersal of Energy: Entropy

- Understand the concept of spontaneity: spontaneous processes occur without outside intervention and proceed to equilibrium, a result of energy dispersal. **1, 2.**
- Know the second law of thermodynamics: a spontaneous process is one that leads to an increase in entropy in the universe. **3, 4.**
- Recognize that an entropy change is the energy transferred as heat for a reversible process divided by the kelvin temperature. **7–12, 60, 61.**

18.2 Entropy: A Microscopic Understanding

- Understand the statistical basis of entropy, that entropy is proportional to the number of ways that energy can be dispersed, that is, to the number of microstates available to a system. **13, 14.**

18.3 Entropy Measurement and Values

- Recognize that assigning a perfect crystal at 0 K to have zero entropy (the third law of thermodynamics) establishes a means of evaluating the entropy of a substance. **15, 88.**
- Define standard molar entropies, $S°$, and evaluate and compare factors affecting $S°$ values (temperature, volume, molecular structure, states of matter). **16–18, 51.**
- Use values of standard molar entropies to calculate changes in entropy, $\Delta S°$, for a chemical reaction. **19–24, 52, 78, 93.**

18.4 Entropy Changes and Spontaneity

- Calculate the change in entropy for a system, its surroundings, and the universe to determine whether a process is spontaneous under standard conditions. **25–28, 55, 58, 74.**
- Recognize how reaction conditions influence whether a reaction is spontaneous. **29, 30.**

18.5 Gibbs Free Energy

- Define the Gibbs free energy change, ΔG, and relate $\Delta_r G°$ to $\Delta_r H°$ and $\Delta_r S°$. **31–34.**
- Relate $\Delta_r G°$, Q, and K to reaction spontaneity and product- and reactant-favorability. **31–34, 49, 50, 53, 54, 66, 67, 75.**

Q	$\Delta_r G$	Spontaneous?
$Q < K$	$\Delta_r G < 0$	Spontaneous to the right as the equation is written
$Q = K$	$\Delta_r G = 0$	Reaction is at equilibrium
$Q > K$	$\Delta_r G > 0$	Not spontaneous to the right; spontaneous to the left

Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

18.6 Calculating and Using Standard Free Energies, $\Delta_r G°$

- Use free energies of formation, $\Delta_f G°$, to calculate the standard free energy change for a reaction. **35–38, 56, 95, 103, 104.**
- Use the equation $\Delta_r G° = \Delta_r H° - T\Delta_r S°$ to assess the effect of changes in temperature on the favorability of a reaction. **39–42, 63, 73, 79, 100, 101.**
- Relate $\Delta_r G°$ and the equilibrium constant for a reaction. **43–48, 59, 69, 71, 72, 84, 90.**

K	$\Delta_r G°$	Reactant-Favored or Product-Favored at Equilibrium?
$K >> 1$	$\Delta_r G° < 0$	Product-favored
$K = 1$	$\Delta_r G° = 0$	$[C]^c[D]^d = [A]^a[B]^b$ at equilibrium
$K << 1$	$\Delta_r G° > 0$	Reactant-favored

18.7 The Interplay of Kinetics and Thermodynamics

- Understand how both thermodynamics and kinetics affect chemical reactions. **86, 107.**

KEY EQUATIONS

Equation 18.1 (page 817) Calculate the entropy change from the energy transferred as heat for a reversible process and the temperature at which it occurs.

$$\Delta S = \frac{q_{rev}}{T}$$

Equation 18.2 (page 820) The Boltzmann equation: The entropy of a system, S, is proportional to the number of accessible microstates, W, belonging to a given energy of a system or substance.

$$S = k \ln W$$

Equation 18.3 (page 824) Calculate the standard entropy change for a process from the tabulated entropies of the products and reactants and the stoichiometric coefficients (n) of the substances in the balanced chemical equation for the reaction.

$$\Delta_r S° = \Sigma nS°(\text{products}) - \Sigma nS°(\text{reactants})$$

Equation 18.4 (page 825) Calculate the total entropy change for a system and its surroundings, to determine whether a process is spontaneous under standard conditions.

$$\Delta S°(\text{universe}) = \Delta S°(\text{system}) + \Delta S°(\text{surroundings})$$

Equation 18.5 (page 830) Calculate the free energy change for a process from enthalpy and entropy changes.

$$\Delta_r G° = \Delta_r H° - T\Delta_r S°$$

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Equation 18.6 (page 832) Calculate the free energy change under nonstandard conditions ($\Delta_r G$) from the standard free energy change ($\Delta_r G°$) and the reaction quotient Q.

$$\Delta_r G = \Delta_r G° + RT \ln Q$$

Equation 18.7 (page 832) Calculate the standard free energy change for a reaction from its equilibrium constant.

$$\Delta_r G° = -RT \ln K$$

Equation 18.8 (page 833) Calculate the standard free energy change for a reaction using tabulated values of $\Delta_f G°$ and the stoichiometric coefficients (n) of the substances in the balanced chemical equation for the reaction.

$$\Delta_r G° = \Sigma n \Delta_f G°(\text{products}) - \Sigma n \Delta_f G°(\text{reactants})$$

Equation 18.9 (page 838) Calculate the equilibrium constant for a reaction from its standard free energy change.

$$K = e^{-\frac{\Delta_r G°}{RT}}$$

STUDY QUESTIONS

▲ denotes challenging questions. **Blue-numbered questions** have answers in Appendix N and fully worked solutions in the *Student Solutions Manual.*

Practicing Skills

Entropy and the Second and Third Laws of Thermodynamics

(See Sections 18.1-18.3)

1. Solid NH_4NO_3 is placed in a beaker containing water at 25 °C. When the solid has completely dissolved, the temperature of the solution is 23.5 °C.
   (a) Was the process exothermic or endothermic?
   (b) Was the process spontaneous?
   (c) Did the entropy of the system increase?
   (d) Did the entropy of the universe increase?
2. Acetic acid, a weak acid, was added to a beaker containing water at 25 °C, giving a solution containing molecular acetic acid, hydronium ion, and acetate ion at equilibrium. The temperature did not change.
   (a) Is the solution process exothermic or endothermic?
   (b) Was the dissolving process and partial ionization spontaneous?
   (c) Did the entropy of the system increase or decrease?
   (d) Did the entropy of the universe increase or decrease?
3. Identify the following processes as either spontaneous or not spontaneous.
   (a) Ice melts when placed in a flask containing water at 5 °C.
   (b) Hydrogen iodide molecules decompose at 400 K to give a mixture of H_2, I_2, and HI.
   (c) Ethanol and water are mixed to form a solution.
   (d) Slightly soluble $PbCl_2$ ($K_{sp} = 1.7 \times 10^{-5}$) dissolves in water to form a saturated solution.
4. Identify the following processes as either spontaneous or not spontaneous.
   (a) Liquid water turns to ice when placed in a freezer at −5 °C.
   (b) Nitrogen gas is compressed to one half its original volume.
   (c) Sodium reacts with water forming H_2(g) and NaOH(aq).
   (d) Slightly soluble $CaSO_4$ ($K_{sp} = 4.5 \times 10^{-5}$) dissolves in water to form a saturated solution.

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

5. Predict whether each of the following processes results in an increase in entropy in the system. (Define reactants and products as the system.)
   (a) Water vapor condenses as dew (liquid water) at 0 °C and 1 atm pressure.
   (b) An exothermic reaction of Al(s) and $Br_2(\ell)$ forms $Al_2Br_6(s)$.
   (c) The endothermic decomposition of solid $CaCO_3$ at 800 °C to produce an equilibrium mixture containing solid $CaCO_3$, solid CaO, and gaseous CO_2.
   (d) One mol of AgCl(s) decomposes, forming 1.0 mole of Ag(s) and 0.5 mol $Cl_2(g)$.

6. Predict whether each of the following processes results in an increase in entropy in the system. (Define reactants and products as the system.)
   (a) Water vapor condenses to liquid water at 90 °C and 1 atm pressure.
   (b) The exothermic reaction of Na(s) and $Cl_2(g)$ forms NaCl(s).
   (c) The endothermic reaction of H_2 and I_2 produces an equilibrium mixture of $H_2(g)$, $I_2(g)$,and HI(g).
   (d) Solid NaCl dissolves in water forming a saturated solution.

7. Indicate which of the following processes are reversible.
   (a) Nitrogen gas expands into a vacuum.
   (b) Dry ice, $CO_2(s)$, sublimes at 25 °C and 1.0 atm.
   (c) Energy as heat is added to a mixture of ice and water at 0 °C, causing some of the ice to melt.
   (d) Methanol and ethanol mix forming a homogeneous solution.

8. Indicate which of the following processes are reversible.
   (a) Nitrogen and oxygen gases diffuse to give a homogeneous mixture.
   (b) Ice sublimes at −5 °C and 1.0 atm.
   (c) Energy as heat is transferred to the surroundings from a mixture of ice and water at 0 °C, causing more ice to form.
   (d) Bromine evaporates and the gaseous molecules diffuse into the atmosphere.

9. What information is needed to calculate the entropy change that occurs when 1.00 mole of water vapor condenses to liquid water at 100 °C?

10. What information is needed to calculate the entropy change when a 2.25 g sample of liquid water is warmed from 20 °C to 25 °C?

11. Calculate the entropy change that occurs when 0.50 mol of ice is converted to liquid water at 0 °C in a reversible process. (q_{fus} = 333 J/g)

12. Calculate the entropy change that occurs when 1.00 mol of steam is converted to liquid water at 100 °C in a reversible process. (q_{vap} = 40. 7 kJ/mol)

13. Calculate the change in entropy for a system in going from a condition of 5 accessible microstates to 30 accessible microstates.

14. Calculate the change in entropy of a system with an increase in volume from 1.0 L to 2.0 L.

15. The third law of thermodynamics says that a perfect crystal at 0 K has zero entropy. The standard entropy of a substance, $S°$ can be determined by evaluating the energy required to carry out conversion from 0 K to standard conditions. What information would be needed to calculate $S°$ for liquid water at 298 K and 1 bar?

16. Identify trends in $S°$ values:
   (a) For the halogens: $F_2(g)$, $Cl_2(g)$, $Br_2(\ell)$, $I_2(s)$.
   (b) For the gaseous hydrocarbons: CH_4, C_2H_6, C_3H_8.

Entropy

(See Sections 18.1–18.3 and Examples 18.1 and 18.2.)

17. Which substance has the higher entropy?
   (a) dry ice (solid CO_2) at −78 °C or $CO_2(g)$ at 0 °C
   (b) liquid water at 25 °C or liquid water at 50 °C
   (c) pure alumina, $Al_2O_3(s)$, or ruby (ruby is Al_2O_3 in which some Al^{3+} ions in the crystalline lattice are replaced with Cr^{3+} ions)
   (d) one mole of $N_2(g)$ at 1 bar pressure or one mole of $N_2(g)$ at 10 bar pressure (both at 298 K)

18. Which substance has the higher entropy?
   (a) a sample of pure silicon (to be used in a computer chip) or a piece of silicon containing a trace of another element such as boron or phosphorus
   (b) $O_2(g)$ at 0 °C or $O_2(g)$ at −50 °C
   (c) $I_2(s)$ or $I_2(g)$, both at room temperature
   (d) one mole of $O_2(g)$ at 1 bar pressure or one mole of $O_2(g)$ at 0.01 bar pressure (both at 298 K)

19. Use $S°$ values to calculate the standard entropy change, $\Delta_r S°$, for each of the following processes and comment on the sign of the change.
(a) $KOH(s) \rightarrow KOH(aq)$
(b) $Na(g) \rightarrow Na(s)$
(c) $Br_2(\ell) \rightarrow Br_2(g)$
(d) $HCl(g) \rightarrow HCl(aq)$

20. Use $S°$ values to calculate the standard entropy change, $\Delta_r S°$, for each of the following processes, and comment on the sign of the change.
(a) $NH_4Cl(s) \rightarrow NH_4Cl(aq)$
(b) $CH_3OH(\ell) \rightarrow CH_3OH(g)$
(c) $CCl_4(g) \rightarrow CCl_4(\ell)$
(d) $NaCl(s) \rightarrow NaCl(g)$

21. Calculate the standard entropy change for the formation of 1.0 mol of the following compounds from the elements at 25 °C.
(a) $HCl(g)$ (b) $Ca(OH)_2(s)$

22. Calculate the standard entropy change for the formation of 1.0 mol of the following compounds from the elements at 25 °C.
(a) $H_2S(g)$ (b) $MgCO_3(s)$

23. Calculate the standard entropy change for the following reactions at 25 °C. Comment on the sign of $\Delta_r S°$.
(a) $2\ Al(s) + 3\ Cl_2(g) \rightarrow 2\ AlCl_3(s)$
(b) $2\ CH_3OH(\ell) + 3\ O_2(g) \rightarrow 2\ CO_2(g) + 4\ H_2O(g)$

24. Calculate the standard entropy change for the following reactions at 25 °C. Comment on the sign of $\Delta_r S°$.
(a) $2\ Na(s) + 2\ H_2O(\ell) \rightarrow 2\ NaOH(aq) + H_2(g)$
(b) $Na_2CO_3(s) + 2\ HCl(aq) \rightarrow 2\ NaCl(aq) + H_2O(\ell) + CO_2(g)$

$\Delta_r S°$(universe) and Spontaneity

(See Sections 18.1–18.4 and Example 18.3.)

25. Is the reaction $Si(s) + 2\ Cl_2(g) \rightarrow SiCl_4(g)$ spontaneous under standard conditions at 298.15 K? Answer this question by calculating $\Delta S°$(system), $\Delta S°$(surroundings), and $\Delta S°$(universe). (Define reactants and products as the system.)

26. Is the reaction $Si(s) + 2\ H_2(g) \rightarrow SiH_4(g)$ spontaneous under standard conditions at 298.15 K? Answer this question by calculating $\Delta S°$(system), $\Delta S°$(surroundings), and $\Delta S°$(universe). (Define reactants and products as the system.)

27. Calculate $\Delta S°$(universe) for the decomposition of 1 mol of liquid water to form gaseous hydrogen and oxygen. Is this reaction spontaneous under standard conditions at 25 °C? Explain your answer briefly.

28. Calculate $\Delta S°$(universe) for the formation of 1 mol HCl(g) from gaseous hydrogen and chlorine. Is this reaction spontaneous under standard conditions at 25 °C? Explain your answer briefly.

29. Classify each of the reactions according to one of the four reaction types summarized in Table 18.1.
(a) $Fe_2O_3(s) + 2\ Al(s) \rightarrow 2\ Fe(s) + Al_2O_3(s)$
$\Delta_r H° = -851.5$ kJ/mol-rxn
$\Delta_r S° = -375.2$ J/K · mol-rxn
(b) $N_2(g) + 2\ O_2(g) \rightarrow 2\ NO_2(g)$
$\Delta_r H° = 66.2$ kJ/mol-rxn
$\Delta_r S° = -121.6$ J/K · mol-rxn

30. Classify each of the reactions according to one of the four reaction types summarized in Table 18.1.
(a) $C_6H_{12}O_6(s) + 6\ O_2(g) \rightarrow 6\ CO_2(g) + 6\ H_2O(\ell)$
$\Delta_r H° = -673$ kJ/mol-rxn
$\Delta_r S° = 60.4$ J/K · mol-rxn
(b) $MgO(s) + C(\text{graphite}) \rightarrow Mg(s) + CO(g)$
$\Delta_r H° = 490.7$ kJ/mol-rxn
$\Delta_r S° = 197.9$ J/K · mol-rxn

Gibbs Free Energy

(See Sections 18.5 and 18.6 and Example 18.4.)

31. Using values of $\Delta_f H°$ and $S°$, calculate $\Delta_r G°$ for each of the following reactions at 25 °C.
(a) $2\ Pb(s) + O_2(g) \rightarrow 2\ PbO(s)$
(b) $NH_3(g) + HNO_3(aq) \rightarrow NH_4NO_3(aq)$
Which of these reactions is (are) predicted to be product-favored at equilibrium? Are the reactions enthalpy- or entropy-driven?

32. Using values of $\Delta_f H°$ and $S°$, calculate $\Delta_r G°$ for each of the following reactions at 25 °C.
(a) $2\ Na(s) + 2\ H_2O(\ell) \rightarrow 2\ NaOH(aq) + H_2(g)$
(b) $6\ C(\text{graphite}) + 3\ H_2(g) \rightarrow C_6H_6(\ell)$
Which of these reactions is (are) predicted to be product-favored at equilibrium? Are the reactions enthalpy- or entropy-driven?

33. Using values of $\Delta_f H°$ and $S°$, calculate the standard molar free energy of formation, $\Delta_f G°$, for each of the following compounds:
(a) $CS_2(g)$ (b) $NaOH(s)$ (c) $ICl(g)$
Compare your calculated values of $\Delta_f G°$ with those listed in Appendix L. Which of these formation reactions are predicted to be product-favored at equilibrium at 25 °C?

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

34. Using values of $\Delta_f H°$ and $S°$, calculate the standard molar free energy of formation, $\Delta_f G°$, for each of the following:

(a) $Ca(OH)_2(s)$

(b) $Cl(g)$

(c) $Na_2CO_3(s)$

Compare your calculated values of $\Delta_f G°$ with those listed in Appendix L. Which of these formation reactions are predicted to be product-favored at equilibrium at 25 °C?

Free Energy of Formation

(See Section 18.6 and Example 18.5.)

35. Using values of $\Delta_f G°$, calculate $\Delta_r G°$ for each of the following reactions at 25 °C. Which are product-favored at equilibrium?

(a) $2\ K(s) + Cl_2(g) \rightarrow 2\ KCl(s)$

(b) $2\ CuO(s) \rightarrow 2\ Cu(s) + O_2(g)$

(c) $4\ NH_3(g) + 7\ O_2(g) \rightarrow 4\ NO_2(g) + 6\ H_2O(g)$

36. Using values of $\Delta_f G°$, calculate $\Delta_r G°$ for each of the following reactions at 25 °C. Which are product-favored at equilibrium?

(a) $HgS(s) + O_2(g) \rightarrow Hg(\ell) + SO_2(g)$

(b) $2\ H_2S(g) + 3\ O_2(g) \rightarrow 2\ H_2O(g) + 2\ SO_2(g)$

(c) $SiCl_4(g) + 2\ Mg(s) \rightarrow 2\ MgCl_2(s) + Si(s)$

37. For the reaction $BaCO_3(s) \rightarrow BaO(s) + CO_2(g)$, $\Delta_r G° = +219.7$ kJ/mol-rxn. Using this value and other data available in Appendix L, calculate the value of $\Delta_f G°$ for $BaCO_3(s)$.

38. For the reaction $TiCl_2(s) + Cl_2(g) \rightarrow TiCl_4(\ell)$, $\Delta_r G° = -272.8$ kJ/mol-rxn. Using this value and other data available in Appendix L, calculate the value of $\Delta_f G°$ for $TiCl_2(s)$.

Effect of Temperature on ΔG

(See Section 18.6 and Example 18.6.)

39. Determine whether the reactions listed below are entropy-favored or disfavored under standard conditions. Predict how an increase in temperature will affect the value of $\Delta_r G°$.

(a) $N_2(g) + 2\ O_2(g) \rightarrow 2\ NO_2(g)$

(b) $2\ C(s) + O_2(g) \rightarrow 2\ CO(g)$

(c) $CaO(s) + CO_2(g) \rightarrow CaCO_3(s)$

(d) $2\ NaCl(s) \rightarrow 2\ Na(s) + Cl_2(g)$

40. Determine whether the reactions listed below are entropy-favored or disfavored under standard conditions. Predict how an increase in temperature will affect the value of $\Delta_r G°$.

(a) $I_2(g) \rightarrow 2\ I(g)$

(b) $2\ SO_2(g) + O_2(g) \rightarrow 2\ SO_3(g)$

(c) $SiCl_4(g) + 2\ H_2O(\ell) \rightarrow SiO_2(s) + 4\ HCl(g)$

(d) $P_4(s, \text{white}) + 6\ H_2(g) \rightarrow 4\ PH_3(g)$

41. Heating some metal carbonates, among them magnesium carbonate, leads to their decomposition.

$$MgCO_3(s) \rightarrow MgO(s) + CO_2(g)$$

(a) Calculate $\Delta_r G°$ and $\Delta_r S°$ for the reaction.

(b) Is the reaction product-favored at equilibrium at 298 K?

(c) Is the reaction predicted to be product-favored at equilibrium at higher temperatures?

42. Calculate $\Delta_r H°$ and $\Delta_r S°$ for the reaction of tin(IV) oxide with carbon.

$$SnO_2(s) + C(s) \rightarrow Sn(s) + CO_2(g)$$

(a) Is the reaction product-favored at equilibrium at 298 K?

(b) Is the reaction predicted to be product-favored at equilibrium at higher temperatures?

Free Energy and Equilibrium Constants

(See Section 18.6 and Examples 18.7 and 18.8.)

43. The ionization constant, K_a, for acetic acid is 1.8×10^{-5} at 25 °C. What is the value of $\Delta_r G°$ for this reaction? Is this reaction product- or reactant-favored at equilibrium?

44. The formation constant, K_f, for the reaction

$$Ag^+(aq) + 2\ NH_3(aq) \rightleftharpoons [Ag(NH_3)_2]^+(aq)$$

is 1.1×10^7. What is the value of $\Delta_r G°$ for this reaction? Is the reaction product- or reactant-favored at equilibrium?

45. The standard free energy change, $\Delta_r G°$, for the formation of NO(g) from its elements is +86.58 kJ/mol-rxn at 25 °C. Calculate K_p at this temperature for the equilibrium

$$\tfrac{1}{2}\ N_2(g) + \tfrac{1}{2}\ O_2(g) \rightleftharpoons NO(g)$$

Comment on the sign of $\Delta_r G°$ and the magnitude of K_p.

46. The standard free energy change, $\Delta_r G°$, for the formation of $O_3(g)$ from $O_2(g)$ is +163.2 kJ/mol-rxn at 25 °C. Calculate K_p at this temperature for the equilibrium

$$3\ O_2(g) \rightleftharpoons 2\ O_3(g)$$

Comment on the sign of $\Delta_r G°$ and the magnitude of K_p.

47. Calculate $\Delta_r G°$ at 25 °C for the formation of 1.00 mol of $C_2H_6(g)$ from $C_2H_4(g)$ and $H_2(g)$. Use this value to calculate K_p for the equilibrium.

$$C_2H_4(g) + H_2(g) \rightleftharpoons C_2H_6(g)$$

Comment on the sign of $\Delta_r G°$ and the magnitude of K_p.

48. Calculate $\Delta_r G°$ at 25 °C for the formation of 1.00 mol of $C_2H_5OH(g)$ from $C_2H_4(g)$ and $H_2O(g)$. Use this value to calculate K_p for the equilibrium.

$$C_2H_4(g) + H_2O(g) \rightleftharpoons C_2H_5OH(g)$$

Comment on the sign of $\Delta_r G°$ and the magnitude of K_p.

Free Energy and Reaction Conditions

(See Section 18.6 and Example 18.9.)

49. For the synthesis of ammonia from its elements at 25 °C,

$$N_2(g) + 3\ H_2(g) \rightarrow 2\ NH_3(g)$$

(a) Calculate $\Delta_r G°$ using values of $\Delta_f G°$. Is the reaction product-favored at equilibrium?

(b) Calculate $\Delta_r G$ when the reactants and product are each present at a partial pressure of 0.10 atm. Is the reaction spontaneous under these conditions?

50. For the decomposition of solid calcium carbonate at 25 °C,

$$CaCO_3(s) \rightarrow CaO(s) + CO_2(g)$$

(a) Calculate $\Delta_r G°$ using values of $\Delta_f G°$. Is the reaction product-favored at equilibrium?

(b) Calculate $\Delta_r G$ when the partial pressure of carbon dioxide is 0.10 atm in the presence of both calcium carbonate and calcium oxide. Is the reaction spontaneous under these conditions?

General Questions

These questions are not designated as to type or location in the chapter. They may combine several concepts.

51. Compare the compounds in each set below and decide which is expected to have the higher entropy. Assume all are at the same temperature. Check your answers using data in Appendix L.

(a) HF(g), HCl(g), or HBr(g)

(b) $NH_4Cl(s)$ or $NH_4Cl(aq)$

(c) $C_2H_4(g)$ or $N_2(g)$ (two substances with the same molar mass)

(d) NaCl(s) or NaCl(g)

52. Using standard entropy values, calculate $\Delta_r S°$ for the formation of 1.0 mol of $NH_3(g)$ from $N_2(g)$ and $H_2(g)$ at 25 °C.

53. About 5 billion kilograms of benzene, C_6H_6, are made each year. Benzene is used as a starting material for many other compounds and as a solvent (although it is also a carcinogen, and its use is restricted). One compound that can be made from benzene is cyclohexane, C_6H_{12}.

$$C_6H_6(\ell) + 3\ H_2(g) \rightarrow C_6H_{12}(\ell)$$

$$\Delta_r H° = -206.7\ \text{kJ/mol-rxn};\quad \Delta_r S° = -361.5\ \text{J/K} \cdot \text{mol-rxn}$$

Is this reaction predicted to be product-favored at equilibrium at 25 °C? Is the reaction enthalpy- or entropy-driven?

54. Hydrogenation, the addition of hydrogen to an organic compound, is an industrially important reaction. Calculate $\Delta_r H°$, $\Delta_r S°$, and $\Delta_r G°$ for the hydrogenation of octene, C_8H_{16}, to give octane, C_8H_{18}, at 25 °C. Is the reaction product- or reactant-favored at equilibrium?

$$C_8H_{16}(g) + H_2(g) \rightarrow C_8H_{18}(g)$$

Along with data in Appendix L, the following information is needed for this calculation.

Compound	$\Delta_f H°$ (kJ/mol)	$S°$ (J/K · mol)
Octene	−82.93	462.8
Octane	−208.45	463.639

55. Is the combustion of ethane, C_2H_6, product-favored at equilibrium at 25 °C?

$$C_2H_6(g) + {}^7/_2\ O_2(g) \rightarrow 2\ CO_2(g) + 3\ H_2O(g)$$

Answer the question by calculating the value of $\Delta S°$(universe) at 298 K, using values of $\Delta_f H°$ and $S°$ in Appendix L. Does the answer agree with your preconceived idea of this reaction?

56. Write a balanced equation that depicts the formation of 1 mol of $Fe_2O_3(s)$ from its elements. What is the standard free energy of formation of 1.00 mol of $Fe_2O_3(s)$? What is the value of $\Delta G°$ when 454 g (1 lb) of $Fe_2O_3(s)$ is formed from the elements?

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

57. When vapors from hydrochloric acid and aqueous ammonia come in contact, they react, producing a white "cloud" of solid NH_4Cl (Figure 18.9).

$$HCl(g) + NH_3(g) \rightleftharpoons NH_4Cl(s)$$

Defining the reactants and products as the system under study:

(a) Predict whether $\Delta S°$(system), $\Delta S°$(surroundings), $\Delta S°$(universe), $\Delta_r H°$, and $\Delta_r G°$ (at 298 K) are greater than zero, equal to zero, or less than zero; and explain your prediction. Verify your predictions by calculating values for each of these quantities.

(b) Calculate the value of K_p for this reaction at 298 K.

58. Calculate $\Delta S°$(system), $\Delta S°$(surroundings), and $\Delta S°$(universe) for each of the following processes at 298 K, and comment on how these systems differ.

(a) $HNO_3(g) \rightarrow HNO_3(aq)$

(b) $NaOH(s) \rightarrow NaOH(aq)$

59. Methanol is now widely used as a fuel in race cars. Consider the following reaction as a possible synthetic route to methanol.

$$C(\text{graphite}) + \tfrac{1}{2}\,O_2(g) + 2\,H_2(g) \rightleftharpoons CH_3OH(\ell)$$

Calculate K_p for the formation of methanol at 298 K using this reaction. Would this reaction be more product-favored at a different temperature?

60. The enthalpy of vaporization of liquid diethyl ether, $(C_2H_5)_2O$, is 26.0 kJ/mol at the boiling point of 35.0 °C. Calculate $\Delta S°$ for a vapor-to-liquid transformation at 35.0 °C.

61. Calculate the entropy change, $\Delta_r S°$, for the vaporization of ethanol, C_2H_5OH, at its normal boiling point, 78.0 °C. The enthalpy of vaporization of ethanol is 39.3 kJ/mol.

62. Using thermodynamic data, estimate the normal boiling point of ethanol. (Recall that liquid and vapor are in equilibrium at 1.0 atm pressure at the normal boiling point.) The actual normal boiling point is 78 °C. How well does your calculated result agree with the actual value?

63. The following reaction is reactant-favored at equilibrium at room temperature.

$$COCl_2(g) \rightarrow CO(g) + Cl_2(g)$$

Will raising or lowering the temperature make it product-favored?

64. When calcium carbonate is heated strongly, CO_2 gas is evolved. The equilibrium pressure of CO_2 is 1.00 bar at 897 °C, and $\Delta_r H°$ at 298 K is 179.0 kJ/mol-rxn.

$$CaCO_3(s) \rightarrow CaO(s) + CO_2(g)$$

Estimate the value of $\Delta_r S°$ at 897 °C for the reaction.

65. Sodium reacts violently with water according to the equation

$$Na(s) + H_2O(\ell) \rightarrow NaOH(aq) + \tfrac{1}{2}\,H_2(g)$$

Without doing calculations, predict the signs of $\Delta_r H°$ and $\Delta_r S°$ for the reaction. Verify your prediction with a calculation.

66. Yeast can produce ethanol by the fermentation of glucose ($C_6H_{12}O_6$), which is the basis for the production of most alcoholic beverages.

$$C_6H_{12}O_6(aq) \rightarrow 2\,C_2H_5OH(\ell) + 2\,CO_2(g)$$

Calculate $\Delta_r H°$, $\Delta_r S°$, and $\Delta_r G°$ for the reaction at 25 °C. Is the reaction product- or reactant-favored at equilibrium? In addition to the thermodynamic values in Appendix L, you will need the following data for $C_6H_{12}O_6(aq)$:

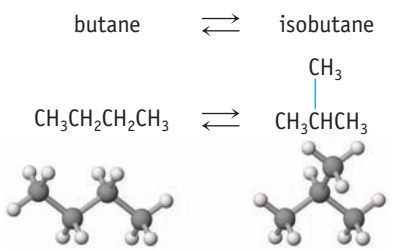
$$\Delta_f H° = -1260.0 \text{ kJ/mol};\ S° = 289 \text{ J/K} \cdot \text{mol};\ \text{and } \Delta_f G° = -918.8 \text{ kJ/mol}.$$

67. Elemental boron, in the form of thin fibers, can be made by reducing a boron halide with H_2.

$$BCl_3(g) + \tfrac{3}{2}\,H_2(g) \rightarrow B(s) + 3\,HCl(g)$$

Calculate $\Delta_r H°$, $\Delta_r S°$, and $\Delta_r G°$ at 25 °C for this reaction. Is the reaction predicted to be product-favored at equilibrium at 25 °C? If so, is it enthalpy- or entropy-driven? [$S°$ for B(s) is 5.86 J/K · mol.]

68. ▲ Estimate the vapor pressure of ethanol at 37 °C using thermodynamic data. Express the result in millimeters of mercury.



69. The equilibrium constant, K_p, for $N_2O_4(g) \rightleftharpoons 2\,NO_2(g)$ is 0.14 at 25 °C. Calculate $\Delta_r G°$ for the conversion of $N_2O_4(g)$ to $NO_2(g)$ from this constant, and compare this value with that determined from the $\Delta_f G°$ values in Appendix L.

70. ▲ Estimate the boiling point of water in Denver, Colorado (where the altitude is 1.60 km and the atmospheric pressure is 630 mm Hg or 0.840 bar).

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

71. The equilibrium constant for the butane $\rightleftharpoons$ isobutane equilibrium at 25 °C is 2.50. Calculate $\Delta_r G°$ at this temperature in units of kJ/mol.

$$K_c = \frac{[\text{isobutane}]}{[\text{butane}]} = 2.50 \text{ at } 298 \text{ K}$$

72. A crucial reaction for the production of synthetic fuels is the production of H_2 by the reaction of coal with steam. The chemical reaction is

$$C(s) + H_2O(g) \rightarrow CO(g) + H_2(g)$$

(a) Calculate $\Delta_r G°$ for this reaction at 25 °C, assuming C(s) is graphite.

(b) Calculate K_p for the reaction at 25 °C.

(c) Is the reaction predicted to be product-favored at equilibrium at 25 °C? If not, at what temperature will it become so?

73. Calculate $\Delta_r G°$ for the decomposition of sulfur trioxide to sulfur dioxide and oxygen.

$$2\ SO_3(g) \rightleftharpoons 2\ SO_2(g) + O_2(g)$$

(a) Is the reaction product-favored at equilibrium at 25 °C?

(b) If the reaction is not product-favored at 25 °C, is there a temperature at which it will become so? Estimate this temperature.

(c) Estimate the equilibrium constant for the reaction at 1500 °C.

74. Methanol can be made by partial oxidation of methane by $O_2(g)$.

$$CH_4(g) + \tfrac{1}{2}\ O_2(g) \rightleftharpoons CH_3OH(\ell)$$

(a) Determine $\Delta S°$(system), $\Delta S°$(surroundings), and $\Delta S°$(universe) for this process.

(b) Is this reaction product-favored at equilibrium at 25 °C?

75. A cave in Mexico was recently discovered to have some interesting chemistry. Hydrogen sulfide, H_2S, reacts with oxygen in the cave to give sulfuric acid, which drips from the ceiling in droplets with a pH less than 1. The reaction occurring is

$$H_2S(g) + 2\ O_2(g) \rightarrow H_2SO_4(\ell)$$

Calculate $\Delta_r H°$, $\Delta_r S°$, and $\Delta_r G°$. Is the reaction product-favored at equilibrium at 25 °C? Is it enthalpy- or entropy-driven?

76. Wet limestone is used to scrub SO_2 gas from the exhaust gases of power plants. One possible reaction gives hydrated calcium sulfite:

$$CaCO_3(s) + SO_2(g) + \tfrac{1}{2}\ H_2O(\ell) \rightleftharpoons CaSO_3 \cdot \tfrac{1}{2}\ H_2O(s) + CO_2(g)$$

Another reaction gives hydrated calcium sulfate:

$$CaCO_3(s) + SO_2(g) + \tfrac{1}{2}\ H_2O(\ell) + \tfrac{1}{2}\ O_2(g) \rightleftharpoons CaSO_4 \cdot \tfrac{1}{2}\ H_2O(s) + CO_2(g)$$

(a) Which reaction is more product-favored at equilibrium? Use the data in the table below and any other information needed in Appendix L to calculate $\Delta_r G°$ for each reaction at 25 °C.

	$CaSO_3 \cdot \frac{1}{2}\ H_2O(s)$	$CaSO_4 \cdot \frac{1}{2}\ H_2O(s)$
$\Delta_f H°$ (kJ/mol)	−1311.7	−1574.65
$S°$ (J/K · mol)	121.3	134.8

(b) Calculate $\Delta_r G°$ for the reaction

$$CaSO_3 \cdot \tfrac{1}{2}\ H_2O(s) + \tfrac{1}{2}\ O_2(g) \rightleftharpoons CaSO_4 \cdot \tfrac{1}{2}\ H_2O(s)$$

Is this reaction product- or reactant-favored at equilibrium?

77. Sulfur undergoes a phase transition between 80 and 100 °C.

$$S_8(\text{rhombic}) \rightarrow S_8(\text{monoclinic})$$

$$\Delta_r H° = 3.213 \text{ kJ/mol-rxn} \quad \Delta_r S° = 8.7 \text{ J/K} \cdot \text{mol-rxn}$$

(a) Estimate $\Delta_r G°$ for the transition at 80.0 °C and 110.0 °C. What do these results tell you about the stability of the two forms of sulfur at each of these temperatures?

(b) Calculate the temperature at which $\Delta_r G° = 0$. What is the significance of this temperature?

78. Calculate the entropy change for dissolving HCl gas in water at 25 °C. Is the sign of $\Delta_r S°$ what you expected? Why or why not?

In the Laboratory

79. Some metal oxides can be decomposed to the metal and oxygen under reasonable conditions. Is the decomposition of silver(I) oxide product-favored at equilibrium at 25 °C?

$$2\ Ag_2O(s) \rightarrow 4\ Ag(s) + O_2(g)$$

If not, can it become so if the temperature is raised? At what temperature does the reaction become product-favored at equilibrium?

80. Copper(II) oxide, CuO, can be reduced to copper metal with hydrogen at higher temperatures.

$$CuO(s) + H_2(g) \rightarrow Cu(s) + H_2O(g)$$

Is this reaction product- or reactant-favored at equilibrium at 298 K?

© Cengage Learning/Charles D. Winters

If copper metal is heated in air, a black film of CuO forms on the surface. In this photo, the heated bar, covered with a black CuO film, has been bathed in hydrogen gas. Black, solid CuO is reduced rapidly to copper at higher temperatures.

81. Calculate $\Delta_f G°$ for HI(g) at 350 °C, given the following equilibrium partial pressures: $P(H_2) = 0.132$ bar, $P(I_2) = 0.295$ bar, and $P(HI) = 1.61$ bar. At 350 °C and 1 bar, I_2 is a gas.

$$\tfrac{1}{2}\, H_2(g) + \tfrac{1}{2}\, I_2(g) \rightleftharpoons HI(g)$$

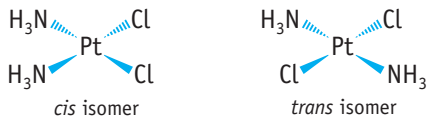
82. Calculate the equilibrium constant for the formation of NiO at 1627 °C. Can the reaction proceed in the forward direction if the initial pressure of O_2 is below 1.00 mm Hg? {$\Delta_f G°$ [NiO(s)] = −72.1 kJ/mol at 1627 °C}

$$Ni(s) + \tfrac{1}{2}\, O_2(g) \rightleftharpoons NiO(s)$$

83. Titanium(IV) oxide is converted to titanium carbide with carbon at a high temperature.

$$TiO_2(s) + 3\ C(s) \rightarrow 2\ CO(g) + TiC(s)$$

Compound	Free Energies of Formation at 727 °C, kJ/mol
$TiO_2(s)$	−757.8
TiC(s)	−162.6
CO(g)	−200.2



(a) Calculate $\Delta_r G°$ and K at 727 °C.

(b) Is the reaction product-favored at equilibrium at this temperature?

(c) How can the reactant or product concentrations be adjusted for the reaction to proceed at 727 °C?

84. Cisplatin [*cis*-diamminedichloroplatinum(II)] is a potent treatment for certain types of cancers, but the *trans* isomer is not effective. What is the equilibrium constant at 298 K for the transformation of the *cis* to the *trans* isomer? Which is the favored isomer at 298 K, the *cis* or the *trans* isomer?

Compound	$\Delta_f H°$ (kJ/mol, 298 K)	$\Delta_f G°$ (kJ/mol, 298 K)
Cis-$Pt(NH_3)_2Cl_2$	−467.4	−228.7
Trans-$Pt(NH_3)_2Cl_2$	−480.3	−222.8

Summary and Conceptual Questions

The following questions may use concepts from this and previous chapters.

85. ▲ Mercury vapor is dangerous because breathing it brings this toxic element into the lungs. We wish to estimate the vapor pressure of mercury at two different temperatures from the following data:

	$\Delta_f H°$ (kJ/mol)	$S°$ (J/K · mol)	$\Delta_f G°$ (kJ/mol)
Hg(ℓ)	0	76.02	0
Hg(g)	61.38	174.97	31.88

Estimate the temperature at which K_p for the process $Hg(\ell) \rightleftharpoons Hg(g)$ is equal to 1.00 (and the vapor pressure of Hg is 1.00 bar). Next, estimate the temperature at which the vapor pressure is (1/760) bar. (Experimental vapor pressures are 1.00 mm Hg at 126.2 °C and 1.00 bar at 356.6 °C.) (*Note:* The temperature at which $P = 1.00$ bar can be calculated from thermodynamic data. To find the other temperature, you will need to use the temperature for $P = 1.00$ bar and the Clausius–Clapeyron equation in Section 11.6.)

86. Explain why each of the following statements is incorrect.

(a) Entropy increases in all spontaneous reactions.

(b) Reactions with a negative free energy change ($\Delta_r G° < 0$) are product-favored and occur with rapid transformation of reactants to products.

(c) All spontaneous processes are exothermic.

(d) Endothermic processes are never spontaneous.

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

87. Decide whether each of the following statements is true or false. If false, rewrite it to make it true.

(a) The entropy of a substance increases on going from the liquid to the vapor state at any temperature.

(b) An exothermic reaction will always be spontaneous.

(c) Reactions with a positive $\Delta_r H°$ and a positive $\Delta_r S°$ can never be product-favored.

(d) If $\Delta_r G°$ for a reaction is negative, the reaction will have an equilibrium constant greater than 1.

88. Under what conditions is the entropy of a pure substance 0 J/K · mol? Could a substance at standard conditions at 25 °C have a value of 0 J/K · mol? A negative entropy value? Are there any conditions under which a substance will have negative entropy? Explain your answer.

89. In Chapter 13, you learned that entropy, as well as enthalpy, plays a role in the solution process. If $\Delta H°$ for the solution process is zero, explain how the process can be driven by entropy.

90. ▲ Consider the formation of NO(g) from its elements.

$$N_2(g) + O_2(g) \rightleftharpoons 2\ NO(g)$$

(a) Calculate K_p at 25 °C. Is the reaction product-favored at equilibrium at this temperature?

(b) Assuming $\Delta_r H°$ and $\Delta_r S°$ are nearly constant with temperature, calculate $\Delta_r G°$ at 700 °C. Estimate K_p from the new value of $\Delta_r G°$ at 700 °C. Is the reaction product-favored at equilibrium at 700 °C?

(c) Using K_p at 700 °C, calculate the equilibrium partial pressures of the three gases if you mix 1.00 bar each of N_2 and O_2.

91. Write a chemical equation for the oxidation of $C_2H_6(g)$ by $O_2(g)$ to form $CO_2(g)$ and $H_2O(g)$. Defining this as the system:

(a) Predict whether the signs of $\Delta S°$(system), $\Delta S°$(surroundings), and $\Delta S°$(universe) will be greater than zero, equal to zero, or less than zero. Explain your prediction.

(b) Predict the signs of $\Delta_r H°$ and $\Delta_r G°$. Explain how you made this prediction.

(c) Will the value of K_p be very large, very small, or near 1? Will the equilibrium constant, K_p, for this system be larger or smaller at temperatures greater than 298 K? Explain how you made this prediction.

92. The normal melting point of benzene, C_6H_6, is 5.5 °C. For the process of melting, what is the sign of each of the following?

(a) $\Delta_r H°$

(b) $\Delta_r S°$

(c) $\Delta_r G°$ at 5.5 °C

(d) $\Delta_r G°$ at 0.0 °C

(e) $\Delta_r G°$ at 25.0 °C

93. Calculate the standard molar entropy change, $\Delta_r S°$, for each of the following reactions at 25 °C:

(a) $C(s) + 2\ H_2(g) \rightarrow CH_4(g)$

(b) $CH_4(g) + \frac{1}{2}\ O_2(g) \rightarrow CH_3OH(\ell)$

(c) $C(s) + 2\ H_2(g) + \frac{1}{2}\ O_2(g) \rightarrow CH_3OH(\ell)$

Verify that these values are related by the equation $\Delta_r S°(1) + \Delta_r S°(2) = \Delta_r S°(3)$. What general principle is illustrated here?

94. For each of the following processes, predict the algebraic sign of $\Delta_r H°$, $\Delta_r S°$, and $\Delta_r G°$. No calculations are necessary; use your common sense.

(a) The decomposition of liquid water to give gaseous oxygen and hydrogen, a process that requires a considerable amount of energy.

(b) Dynamite is a mixture of nitroglycerin, $C_3H_5N_3O_9$, and diatomaceous earth. The explosive decomposition of nitroglycerin gives gaseous products such as water, CO_2, and others; much heat is evolved.

(c) The combustion of gasoline in the engine of your car, as exemplified by the combustion of octane.

$$2\ C_8H_{18}(g) + 25\ O_2(g) \rightarrow 16\ CO_2(g) + 18\ H_2O(g)$$

95. "Heater Meals" are food packages that contain their own heat source. Just pour water into the heater unit, wait a few minutes, and voilà! You have a hot meal.

$$Mg(s) + 2\ H_2O(\ell) \rightarrow Mg(OH)_2(s) + H_2(g)$$

© Cengage Learning/Charles D. Winters

The heat for the heater unit is produced by the reaction of magnesium with water.

(a) Confirm that this is a product-favored reaction at equilibrium at 25 °C.

(b) What mass of magnesium is required to produce sufficient energy to heat 225 mL of water (density = 0.995 g/mL) from 25 °C to the boiling point?

96. Use values of $\Delta_f G°$ for solid and gaseous iodine at 25 °C (Appendix L) to calculate the equilibrium vapor pressure of iodine at this temperature.

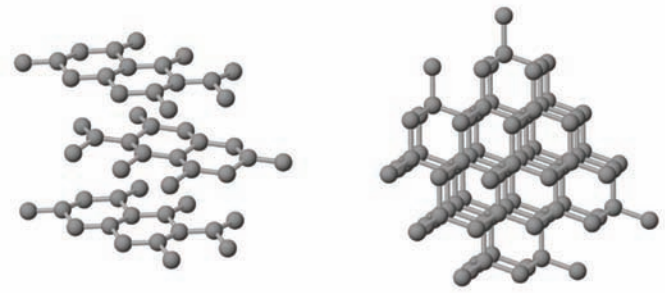
© Cengage Learning/Charles D. Winters

Iodine, I_2, readily sublimes at room temperature.

97. Oxygen dissolved in water can cause corrosion in hot-water heating systems. To remove oxygen, hydrazine (N_2H_4) is often added. Hydrazine reacts with dissolved O_2 to form water and N_2.

(a) Write a balanced chemical equation for the reaction of hydrazine and oxygen. Identify the oxidizing and reducing agents in this redox reaction.

(b) Calculate $\Delta_r H°$, $\Delta_r S°$, and $\Delta_r G°$ for this reaction involving 1 mol of N_2H_4 at 25 °C.



(c) Because this is an exothermic reaction, energy is evolved as heat. What temperature change is expected in a heating system containing 5.5×10^4 L of water? (Assume no energy is lost to the surroundings.)

(d) The mass of a hot-water heating system is 5.5×10^4 kg. What amount of O_2 (in moles) would be present in this system if it is filled with water saturated with O_2? (The solubility of O_2 in water at 25 °C is 0.000434 g per 100 g of water.)

(e) Assume hydrazine is available as a 5.0% solution in water. What mass of this solution should be added to totally consume the dissolved O_2 [described in part (d)]?

(f) Assuming the N_2 escapes as a gas, calculate the volume of N_2(g) (measured at 273 K and 1.00 atm) that will be produced.

98. The formation of diamond from graphite is a process of considerable importance.

graphite diamond

(a) Using data in Appendix L, calculate $\Delta_r S°$, $\Delta_r H°$, and $\Delta_r G°$ for this process at 25 °C.

(b) The calculations will suggest that this process is not possible at any temperature. However, the synthesis of diamonds by this reaction is a commercial process. How can this contradiction be rationalized? (*Note:* In the industrial synthesis, high pressure and high temperatures are used.)

99. Iodine, I_2, dissolves readily in carbon tetrachloride. For this process, $\Delta H° = 0$ kJ/mol.

$$I_2(s) \rightarrow I_2 \text{ (in } CCl_4 \text{ solution)}$$

What is the sign of $\Delta_r G°$? Is the dissolving process entropy-driven or enthalpy-driven? Explain briefly.

100. Write an equation for the reaction of Fe_2O_3(s) and C(s) to give Fe(s) and CO(g) (one of the reactions occurring in a blast furnace). How does $\Delta_r G°$ vary with temperature? Is there a temperature at which the reaction is product-favored at equilibrium?

101. Write an equation for the decomposition of 1.0 mol of gaseous methanol to the elements in their standard states.

(a) How does the value of $\Delta_r G°$ change as the temperature increases?

(b) Is there a temperature between 400 K and 1000 K at which the decomposition is product-favored at equilibrium?

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

102. Consider the reaction of NO and Cl_2 to produce NOCl.

(a) What is $\Delta S°$(system) for this reaction?

(b) Does $\Delta S°$(system) change with temperature?

(c) Does $\Delta S°$(surroundings) change with temperature?

(d) Does $\Delta S°$(universe) always change with an increase in temperature?

(e) Do exothermic reactions always lead to positive values of $\Delta S°$(universe)?

(f) Is the NO + Cl_2 reaction spontaneous at 298 K? At 700 K?

103. Two processes that can be used to generate hydrogen are the electrolysis of water

$$2\ H_2O(\ell) \rightarrow 2\ H_2(g) + O_2(g)$$

and the reaction of methane with steam

$$CH_4(g) + H_2O(g) \rightarrow 3\ H_2(g) + CO(g)$$

(a) Calculate $\Delta_r G°$ for each reaction.

(b) For each reaction, calculate $\Delta G°$ per mole of hydrogen produced.

(c) Which process do you think is better to use to obtain hydrogen? Explain.

104. Hydrogen and methane are two possible replacements for gasoline in automobiles. The reactions for their combustion are as follows:

$$H_2(g) + \tfrac{1}{2}\ O_2(g) \rightarrow H_2O(\ell)$$

$$CH_4(g) + 2\ O_2(g) \rightarrow CO_2(g) + 2\ H_2O(\ell)$$

(a) Calculate $\Delta_r G°$ for each reaction.

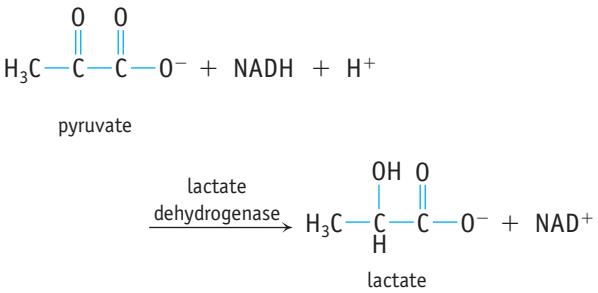
(b) Calculate $\Delta G°$ for each fuel on a per gram basis.

(c) Which is a better fuel? Explain.

105. ▲ The Haber–Bosch process for the production of ammonia is one of the key industrial processes in developed countries.

$$N_2(g) + 3\ H_2(g) \rightleftharpoons 2\ NH_3(g)$$

(a) Calculate $\Delta_r G°$ for the reaction at 298 K, 800 K, and 1300 K. Data at 298 K are given in Appendix L. Data for the other temperatures are as follows:



Temperature	$\Delta_r H°$ (kJ/mol)	$\Delta_r S°$ (J/K · mol)
800 K	−107.4	−225.4
1300 K	−112.4	−228.0

How does the $\Delta_r G°$change with temperature?

(b) Calculate the equilibrium constant for the reaction at 298 K, 800 K, and 1300 K.

(c) At what temperature (298 K, 800 K, or 1300 K) is the mole fraction of NH_3 the greatest?

106. ▲ Muscle cells need energy to contract. One biochemical pathway for energy transfer is the breakdown of glucose to pyruvate in a process called *glycolysis*. In the presence of sufficient oxygen in the cell, pyruvate is oxidized to CO_2 and H_2O to make further energy available. However, under extreme conditions not enough oxygen can be supplied to the cells, so muscle cells produce lactate ion according to the reaction

where $\Delta_r G°' = -25.1$ kJ/mol. In living cells, the pH value is about 7. The hydronium ion concentration is constant and is included in $\Delta G°$, which is then called $\Delta_r G°'$ (*Applying Chemical Principles 18.1 Thermodynamics and Living Things*). *(This problem is taken from the problems for the 36th International Chemistry Olympiad for high school students held in Kiel, Germany, in 2004.)*

(a) Calculate $\Delta_r G°$ for the reaction at 25 °C.

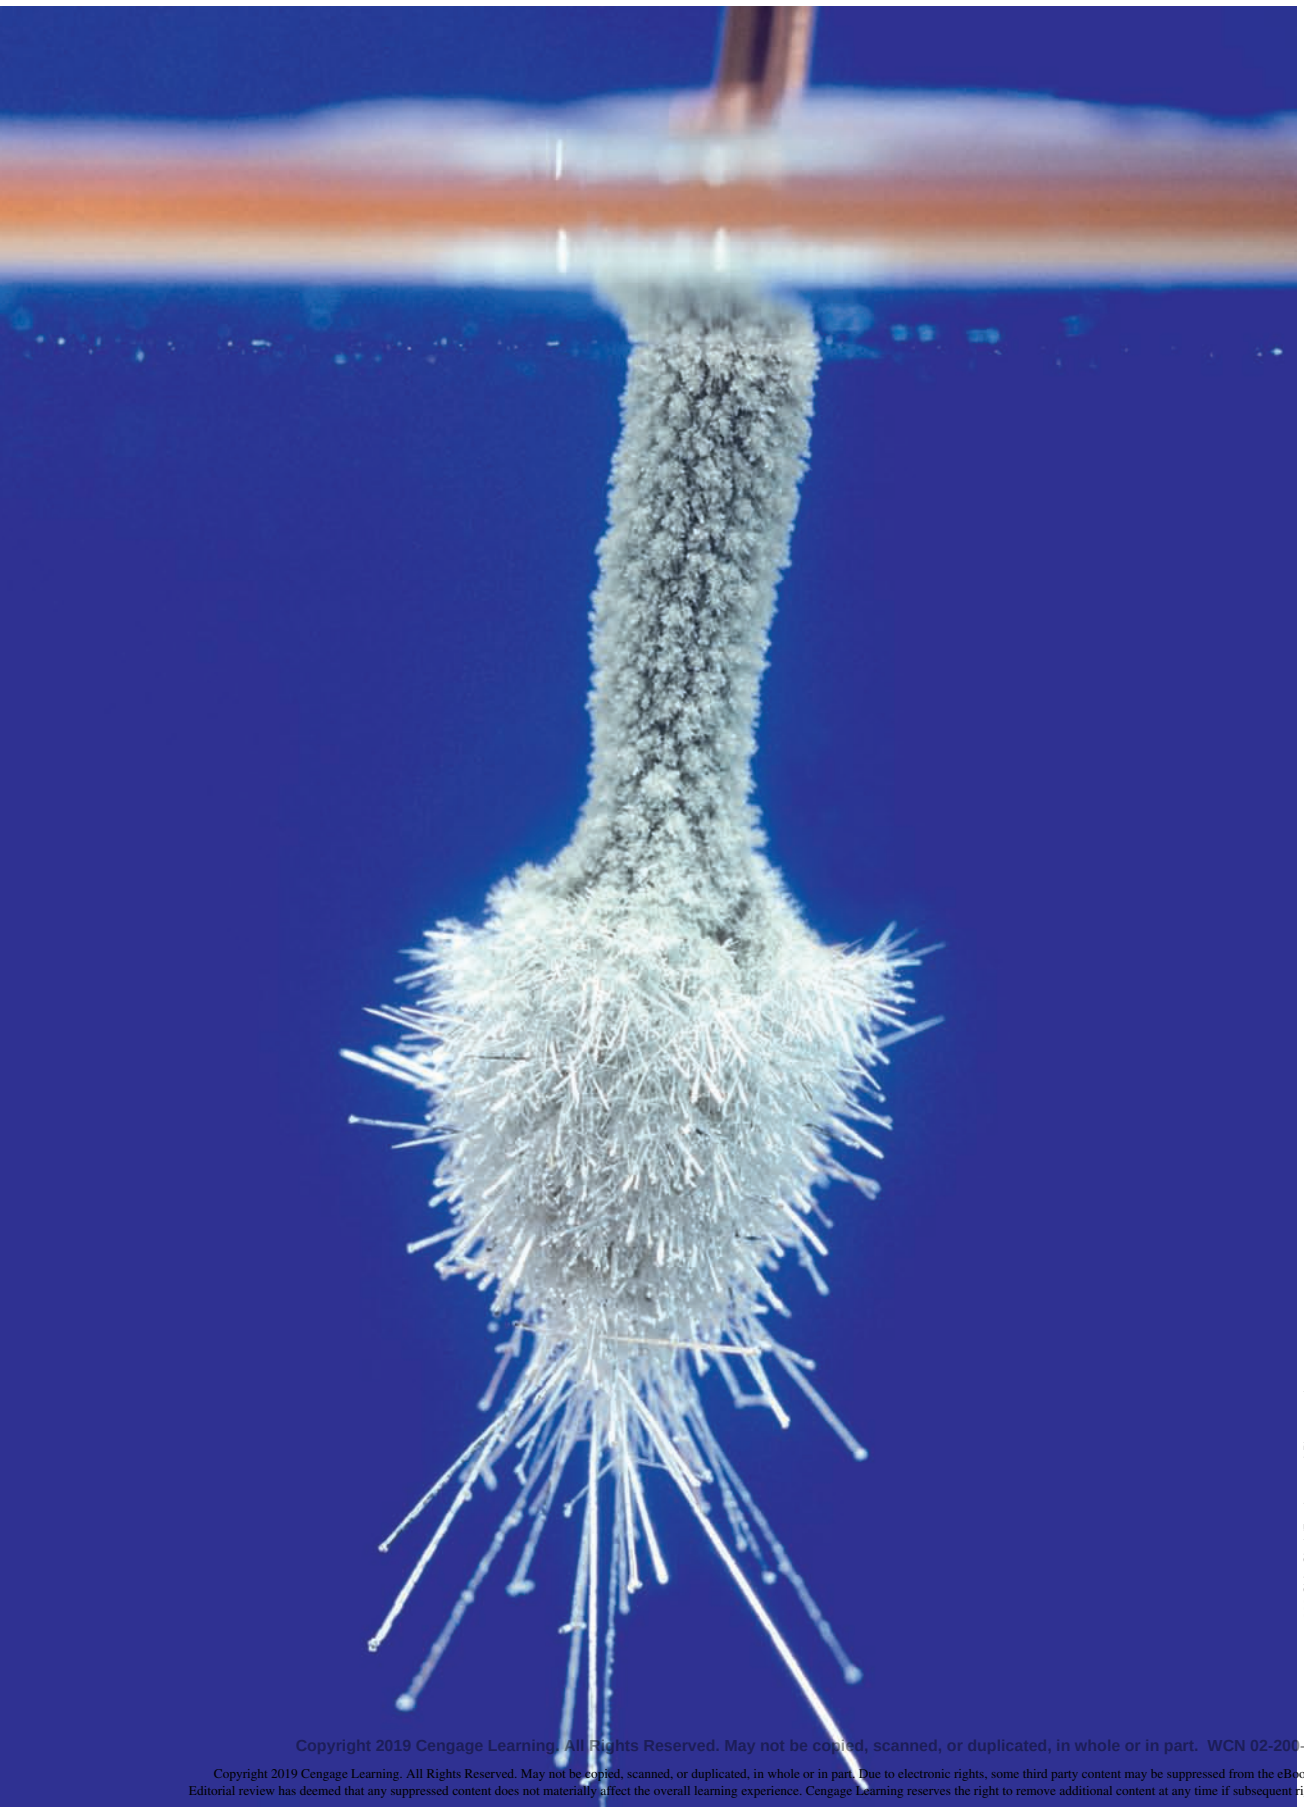
(b) Calculate the equilibrium constant K'. (The hydronium ion concentration is included in the constant. That is, $K' = K \cdot [H_3O^+]$ for the reaction at 25 °C and pH = 7.0.)

(c) $\Delta_r G°'$ is the free energy change under standard conditions; that is, the concentrations of all reactants (except H_3O^+) are 1.00 mol/L. Calculate $\Delta_r G'$ at 25 °C, assuming the following concentrations in the cell: pyruvate, 380 μmol/L; NADH, 50 μmol/L; lactate ion, 3700 μmol/L; and NAD^+ ion, 540 μmol/L.

107. Determine if each of the following statements is true or false.

(a) For a reaction that can yield more than one product, the most stable product is always formed in the greatest amount.

(b) For a reaction that can yield more than one product, the pathway that has the lowest activation energy always occurs more quickly.



(c) Reactions that are thermodynamically favored are always fast.

(d) Diamond is always more stable than graphite.

CHAPTER OUTLINE

19.1 Oxidation–Reduction Reactions

19.2 Simple Voltaic Cells

19.3 Commercial Voltaic Cells

19.4 Standard Electrochemical Potentials

19.5 Electrochemical Cells Under Nonstandard Conditions

19.6 Electrochemistry and Thermodynamics

19.7 Electrolysis: Chemical Change Using Electrical Energy

19.8 Counting Electrons

19.9 Corrosion: Redox Reactions in the Environment

19.1 Oxidation–Reduction Reactions

Goal for Section 19.1

- Balance equations for oxidation-reduction reactions in acidic or basic conditions using the half-reaction approach.

Electrochemistry is the field of chemistry that studies chemical reactions that produce or are caused by electrical energy. Because all electrochemical reactions are oxidation–reduction (redox) reactions, we begin our exploration of this subject by first describing electron transfer reactions in more detail.

In an oxidation–reduction reaction, electron transfer occurs between a reducing agent and an oxidizing agent (Section 3.8). The essential features of all electron transfer reactions are that:

- One reactant is oxidized, and one is reduced.
- The extent of oxidation and reduction must balance.
- The oxidizing agent (the chemical species causing oxidation) is reduced.
- The reducing agent (the chemical species causing reduction) is oxidized.

Oxidation Numbers Oxidation numbers (Section 3.8) can be used to determine whether a substance is oxidized or reduced. An element is oxidized if its oxidation number increases. The oxidation number decreases in a reduction.

◀ **Redox Reactions.** The oxidation of copper wire in a solution of silver nitrate leads to the growth of silver crystals on the copper wire. See Figure 19.1 for more details.

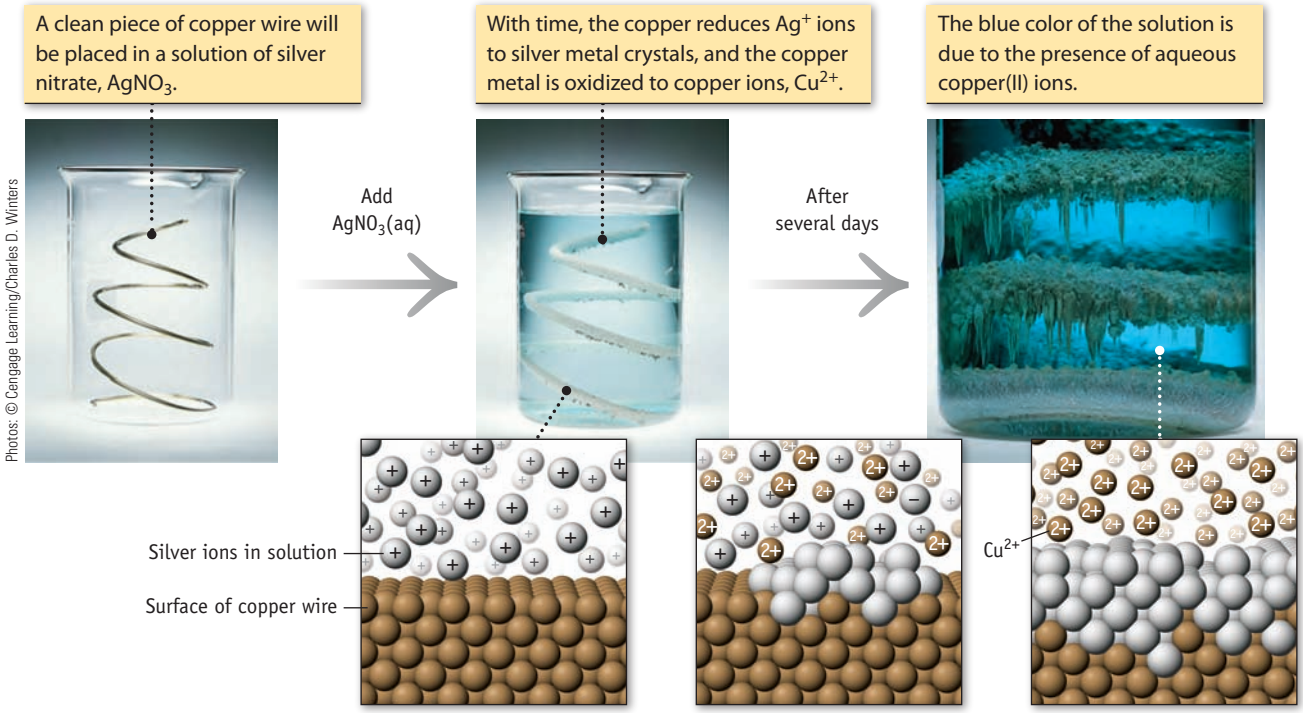

Figure 19.1 The oxidation of copper by silver ions. For clarity, water molecules are not shown.

These aspects of oxidation–reduction or redox reactions are illustrated for the reaction of copper metal and silver ion (Figure 19.1).

Cu oxidized, oxidation number increases;
Cu is the reducing agent.

$$Cu(s) + 2\ Ag^+(aq) \longrightarrow Cu^{2+}(aq) + 2\ Ag(s)$$

Ag^+ reduced, oxidation number decreases;
Ag^+ is the oxidizing agent.

Balancing Oxidation–Reduction Equations

All equations for oxidation–reduction reactions must be balanced for both mass and charge. The same number of atoms appear in the products and reactants of an equation, and the sum of electric charges of all the species on each side of the equation arrow must be the same. Charge balance means that the number of electrons produced in oxidation equals the number of electrons consumed in reduction.

Balancing some redox equations can be complicated. Fortunately, systematic procedures, such as the **half-reaction method**, can be used. When a reaction has been determined to involve oxidation and reduction (by noting, for example, that oxidation state changes have occurred), the equation is separated into two half-reactions, which are then balanced for mass and charge. The equation for the overall reaction is the sum of these two balanced half-reactions, after adjustments have been made (if necessary) in one or both half-reaction equations so that the numbers of electrons transferred from reducing agent to oxidizing agent balance. For example, the half-reactions for the reaction of aluminum metal with copper ions to give copper metal and aluminum ions (Figure 19.2) are

Reduction half-reaction: $Cu^{2+}(aq) + 2\ e^- \longrightarrow Cu(s)$

Oxidation half-reaction: $Al(s) \longrightarrow Al^{3+}(aq) + 3\ e^-$

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. (a) A ball of aluminum foil is added to a solution of $Cu(NO_3)_2$ and NaCl.

(b) A coating of copper is soon seen on the surface of the aluminum, and the reaction generates a significant amount of energy as heat.

Photos: © Cengage Learning/Charles D. Winters

Figure 19.2 Reduction of Cu^{2+} by Al. Aluminum always has a thin coating of Al_2O_3 on the surface, which protects the metal from further reaction. However, in the presence of Cl^- ion, the coating is breached, and reaction occurs.

Notice that the equations for the half-reactions are themselves balanced for mass and charge. In the copper half-reaction, there is one Cu atom on each side of the equation (mass balance). The electric charge on the left side of the equation is 0 (the sum of +2 for the ion and −2 for two electrons), as it is on the right side (charge balance).

To produce the net chemical equation, we will add the two half-reactions. First, however, we must balance the reactions so that the same number of electrons are gained in the reduction half-reaction as are lost in the oxidiation half-reaction. This is accomplished by multiplying the copper ion half-reaction by 3 and the aluminum half-reaction by 2.

$$3\ Cu^{2+}(aq) + 6\ e^- \longrightarrow 3\ Cu(s)$$

$$2\ Al(s) \longrightarrow 2\ Al^{3+}(aq) + 6\ e^-$$

Two moles of aluminum atoms produce six moles of electrons, and three moles of Cu^{2+} ions are required to consume those electrons.

Finally, adding the two half-reactions and canceling electrons from both sides leads to the net ionic equation for the reaction.

Reduction half-reaction:	$3\ Cu^{2+}(aq) + 6\ e^- \longrightarrow 3\ Cu(s)$
Oxidation half-reaction:	$2\ Al(s) \longrightarrow 2\ Al^{3+}(aq) + 6\ e^-$
Net ionic equation	$3\ Cu^{2+}(aq) + 2\ Al(s) \longrightarrow 3\ Cu(s) + 2\ Al^{3+}(aq)$

The resulting net ionic equation is balanced for mass and charge.

Balancing Equations in Acidic or Basic Solutions

When balancing equations for redox reactions in aqueous solution, it is sometimes necessary to add water molecules (H_2O) and either $H^+(aq)$ in acidic solution or $OH^-(aq)$ in basic solution to the equation. The process is outlined in Example 19.1 for the reduction of an oxocation in acid solution and in Example 19.2 for a reaction in basic solution.

Balancing Equations in Acid Solution To simplify equations, we shall use H^+ instead of H_3O^+ when balancing equations in acid solution.

EXAMPLE 19.1

Balancing Equations for Oxidation–Reduction Reactions in Acid Solution

Problem Balance the net ionic equation for the reaction of the dioxovanadium(V) ion, VO_2^+, with zinc in acid solution to form VO^{2+} (Figure 19.3).

$$VO_2^+(aq) + Zn(s) \longrightarrow VO^{2+}(aq) + Zn^{2+}(aq)$$

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

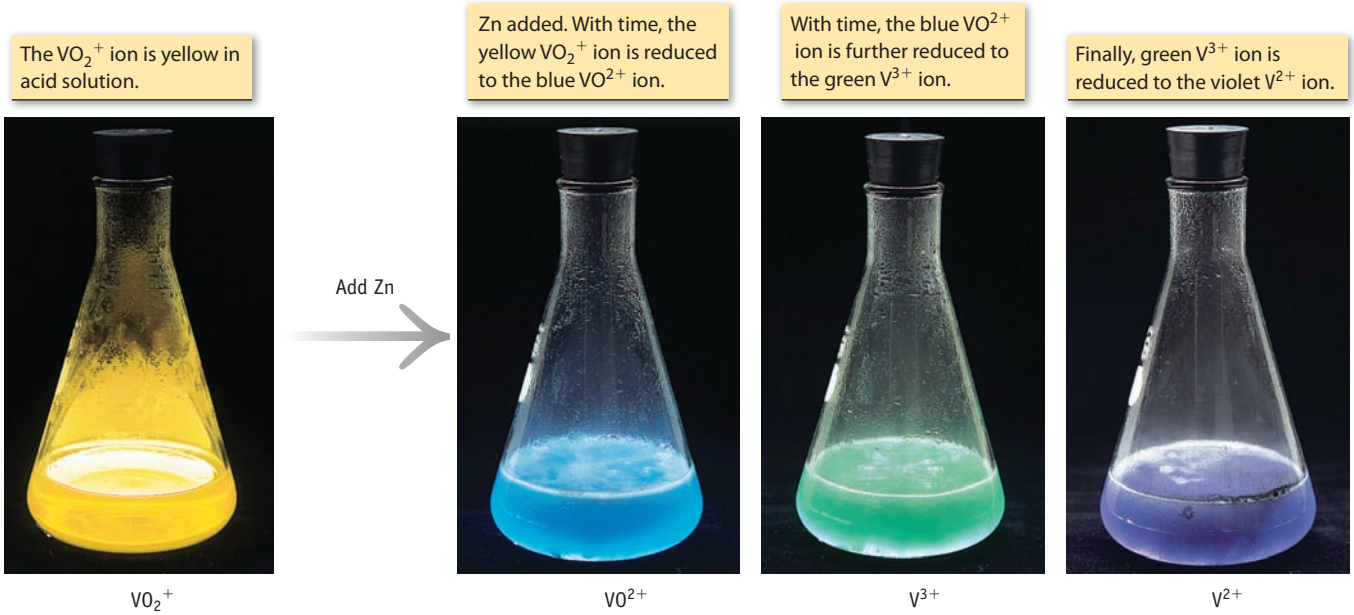

Figure 19.3 Reduction of vanadium(V) with zinc. See Example 19.1 for the balanced equation for the first reaction in this sequence.

What Do You Know? You know that the VO_2^+ ions produce VO^{2+} ions, and Zn metal produces Zn^{2+} ions. You know that H^+ ions and water are used to balance the O atoms involved in the reaction.

Strategy Follow the steps below to balance each half-reaction for both mass and charge, then combine the half-reactions to produce a balanced chemical equation. Note that water and H^+ ions will appear in the half-reaction for the reduction of the VO_2^+ ion.

SOLUTION

Step 1. *Recognize the Reaction as an Oxidation–Reduction Reaction.*

The oxidation number of V changes from +5 in VO_2^+ to +4 in VO^{2+}. The oxidation number of Zn changes from 0 in the metal to +2 in Zn^{2+}.

Step 2. *Separate the Process into Half-Reactions.*

Oxidation: $Zn(s) \rightarrow Zn^{2+}(aq)$

($Zn(s)$ is oxidized and is the reducing agent.)

Reduction: $VO_2^+(aq) \rightarrow VO^{2+}(aq)$

($VO_2^+(aq)$ is reduced and is the oxidizing agent.)

Step 3. *Balance the Half-Reactions for Mass.*

Begin by balancing all atoms except H and O. (These atoms are always the last to be balanced because they often appear in more than one reactant or product.)

Zinc half-reaction: $Zn(s) \rightarrow Zn^{2+}(aq)$

The zinc half-reaction is already balanced for mass.

Vanadium half-reaction: $VO_2^+(aq) \rightarrow VO^{2+}(aq)$

The V atoms in this half-reaction are already balanced. An oxygen-containing species must be added to the right side of the equation to achieve an O atom balance, however.

$$VO_2^+(aq) \rightarrow VO^{2+}(aq) + (\text{need 1 O atom})$$

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

In acid solution, add H_2O to the side requiring O atoms, one H_2O molecule for each O atom required.

$$VO_2^+(aq) \longrightarrow VO^{2+}(aq) + H_2O(\ell)$$

There are now two unbalanced H atoms on the right. Because the reaction occurs in an acidic solution, H^+ ions are present. Therefore, a mass balance for H can be achieved by adding H^+ to the side of the equation deficient in H atoms. Here, two H^+ ions are added to the left side of the equation, and the equation is balanced for mass.

$$2\ H^+(aq) + VO_2^+(aq) \longrightarrow VO^{2+}(aq) + H_2O(\ell)$$

Step 4. *Balance the Half-Reactions for Charge by Adding Electrons to the More Positive Side to Make the Charges Equal on Both Sides.*

Two electrons are added to the right side of the zinc half-reaction to bring its charge down to the same value as is present on the left side (in this case, zero).

Zinc half-reaction: $Zn(s) \longrightarrow Zn^{2+}(aq) + 2\ e^-$

The mass-balanced VO_2^+ equation has a net charge of 3+ on the left side and 2+ on the right. Therefore, 1 e^- is added to the more positive left side.

Vanadium half-reaction: $e^- + 2\ H^+(aq) + VO_2^+(aq) \longrightarrow VO^{2+}(aq) + H_2O(\ell)$

As a check on your work, notice that the vanadium atom changes in oxidation number from +5 to +4 and so needs to acquire one electron for each vanadium atom reduced.

Step 5. *Multiply the Half-Reactions by Appropriate Factors so That the Reducing Agent Supplies as Many Electrons as the Oxidizing Agent Consumes.*

Here, the oxidation half-reaction supplies two electrons per Zn atom, and the reduction half-reaction consumes one electron per VO_2^+ ion. Therefore, the reduction half-reaction must be multiplied by two. Now two ions of the oxidizing agent (VO_2^+) consume the two electrons provided per atom of the reducing agent (Zn).

$$Zn(s) \longrightarrow Zn^{2+}(aq) + 2\ e^-$$

$$2[e^- + 2\ H^+(aq) + VO_2^+(aq) \longrightarrow VO^{2+}(aq) + H_2O(\ell)]$$

Step 6. *Add the Half-Reactions to Give the Balanced, Overall Equation.*

Oxidation half-reaction: $Zn(s) \longrightarrow Zn^{2+}(aq) + 2\ e^-$

Reduction half-reaction: $2\ e^- + 4\ H^+(aq) + 2\ VO_2^+(aq) \longrightarrow 2\ VO^{2+}(aq) + 2\ H_2O(\ell)$

Net ionic equation: $Zn(s) + 4\ H^+(aq) + 2\ VO_2^+(aq) \longrightarrow Zn^{2+}(aq) + 2\ VO^{2+}(aq) + 2\ H_2O(\ell)$

Step 7. *Simplify by Eliminating Reactants and Products That Appear on Both Sides.*

This step is not required here.

Think about Your Answer Check the overall equation to ensure that there is a mass and charge balance.

Mass balance: 1 Zn, 2 V, 4 H, and 4 O on each side of the equation.

Charge balance: Each side has a net charge of +6.

Check Your Understanding

A common laboratory analysis for iron is to titrate aqueous iron(II) ion with a solution of potassium permanganate of precisely known concentration. Use the half-reaction method to write the balanced net ionic equation for the reaction in acid solution.

$$MnO_4^-(aq) + Fe^{2+}(aq) \longrightarrow Mn^{2+}(aq) + Fe^{3+}(aq)$$

Identify the oxidizing agent, the reducing agent, the substance oxidized, and the substance reduced (Figure 19.4).

Problem Solving Tip 19.1 Balancing Oxidation–Reduction Equations: A Summary

- Hydrogen balance can be achieved only with H^+/H_2O (in acid) or OH^-/H_2O (in base). Never add H or H_2 to balance hydrogen.
- Use H_2O or OH^- as appropriate to balance oxygen. Never add O atoms, O^{2-} ions, or O_2 for O balance.
- Never include $H^+(aq)$ and $OH^-(aq)$ in the same equation. A solution can be either acidic or basic, never both.
- The number of electrons in a half-reaction reflects the change in oxidation number of the element being oxidized or reduced.
- Electrons are always a component of half-reactions but should never appear in the overall equation.
- Include charges in the formulas for ions. Omitting the charge, or writing the charge incorrectly, is one of the most common errors seen on student papers.
- The best way to become competent in balancing redox equations is to practice, practice, practice.

EXAMPLE 19.2

Balancing Equations for Oxidation–Reduction Reactions in Basic Solution

Problem Aluminum metal is oxidized in aqueous base, with water serving as the oxidizing agent. The products of the reaction are $[Al(OH)_4]^-(aq)$ and $H_2(g)$. Write a balanced net ionic equation for this reaction.

What Do You Know? You know the reactants and products. Here the reaction is in basic solution, so the balanced equation may require OH^- and H_2O.

Strategy The strategy is basically that of Example 19.1 except that you will need to decide if OH^- ions are involved and if H_2O is also included in the half-reactions.

SOLUTION

Step 1. *Recognize the Reaction as an Oxidation–Reduction Reaction.*

The unbalanced equation is

$$Al(s) + H_2O(\ell) \rightarrow [Al(OH)_4]^-(aq) + H_2(g)$$

Here, aluminum is oxidized, with its oxidation number changing from 0 to +3. Hydrogen is reduced, with its oxidation number decreasing from +1 to zero.

Step 2. *Separate the Process into Half-Reactions.*

Oxidation half-reaction: $Al(s) \rightarrow [Al(OH)_4]^-(aq)$

(Al oxidation number increased from 0 to +3.)

Reduction half-reaction: $H_2O(\ell) \rightarrow H_2(g)$

(H oxidation number decreased from +1 to 0.)

Step 3. *Balance the Half-Reactions for Mass.*

Addition of OH^- or OH^- and H_2O is required for mass balance in both half-reactions. In the case of the aluminum half-reaction, we simply add OH^- ions to the left side.

Oxidation half-reaction: $Al(s) + 4\ OH^-(aq) \rightarrow [Al(OH)_4]^-(aq)$

To balance the half-reaction for water reduction, notice that an oxygen-containing species must appear on the right side of the equation. Because H_2O is a reactant, we use OH^-, which is present in this basic solution, as the other product.

Reduction half-reaction: $2\ H_2O(\ell) \rightarrow H_2(g) + 2\ OH^-(aq)$

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Step 4. *Balance the Half-Reactions for Charge.*

Electrons are added to balance charge.

Oxidation half-reaction: $Al(s) + 4\ OH^-(aq) \longrightarrow [Al(OH)_4]^-(aq) + 3\ e^-$

Reduction half-reaction: $2\ H_2O(\ell) + 2\ e^- \longrightarrow H_2(g) + 2\ OH^-(aq)$

Step 5. *Multiply the Half-Reactions by Appropriate Factors so That the Reducing Agent Donates as Many Electrons as the Oxidizing Agent Consumes.*

Here, electron balance is achieved by using two Al atoms to provide six electrons, which are then acquired by six H_2O molecules.

Oxidation half-reaction: $2[Al(s) + 4\ OH^-(aq) \longrightarrow [Al(OH)_4]^-(aq) + 3\ e^-]$

Reduction half-reaction: $3[2\ H_2O(\ell) + 2\ e^- \longrightarrow H_2(g) + 2\ OH^-(aq)]$

Step 6. *Add the Half-Reactions.*

$$2\ Al(s) + 8\ OH^-(aq) \longrightarrow 2\ [Al(OH)_4]^-(aq) + 6\ e^-$$
$$6\ H_2O(\ell) + 6\ e^- \longrightarrow 3\ H_2(g) + 6\ OH^-(aq)$$

Net equation: $2\ Al(s) + 8\ OH^-(aq) + 6\ H_2O(\ell) \longrightarrow 2\ [Al(OH)_4]^-(aq) + 3\ H_2(g) + 6\ OH^-(aq)$

Step 7. *Simplify by Eliminating Reactants and Products That Appear on Both Sides.*

Six OH^- ions can be canceled from the two sides of the equation:

$$2\ Al(s) + 2\ OH^-(aq) + 6\ H_2O(\ell) \longrightarrow 2\ [Al(OH)_4]^-(aq) + 3\ H_2(g)$$

Think about Your Answer The final equation is balanced for mass and charge.

Mass balance: 2 Al, 14 H, and 8 O on each side of the equation.

Charge balance: There is a net −2 charge on each side.

Check Your Understanding

Batteries based on the reduction of sulfur are under development. One such cell involves the reaction of sulfur with aluminum under basic conditions.

$$Al(s) + S(s) \longrightarrow Al(OH)_3(s) + HS^-(aq)$$

(a) Balance this equation, showing each balanced half-reaction.

(b) Identify the oxidizing and reducing agents, the substance oxidized, and the substance reduced.

Problem Solving Tip 19.2 An Alternative Method of Balancing Equations in Basic Solution

Balancing redox equations in basic solution, which may require you to use OH^- ions and H_2O, can sometimes be more challenging than balancing equations in acidic solution. Rather than learn a separate method for balancing equations in basic solution, some students find it easier to first balance an equation as if it were in acidic solution and then add enough OH^- ions to *both sides* of the equation so that H^+ ions are converted to water. Let us show how this works for balancing the reaction of hypochlorite ion with manganese(IV) oxide to form chloride ion and permanganate ion.

(a) Balance the equation as if the reaction were carried out in acid by following Steps 1–7 in Example 19.1:

$$3\ ClO^-(aq) + H_2O(\ell) + 2\ MnO_2(s) \longrightarrow 3\ Cl^-(aq) + 2\ MnO_4^-(aq) + 2\ H^+(aq)$$

(b) To adjust for the fact that this reaction is carried out in base rather than in acid, the same number of hydroxide ions (two) are added to both sides of the equation as there are $H^+(aq)$ ions. On the side that had the $H^+(aq)$ ions, the $H^+(aq)$ ions and $OH^-(aq)$ ions will form $H_2O(\ell)$.

$$3\ ClO^-(aq) + H_2O(\ell) + 2\ MnO_2(s) + 2\ OH^-(aq) \longrightarrow 3\ Cl^-(aq) + 2\ MnO_4^-(aq) + 2\ H^+(aq) + 2\ OH^-(aq)$$

$$3\ ClO^-(aq) + H_2O(\ell) + 2\ MnO_2(s) + 2\ OH^-(aq) \longrightarrow 3\ Cl^-(aq) + 2\ MnO_4^-(aq) + 2\ H_2O(\ell)$$

(c) Simplify the equation.

$$3\ ClO^-(aq) + 2\ MnO_2(s) + 2\ OH^-(aq) \longrightarrow 3\ Cl^-(aq) + 2\ MnO_4^-(aq) + H_2O(\ell)$$

19.2 Simple Voltaic Cells

Goal for Section 19.2

- In a voltaic cell, identify the half-reactions occurring at the anode and the cathode, the polarity of the electrodes, the direction of electron flow in the external circuit, and the direction of ion flow in the salt bridge.

Voltaic and Galvanic. Voltaic cells are named for Alessandro Volta (1745–1827), who studied reactions producing an electric current. Galvanic cells are named for Dr. Luigi Galvani (1737–1798), who made early studies of animal electricity and made electricity chemically.

Two Types of Electrochemical Processes

- Chemical change can produce an electric current in a voltaic cell.
- Electric energy can cause chemical change in the process of electrolysis.

Devices that use chemical reactions to produce an electric current are called **voltaic cells** or **galvanic cells**. All voltaic cells work in the same general way: They use product-favored redox reactions, and the electrons from the species being oxidized (the reducing agent) are transferred through an electric circuit to the species being reduced.

A voltaic cell converts chemical energy to electrical energy. The opposite process, the use of electric energy to effect a chemical change, occurs in **electrolysis**. An example is the electrolysis of water, in which electrical energy is used to split water into hydrogen and oxygen. Electrolysis is also used to electroplate one metal onto another, to obtain aluminum from its common ore (bauxite, mostly Al_2O_3), and to prepare important chemicals such as chlorine.

The reaction of copper metal and silver ions (Figure 19.1) can be used as the basis of a voltaic cell. By placing the components of the two half-reactions in separate compartments, referred to as **half-cells** (Figure 19.5), electrons can only be transferred from copper metal to silver ions through an external circuit, and useful work can potentially be done.

The copper half-cell (on the left in Figure 19.5) consists of copper metal that serves as one electrode and a solution containing copper(II) ions. The half-cell on the right uses a silver electrode and a solution containing silver(I) ions. Important features of this simple cell are as follows:

- *In all electrochemical cells, the **anode** is the electrode at which oxidation occurs. The electrode at which reduction occurs is always the **cathode**.*
- *A negative sign can be assigned to the anode in a voltaic cell, and the cathode is marked with a positive sign.* The chemical oxidation, which occurs at the anode and produces electrons, gives it a negative charge.

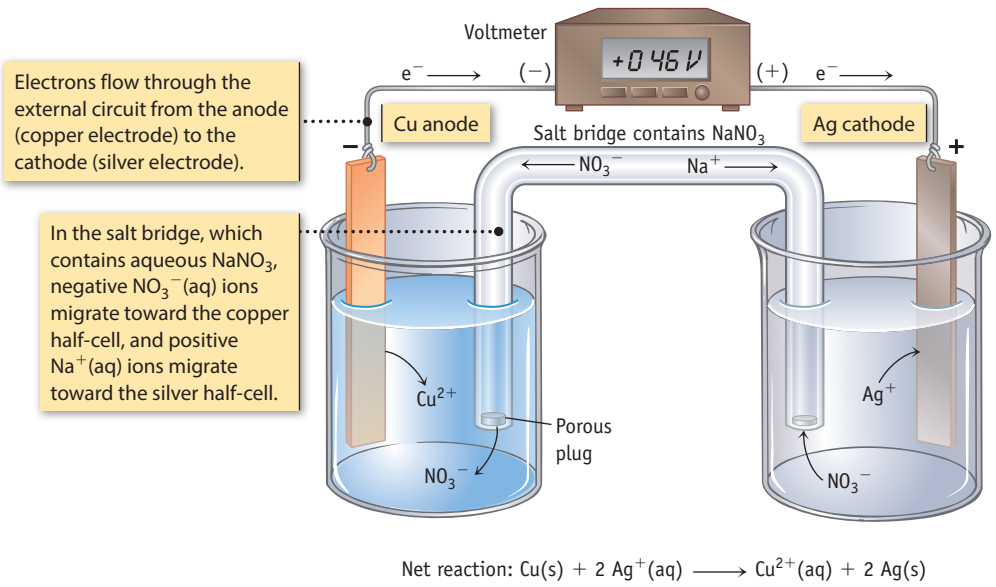

Figure 19.5 **A voltaic cell using Cu(s) | Cu^{2+}(aq) and Ag(s) | Ag^{+}(aq) half-cells.**

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

- *In all electrochemical cells, electrons flow in the external circuit from the anode to the cathode.* Electric current in the external circuit of a voltaic cell consists of electrons moving from the negative to the positive electrode.
- *The two half-cells are connected with a* ***salt bridge*** *that allows cations and anions to move between the two half-cells.* The electrolyte chosen for the salt bridge should contain ions that will not react with chemical reagents in either half-cell (such as $NaNO_3$ in Figure 19.5).

The chemistry occurring in the cell pictured in Figure 19.5 is summarized by the following half-reactions and net ionic equation:

Cathode, reduction: $2\ Ag^+(aq) + 2\ e^- \longrightarrow 2\ Ag(s)$

Anode, oxidation: $Cu(s) \longrightarrow Cu^{2+}(aq) + 2\ e^-$

Net ionic equation: $Cu(s) + 2\ Ag^+(aq) \longrightarrow Cu^{2+}(aq) + 2\ Ag(s)$

The electrodes are connected by wires to a voltmeter. In an alternative setup, the connections might be to a lightbulb or other device that uses electricity. Electrons are produced by oxidation of copper, and $Cu^{2+}(aq)$ ions enter the solution. The electrons traverse the external circuit to the silver electrode, where they reduce $Ag^+(aq)$ ions to silver metal.

A salt bridge is always required in a voltaic cell because there must be a complete circuit of charges for current to flow. If the salt bridge is removed, electrode reactions will cease. In the Cu/Ag^+ voltaic cell, anions move in the salt bridge toward the copper half-cell, and cations move toward the silver half-cell. As $Cu^{2+}(aq)$ ions are formed in the copper half-cell by oxidation of copper metal, negative ions enter that cell from the salt bridge (and positive ions leave the cell) so that the numbers of positive and negative charges in the half-cell compartment remain in balance. The silver half-cell contains $AgNO_3$, so, as $Ag^+(aq)$ ions are reduced to silver metal, negative ions (NO_3^-) move out of the half-cell into the salt bridge, and positive ions move from anode to cathode through the salt bridge. The main features of this and of all other voltaic cells are summarized in Figure 19.6.

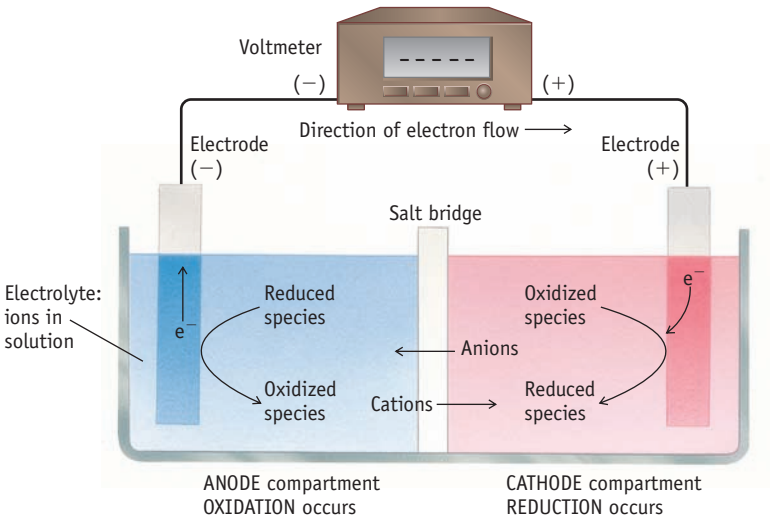

Figure 19.6 Summary of terms used in a voltaic cell. Electrons move from the anode, the site of oxidation, through the external circuit to the cathode, the site of reduction. Charge balance in each half-cell is achieved by migration of ions through the salt bridge. Negative ions move from the reduction half-cell to the oxidation half-cell and positive ions move in the opposite direction.

EXAMPLE 19.3

Electrochemical Cells

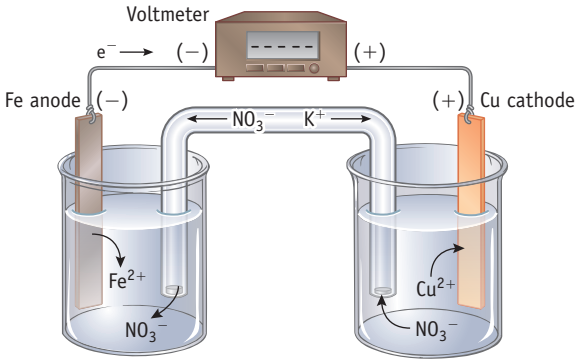
Problem Describe how to set up a voltaic cell to generate an electric current using the reaction

$$Fe(s) + Cu^{2+}(aq) \longrightarrow Cu(s) + Fe^{2+}(aq)$$

Which electrode is the anode, and which is the cathode? In which direction do electrons flow in the external circuit? In which direction do the positive and negative ions flow in the salt bridge? Write equations for the half-reactions that occur at each electrode.

What Do You Know? You know the reaction proceeds in the direction written. You also know the half-reaction occurring in one half-cell will involve an iron electrode and a solution containing $Fe^{2+}(aq)$ ions. The other half-cell consists of a copper electrode and solution containing $Cu^{2+}(aq)$ ions.

Strategy First, identify the two different half-cells that make up the cell. Next, these two half-cells are linked together with a salt bridge and an external circuit.



SOLUTION This voltaic cell is similar to the one diagrammed in Figure 19.5. Here we assume the two half-cells are linked with a salt bridge containing KNO_3 as the electrolyte.

Iron is oxidized, so the iron electrode is the anode:

Oxidation, anode: $Fe(s) \longrightarrow Fe^{2+}(aq) + 2\ e^-$

Because copper(II) ions are reduced, the copper electrode is the cathode. The cathodic half-reaction is

Reduction, cathode: $Cu^{2+}(aq) + 2\ e^- \longrightarrow Cu(s)$

In the external circuit, electrons flow from the iron electrode (anode) to the copper electrode (cathode). In the salt bridge, negative ions flow toward the iron/iron(II) half-cell, and positive ions flow in the opposite direction.

Think about Your Answer A good way to understand voltaic cells is to focus on the movement of the negative species in the cell (electron flow in the external circuit and anion flow in the salt bridge). These species always move in a circular fashion: electrons from anode to cathode, and anions in the salt bridge in the opposite direction. If you establish which reactant is oxidized (provides electrons), you then know which electrode is the anode, in which direction electrons move in the external circuit, and in which direction anions flow in the salt bridge. (That said, don't ignore the fact that cations flow in the opposite direction to the anions in the salt bridge.)

Check Your Understanding

Describe how to set up a voltaic cell using the following half-reactions:

Reduction half-reaction: $Ag^+(aq) + e^- \rightarrow Ag(s)$

Oxidation half-reaction: $Ni(s) \rightarrow Ni^{2+}(aq) + 2\ e^-$

Which electrode is the anode, and which is the cathode? What is the overall cell reaction? What is the direction of electron flow in an external wire connecting the two electrodes? Describe the ion flow in a salt bridge (with $NaNO_3$) connecting the cell compartments.

Voltaic Cells with Inert Electrodes

In the half-cells described so far, the metal used as an electrode is also a reactant or a product in the redox reaction. Not all half-reactions involve a metal as a reactant or product, however. With the exception of carbon in the form of graphite, nonmetals are unsuitable as electrode materials because they do not conduct electricity. It is not possible to make an electrode from a gas, a liquid (except mercury), or a solution. Ionic solids do not make satisfactory electrodes because the ions are locked tightly in a crystal lattice, and these materials do not conduct electricity.

In situations where reactants and products cannot serve as the electrode material, an inert or chemically unreactive electrode must be used. Such electrodes are made of materials that conduct an electric current but that are neither oxidized nor reduced in the cell.

Consider constructing a voltaic cell to accommodate the following product-favored reaction:

$$2\ Fe^{3+}(aq) + H_2(g) \rightarrow 2\ Fe^{2+}(aq) + 2\ H^+(aq)$$

Reduction half-reaction: $Fe^{3+}(aq) + e^- \rightarrow Fe^{2+}(aq)$

Oxidation half-reaction: $H_2(g) \rightarrow 2\ H^+(aq) + 2\ e^-$

Neither the reactants nor the products can be used as an electrode material. Therefore, the two half-cells are set up so that the reactants and products come in contact with an electrode where they can accept or give up electrons. Graphite is a commonly used electrode material: It is a conductor of electricity, inexpensive, and is not readily oxidized under the conditions encountered in most cells. Mercury is used in certain types of cells. Platinum and gold are also commonly used in the laboratory because both are chemically inert under most circumstances, but they are generally too costly for commercial cells.

The *hydrogen electrode* (Figure 19.7) is particularly important in the field of electrochemistry because it is used as a reference in assigning cell voltages (Section 19.4). The electrode material is platinum, chosen because hydrogen adsorbs on the metal's surface. In this half-cell's operation, hydrogen is bubbled over the electrode, and adsorption on the large surface area maximizes the contact of the gas and the electrode. The aqueous solution contains $H^+(aq)$. The half-reactions involving $H^+(aq)$ and $H_2(g)$

$$2\ H^+(aq) + 2\ e^- \rightarrow H_2(g) \qquad \text{or} \qquad H_2(g) \rightarrow 2\ H^+(aq) + 2\ e^-$$

take place at the electrode surface, and the electrons involved in the reaction are conducted to or from the reaction site by the metal electrode.

A half-cell using the reduction of $Fe^{3+}(aq)$ to $Fe^{2+}(aq)$ can also be set up with a platinum electrode. In this case, the solution surrounding the electrode contains iron ions in two different oxidation states. Transfer of electrons to or from the reactant occurs at the electrode surface.

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

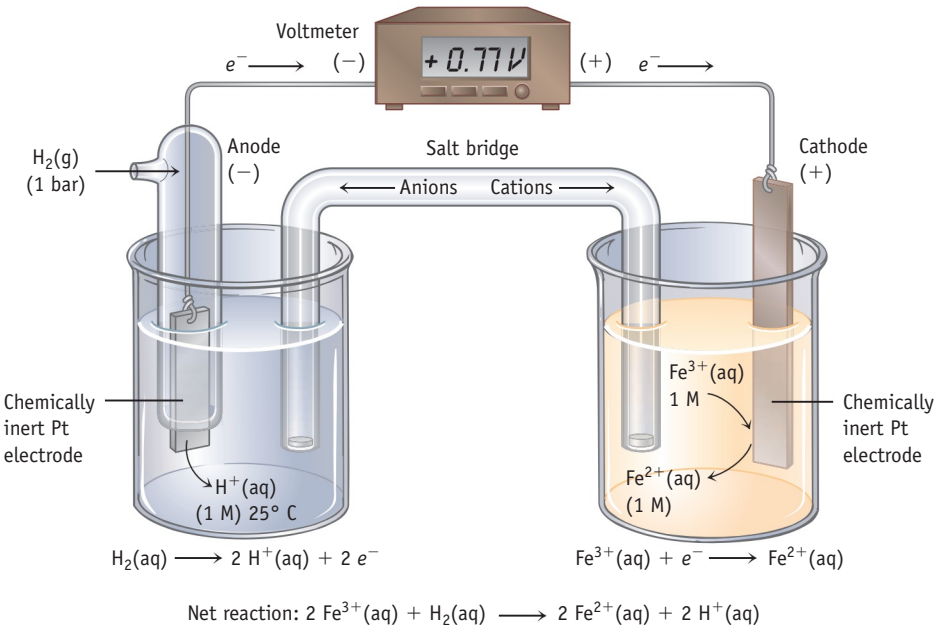

Figure 19.8 A voltaic cell with a hydrogen electrode. This cell has Fe^{2+}(aq, 1.0 M) and Fe^{3+}(aq, 1.0 M) in the cathode compartment and H_2(g) and H^+(aq, 1.0 M) in the anode compartment. At 25 °C, the cell generates 0.77 V. (The hydrogen electrode in the anode compartment in this illustration is a simplified schematic. See Figure 19.7 for a photograph of a commercial hydrogen electrode.)

A voltaic cell involving the reduction of Fe^{3+}(aq, 1.0 M) to Fe^{2+}(aq, 1.0 M) with H_2 gas is illustrated in Figure 19.8. In this cell, the hydrogen electrode is the anode (H_2 is oxidized to H^+), and the iron-containing compartment is the cathode (Fe^{3+} is reduced to Fe^{2+}). The cell produces 0.77 V.

Electrochemical Cell Notations

Chemists use a shorthand notation to simplify cell descriptions. For example, the cell involving the reduction of silver ion with copper metal is written as

$$\underset{\text{Anode information}}{Cu(s)\,|\,Cu^{2+}(aq,\ 1.0\ M)}\,||\,\underset{\text{Cathode information}}{Ag^+(aq,\ 1.0\ M)\,|\,Ag(s)}$$

The cell using H_2 gas to reduce Fe^{3+} ions is written as

$$\underset{\text{Anode information}}{Pt\,|\,H_2(P = 1\ bar)\,|\,H^+(aq,\ 1.0\ M)}\,||\,\underset{\text{Cathode information}}{Fe^{3+}(aq,\ 1.0\ M),\ Fe^{2+}(aq,\ 1.0\ M)\,|\,Pt}$$

By convention, on the left we write the anode and information with respect to the solution with which it is in contact. A single vertical line (|) indicates a phase boundary, and double vertical lines (||) indicate a salt bridge.

EXAMPLE 19.4

Electrochemical Cell Notation

Problem Determine the oxidation and reduction half-reactions and the overall chemical equation for the following electrochemical cell:

$$Pt\,|\,H_2(P = 1\ bar))\,|\,H^+(aq,\ 1.0\ M)\,||\,Br^-(aq,\ 1.0\ M)\,|\,AgBr(s)\,|\,Ag(s)$$

What Do You Know? You know that oxidation takes place in the half-cell that contains hydrogen gas and hydronium ions in contact with an inert Pt electrode. (In the shorthand description, the oxidation half-cell is on the left.) The cell in which reduction takes place contains bromide ion, silver bromide, and a silver electrode.

Strategy Identify an element in each half-cell that is present in two different oxidation states. Write a balanced oxidation half-reaction for the oxidation and reduction half-reactions. Combine the two half-reactions into an overall chemical equation.

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

SOLUTION The oxidation half-reaction involves hydrogen gas (oxidation state = 0) and hydrogen ion (oxidation state = +1). The reaction at the anode is:

Oxidation half-reaction: $H_2(g) \rightarrow 2\ H^+(aq) + 2\ e^-$

The reduction half-reaction involves silver bromide (oxidation state of the Ag ion in AgBr = +1) and silver metal (oxidation state = 0). The reaction at the cathode is:

Reduction half-reaction: $AgBr(s) + e^- \rightarrow Ag(s) + Br^-(aq)$

Before combining the half-reactions, multiply the reduction half-reaction by 2 so that as many electrons are gained in the reduction half-reaction as are lost in the oxidation half-reaction.

Overall chemical equation: $2\ AgBr(s) + H_2(g) \rightarrow 2\ Ag(s) + 2\ H^+(aq) + 2\ Br^-(aq)$

Think about Your Answer Verify that the overall chemical equation is balanced for each type of atom, as well as for charge.

Check Your Understanding

The following overall chemical reaction occurs in an electrochemical cell.

Overall chemical equation: $Zn(s) + PbSO_4(s) \rightarrow Zn^{2+}(aq) + Pb(s) + SO_4^{2-}(aq)$

Use cell notation to describe the electrochemical cell.

19.3 Commercial Voltaic Cells

Goals for Section 19.3

- Understand the chemistry and advantages and disadvantages of dry cells, alkaline batteries, lead storage batteries, lithium batteries, and Ni-cad batteries.
- Understand how fuel cells work, and recognize the difference between batteries and fuel cells.

The cells described so far are unlikely to have practical use. They are neither compact nor robust. In most situations, it is also important that the cell produce a constant voltage, even while current is drawn from the cell. A problem with the cells described so far is that the voltage produced varies as the concentrations of reactants and products change (Section 19.5). Drawing a current results in a decrease in the voltage if reactant concentrations near the anode or the cathode are depleted faster than they can be replenished from the bulk of the solution. Similarly, a decrease in voltage occurs if product concentrations increase near the electrodes faster than they move into the bulk solution.

The electrical work that can be drawn from a voltaic cell depends on the quantity of reagents consumed. A voltaic cell must have a large mass of reactants to produce current over a prolonged period. In addition, a voltaic cell that can be recharged is attractive. Recharging a cell means returning the reagents to their original sites in the cell. In many types of electrochemical cells, the movement of ions in the cell mixes the reagents, and they cannot be "unmixed" after the cell has been running.

Batteries can be classified as primary and secondary. **Primary batteries** cannot be returned to their original state by recharging, so when the reactants are consumed, the battery is "dead" and must be discarded. **Secondary batteries** are often called **storage batteries** or **rechargeable batteries**. The reactions in these batteries can be reversed, so the batteries can be recharged.

Batteries The word *battery* has become part of our common language, designating any self-contained device that generates an electric current. The term battery has a more precise scientific meaning, however. It refers to a collection of two or more voltaic cells. For example, the 12-volt battery used in automobiles is made up of six voltaic cells. Each voltaic cell develops a voltage of 2 volts. Six cells connected in series produce 12 volts.

Figure 19.9 Some commercial voltaic cells. Commercial voltaic cells provide energy for a wide range of devices, come in a myriad of sizes and shapes, and produce different voltages. Some are rechargeable; others are discarded after use. One might think that there is nothing further to learn about batteries, but this is not true. Research on these devices is actively pursued in the chemical community.

Years of development have led to many different commercial voltaic cells to meet specific needs (Figure 19.9), and several common ones are described below. All adhere to the principles that have been developed in earlier discussions.

Primary Batteries: Dry Cells and Alkaline Batteries

If you buy an inexpensive flashlight battery or dry cell battery, it might be a modern version of a voltaic cell invented by George LeClanché in 1866. Zinc serves as the anode, and the cathode is a graphite rod placed down the center of the device. These cells are often called "dry cells" because there is no visible liquid phase. However, the cell contains a moist paste of NH_4Cl, $ZnCl_2$, and MnO_2, so water is present. The moisture is necessary because the ions present must be able to migrate between the carbon cathode and the zinc anode. The cell generates a potential of 1.5 V using the following half-reactions:

Cathode, reduction: $2\ NH_4^+(aq) + 2\ e^- \longrightarrow 2\ NH_3(g) + H_2(g)$

Anode, oxidation: $Zn(s) \longrightarrow Zn^{2+}(aq) + 2\ e^-$

The products at the cathode are gases, which could build up pressure in the cell and cause it to rupture. The problem is avoided, however, by two other reactions that take place in the cell. Ammonia molecules bind to Zn^{2+} ions, and hydrogen gas is oxidized by MnO_2 to water.

$$Zn^{2+}(aq) + 2\ NH_3(g) + 2\ Cl^-(aq) \longrightarrow Zn(NH_3)_2Cl_2(s)$$

$$2\ MnO_2(s) + H_2(g) \longrightarrow Mn_2O_3(s) + H_2O(\ell)$$

Zinc-carbon dry cells were widely used because of their low cost, but they have several disadvantages. If current is drawn from the battery rapidly, the gaseous products cannot be consumed rapidly enough, so the cell resistance rises, and the voltage drops. In addition, the zinc electrode and ammonium ions are in contact in the cell, and these chemicals react slowly. (The ammonium ion, NH_4^+, is a weak Brønsted acid and reacts slowly with zinc to form Zn^{2+} and hydrogen gas.) Because of this reaction, these voltaic cells cannot be stored indefinitely, a fact you may have learned from experience. When the zinc outer shell deteriorates, the contents of the battery can leak and perhaps damage the appliance in which it is contained.

At the present time, you are more likely to use **alkaline batteries** (Figure 19.10) in your camera or flashlight because they generate current up to 50% longer than a dry cell of the same size. The chemistry of alkaline cells is similar to that in a zinc-carbon dry cell, except that the material inside the cell is basic (alkaline). Alkaline

cells also use the oxidation of zinc and the reduction of MnO_2 to generate a current, but NaOH or KOH is used in the cell instead of the acidic salt NH_4Cl.

Cathode, reduction: $2\ MnO_2(s) + H_2O(\ell) + 2\ e^- \rightarrow Mn_2O_3(s) + 2\ OH^-(aq)$

Anode, oxidation: $Zn(s) + 2\ OH^-(aq) \rightarrow ZnO(s) + H_2O(\ell) + 2\ e^-$

Alkaline cells, which produce nominally 1.5 V (approximately the same voltage as the zinc-carbon dry cell), have the further advantage that the cell potential does not decline under high current loads because no gases are formed.

Button batteries, also known as coin batteries, are used in small devices such as watches, hearing aids, and key fobs for cars. Two common examples of button batteries are silver oxide batteries and zinc-oxygen batteries. Both operate under alkaline conditions, and both have zinc anodes. In the silver oxide battery, which produces a voltage of about 1.5 V, the cell reactions are

Cathode, reduction: $Ag_2O(s) + H_2O(\ell) + 2\ e^- \rightarrow 2\ Ag(s) + 2\ OH^-(aq)$

Anode, oxidation: $Zn(s) + 2\ OH^-(aq) \rightarrow ZnO(s) + H_2O(\ell) + 2\ e^-$

The zinc-oxygen battery, which produces about 1.15–1.35 V, is unique in that atmospheric oxygen and not a metal oxide is the oxidizing agent.

Cathode, reduction: $O_2(g) + 2\ H_2O(\ell) + 4\ e^- \rightarrow 4\ OH^-(aq)$

Anode, oxidation: $Zn(s) + 2\ OH^-(aq) \rightarrow ZnO(s) + H_2O(\ell) + 2\ e^-$

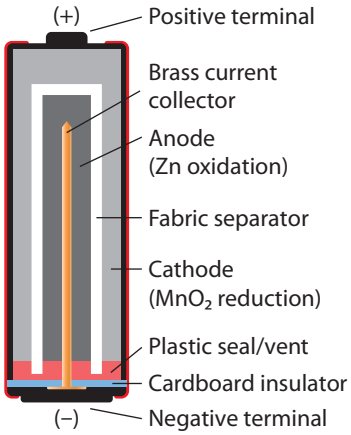

Figure 19.10 Alkaline battery.

Secondary or Rechargeable Batteries

When a zinc-carbon dry cell or an alkaline cell ceases to produce a usable electric current, it is discarded. In contrast, some types of cells can be recharged, often hundreds of times. Recharging requires applying an electric current from an external source to restore the cell to its original state. There are a number of well-known types of secondary batteries in common use.

Lead Storage Battery

An automobile battery—the lead storage battery—is probably the best-known rechargeable battery (Figure 19.11). The 12-V version of this battery contains six voltaic cells, each generating about 2 V. The lead storage battery can produce a large initial current, an essential feature when starting an automobile engine.

The anode of a lead storage battery is metallic lead. The cathode is also made of lead, but it is covered with a layer of compressed, insoluble lead(IV) oxide, PbO_2. The electrodes, arranged alternately in a stack and separated by thin fiberglass sheets, are immersed in aqueous sulfuric acid. When the cell supplies electrical energy, the lead anode is oxidized to insoluble lead(II) sulfate that adheres to the electrode surface. The two electrons produced per lead atom move through the external circuit to the cathode, where PbO_2 is reduced to Pb^{2+} ions that, in the presence of H_2SO_4, also form lead(II) sulfate.

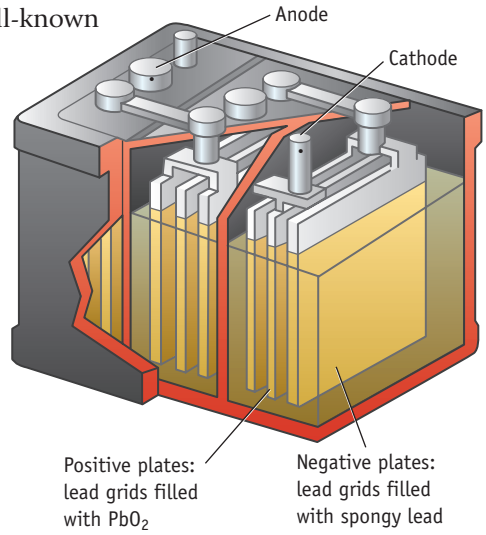

Figure 19.11 Lead storage battery, a secondary or rechargeable battery. Each cell of the battery generates 2 V. This figure shows 3 cells; a 12 V car battery contains 6 cells.

Cathode, reduction: $PbO_2(s) + 4\ H^+(aq) + SO_4^{2-}(aq) + 2\ e^- \rightarrow PbSO_4(s) + 2\ H_2O(\ell)$

Anode, oxidation: $Pb(s) + SO_4^{2-}(aq) \rightarrow PbSO_4(s) + 2\ e^-$

Net ionic equation: $Pb(s) + PbO_2(s) + 2\ H_2SO_4(aq) \rightarrow 2\ PbSO_4(s) + 2\ H_2O(\ell)$

When current is generated, sulfuric acid is consumed and water is formed. Because water is less dense than sulfuric acid, the density of the solution decreases during this process. Therefore, one way to determine whether a lead storage battery needs to be recharged is to measure the density of the solution.

A lead storage battery is recharged by supplying electrical energy. The $PbSO_4$ coating the surfaces of the electrodes is converted back to metallic lead and PbO_2, and sulfuric acid is regenerated. Recharging this battery is possible because the reactants and products remain attached to the electrode surface. The lifetime of a lead

storage battery is limited, however, because, the coatings of PbO_2 and $PbSO_4$ flake off of the surface with time and fall to the bottom of the battery case.

Scientists and engineers would like to find an alternative to lead storage batteries, especially for use in cars. Lead storage batteries have the disadvantages that they are large and heavy, and lead and its compounds are toxic, making disposal complicated. Nevertheless, the advantages of lead storage batteries, such as high current density and long-term stability, often outweigh their disadvantages.

Nickel-Cadmium Batteries

Nickel-cadmium ("Ni-cad") batteries, used in a variety of cordless appliances such as telephones, video camcorders, and cordless power tools, are lightweight and rechargeable. The chemistry of the cell is based on the oxidation of cadmium and the reduction of nickel(III) oxide under basic conditions. As with the lead storage battery, the reactants and products formed when producing a current are solids that adhere to the electrodes.

Cathode, reduction: $NiO(OH)(s) + H_2O(\ell) + e^- \rightarrow Ni(OH)_2(s) + OH^-(aq)$

Anode, oxidation: $Cd(s) + 2\ OH^-(aq) \rightarrow Cd(OH)_2(s) + 2\ e^-$

Ni-cad batteries produce a nearly constant voltage (1.2 V). However, their cost is relatively high, and there are restrictions on their disposal because cadmium compounds are toxic and are an environmental hazard.

Nickel-Metal Hydride

Rechargeable nickel-metal hydride batteries (NiMH) are now in common use. You may have them in your camera or portable music player. Their most important use, however, is in many electric or hybrid cars.

In the nickel-metal hydride battery, electrons are generated when H atoms interact with OH^- ions at the metal alloy anode.

$$Alloy(H) + OH^- \rightarrow Alloy + H_2O + e^-$$

The reaction at the cathode is the same as in Ni-cad batteries.

$$NiO(OH) + H_2O + e^- \rightarrow Ni(OH)_2 + OH^-$$

The "alloy" in NiMH batteries is generally a mixture of a rare earth metal such as lanthanum, cerium, or neodymium and another metal such as nickel, cobalt, manganese, or aluminum. These batteries also generate 1.2 V.

Lithium Batteries

Be Alert: Children Can Ingest Lithium Batteries! Very small lithium batteries are used in many devices such as toys, musical greeting cards, and appliances. Unfortunately, because they are small and shiny, children put them in their mouths and can swallow them. In 2010 the *New York Times* (June 1, 2010, page D5) reported that an increasing number of children have died from reactions induced by the battery's current when the battery was swallowed.

Lithium-ion batteries are now commonly used to power devices from small electronics (such as cell phones and portable computers) to electric vehicles. There are two types in common use: lithium-ion and a variant, lithium-ion polymer batteries. The chemistry of both is the same (Figure 19.12).

Cathode, reduction: $Li_{1-x}CoO_2(s) + x\ Li^+ + x\ e^- \rightarrow LiCoO_2(s)$

Anode, oxidation: $Li_xC_6(s) \rightarrow x\ Li^+ + x\ e^- + 6\ C(s)$

Lithium is oxidized at the anode. At the cathode, cobalt(IV) oxide undergoes a one electron reduction, producing $LiCoO_2$. The battery generates a 3.6-V potential.

The key to the success of lithium-ion batteries is **intercalation**—the ability to insert atoms, ions, and even small molecules into layered compounds. Lithium ions migrate out of the graphite anode and into the cobalt oxide cathode as the battery discharges. During recharging, lithium ions move out of the cobalt oxide and into the graphite. Intercalation increases both the energy storage and current density of a battery. Optimally, the value of x would equal 1 in both Li_xC_6 and Li_xCoO_2. However, nonstoichiometric compounds are common as intercalation rarely fills all available sites in a solid.

An important reason for the development of lithium-based batteries is their light weight. Lithium has a much lower molar mass (6.941 g/mol) than cadmium (112.4 g/mol), nickel (58.69 g/mol), or lead (207.2 g/mol). The oxidation of

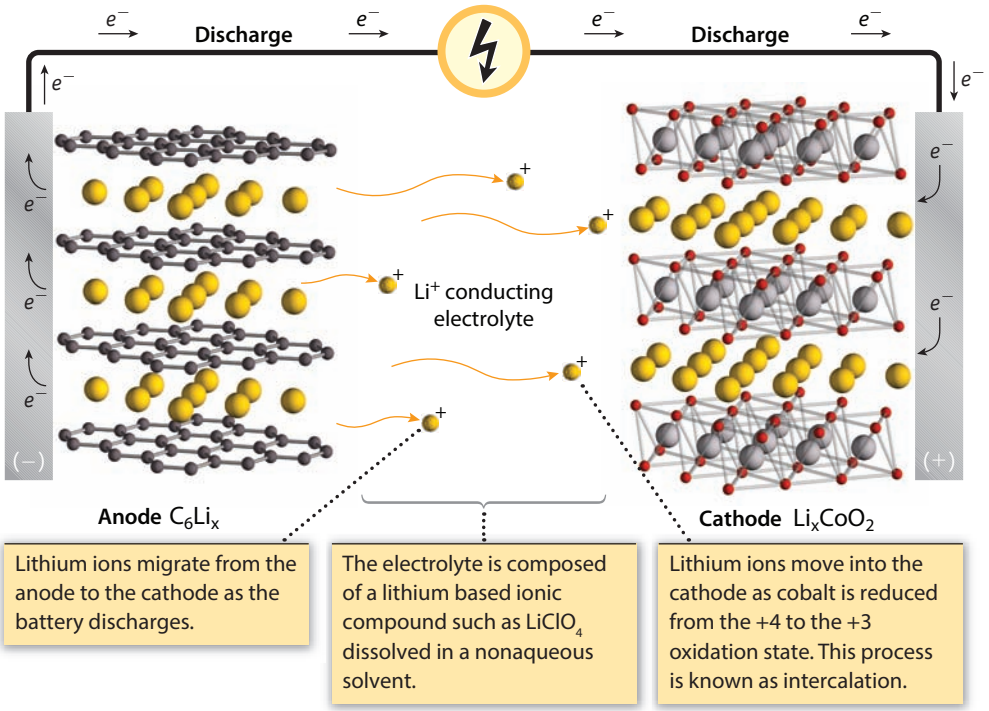

Figure 19.12 Lithium ion battery. During the discharging cycle, lithium is oxidized at the anode. Cobalt(IV) is reduced to cobalt(III) at the cathode. Lithium ions migrate out of the anode and into the cathode. During the charging cycle, this process is reversed.

7 grams of lithium produces the same number of electrons as the oxidation of 104 grams of lead. When the masses of all the components of lithium-ion and lead-acid batteries are taken into account, lithium-ion batteries can deliver the same energy as a lead-acid battery at approximately a quarter of the mass. This is important not only in portable devices where people do not want to carry around heavy objects but also in the automobile and aircraft industry. Having a lighter-weight battery in a car or airplane means more of the energy is going into moving the vehicle and less is being used simply to transport the battery.

Though they are popular, lithium-ion batteries are not perfect. Due to the reactivity of lithium, problems in the manufacturing or damage to the battery can cause violent reactions. Researchers are working to improve the safety of lithium-ion batteries by making changes to the anode, cathode, or electrolyte.

Fuel Cells

An advantage of voltaic cells is that they are small and portable, but their size is also a limitation. The amount of electric current produced is limited by the quantity of reactants contained in the cell. When one of the reactants is completely consumed, the cell will no longer generate a current. Fuel cells avoid this limitation because the reactants (fuel and oxidant) can be supplied continuously to the cell from an external reservoir.

Although the first fuel cells were constructed more than 150 years ago, little was done to develop this technology until the space program rekindled interest. Hydrogen-oxygen fuel cells have been used in NASA's Gemini, Apollo, and Space Shuttle programs. Not only are they lightweight and efficient, but they also have the added benefit that they generate drinking water for the ship's crew.

In a hydrogen-oxygen fuel cell (Figure 19.13), hydrogen is pumped onto the anode of the cell, and O_2 (or air) is directed to the cathode where the following reactions occur:

Cathode, reduction: $O_2(g) + 2\ H_2O(\ell) + 4\ e^- \longrightarrow 4\ OH^-(aq)$

Anode, oxidation: $H_2(g) \longrightarrow 2\ H^+(aq) + 2\ e^-$

The two halves of the cell are separated by a special material called a proton exchange membrane (PEM). Protons, $H^+(aq)$, formed at the anode traverse the PEM

Energy for Automobiles Energy available from systems that can be used to power an automobile.

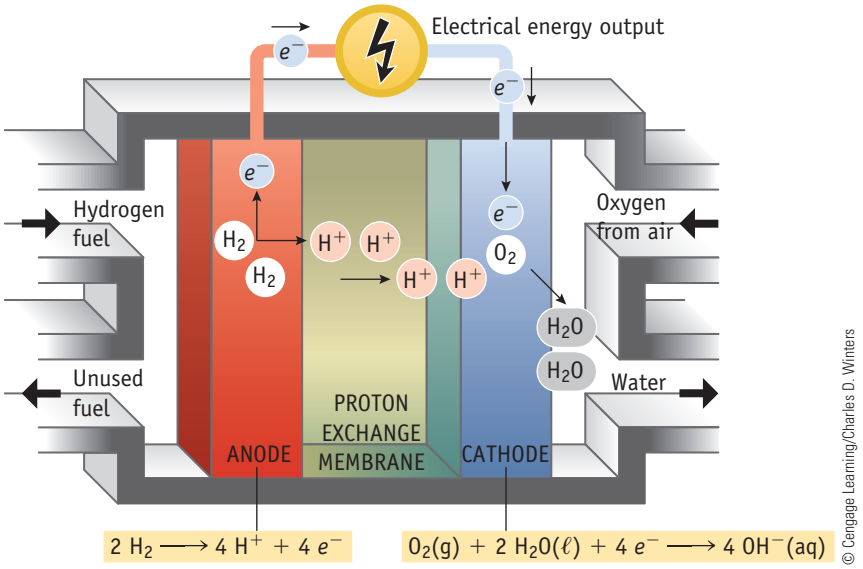

Figure 19.13 Fuel cell design. Hydrogen gas is oxidized to $H^+(aq)$ at the anode surface. On the other side of the proton exchange membrane (PEM), oxygen gas is reduced to $OH^-(aq)$. The $H^+(aq)$ ions travel through the PEM and combine with $OH^-(aq)$, forming water.

and react with the hydroxide ions produced at the cathode, forming water. The net reaction in the cell is thus the formation of water from H_2 and O_2. Cells currently in use produce about 0.9 V.

Hydrogen-oxygen fuel cells operate at 40–60% efficiency and meet most of the requirements for use in automobiles: They operate at room temperature or slightly above, start rapidly, and develop a high-current density. However, cost is a serious problem as is the absence of an economical, carbon-free way of making hydrogen. These faults, and the cost and difficulty of building a nationwide infrastructure for distributing hydrogen, remain major stumbling blocks that would need to be overcome before hydrogen fuel cells could be adopted for widespread use in automobiles.

19.4 Standard Electrochemical Potentials

Goals for Section 19.4

- Use standard reduction potentials to determine cell voltages for cells under standard conditions.
- Use a table of standard reduction potentials to rank the strengths of oxidizing and reducing agents, to predict which substances can reduce or oxidize another species, and to predict whether redox reactions will be product-favored or reactant-favored at equilibrium.

Different electrochemical cells produce different potentials: 1.5 V for alkaline cells, about 3.6 V for a lithium-ion battery, and about 2.0 V for the individual cells in a lead storage battery. In this section, we want to identify the factors affecting cell voltages and develop ways to calculate the expected potential of a cell based on the chemistry in the cell and the conditions used.

Electromotive Force

Electrochemical Units
- The coulomb (abbreviated C) is the standard (SI) unit of electrical charge (Appendix C, Table 6).
- 1 joule = 1 volt × 1 coulomb.
- 1 coulomb = 1 ampere × 1 second.

Electrons generated at the anode of an electrochemical cell move through the external circuit toward the cathode, and the force needed to move the electrons arises from a difference in the potential energy of electrons at the two electrodes. This difference in potential energy per electrical charge is called the **electromotive force** or **emf**, which literally means the "force causing electrons to move." Emf has units of volts (V); 1 volt is the potential difference needed to impart one joule of energy to an electric charge of one coulomb (1 V = 1 J / 1 C). *One coulomb is the quantity of*

A CLOSER LOOK

EMF, Cell Potential, and Voltage

Electromotive force (emf) and cell potential (E_{cell}) are often used synonymously, but the two are subtly different. E_{cell} is a measured quantity, so its value is affected by how the measurement is made. To understand this point, consider as an analogy water in a pipe under pressure. Water pressure can be viewed as analogous to emf; it represents a force that will cause water in the pipe to move. If we open a faucet, water will flow. Opening the faucet will, however, decrease the pressure in the system.

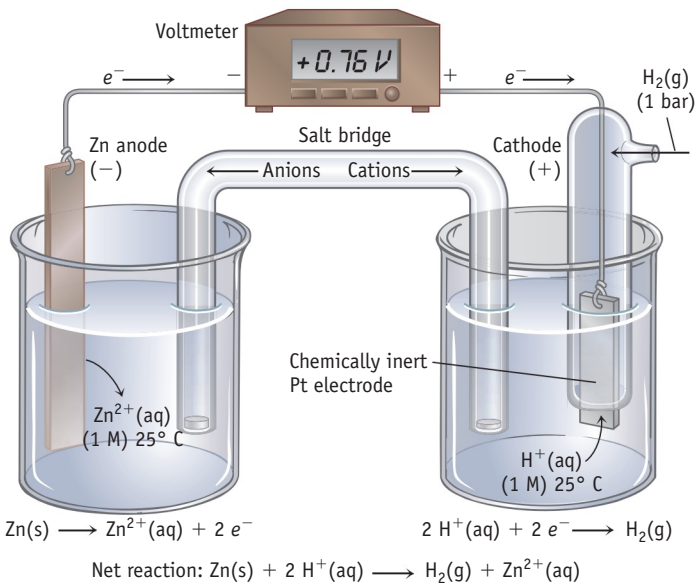
Emf is the potential difference when no current flows. To measure E_{cell}, a voltmeter is placed in the external circuit. Although voltmeters have high internal resistance to minimize current flow, a small current flows nonetheless. As a result, the value of E_{cell} will be slightly different than the emf.

Finally, there is a difference between a *potential* and a *voltage*. The voltage of a cell has a magnitude but no sign. In contrast, the potential of a half-reaction or a cell has a sign (+ or −) and a magnitude.

charge that passes a point in an electric circuit when a current of 1 ampere flows for 1 second (1 C = 1 A × 1 s).

Measuring Standard Potentials

Imagine you planned to study cell voltages in a laboratory with two objectives: (1) to understand the factors that affect these values and (2) to be able to predict the potential of a voltaic cell. You might construct a number of different half-cells, link them together in various combinations to form voltaic cells (as in Figure 19.14), and measure the cell potentials. After a few experiments, it would become apparent that cell potentials depend on a number of factors: the half-cells used (i.e., the reaction in each half-cell and the overall or net reaction in the cell), the concentrations of reactants and products in solution, the pressure of gaseous reactants, and the temperature.



To simplify matters for now, let us consider only cell potentials measured under **standard conditions**:

- Reactants and products are present in their standard states.
- Solutes in aqueous solution have a concentration of 1.0 M.
- Gaseous reactants or products have a pressure of 1.0 bar.

© Cengage Learning/Charles D. Winters

(a) The reaction of $H^+(aq)$ with Zn(s) to produce $H_2(g)$ and Zn^{2+} ions is product-favored at equilibrium.

(b) A voltaic cell that makes use of the reduction of aqueous hydrogen ions by zinc.

Figure 19.14 A voltaic cell using Zn | Zn^{2+}(aq, 1.0 M) and H_2 | H^+(aq, 1.0 M) half-cells.

- The cell generates a potential of 0.76 V under standard conditions.
- The electrode in the H_2 | H^+(aq, 1.0 M) half-cell is the cathode, and the Zn electrode is the anode.
- Electrons flow in the external circuit to the hydrogen half-cell from the zinc half-cell.
- The positive sign of the measured voltage indicates that the hydrogen electrode is the cathode or positive electrode.

A cell potential measured under these conditions is called the **standard potential** and is denoted by $E°_{cell}$. Unless otherwise specified, all values of $E°_{cell}$ refer to measurements at 298 K (25 °C).

Suppose you set up a number of standard half-cells and connect each in turn to a **standard hydrogen electrode (SHE)**. Your apparatus would look like the voltaic cell in Figure 19.14b. For now, we will concentrate on three aspects of this cell:

1. *The reaction that occurs.* The reaction occurring in the cell pictured in Figure 19.14 could be *either* the reduction of Zn^{2+} ions with H_2 gas

$$Zn^{2+}(aq) + H_2(g) \rightarrow Zn(s) + 2\ H^+(aq)$$

$Zn^{2+}(aq)$ is the oxidizing agent, and H_2 is the reducing agent.
Standard hydrogen electrode would be the anode (negative electrode).

   or the reduction of $H^+(aq)$ ions by Zn(s).

$$Zn(s) + 2\ H^+(aq) \rightarrow Zn^{2+}(aq) + H_2(g)$$

Zn is the reducing agent, and $H^+(aq)$ is the oxidizing agent.
Standard hydrogen electrode would be the cathode (positive electrode).

   In this case we know that the reduction of H^+ ions by zinc metal is the product-favored reaction at equilibrium (Figure 19.14a).
2. *Direction of electron flow in the external circuit.* In a voltaic cell, electrons always flow from the anode (negative electrode) to the cathode (positive electrode). We can tell the direction of electron movement—and therefore which is the anode and which is the cathode—by placing a voltmeter in the circuit. A positive potential is observed if the voltmeter terminal with a plus sign (+) is connected to the positive electrode or cathode [and the terminal with the minus sign (−) is connected to the negative electrode or anode]. Connected in the opposite way (plus to minus and minus to plus), the voltmeter will indicate a negative potential.
3. *Cell potential.* In Figure 19.14, the voltmeter is hooked up with its positive terminal connected to the hydrogen half-cell, and a reading of +0.76 V is observed. The hydrogen electrode is thus the positive electrode or cathode, and the reactions occurring in this cell must be

Reduction, cathode:	$2\ H^+(aq) + 2\ e^- \rightarrow H_2(g)$
Oxidation, anode:	$Zn(s) \rightarrow Zn^{2+}(aq) + 2\ e^-$
Net cell reaction:	$Zn(s) + 2\ H^+(aq) \rightarrow Zn^{2+}(aq) + H_2(g)$

   All of the species are present in the cell at standard conditions, so the reaction can, in principle, proceed in either direction. This reaction, however, proceeds from left to right as written. This shows us that, of the two reducing agents present, zinc is better than H_2, and H^+ ions are a better oxidizing agent than zinc ions.

The potential of +0.76 V measured for the oxidation of zinc with hydrogen ions also reflects the difference in potential energy of an electron at each electrode. From the direction of flow of electrons in the external circuit (Zn electrode → H_2 electrode), we conclude that the potential energy of an electron at the zinc electrode is higher than the potential energy of the electron at the hydrogen electrode.

Hundreds of electrochemical cells like that shown in Figure 19.14 can be set up, allowing us to determine the relative oxidizing or reducing ability of various chemical species and to determine the electrical potential generated by the reaction under standard conditions. A few results are given in Figure 19.15, where half-reactions are listed as reductions. That is, the chemical species on the left are oxidizing agents and are listed in descending oxidizing ability.

Standard Reduction Potentials

By doing experiments such as that illustrated by Figure 19.14, we not only learn the relative oxidizing and reducing abilities of various chemical species, but we can also rank them quantitatively.

If $E°_{cell}$ is a measure of the standard potential for the cell, then $E°_{cathode}$ and $E°_{anode}$ can be taken as measures of electrode potential. Because $E°_{cell}$ reflects the *difference* in electrode potentials, $E°_{cell}$ must be the difference between $E°_{cathode}$ and $E°_{anode}$.

$$E°_{cell} = E°_{cathode} - E°_{anode} \qquad (19.1)$$

Here, $E°_{cathode}$ and $E°_{anode}$ are the standard *reduction* potentials for the half-cell reactions that occur at the cathode and anode, respectively. Equation 19.1 is important for three reasons:

- If you have values for $E°_{cathode}$ and $E°_{anode}$, you can calculate the standard potential, $E°_{cell}$, for a voltaic cell.
- *When the calculated value of $E°_{cell}$ is positive, the reaction as written is predicted to be product-favored at equilibrium.* Conversely, if the calculated value of $E°_{cell}$ is negative, the reaction is predicted to be reactant-favored at equilibrium. Such a reaction will be product-favored at equilibrium in a direction opposite to the way it is written.
- If you measure $E°_{cell}$ and know either $E°_{cathode}$ or $E°_{anode}$, you can calculate the other value. This value would tell you how one half-cell reaction compares with others in terms of relative oxidizing or reducing ability.

Equation 19.1 Equation 19.1 is another example of calculating a change from $X_{final} - X_{initial}$. Electrons move to the cathode (the "final" state) from the anode (the "initial" state). Thus, Equation 19.1 resembles equations you have seen previously in this book (such as Equations 5.6 and 6.5).

But here is a dilemma. Individual half-cell potentials cannot be measured. Just as values for $\Delta_f H°$ and $\Delta_f G°$ were established by choosing a reference point (the elements in their standard states), scientists have selected a reference point for half-reactions. A potential of exactly 0 V is assigned to the half-reaction that occurs at a standard hydrogen electrode (SHE).

$$2\ H^+(aq,\ 1\ M) + 2\ e^- \longrightarrow H_2(g,\ 1\ bar)\quad E° = 0.00\ V$$

With this standard, we can now determine $E°$ values for half-cells by measuring $E°_{cell}$ in experiments such as those described in Figures 19.8 and 19.14, where one of the electrodes has a known potential versus SHE. We can then quantify the information with reduction potential tables such as Figure 19.15 and use these values to make predictions about $E°_{cell}$ for new voltaic cells.

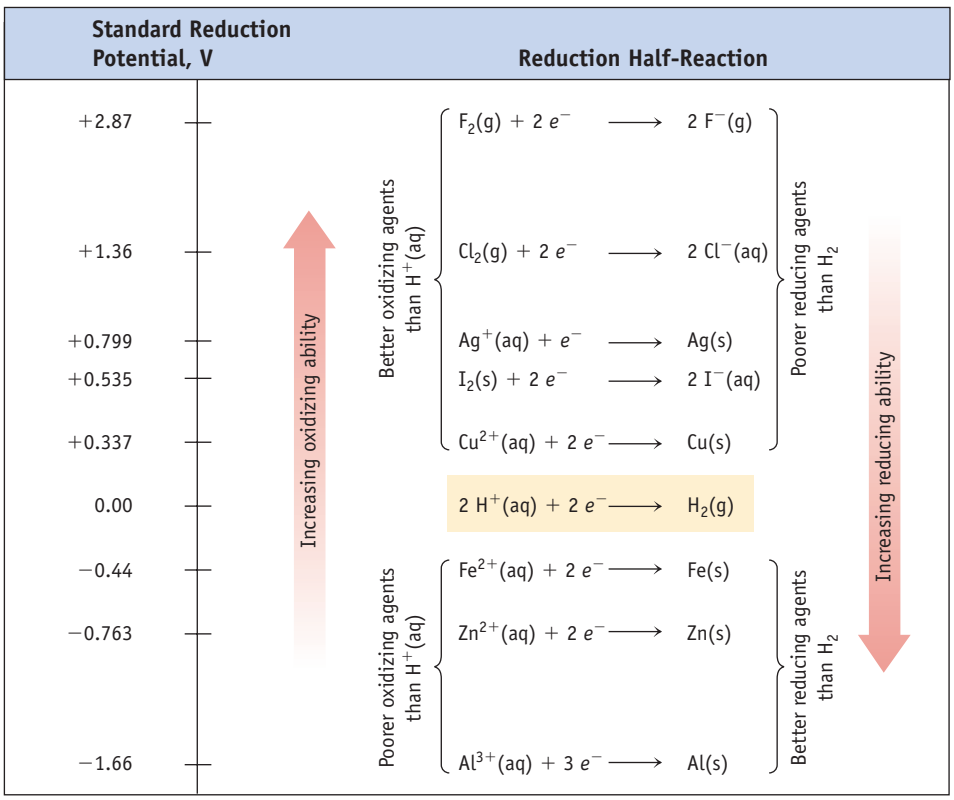

Figure 19.15 A potential "ladder" for reduction half-reactions.

- The position of a half-reaction on this potential ladder reflects the relative ability of the species at the left to act as an oxidizing agent.
- The higher the compound or ion is in the list, the better it is as an oxidizing agent. Conversely, the atoms or ions on the right are reducing agents. The lower they are in the list, the better they are as a reducing agent.
- The potential for each half-reaction is given with its standard reduction potential, $E°_{reduction}$.

Tables of Standard Reduction Potentials

$E°$ Values An extensive listing of $E°$ values is found in Appendix M, and still larger tables of data can be found in chemistry reference books. A common convention, used in Appendix M, lists standard reduction potentials in two groups, one for acidic and neutral solutions and the other for basic solutions.

The experimental approach just described leads to lists of $E°$ values such as seen in Figure 19.15, Table 19.1, and Appendix M. Let us list some important points concerning these tables and then illustrate them in the discussion and examples that follow.

1. The half-reactions are written as "oxidized form + electrons → reduced form." The species on the left side of the reaction arrow is an oxidizing agent, and the species on the right side of the reaction arrow is a reducing agent. Therefore, *all potentials are for reduction reactions*, and the potentials (in volts versus SHE) are called *standard reduction potentials*.
2. The more positive the value of $E°$ for the reactions, the better the oxidizing ability of the ion or compound on the left side of the reaction. This means *$F_2(g)$ is the best oxidizing agent in the table*. Lithium ion at the lower-left corner of Table 19.1 is the poorest oxidizing agent because its $E°$ value is the most negative.
3. The more negative the value of the reduction potential, $E°$, the less likely the half-reaction will occur as a reduction, and the more likely the reverse half-reaction will occur (as an oxidation). Thus, Li(s) is the strongest reducing agent in the table, and F^- is the weakest reducing agent. The reducing agents in the table (the ions, elements, and compounds at the right) increase in strength from the top to the bottom.
4. The reaction between any substance on the left in this table (an oxidizing agent) with any substance *lower* than it on the right (a reducing agent) is product-favored at equilibrium. This has been called the *northwest–southeast rule*: For example, Zn can reduce Fe^{2+}, H^+, Cu^{2+}, and I_2, but, of the species on this list, Cu can reduce only I_2.

Northwest–Southeast Rule This guideline is a reflection of the idea of moving down a potential energy "ladder" in a product-favored reaction.

5. The + or − sign of the half-reaction reduction potential is the sign of the electrode when it is attached to the H_2/H^+ standard cell (Figures 19.8 and 19.14).
6. Electrochemical potentials depend on the nature of the reactants and products and their concentrations, not on the quantities of material used. Therefore, changing the stoichiometric coefficients for a half-reaction does not change the value of $E°$. For example, the reduction of Fe^{3+} has an $E°$ of +0.771 V, whether the reaction is written as

Changing Stoichiometric Coefficients The volt is defined as "energy/charge" (V = J/C). Multiplying a reaction by some number causes both the energy and the charge to be multiplied by that number. Thus, the ratio "energy/charge = volt" does not change.

$$Fe^{3+}(aq, 1\ M) + e^- \rightarrow Fe^{2+}(aq, 1\ M) \qquad E° = +0.771\ V$$

or as

$$2\ Fe^{3+}(aq, 1\ M) + 2\ e^- \rightarrow 2\ Fe^{2+}(aq, 1\ M) \qquad E° = +0.771\ V$$

Using Tables of Standard Reduction Potentials

Tables or "ladders" of standard reduction potentials are very useful. They allow you to predict the potential of a new voltaic cell (under standard conditions), provide information that can be used to balance redox equations, and help predict which redox reactions are product-favored at equilibrium.

Calculating Standard Cell Potentials, $E°_{cell}$

The standard reduction potentials for half-reactions were obtained by measuring cell potentials. It makes sense, therefore, that these values can be used to calculate the potential of some new cell.

The net reaction occurring in a voltaic cell using silver and copper half-cells is

$$2\ Ag^+(aq) + Cu(s) \rightarrow 2\ Ag(s) + Cu^{2+}(aq)$$

The silver electrode is the cathode, and the copper electrode is the anode. We know this because silver ion is reduced (to silver metal) and copper metal is oxidized (to

Cu^{2+} ions). Also notice that Cu is "southeast" of Ag^+ in the potential ladder (Figure 19.15 and Table 19.1).

The potential for the voltaic cell is the difference between the standard reduction potentials for the two half-reactions.

$$E°_{cell} = E°_{cathode} - E°_{anode}$$

$$E°_{cell} = (+0.799\ V) - (+0.337\ V)$$

$$E°_{cell} = +0.462\ V$$

Notice that the value of $E°_{cell}$ is related to the "distance" between the cathode and anode reactions on the potential ladder. The products have a lower potential energy than the reactants, and the cell potential, $E°_{cell}$, has a positive value.

A positive potential calculated for the $Ag^+|Ag$ and $Cu^{2+}|Cu$ cell ($E°_{cell} = +0.462$ V) confirms that the reduction of silver ions in water with copper metal is product-favored at equilibrium (Figure 19.1). We might ask, however, about the value of $E°_{cell}$ if a reactant-favored equation had been selected. For example, what is $E°_{cell}$ for the reduction of copper(II) ions with silver metal?

Cathode, reduction: $Cu^{2+}(aq) + 2\ e^- \rightarrow Cu(s)$

Anode, oxidation: $2\ Ag(s) \rightarrow 2\ Ag^+(aq) + 2\ e^-$

Net ionic equation: $2\ Ag(s) + Cu^{2+}(aq) \rightarrow 2\ Ag^+(aq) + Cu(s)$

Cell Voltage Calculation

$$E°_{cathode} = +0.337\ V \text{ and } E°_{anode} = +0.799\ V$$

$$E°_{cell} = E°_{cathode} - E°_{anode} = (+0.337\ V) - (0.799\ V)$$

$$E°_{cell} = -0.462\ V$$

The negative sign for $E°_{cell}$ indicates that the reaction as written is reactant-favored at equilibrium. The products of the reaction (Ag^+ and Cu) have a higher potential energy than the reactants (Ag and Cu^{2+}). For the indicated reaction to occur, a potential of at least 0.462 V would have to be imposed on the system by an external source of electricity (Section 19.7).

Relative Strengths of Oxidizing and Reducing Agents

Five half-reactions, selected from Appendix M, are arranged from the half-reaction with the highest (most positive) $E°$ value to the one with the lowest (most negative) value.

$E°$, V		Reduction Half-Reaction
+1.36	Increasing strength as oxidizing agents ↑	$Cl_2(g) + 2\ e^- \longrightarrow 2\ Cl^-(aq)$
+0.80		$Ag^+(aq) + e^- \longrightarrow Ag(s)$
+0.00		$2\ H^+(aq) + 2\ e^- \longrightarrow H_2(g)$
−0.25		$Ni^{2+}(aq) + 2\ e^- \longrightarrow Ni(s)$
−0.76		$Zn^{2+}(aq) + 2\ e^- \longrightarrow Zn(s)$

- The list on the left is headed by Cl_2, an element that is a strong oxidizing agent and thus is easily reduced. At the bottom of the list is $Zn^{2+}(aq)$, an ion not easily reduced and thus a poor oxidizing agent.

A CLOSER LOOK

An Electrochemical Toothache

A 66-year-old woman had intense pain that was traced to her dental work (*New England Journal of Medicine*, Vol. 342, p. 2000, 2003). A root canal procedure had moved a mercury amalgam filling on one tooth slightly closer to a gold alloy crown on an adjacent tooth. Eating acidic foods caused her intense pain. When dental amalgams of dissimilar metals come in contact with saliva, a voltaic cell is formed that generates potentials up to several hundred millivolts—and you feel it! You can do it, too, if you chew an aluminum foil gum wrapper with teeth that have been filled with a dental amalgam. Ouch!

- On the right, the list is headed by $Cl^-(aq)$, an ion that can be oxidized to Cl_2 only with difficulty. It is a very poor reducing agent. At the bottom of the list is zinc metal, which is readily oxidized and is a good reducing agent.

By arranging these half-reactions based on $E°$ values, we have also arranged the chemical species on the two sides of the equation in order of their strengths as oxidizing or reducing agents. In this list, from strongest to weakest, the order is

$$\text{Oxidizing agents: } Cl_2 > Ag^+ > H^+ > Ni^{2+} > Zn^{2+}$$
$$\text{strong} \longrightarrow \text{weak}$$

$$\text{Reducing agents: } Zn > Ni > H_2 > Ag > Cl^-$$
$$\text{strong} \longrightarrow \text{weak}$$

Finally, notice that the value of $E°_{cell}$ is greater the farther apart the oxidizing and reducing agents are on the potential ladder. For example,

$$Zn(s) + Cl_2(g) \rightarrow Zn^{2+}(aq) + 2\ Cl^-(aq) \qquad E° = +2.12\ V$$

is more strongly product-favored than the reduction of hydrogen ions with nickel metal.

$$Ni(s) + 2\ H^+(aq) \rightarrow Ni^{2+}(aq) + H_2(g) \qquad E° = +0.25\ V$$

EXAMPLE 19.5

Ranking Oxidizing and Reducing Agents

Problem Use the table of standard reduction potentials (Table 19.1) to do the following:

(a) Rank the halogens in order of their strength as oxidizing agents.

(b) Decide whether hydrogen peroxide (H_2O_2) in acid solution is a stronger oxidizing agent than Cl_2.

(c) Decide which of the halogens is capable of oxidizing gold metal to $Au^{3+}(aq)$.

What Do You Know? A table of electrode potentials, such as Table 19.1 or Appendix M, contains the information needed to answer these questions.

Strategy The ability of a species on the left side of the $E°$ table to function as an oxidizing agent declines on descending the list.

SOLUTION

(a) Ranking halogens according to oxidizing ability: The halogens (F_2, Cl_2, Br_2, and I_2) appear in the upper-left portion of Table 19.1, with F_2 being highest, followed in order by the other three species. Their strengths as oxidizing agents are $F_2 > Cl_2 > Br_2 > I_2$. (The ability of bromine to oxidize iodide ions to molecular iodine is illustrated in Figure 19.16.)

(b) Comparing hydrogen peroxide and chlorine: H_2O_2 lies just below F_2 but well above Cl_2 in the potential ladder (Table 19.1). Thus, H_2O_2 is a weaker oxidizing agent than F_2 but a stronger one than Cl_2. (Note that the $E°$ value for H_2O_2 refers to an acidic solution and standard conditions.)

(c) Which halogen will oxidize gold metal to gold(III) ions? The $Au^{3+}|Au$ half-reaction is listed below the $F_2|F^-$ half-reaction and just above the $Cl_2|Cl^-$ half-reaction. This tells us that, among the halogens, only F_2 is capable of oxidizing Au to Au^{3+} under standard conditions. That is, for the reaction of Au and F_2,

Oxidation, anode: $2[Au(s) \longrightarrow Au^{3+}(aq) + 3\ e^-]$

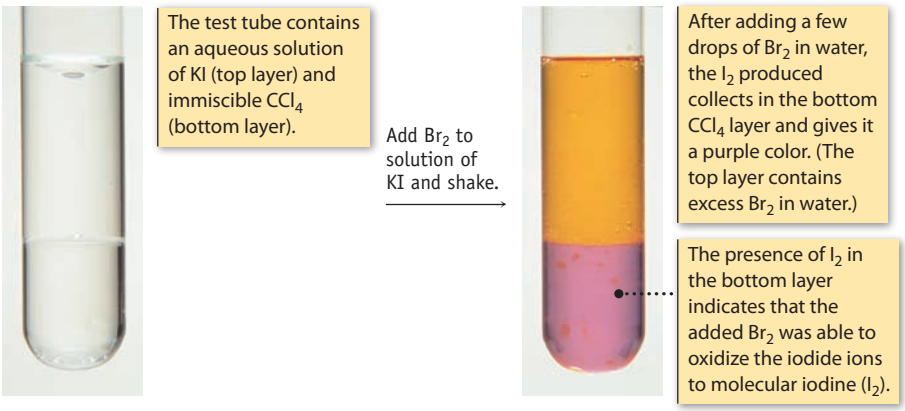
Reduction, cathode: $3[F_2(g) + 2\ e^- \longrightarrow 2\ F^-(aq)]$

Net ionic equation: $3\ F_2(g) + 2\ Au(s) \longrightarrow 6\ F^-(aq) + 2\ Au^{3+}(aq)$

$$E°_{cell} = E°_{cathode} - E°_{anode} = +2.87\ V - (+1.50\ V) = +1.37\ V$$

F_2 is a stronger oxidizing agent than Au^{3+}, so the reaction proceeds from left to right as written. (This is confirmed by a positive value of $E°_{cell}$.) For the reaction of Cl_2 and Au, Table 19.1 shows us that Cl_2 is a weaker oxidizing agent than Au^{3+}, so the reaction would be expected to proceed in the opposite direction under standard conditions.

Oxidation, anode: $2[Au(s) \longrightarrow Au^{3+}(aq) + 3\ e^-]$



Reduction, cathode: $3[Cl_2(aq) + 2\ e^- \longrightarrow 2\ Cl^-(aq)]$

Net ionic equation: $3\ Cl_2(aq) + 2\ Au(s) \longrightarrow 6\ Cl^-(aq) + 2\ Au^{3+}(aq)$

$$E°_{cell} = E°_{cathode} - E°_{anode} = +1.36\ V - (+1.50\ V) = -0.14\ V$$

This is confirmed by the negative value for $E°_{cell}$.

Think about Your Answer In part (c), we calculated $E°_{cell}$ for two reactions. To achieve a balanced net ionic equation, we added the half-reactions, but only after multiplying the gold half-reaction by 2 and the halogen half-reaction by 3. (This means 6 mol of electrons were transferred from 2 mol Au to 3 mol Cl_2.) Notice that this multiplication does not change the value of $E°$ for the half-reactions because cell potentials do not depend on the quantity of material.

(a) Rank the following metals in their ability to function as reducing agents: Hg, Sn, and Pb.

(b) Which halogens will oxidize mercury to mercury(II)?

19.5 Electrochemical Cells Under Nonstandard Conditions

Goals for Section 19.5

- Use the Nernst equation to calculate the cell potential under nonstandard conditions.
- Use cell voltage to determine the pH and other ion concentrations.

In the real world, electrochemical cells seldom operate under standard conditions. Even if the cell is constructed with all dissolved species at 1 M, reactant concentrations decrease and product concentrations increase in the course of the reaction. Changing concentrations of reactants and products, as well as the temperature, will affect the cell voltage. Therefore, we need to examine what happens to cell potentials under nonstandard conditions.

The Nernst Equation

Based on both theory and experimental results, it has been determined that cell potentials are related to concentrations of reactants and products and to temperature, as follows:

$$E = E° - (RT/nF)\ \ln Q \tag{19.2}$$

In this equation, which is known as the **Nernst equation**, R is the gas constant (8.3144598 J/K · mol); T is the temperature (K); and n is the number of moles of electrons transferred between oxidizing and reducing agents (as determined by the balanced equation for the reaction). The symbol F represents the **Faraday constant** (9.648533289×10^4 C/mol). *One Faraday is the quantity of electric charge carried by one mole of electrons.* The term Q is the reaction quotient (Equation 15.2, Section 15.2). Substituting values for the constants in Equation 19.2, and using 298 K as the temperature, gives

$$E = E° - \frac{0.0257}{n} \ln Q \quad \text{at 298 K} \tag{19.3}$$

or, in a commonly used form using base-10 logarithms,

$$E = E° - \frac{0.0592}{n} \log Q$$

In essence, the term $(RT/nF)\ln Q$ "corrects" the standard potential $E°$ for nonstandard conditions or concentrations.

EXAMPLE 19.6

Using the Nernst Equation

Problem A voltaic cell is set up at 25 °C with the half-cells $Al^{3+}(0.0010\ M)|Al$ and $Ni^{2+}(0.50\ M)|Ni$. Write an equation for the reaction that occurs when the cell generates an electric current and determine the cell potential.

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

What Do You Know? You know the temperature and the identity and concentrations of the reactants and products.

Strategy

Step 1: *Determine which substance is oxidized (Al or Ni) by looking at the appropriate half-reactions in Table 19.1 and deciding which is the better reducing agent (Example 19.5).*

Step 2: *Add the half-reactions to determine the net ionic equation and calculate $E°_{cell}$.*

Step 3: *Use the Nernst equation to calculate E, the potential.*

SOLUTION

Step 1. *Determine which substance is oxidized.*

Aluminum metal is a stronger reducing agent than Ni metal. (Conversely, Ni^{2+} is a better oxidizing agent than Al^{3+}.) Therefore, Al is oxidized, and the $Al^{3+}|Al$ compartment is the anode.

Step 2. *Add the half-reactions to determine the net ionic equation and calculate $E°_{cell}$.*

Cathode, reduction: $3\ [Ni^{2+}(aq) + 2\ e^- \longrightarrow Ni(s)]$

Anode, oxidation: $2\ [Al(s) \longrightarrow Al^{3+}(aq) + 3\ e^-]$

Net ionic equation: $2\ Al(s) + 3\ Ni^{2+}(aq) \longrightarrow 2\ Al^{3+}(aq) + 3\ Ni(s)$

$$E°_{cell} = E°_{cathode} - E°_{anode}$$

$$E°_{cell} = (-0.25\ V) - (-1.66\ V) = 1.41\ V$$

Step 3. *Use the Nernst equation to calculate E, the potential.*

The expression for Q is written based on the cell reaction. In the net reaction, $Al^{3+}(aq)$ has a coefficient of 2, so this concentration is squared. Similarly, $[Ni^{2+}(aq)]$ is cubed. Solids are not included in the expression for Q (Section 15.2).

$$Q = \frac{[Al^{3+}]^2}{[Ni^{2+}]^3}$$

The net equation requires transfer of six moles of electrons from two moles of Al atoms to three moles of Ni^{2+} ions, so $n = 6$, and the Nernst equation gives

$$E_{cell} = E°_{cell} - \frac{0.0257}{n} \ln \frac{[Al^{3+}]^2}{[Ni^{2+}]^3}$$

$$= +1.41\ V - \frac{0.0257}{6} \ln \frac{[0.0010]^2}{[0.50]^3}$$

$$= +1.41\ V - 0.004283\ \ln(8.00 \times 10^{-6})$$

$$= +1.41\ V - 0.004283\ (-11.736)$$

$$= 1.46\ V$$

Think about Your Answer The concentrations of Al^{3+} and Ni^{2+} both affect the cell potential. Analysis of the ln$Q$ term in the Nernst equation shows that if $[Ni^{2+}] = 1$ M but $[Al^{3+}] < 1$ M, then $E_{cell} > E°_{cell}$. The reaction is more product-favored in this situation. The reverse situation (with $[Ni^{2+}] < 1$ M and $[Al^{3+}] = 1$ M) would lead to $E_{cell} < E°_{cell}$. In this example, the very low value of $[Al^{3+}]$ has the greater effect, and E_{cell} is greater than $E°_{cell}$.

Check Your Understanding

A voltaic cell is set up with an aluminum electrode in a 0.025 M $Al(NO_3)_3(aq)$ solution and an iron electrode in a 0.50 M $Fe(NO_3)_2(aq)$ solution. Determine the cell potential, E_{cell}, at 298 K.

Example 19.6 demonstrated the calculation of a cell potential if concentrations are known. It is also useful to apply the Nernst equation in the opposite sense, using a measured cell potential to determine an unknown concentration.

EXAMPLE 19.7

Variation of Cell Potential with Concentration

Problem A voltaic cell is set up with copper and hydrogen half-cells. Standard conditions are used in the copper half-cell, $Cu^{2+}(aq, 1.00\ M)|Cu(s)$. The hydrogen gas pressure is 1.00 bar. A value of 0.490 V is recorded for E_{cell} at 298 K. Determine the concentration of H^+ and the pH of the solution.

What Do You Know? You know the temperature, the identity of the reactants and products, the concentration of the Cu^{2+} ion, the partial pressure of H_2, and E_{cell}.

Strategy

Step 1: *Determine which is the better oxidizing and reducing agent in order to decide what net reaction is occurring in the cell. Write a balanced equation for the reaction.*

Step 2: *Calculate $E°_{cell}$ from values of E° (Table 19.1).*

Step 3: *Use the Nernst equation with the given Cu^{2+} ion concentration to calculate the hydrogen ion concentration. Calculate the pH.*

SOLUTION

Step 1. *Determine which substance is oxidized. Write a balanced equation.*

Based on their positions in a table of standard reduction potentials, Cu^{2+} is a better oxidizing agent than H^+, so $Cu(s)|Cu^{2+}(aq, 1.00\ M)$ is the cathode, and $H_2(g, 1.00\ bar)|H^+(aq, ?\ M)$ is the anode.

Cathode, reduction: $Cu^{2+}(aq) + 2\ e^- \longrightarrow Cu(s)$

Anode, oxidation: $H_2(g) \longrightarrow 2\ H^+(aq) + 2\ e^-$

Net ionic equation: $H_2(g) + Cu^{2+}(aq) \longrightarrow Cu(s) + 2\ H^+(aq)$

Step 2. *Calculate $E°_{cell}$ from values of E°.*

$$E°_{cell} = E°_{cathode} - E°_{anode}$$

$$E°_{cell} = (+0.337\ V) - (0.00\ V) = +0.337\ V$$

Step 3. *Use the Nernst equation to calculate $[H^+]$. Calculate the pH.*

The reaction quotient, Q, is derived from the balanced net ionic equation.

$$Q = \frac{[H^+]^2}{[Cu^{2+}]P_{H_2}}$$

The net equation requires the transfer of two moles of electrons, so $n = 2$. The value of $[Cu^{2+}]$ is 1.00 M, and the pressure of H_2 is 1.0 bar, but $[H^+]$ is unknown. Substitute this information into the Nernst equation (and do not overlook the fact that $[H^+]$ is squared in the expression for Q).

$$E = E° - \frac{0.0257}{n} \ln \frac{[H^+]^2}{[Cu^{2+}]P_{H_2}}$$

$$0.490\ V = 0.337\ V - \frac{0.0257}{2} \ln \frac{[H^+]^2}{(1.00)(1.00)}$$

$$-11.91 = \ln[H^+]^2$$

$$[H^+] = 2.6 \times 10^{-3}\ M = 3 \times 10^{-3}\ M$$

$$pH = 2.6$$

Think about Your Answer Be sure to write the balanced equation. Without it you may not have the correct exponents in the term for Q in the Nernst equation.

Check Your Understanding

The half-cells $Ag^+(aq, 1.0\ M)|Ag(s)$ and $H^+(aq, ?\ M)|H_2(1.0\ bar)$ are linked by a salt bridge to create a voltaic cell. With the silver electrode as the cathode, a value of 0.902 V is recorded for E_{cell} at 298 K. Determine the concentration of H^+ and the pH of the solution.

A pH meter is a device that uses a measured cell potential to determine hydrogen ion concentrations. In an electrochemical cell in which $H^+(aq)$ is a reactant or product, the cell voltage will vary predictably with the hydrogen ion concentration. The cell voltage is measured and the value used to calculate pH. Example 19.7 illustrates how E_{cell} can depend on the hydrogen ion concentration in a simple cell.

In the real world, using a hydrogen electrode in a pH meter is not practical. The apparatus is clumsy; it is anything but robust; and platinum (for the electrode) is costly. Common pH meters use a glass electrode, so called because it contains a thin glass membrane separating the cell from the solution whose pH is to be measured (Figure 19.17). Inside the glass electrode is a silver wire coated with AgCl and a solution of HCl; outside is the solution of unknown pH to be evaluated. An Ag/AgCl or calomel electrode—the latter a common reference electrode using a mercury(I)–mercury redox couple ($Hg_2Cl_2|Hg$)—serves as the second electrode of the cell. The potential across the glass membrane depends on $[H^+]$. Common pH meters give a direct readout of pH.

19.6 Electrochemistry and Thermodynamics

Goal for Section 19.6

- Use the relationship between cell voltage ($E°_{cell}$) and free energy ($\Delta_r G°$) and between $E°_{cell}$ and an equilibrium constant for the cell reaction.

Work and Free Energy

The first law of thermodynamics states that the internal energy change in a system (ΔU) is related to two quantities, heat (q) and work (w): $\Delta U = q + w$ (Section 5.4). This equation also applies to chemical changes that occur in a voltaic cell. As current flows, energy is transferred from the system (the voltaic cell) to the surroundings.

In a voltaic cell, the decrease in internal energy in the system will manifest itself ideally as electrical work done on the surroundings by the system. The maximum work done by an electrochemical system (ideally, assuming no heat is generated) is proportional to the potential difference (volts) and the quantity of charge (coulombs):

$$w_{max} = nFE \tag{19.4}$$

In this equation, E is the cell potential, and nF is the quantity of electric charge transferred from anode to cathode.

The free energy change for a process is, by definition, the maximum amount of work that can be obtained (Section 18.6). Because the maximum work and the cell potential are related, $E°$ and $\Delta_r G°$ can be related mathematically (taking care to assign signs correctly). The maximum work done on the surroundings when electricity is produced by a voltaic cell is $+nFE$, with the positive sign denoting an increase in energy in the surroundings. The energy content of the cell decreases by this amount. Thus, $\Delta_r G$ for the voltaic cell has the opposite sign.

$$\Delta_r G = -nFE \tag{19.5}$$

Under standard conditions, the appropriate equation is

$$\Delta_r G° = -nFE° \tag{19.6}$$

This expression shows that the more positive the value of $E°$, the more negative the value of $\Delta_r G°$ for the reaction. Also, because of the relationship between $\Delta_r G°$ and the equilibrium constant (K), the farther apart the half-reactions are on the potential ladder, the more strongly product-favored the reaction is at equilibrium.

Units in Equation 19.6 n has units of mol e^-, and F has units of (C/mol e^-).Therefore, nF has units of coulombs (C). Because 1 J = 1 C · V, the product nFE will have units of energy (J).

EXAMPLE 19.8

Relating $E°$ and $\Delta_r G°$

Problem The standard cell potential, $E°_{cell}$, for the reduction of silver ions with copper metal (Figure 19.5) is +0.462 V at 25 °C. Calculate $\Delta_r G°$ for this reaction.

What Do You Know? You know the cell potential under standard conditions and therefore know to use Equation 19.6 to calculate the change in free energy. In this equation F is the Faraday constant (96,485 C/mol e^-), but n has to be determined from the balanced equation for the cell reaction.

Strategy Use Equation 19.6 where $E°_{cell}$ and F are known. The value of n, the number of moles of electrons transferred between copper metal and silver ions, comes from the balanced equation.

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

SOLUTION In this cell, copper is the anode, and silver is the cathode. The overall cell reaction is

$$Cu(s) + 2\ Ag^+(aq) \rightarrow Cu^{2+}(aq) + 2\ Ag(s)$$

which means that each mole of copper transfers 2 mol of electrons to 2 mol of Ag^+ ions. That is, $n = 2$. Now use Equation 19.6.

$$\Delta_r G° = -nFE° = -(2\ \text{mol}\ e^-)(96{,}485\ \text{C/mol}\ e^-)(0.462\ \text{V}) = -89{,}200\ \text{C} \cdot \text{V}$$

Because $1\ \text{C} \cdot \text{V} = 1\ \text{J}$, we have

$$\Delta_r G° = -89{,}200\ \text{J or } -89.2\ \text{kJ}$$

Think about Your Answer This example demonstrates an effective method of obtaining thermodynamic values from electrochemical experiments. Keep in mind that a positive $E°$ implies a negative $\Delta_r G°$.

Check Your Understanding

The following reaction has an $E°$ value of -0.76 V:

$$H_2(g) + Zn^{2+}(aq) \rightarrow Zn(s) + 2\ H^+(aq)$$

Calculate $\Delta_r G°$ for this reaction. Is the reaction product- or reactant-favored at equilibrium?

$E°$ and the Equilibrium Constant

When a voltaic cell produces an electric current, the reactant concentrations decrease, and the product concentrations increase. The cell voltage also changes. As reactants are converted to products, the value of E_{cell} decreases and the cell potential eventually reaches zero; no further net reaction occurs, and equilibrium is achieved.

When $E_{cell} = 0$, the reactants and products are at equilibrium, and the reaction quotient, Q, is equal to the equilibrium constant, K. Substituting the appropriate symbols and values into the Nernst equation,

$$E = 0 = E° - \frac{0.0257}{n} \ln K$$

and collecting terms gives an equation that relates the standard cell potential and equilibrium constant:

$$\ln K = \frac{nE°}{0.0257} \quad \text{at } 25°\text{C } (298\ \text{K}) \qquad (19.7)$$

Equation 19.7 can be used to determine values for equilibrium constants, as illustrated in Example 19.9.

EXAMPLE 19.9

$E°$ and Equilibrium Constants

Problem Calculate the equilibrium constant for the reaction at 298 K:

$$Ag^+(aq) + Fe^{2+}(aq) \rightleftharpoons Ag(s) + Fe^{3+}(aq)$$

What Do You Know? You have the balanced chemical equation and know that Equation 19.7 is required. You need to determine $E°$ (from standard reduction potential values in Table 19.1) and n, the number of electrons transferred.

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Strategy First, determine $E°_{cell}$ from $E°$ values for the two half-reactions and from those the value of n, the other parameter required in Equation 19.7.

SOLUTION The half-reactions and $E°$ values are

Cathode, reduction: $Ag^+(aq) + e^- \longrightarrow Ag(s)$

Anode, oxidation: $Fe^{2+}(aq) \longrightarrow Fe^{3+}(aq) + e^-$

Net ionic equation: $Ag^+(aq) + Fe^{2+}(aq) \rightleftharpoons Fe^{3+}(aq) + Ag(s)$

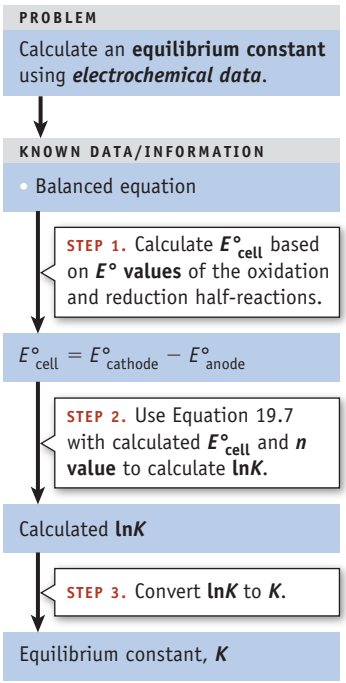
$$E°_{cell} = E°_{cathode} - E°_{anode}$$

$$E°_{cell} = (0.799\ V) - (0.771\ V) = +0.028\ V$$

Now substitute $n = 1$ and $E°_{cell}$ into Equation 19.7.

$$\ln K = \frac{nE°}{0.0257} = \frac{(1)(0.028\ V)}{0.0257} = 1.09$$

$$K = 3$$



Think about Your Answer The relatively small positive voltage (0.028 V) for the cell indicates that the cell reaction is only mildly product-favored at equilibrium. A value of 3 for the equilibrium constant is in accord with this observation.

Check Your Understanding

Calculate the equilibrium constant at 25 °C for the reaction

$$2\ Ag^+(aq) + Hg(\ell) \rightleftharpoons 2\ Ag(s) + Hg^{2+}(aq)$$

Strategy Map 19.9

The relationships between $E°$, K, and $\Delta_r G°$ are summarized in Table 19.2. Values of $E°$ can be used to obtain equilibrium constants for many different chemical systems. One example is the determination of solubility product constants, K_{sp}. Let us begin with an electrode in which an insoluble ionic compound, AgCl, is a component of a half-cell. Figure 19.18 illustrates how the potential for the reduction of AgCl in the presence of Cl^- ion (1.00 M) can be determined.

$$AgCl(s) + e^- \longrightarrow Ag(s) + Cl^-(aq) \qquad E° = +0.222\ V$$

The standard reduction potential for the AgCl | Ag half-cell is +0.222 V. If this half-reaction is paired with a standard silver electrode in a hypothetical voltaic cell, the cell reactions could be written as

Cathode, reduction: $AgCl(s) + e^- \longrightarrow Ag(s) + Cl^-(aq)$

Anode, oxidation: $Ag(s) \longrightarrow Ag^+(aq) + e^-$

Net ionic equation: $AgCl(s) \longrightarrow Ag^+(aq) + Cl^-(aq)$

TABLE 19.2 Summary of the Relationship of K, $\Delta_r G°$, and $E°$

K	$\Delta_r G°$	$E°$	Reactant-Favored or Product-Favored at Equilibrium?
$K >> 1$	$\Delta_r G° < 0$	$E° > 0$	Product-favored
$K = 1$	$\Delta_r G° = 0$	$E° = 0$	$[C]_c[D]_d = [A]_a[B]_b$ at equilibrium
$K << 1$	$\Delta_r G° > 0$	$E° < 0$	Reactant-favored

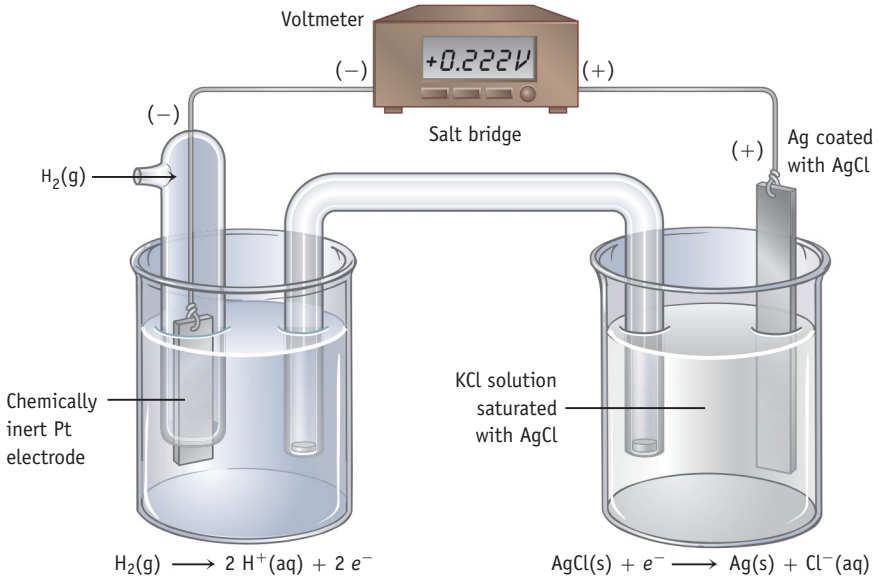

FIGURE 19.18 **Measurement of the standard electrode potential for the Ag | AgCl electrode.**

The equation for the net reaction represents the equilibrium of solid AgCl and its ions. The cell potential is negative,

$$E°_{cell} = E°_{cathode} - E°_{anode} = (+0.222\ V) - (+0.799\ V) = -0.577\ V$$

indicating a reactant-favored process, as would be expected based on the low solubility of AgCl. Using Equation 19.7, the value of K_{sp} can then be obtained from $E°_{cell}$.

$$\ln K = \frac{nE°}{0.0257} = \frac{(1)(-0.577\ V)}{0.0257} = -22.45$$

$$K_{sp} = e^{-22.45} = 2 \times 10^{-10}$$

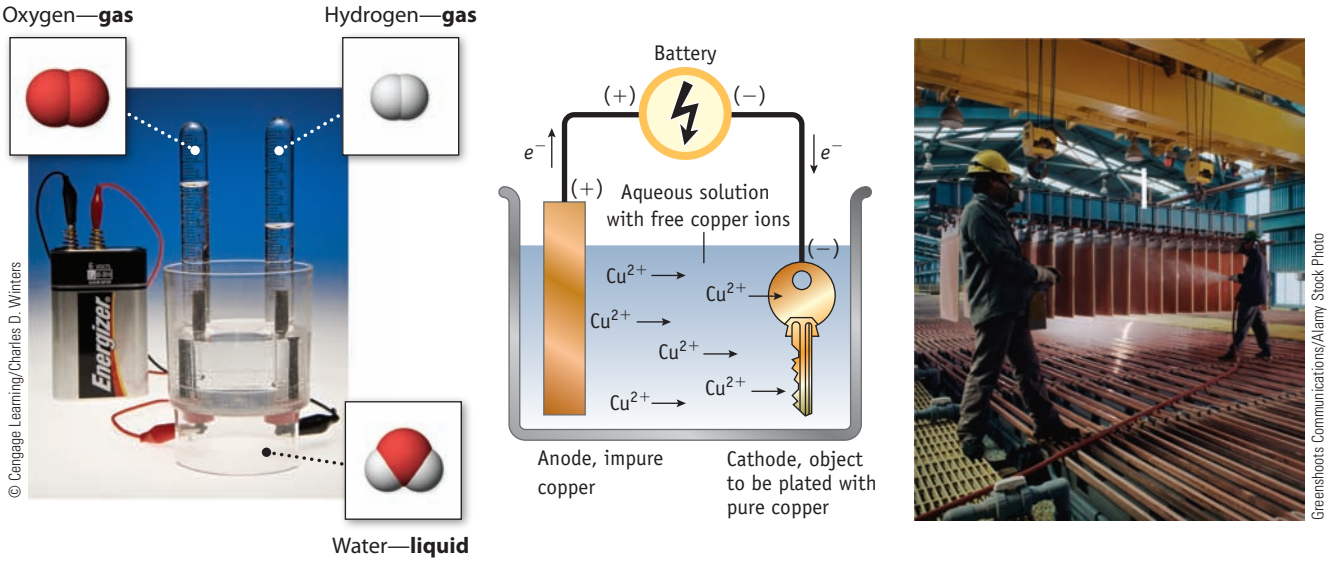
Significant Figures in Calculations Involving Logarithms When rounded to the proper number of significant figures, ln K_{sp} = −22.5. This number has only one significant figure after the decimal point. Thus, the inverse logarithm has only one significant figure.

19.7 Electrolysis: Chemical Change Using Electrical Energy

Goal for Section 19.7

- Describe the chemical processes occurring in an electrolysis. Recognize the factors that determine which substances are oxidized and reduced at the electrodes.

Thus far, we have described electrochemical cells that use product-favored redox reactions to generate an electric current. Equally important, however, is the opposite process, **electrolysis**, the use of electrical energy to bring about chemical change.



Problem Solving Tip 19.3 Electrochemical Conventions: Voltaic Cells and Electrolysis Cells

Whether you are describing a voltaic cell or an electrolysis cell, the terms *anode* and *cathode* always refer to the electrodes at which oxidation and reduction occur, respectively. However, the electrodes in the two types of electrochemical cells have different polarities.

Type of Cell	Electrode	Function	Polarity
Voltaic	Anode	Oxidation	−
	Cathode	Reduction	+
Electrolysis	Anode	Oxidation	+
	Cathode	Reduction	−

(a) Electrolysis of water produces hydrogen (at the cathode) and oxygen gas (at the anode).

(b) Purifying copper by electrolysis. Copper ions are produced at an anode made of impure copper. The ions migrate to the cathode where they are reduced to copper metal. (*Right.* A photo of a commercial electrolysis unit producing copper.)

Figure 19.19 Electrolysis. Electrical energy is used to carry out reactions that are otherwise reactant favored.

Electrolysis of Molten Salts

All electrolysis experiments are set up in a similar manner. The material to be electrolyzed, either a molten salt or a solution, is contained in an electrolysis cell (Figure 19.19). As was the case with voltaic cells, ions must be present in the liquid or solution for a current to flow. The movement of ions constitutes the electric current within the cell. The cell has two electrodes that are connected to a source of DC (direct-current) voltage. If the applied voltage is high enough, chemical reactions occur at the two electrodes. Reduction occurs at the negatively charged cathode, with electrons being transferred from that electrode to a chemical species in the cell. Oxidation occurs at the positive anode, with electrons from a chemical species being transferred to that electrode.

Let us focus our attention on the chemical reactions that occur at each electrode in the electrolysis of a molten salt. Sodium chloride melts at about 800 °C, and in the molten state sodium ions (Na^+) and chloride ions (Cl^-) are freed from their rigid arrangement in the crystalline lattice. If a potential is applied to the electrodes, sodium ions are attracted to the negative electrode, and chloride ions are attracted to the positive electrode (Figure 19.20). If the potential is high enough, chemical reactions occur at each electrode. At the negative cathode, Na^+ ions accept electrons and are reduced to sodium metal (a liquid at this temperature). Simultaneously, at the positive anode, chloride ions give up electrons and form elemental chlorine.

Cathode (−), reduction: $2\ Na^+ + 2\ e^- \longrightarrow 2\ Na(\ell)$

Anode (+), oxidation: $2\ Cl^- \longrightarrow Cl_2(g) + 2\ e^-$

Net ionic equation: $2\ Na^+ + 2\ Cl^- \longrightarrow 2\ Na(\ell) + Cl_2(g)$

Electrons move through the external circuit under the force exerted by the applied potential, and the movement of positive and negative ions in the molten salt constitutes the current within the cell. The energy required for this reactant-favored reaction to occur is provided by an external source such as a battery.

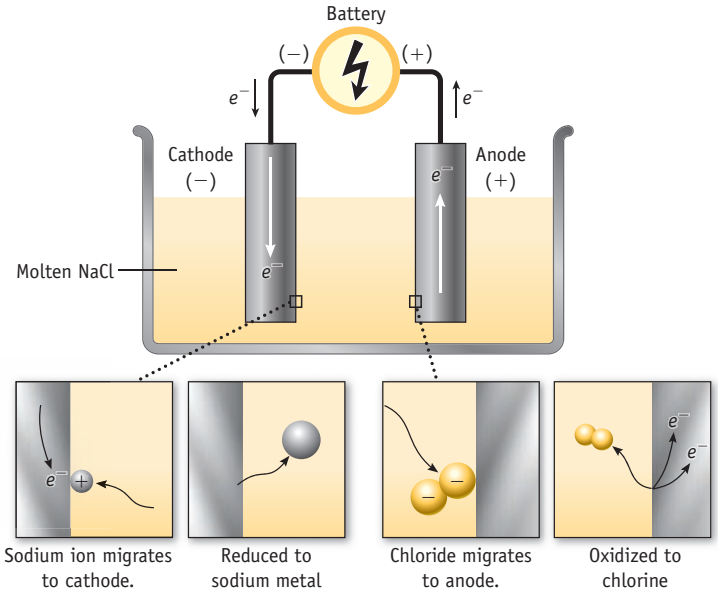

Figure 19.20 The preparation of sodium and chlorine by the electrolysis of molten NaCl. In the molten state, sodium ions migrate to the negative cathode, where they are reduced to sodium metal. Chloride ions migrate to the positive anode, where they are oxidized to elemental chlorine.

Electrolysis of Aqueous Solutions

Sodium ions (Na^+) and chloride ions (Cl^-) are the primary species present in molten NaCl. Only chloride ions can be oxidized, and only sodium ions can be reduced. Electrolysis of a substance in aqueous solution is more complicated than the electrolysis of a molten salt, however, because water is now present. Water is an *electroactive* substance; that is, it can be oxidized or reduced in an electrochemical process.

Consider the electrolysis of aqueous sodium iodide (Figure 19.21). In this experiment, the electrolysis cell contains $Na^+(aq)$, $I^-(aq)$, and H_2O molecules. Possible *reduction reactions* at the *negative cathode* include

$$Na^+(aq) + e^- \longrightarrow Na(s)$$

$$2\ H_2O(\ell) + 2\ e^- \longrightarrow H_2(g) + 2\ OH^-(aq)$$

Possible *oxidation reactions* at the *positive anode* are

$$2\ I^-(aq) \longrightarrow I_2(aq) + 2\ e^-$$

$$2\ H_2O(\ell) \longrightarrow O_2(g) + 4\ H^+(aq) + 4\ e^-$$

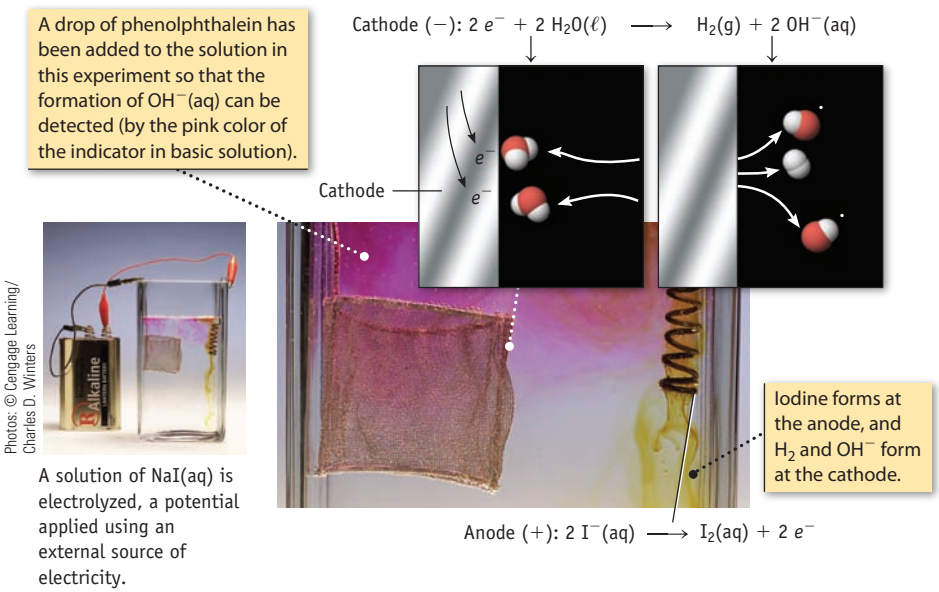

Figure 19.21 Electrolysis of aqueous NaI.

A CLOSER LOOK

Electrochemistry and Michael Faraday

The terms *anion*, *cation*, *electrode*, and *electrolyte* originated with Michael Faraday (1791–1867), one of the most influential people in the history of chemistry. Faraday was apprenticed to a bookbinder in London when he was 13. This situation suited him perfectly, as he enjoyed reading the books sent to the shop for binding. By chance, one of these volumes was a small book on chemistry, which whetted his appetite for science, and he began performing experiments on electricity. In 1812, a patron of the shop invited Faraday to accompany him to the Royal Institution to attend a lecture by one of the most famous chemists of the day, Sir Humphry Davy. Faraday was intrigued by Davy's lecture and wrote to ask Davy for a position as an assistant. His request was granted and he began work in 1813. Faraday was so talented that his work proved extraordinarily fruitful, and only 12 years later he was made the director of the laboratory of the Royal Institution.

It has been said that Faraday's contributions were so enormous that, had there been Nobel Prizes when he was alive, he would have received at least six. These could have been awarded for discoveries such as the following:

- Electromagnetic induction, which led to the first transformer and electric motor
- The laws of electrolysis (the effect of electric current on chemicals)
- The magnetic properties of matter
- Benzene and other organic chemicals (which led to important chemical industries)
- The "Faraday effect" (the rotation of the plane of polarized light by a magnetic field)
- The introduction of the concept of electric and magnetic fields

Oesper Collection in the History of Chemistry/University of Cincinnati

Michael Faraday (1791–1867)

In addition to making discoveries that had profound effects on science, Faraday was an educator. He wrote and spoke about his work in memorable ways, especially in lectures to the general public that helped to popularize science.

A transcript of Faraday's lectures, *The Chemical History of a Candle*, was published in 1867. This small book, still widely available, is a beautiful and readable account of scientific thinking.

In the electrolysis of aqueous NaI, $H_2(g)$ and $OH^-(aq)$ are formed at the cathode, and iodine is formed at the anode. Thus, the overall cell process can be summarized by the following equations:

Cathode (−), reduction: $2\ H_2O(\ell) + 2\ e^- \rightarrow H_2(g) + 2\ OH^-(aq)$

Anode (+), oxidation: $2\ I^-(aq) \rightarrow I_2(aq) + 2\ e^-$

Net ionic equation: $2\ H_2O(\ell) + 2\ I^-(aq) \rightarrow H_2(g) + 2\ OH^-(aq) + I_2(aq)$

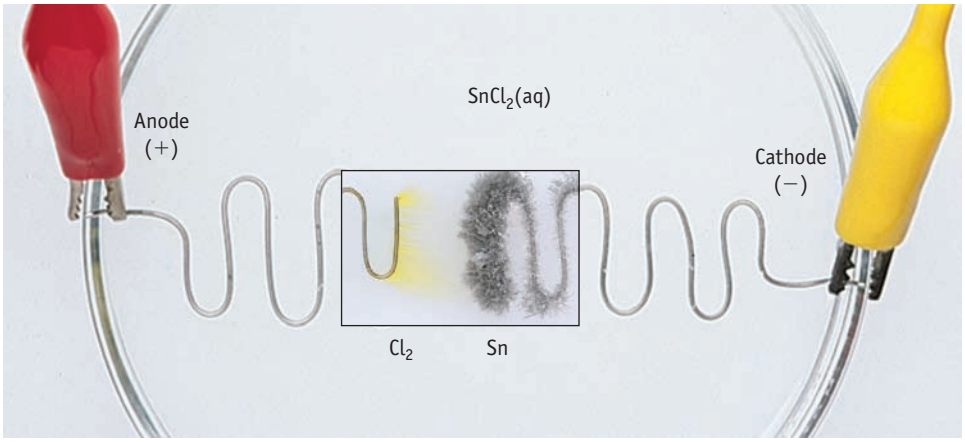
where $E°_{cell}$ has a negative value.

$$E°_{cell} = E°_{cathode} - E°_{anode} = (-0.8277\ V) - (+0.621\ V) = -1.449\ V$$

This process is reactant favored at equilibrium, and a potential of *at least* 1.45 V must be *applied* to the cell for these reactions to occur. If the process had involved the oxidation of water instead of iodide ion at the anode, the required potential would be −2.057 V [$E°_{cathode} - E°_{anode} = (-0.8277\ V) - (+1.229\ V)$], and if the reaction involving the reduction of Na^+ and the oxidation of I^- had occurred, the required potential would be −3.335 V [$E°_{cathode} - E°_{anode} = (-2.714\ V) - (+0.621\ V)$]. The reaction occurring is the one requiring the smallest applied potential, so the net cell reaction in the electrolysis of NaI(aq) is the oxidation of iodide and reduction of water.

What happens if an aqueous solution of some other metal halide such as $SnCl_2$ is electrolyzed? In this case, aqueous Sn^{2+} ion is much more easily reduced ($E° = -0.14$ V) than water ($E° = -0.83$ V) at the cathode, so tin metal is produced. At the anode, two oxidations are possible: $Cl^-(aq)$ to $Cl_2(g)$ or $H_2O(\ell)$ to $O_2(g)$. Experiments show that chloride ion is oxidized in preference to water, so the reactions occurring on electrolysis of aqueous tin(II) chloride are (Figure 19.22)

Cathode (−), reduction: $Sn^{2+}(aq) + 2\ e^- \rightarrow Sn(s)$



Anode (+), oxidation: $2\ Cl^-(aq) \rightarrow Cl_2(g) + 2\ e^-$

Net ionic equation: $Sn^{2+}(aq) + 2\ Cl^-(aq) \rightarrow Sn(s) + Cl_2(g)$

$$E°_{cell} = E°_{cathode} - E°_{anode} = (-0.14\ V) - (+1.36\ V) = -1.50\ V$$

© Cengage Learning/Charles D. Winters

Figure 19.22 Electrolysis of aqueous tin(II) chloride. Tin metal collects at the negative cathode. Chlorine gas is formed at the positive anode. Elemental chlorine is formed in the cell, in spite of the fact that the potential for the oxidation of Cl^- is more negative than that for oxidation of water. (That is, chlorine should be less easily oxidized than water.) This is the result of chemical kinetics and illustrates the complexity of some aqueous electrochemistry.

Formation of Cl_2 at the anode in the electrolysis of $SnCl_2(aq)$ is contrary to a prediction based on $E°$ values. If the electrode reactions were

Cathode (−), reduction: $Sn^{2+}(aq) + 2\ e^- \rightarrow Sn(s)$

Anode (+), oxidation: $2\ H_2O(\ell) \rightarrow O_2(g) + 4\ H^+(aq) + 4\ e^-$

$$E°_{cell} = (-0.14\ V) - (+1.23\ V) = -1.37\ V$$

a smaller applied potential is required. To explain the formation of chlorine instead of oxygen, we must take into account rates of reaction. The oxidation of $Cl^-(aq)$ is much more rapid than the oxidation of H_2O.

In the electrolysis of aqueous NaCl, a voltage high enough to oxidize both Cl^- and H_2O is used. Because chloride ion is oxidized much faster than H_2O, Cl_2 is the major product in this electrolysis. Electrolysis of aqueous NaCl is the predominant means by which chlorine is produced commercially.

Another instance in which rates are important concerns electrode materials. Graphite, commonly used to make inert electrodes, can be oxidized. For the half-reaction $CO_2(g) + 4\ H^+(aq) + 4\ e^- \rightarrow C(s) + 2\ H_2O(\ell)$, $E°$ is +0.20 V, indicating that carbon is slightly easier to oxidize than copper ($E° = +0.34$ V). Based on this value, oxidation of a graphite electrode might reasonably be expected to occur during an electrolysis. And indeed it does, albeit slowly; graphite electrodes used in electrolysis cells slowly deteriorate and eventually have to be replaced.

One other factor—the concentration of electroactive species in solution—must be taken into account when discussing electrolysis. As shown in Section 19.5, the potential at which a species in solution is oxidized or reduced depends on concentration. Unless standard conditions are used, predictions based on $E°$ values are merely qualitative. In addition, the rate of a half-reaction depends on the concentration of the electroactive substance at the electrode surface. At a very low concentration, the rate of the redox reaction may depend on the rate at which an ion diffuses from the solution to the electrode surface.

EXAMPLE 19.10

Electrolysis of Aqueous Solutions

Problem Predict how products of the electrolysis of aqueous solutions of NaF, NaCl, NaBr, and NaI are likely to be different and predict $E°_{cell}$ for each electrolysis. (The electrolysis of NaI is illustrated in Figure 19.21.)

What Do You Know? You know the identity of the compounds to be electrolyzed, but you will need to know the $E°$ values for their half-reactions and for water electrolysis.

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Strategy The main criterion used to predict the chemistry in an electrolytic cell should be the ease of oxidation and reduction, an assessment based on $E°$ values.

SOLUTION The cathode reaction presents no problem: Water is reduced to hydroxide ion and H_2 gas in preference to reduction of $Na^+(aq)$ (as in the electrolysis of aqueous NaI). Thus, the primary cathode reaction in all cases is

$$2\ H_2O(\ell) + 2\ e^- \rightarrow H_2(g) + 2\ OH^-(aq)$$

$$E°_{cathode} = -0.83\ V$$

At the anode, you need to assess the ease of oxidation of the halide ions relative to water. Based on $E°$ values, this should be $I^-(aq) > Br^-(aq) > Cl^-(aq) >> F^-(aq)$. Fluoride ion is much more difficult to oxidize than water, and electrolysis of an aqueous solution containing this ion results exclusively in O_2 formation. That is, the primary anode reaction for NaF(aq) is

$$2\ H_2O(\ell) \rightarrow O_2(g) + 4\ H^+(aq) + 4\ e^-$$

$$E°_{anode} = +1.23\ V$$

Therefore, for NaF,

$$E°_{cell} = (-0.83\ V) - (+1.23\ V) = -2.06\ V$$

Recall that chlorine is the primary product at the anode in the electrolysis of aqueous solutions of chloride salts (as in Figure 19.22). Therefore, the primary anode reaction for NaCl(aq) is

$$2\ Cl^-(aq) \rightarrow Cl_2(g) + 2\ e^-$$

$$E°_{cell} = (-0.83\ V) - (+1.36\ V) = -2.19\ V$$

Bromide ions are considerably easier to oxidize than chloride ions, so Br_2 may be expected as the primary product in the electrolysis of aqueous NaBr. For NaBr(aq), the primary anode reaction is

$$2\ Br^-(aq) \rightarrow Br_2(\ell) + 2\ e^-$$

so $E°_{cell}$ is

$$E°_{cell} = (-0.83\ V) - (+1.08\ V) = -1.91\ V$$

Thus, the electrolysis of NaBr resembles that of NaI (Figure 19.21) in producing the halogen, hydrogen gas, and hydroxide ion. The half-reactions and the cell potential for aqueous NaI were given on page 894.

Think about Your Answer As described above, you would predict from $E°$ values the ease of oxidation of halide ions is $I^-(aq) > Br^-(aq) > Cl^-(aq) >> F^-(aq)$. This is confirmed by the results.

Check Your Understanding

Predict the chemical reactions that will occur at the two electrodes in the electrolysis of an aqueous sodium hydroxide solution.

19.8 Counting Electrons

Goal for Section 19.8

- Relate the quantity of a substance oxidized or reduced to the amount of current and the time the current flows.

In the electrolysis of aqueous $AgNO_3$, one mole of electrons is required to produce one mole of silver. In contrast, two moles of electrons are required to produce one mole of tin (Figure 19.22):

$$Sn^{2+}(aq) + 2\ e^- \rightarrow Sn(s)$$

It follows that if the number of moles of electrons flowing through the electrolysis cell could be measured, the amount of silver or tin produced could be calculated. Conversely, if the amount of silver or tin produced is known, then the number of moles of electrons moving through the circuit could be calculated.

The number of moles of electrons consumed or produced in an electron transfer reaction is obtained by measuring the current flowing in the external electric circuit in a given time. The **current** flowing in an electrical circuit is the amount of charge (in units of coulombs, C) per unit time, and the usual unit for current is the ampere (A). One ampere equals the passage of one coulomb of charge per second.

$$\text{Current (amperes, A)} = \frac{\text{electric charge (coulombs, C)}}{\text{time, } t \text{ (seconds, s)}} \tag{19.8}$$

The current passing through an electrochemical cell and the time for which the current flows are easily measured quantities. Therefore, the charge (in coulombs) that passes through a cell can be obtained by multiplying the current (in amperes) by the time (in seconds). Knowing the charge and using the Faraday constant as a conversion factor, we can calculate the number of moles of electrons that passed through an electrochemical cell. In turn, we can use this quantity to calculate the quantities of reactants and products. The following example illustrates this type of calculation.

Faraday Constant The Faraday constant is the charge carried by 1 mol of electrons: 9.648533289×10^4 C/mol e^-.

EXAMPLE 19.11

Using the Faraday Constant

Problem A current of 2.40 A is passed through a solution containing $Cu^{2+}(aq)$ for 30.0 minutes, with copper metal being deposited at the cathode. What mass of copper, in grams, is deposited?

What Do You Know? You know the current passed through the cell and the time over which it was passed.

Strategy The current and time can be used to calculate the amount of charge that passed through the cell. The Faraday constant can then be used to relate this to the amount (moles) of electrons that were used. This in turn can be related to the amount of copper metal deposited and finally to the mass of copper.

SOLUTION

1. Calculate the charge (number of coulombs) passing through the cell in 30.0 minutes.

$$\begin{aligned}\text{Charge (C)} &= \text{current (A)} \times \text{time (s)} \\ &= (2.40\ \text{A})(30.0\ \text{min})(60.0\ \text{s/min}) \\ &= 4.320 \times 10^3\ \text{C}\end{aligned}$$

2. Calculate the number of moles of electrons (i.e., the number of Faradays of electricity).

$$(4.320 \times 10^3\ \text{C})\left(\frac{1\ \text{mol}\ e^-}{96,485\ \text{C}}\right) = 4.477 \times 10^{-2}\ \text{mol}\ e^-$$

3. Calculate the amount of copper and, from this, the mass of copper.

$$\text{mass of copper} = (4.477 \times 10^{-2}\ \text{mol}\ e^-)\left(\frac{1\ \text{mol Cu}}{2\ \text{mol}\ e^-}\right)\left(\frac{63.55\ \text{g Cu}}{1\ \text{mol Cu}}\right) = 1.42\ \text{g}$$

Think about Your Answer The key relationship in this calculation is "current = charge/time." Most situations will involve knowing two of these three quantities from experiment and calculating the third.

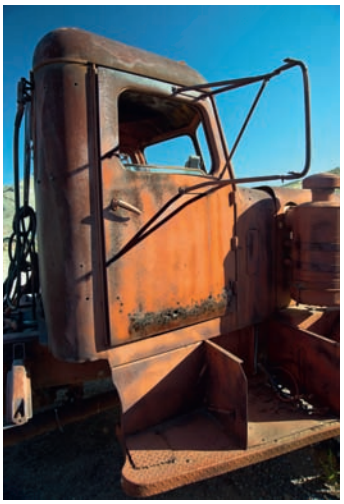
1. Calculate the mass of O_2 produced in the electrolysis of water, using a current of 0.445 A for a period of 45 minutes.
2. In the commercial production of sodium by electrolysis, the cell operates at 7.0 V and a current of 25×10^3 A. What mass of sodium can be produced in 1 hour?

19.9 Corrosion: Redox Reactions in the Environment

Goal for Section 19.9

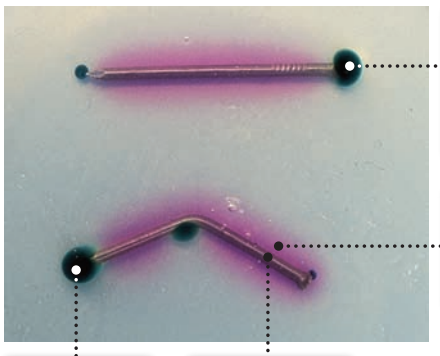


- Understand the oxidation-reduction reactions responsible for the corrosion of metals.

Corrosion: An Electrochemical Process

Corrosion is the deterioration of a substance, usually a metal, in the environment by a product-favored oxidation-reduction reaction. Among common examples are the tarnishing of silver and the conversion of copper (on a roof or drain spout) to an attractive green patina. However, the most obvious example of corrosion occurs with iron, which, depending on conditions, coats the metal with a black deposit of $Fe(OH)_2$ or Fe_3O_4 or reddish deposits of hydrated iron(III) oxide, $Fe_2O_3 \cdot x\ H_2O$ (Figure 19.23).

Let's look at the mechanism of corrosion of iron in more detail. Air and water are reactants in this process; both are sufficiently strong oxidizing agents to oxidize iron, so rusting (oxidation) is expected to be a product-favored reaction.



The corrosion process can be described as a voltaic cell with a cathode and anode, with movement of electrons and ions. First consider the metal surface. Although it may appear smooth and homogeneous, at the microscopic level there are significant irregularities. Stressing and bending during manufacturing lead to regions that are more susceptible to oxidation, as do surface irregularity and the presence of impurities in the metal (Figure 19.24). Now, imagine a piece of iron metal exposed to H_2O and O_2 (Figure 19.25). Sites that are more susceptible to oxidation (anodic sites) become the anode in the cell and the less reactive surfaces of the metal act as a cathode. Electrons can migrate through the metal to the cathodic sites where reduction of H_2O and/or O_2 occurs. The circuit is completed by migration of

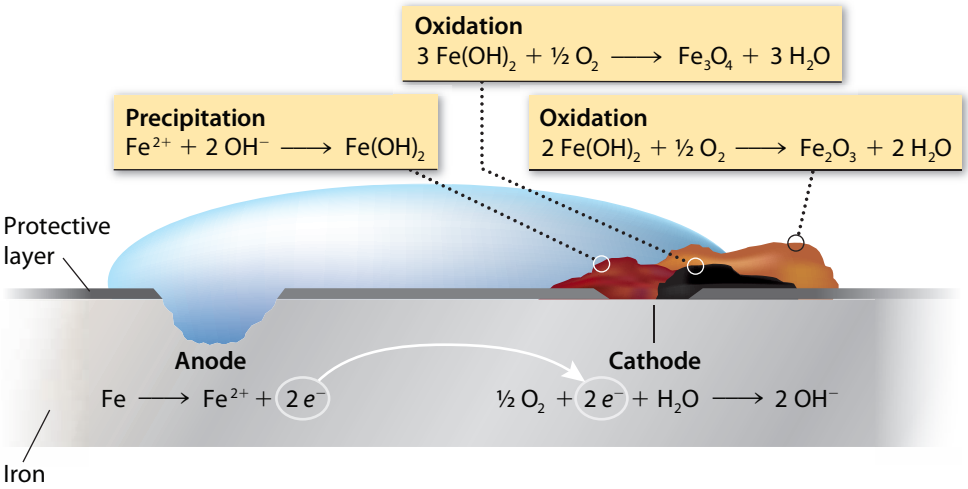

Figure 19.25 Corrosion of iron in the presence of both oxygen and water. Initially, Fe is oxidized by O_2, pitting the anodic region of the surface. Electrons migrate to the cathodic region where water is reduced, forming OH^- ions. $Fe(OH)_2$ precipitates as the Fe^{2+} and OH^- ions interact.

ions within the aqueous solution and formation of the corrosion products on the electrode surface.

The reaction that occurs at the cathode determines the products of corrosion and this in turn is controlled by the rate of the cathodic process. Several cathodic reactions are possible, and the one that is fastest will be determined by acidity and the amount of oxygen present. If little or no oxygen is present—as when a piece of iron is buried in soil such as moist clay— hydronium ions or water are reduced, and $H_2(g)$ and hydroxide ions are the products. Black iron(II) hydroxide is relatively insoluble and will precipitate on the metal surface, inhibiting further formation of $Fe^{2+}(aq)$.

Anode	$Fe(s) \longrightarrow Fe^{2+}(aq) + 2\ e^-$
Cathode	$2\ H_2O(\ell) + 2\ e^- \longrightarrow H_2(g) + 2\ OH^-(aq)$
Precipitation	$Fe^{2+}(aq) + 2\ OH^-(aq) \longrightarrow Fe(OH)_2(s)$
Net reaction	$Fe(s) + 2\ H_2O(\ell) \longrightarrow H_2(g) + Fe(OH)_2(s)$

If both water and O_2 are present, the chemistry of iron corrosion is different, and the corrosion reaction is about 100 times faster than without oxygen.

Anode	$2\ Fe(s) \longrightarrow 2\ Fe^{2+}(aq) + 4\ e^-$
Cathode	$O_2(g) + 2\ H_2O(\ell) + 4\ e^- \longrightarrow 4\ OH^-(aq)$
Precipitation	$2\ Fe^{2+}(aq) + 4\ OH^-(aq) \longrightarrow 2\ Fe(OH)_2(s)$
Net reaction	$2\ Fe(s) + 2\ H_2O(\ell) + O_2(g) \longrightarrow 2\ Fe(OH)_2(s)$

Further oxidation of the $Fe(OH)_2$ leads to the formation of magnetic iron oxide Fe_3O_4 (which can be thought of as a mixed oxide of Fe_2O_3 and FeO) if some additional oxygen is present but not in great excess.

$$6\ Fe(OH)_2(s) + O_2(g) \longrightarrow \underset{\text{green hydrated magnetite}}{2\ Fe_3O_4 \cdot H_2O(s)} + 4\ H_2O(\ell)$$

$$Fe_3O_4 \cdot H_2O(s) \longrightarrow H_2O(\ell) + \underset{\text{black magnetite}}{Fe_3O_4(s)}$$

If the iron object has free access to oxygen and water, as in the open or in flowing water, red-brown iron(III) oxide will form.

$$4\ Fe(OH)_2(s) + O_2(g) \longrightarrow \underset{\text{red-brown}}{2\ Fe_2O_3 \cdot H_2O(s)} + 2\ H_2O(\ell)$$

The overall process of converting Fe(s) to $Fe_2O_3(s)$ is illustrated in Figure 19.25. This is the familiar rust you see on cars and buildings and the substance that colors the water red in some mountain streams or in your home.

Other substances in air and water can assist in corrosion. Chlorides, from sea air or from salt spread on roads in winter, are notorious. Because the chloride ion is relatively small, it can diffuse into and through a protective metal oxide coating. Metal chlorides, which are more soluble than metal oxides or hydroxides, can then form. These chloride salts leach back through the oxide coating, and a path is now open for oxygen and water to further attack the underlying metal. (See Figure 19.2 for an example of aluminum foil corrosion in the presence of aqueous $Cu(NO_3)_2$ and NaCl.) This is the reason that you often see small pits on the surface of a corroded metal.

Protecting Metal Surfaces from Corrosion

There are many methods for stopping a metal object from corroding, some more effective than others, but none totally successful. The general approach is to inhibit either or both the anodic and the cathodic processes. The usual method is **anodic inhibition**, attempting to directly prevent the oxidation reaction by painting the metal surface or by allowing a thin oxide film to form. One method of protecting iron surfaces is by reaction with chromate ion:

$$2\ Fe(s) + 2\ Na_2CrO_4(aq) + 2\ H_2O(\ell) \longrightarrow Fe_2O_3(s) + Cr_2O_3(s) + 4\ NaOH(aq)$$

The iron surface is oxidized by the chromate ion to give iron(III) and chromium(III) oxides. These form a coating impervious to oxygen and water, and further atmospheric oxidation is inhibited.

Another inhibition method of protecting metal surfaces is **phosphating**. The process involves treating the metal with an acidic solution containing dissolved metal phosphates, such as zinc phosphate $[Zn_3(PO_4)_2]$ or iron(III) phosphate ($FePO_4$). Phosphating creates a thin metal phosphate coating on the surface of the metal (Figure 19.26a). These coatings, which adhere well to surfaces and have low solubilities in water, directly provide protection against corrosion. Further protection is provided by one or more layers of paint, which adhere well to the phosphate coating. (*A Closer Look: The Flint, Michigan Water Treatment Problem*, page 929, for an example of using phosphate salts to protect pipes from corrosion in municipal water systems.)

Another way to inhibit metal oxidation is to force the metal to become the cathode, instead of the anode, in an electrochemical cell. This is called **cathodic protection** (Figure 19.26b and 19.26c). A more readily oxidized metal is attached

to the metal in question. An example of this is **galvanized iron**, iron that has been coated with a film of zinc. The $E°$ value for zinc is more negative than the $E°$ value for iron, so the zinc film is oxidized prior to any of the iron. Thus, the zinc coating forms what is called a **sacrificial anode** (*Applying Chemical Principles 19.2—Sacrifice*). Over time, the zinc reacts with oxygen and water to form $Zn(OH)_2(s)$, which adheres to the surface and continues to protect it from corrosion. Further protection is provided as the $Zn(OH)_2(s)$ reacts with carbon dioxide to form an even more protective coating, $ZnCO_3(s)$. Thus, the iron is protected from corrosion even after the zinc anode has been fully oxidized.

APPLYING CHEMICAL PRINCIPLES

19.1 Electric Batteries versus Gasoline

Although a variety of plug-in vehicles are available, most consumers choose to purchase a gasoline-powered vehicle, or a hybrid electric vehicle. Plug-in electric vehicles have some advantages over those with the more common combustion engine. The cost of electricity per mile driven is one-third to one-fourth that of gasoline. The vehicles are environmentally friendly, producing far less greenhouse gases and other pollutants than combustion engine vehicles. In addition, electric engines are quiet and the cars accelerate quickly. Unfortunately, fully electric vehicles suffer from some serious shortcomings. Most of these vehicles have ranges of less than 100 miles between charges, limiting their uses to short urban driving. Furthermore, battery recharging times can be several hours. As battery technology has improved, both driving range and recharging times have improved. Many people believe that it is simply a matter of time before battery technology catches up with combustion technology. Unfortunately, science is not on their side. Simply put, fossil fuels such as gasoline contain far more chemical energy (per unit mass or volume) than any chemical battery.

Lithium ion batteries are a popular choice for electric vehicles. They provide high energy content with a relatively low mass. Lithium is a low-density element, but it is only one of many components in a battery. A battery that contains around 4.0 kg of lithium has a total weight of 300 kg. If all of the lithium can be oxidized when discharging of the battery, 200 MJ (megajoules) of energy are produced. This amounts to 0.67 MJ per kilogram of battery weight. In contrast, the combustion of gasoline produces over 46 MJ/kg. Electric motors are more energy efficient than gasoline-powered motors, but the increase in efficiency is not nearly enough to compensate for the large energy content difference.

ZUMA Press, Inc./Alamy Stock Photo

The chassis of a Tesla Model S electric car showing the battery packs lining the chassis.

Questions:

1. A lithium ion battery produces a voltage of 3.6 V.
   a. What is the energy released for each mole of lithium oxidized during the discharge of the battery?
   b. What is the energy released per kilogram of lithium?
2. Use the energy produced by the combustion of gasoline (46 MJ/kg) to calculate the energy contained in 15 gallons of gasoline. (Assume the density of gasoline is 0.70 kg/L.)
3. What mass of lithium ion batteries would produce the same amount of energy as the combustion of 15 gallons of gasoline?

19.2 Sacrifice!

In the latter half of the 18th century the British sheathed the hulls of their naval fleet with copper to protect the hulls from deterioration. Unfortunately, the copper corroded in sea water, so the navy called upon Sir Humphry Davy to determine the cause of the corrosion and to find a cure. Although Davy initially assumed that impurities in the copper caused the corrosion, he soon learned that high-purity copper corroded faster. Turning his attention to the sea water, Davy determined that the copper is oxidized by oxygen in the sea water. The overall reaction,

$$Cu(s) + \tfrac{1}{2}\, O_2(g) + H_2O(\ell) \rightarrow Cu(OH)_2(s)$$

produces copper(II) hydroxide, which falls from the hull to the sea floor.

Davy, a pioneer in the field of electrochemistry, quickly determined that the corrosion of copper can be prevented by

attaching small pieces of a more easily oxidized metal (such as zinc, tin, or iron) to the copper sheathing. The quantity of the metal may be small in comparison to the copper, but, to be effective, the metal must be positioned below the water line and in direct electrical contact with the copper.

Why is corrosion prevented by attaching a small piece of metal, such as zinc, to the copper? When the two different metals are submerged in seawater they form a galvanic cell. The copper serves as the cathode and the zinc as a "sacrificial" anode. The zinc anode is oxidized instead of the copper. Although the zinc anodes corrode over time and must be replaced, the cost is cheaper than replacing the copper on an entire ship's hull.

In modern fleets, copper-sheathed hulls have given way to steel hulls. Though surface coatings, such as paint, provide some protection against corrosion, sacrificial anodes are still used to protect the steel from corrosion. In addition, sacrificial anodes are now used to protect the steel in underground pipes, as well as in home water heaters, outboard motors, and boilers.

Questions:

1. If an electrically insulating material, such as paint, is placed between the zinc and the copper, the zinc will still corrode in seawater, but it will not protect the copper from corrosion. Explain.
2. Use standard reduction potentials to determine which of the following metals could serve as a sacrificial anode on a copper-sheathed hull. Indicate all correct responses.
   a. tin
   b. silver
   c. iron
   d. nickel
   e. chromium
3. Use standard reduction potentials to determine which of the following metals could serve as a sacrificial anode on a steel hull. Assume the standard reduction potential for steel is the same as that of iron. Indicate all correct responses.
   a. tin
   b. silver
   c. iron
   d. nickel
   e. chromium
4. The overall reaction for the production of $Cu(OH)_2$ from Cu in oxygenated water can be broken into three steps: an oxidation half-reaction, a reduction half-reaction, and a precipitation reaction.
   a. Complete and balance the two missing half-reactions to give the overall equation for the oxidation of copper in seawater.
      Oxidation half-reaction: ?
      Reduction half-reaction: ?
      Precipitation: $Cu^{2+}(aq) + 2\ OH^-(aq) \rightarrow Cu(OH)_2(s)$
      Overall: $Cu(s) + \frac{1}{2}\ O_2(g) + H_2O(\ell) \rightarrow Cu(OH)_2(s)$
   b. Determine the equilibrium constant for the overall reaction at 25 °C using standard reduction potentials and the solubility product constant (K_{sp}) of $Cu(OH)_2(s)$.
5. Assume the following electrochemical cell simulates the galvanic cell formed by copper and zinc in seawater at pH 7.90 and 25 °C.

$$Zn\,|\,Zn(OH)_2(s)\,|\,OH^-(aq)\,||\,Cu(OH)_2(s)\,|\,Cu(s)$$

   a. Write a balanced equation for the reaction that occurs at the cathode.
   b. Write a balanced equation for the reaction that occurs at the anode.
   c. Write a balanced chemical equation for the overall reaction.
   d. Determine the potential (in volts) of the cell.

John C. Kotz

Sacrificial anode attached to a steel-hulled ship. Sacrificial anodes of aluminum or magnesium are also used in home electric hot-water heaters to prevent corrosion in the heater.

CHAPTER GOALS REVISITED

The goals for this chapter are keyed to specific Study Questions to help you organize your review.

19.1 Oxidation–Reduction Reactions

- Balance equations for oxidation-reduction reactions in acidic or basic conditions using the half-reaction approach. 1–6, 57, 58, 92.

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

19.2 Simple Voltaic Cells

- In a voltaic cell, identify the half-reactions occurring at the anode and the cathode, the polarity of the electrodes, the direction of electron flow in the external circuit, and the direction of ion flow in the salt bridge. 7–10, 59.

19.3 Commercial Voltaic Cells

- Understand the chemistry and advantages and disadvantages of dry cells, alkaline batteries, lead storage batteries, lithium batteries, and Ni-cad batteries. 15, 16, 101.
- Understand how fuel cells work, and recognize the difference between batteries and fuel cells. 113.

19.4 Standard Electrochemical Potentials

- Use standard reduction potentials to determine cell voltages for cells under standard conditions. 17–20, 60, 61.
- Use a table of standard reduction potentials to rank the strengths of oxidizing and reducing agents, to predict which substances can reduce or oxidize another species, and to predict whether redox reactions will be product-favored or reactant-favored at equilibrium. 21–28, 63, 64.

19.5 Electrochemical Cells Under Nonstandard Conditions

- Use the Nernst equation to calculate the cell potential under nonstandard conditions. 29–32, 83–87.
- Use cell voltage to determine the pH and other ion concentrations. 33, 34.

19.6 Electrochemistry and Thermodynamics

- Use the relationship between cell voltage ($E°_{cell}$) and free energy ($\Delta_r G°$) and between $E°_{cell}$ and an equilibrium constant for the cell reaction. 35–40, 69–71, 88, 90.

19.7 Electrolysis: Chemical Change Using Electrical Energy

- Describe the chemical processes occurring in an electrolysis. Recognize the factors that determine which substances are oxidized and reduced at the electrodes. 41–46, 82.

19.8 Counting Electrons

- Relate the quantity of a substance oxidized or reduced to the amount of current and the time the current flows. 47–52, 67, 72–74.

19.9 Corrosion: Redox Reactions in the Environment

- Understand the oxidation-reduction reactions responsible for the corrosion of metals. 53–56, 103, 104.

KEY EQUATIONS

Equation 19.1 (page 879) Calculating a standard cell potential, $E°_{cell}$, from standard half-cell potentials.

$$E°_{cell} = E°_{cathode} - E°_{anode}$$

Equation 19.2 (page 885) The Nernst equation, the relationship of the cell potential under nonstandard conditions (E) to that under standard conditions ($E°$). R is the gas constant (8.3144598 J/K · mol); T is the temperature (K); and n is the number of moles of electrons transferred between oxidizing and reducing agents. F is the **Faraday constant** (9.648533289×10^4 C/mol of e^-), and Q is the reaction quotient.

$$E = E° - (RT/nF) \ln Q$$

Equation 19.3 (page 885) Nernst equation (at 298 K).

$$E = E° - \frac{0.0257}{n} \ln Q$$

Equation 19.4 (page 889) The work done (w) by an electrochemical system.

$$w_{max} = nFE$$

Equations 19.5 and 19.6 (page 889) Relationship between free energy change and the cell potential under nonstandard or standard conditions, respectively.

$$\Delta_r G = -nFE \text{ or } \Delta_r G° = -nFE°$$

Equation 19.7 (page 890) Relationship between the equilibrium constant and the standard cell potential for a reaction (at 298 K).

$$\ln K = \frac{nE°}{0.0257}$$

Equation 19.8 (page 898) Relationship between current, electric charge, and time.

$$\text{Current (amperes, A)} = \frac{\text{electric charge (coulombs, C)}}{\text{time, } t \text{ (seconds, s)}}$$

STUDY QUESTIONS

▲ denotes challenging questions. **Blue-numbered questions** have answers in Appendix N and fully worked solutions in the *Student Solutions Manual*.

Practicing Skills

Balancing Equations for Oxidation–Reduction Reactions

(See Section 19.1 and Examples 19.1–19.2.)
When balancing the following redox equations, it may be necessary to add $H^+(aq)$ or $H^+(aq)$ plus H_2O for reactions in acid, and $OH^-(aq)$ or $OH^-(aq)$ plus H_2O for reactions in base.

1. Write balanced equations for the following half-reactions. Specify whether each is an oxidation or reduction.
   (a) $Cr(s) \rightarrow Cr^{3+}(aq)$ (in acid)
   (b) $AsH_3(g) \rightarrow As(s)$ (in acid)
   (c) $VO_3^-(aq) \rightarrow V^{2+}(aq)$ (in acid)
   (d) $Ag(s) \rightarrow Ag_2O(s)$ (in base)

2. Write balanced equations for the following half-reactions. Specify whether each is an oxidation or reduction.
   (a) $H_2O_2(aq) \rightarrow O_2(g)$ (in acid)
   (b) $H_2C_2O_4(aq) \rightarrow CO_2(g)$ (in acid)
   (c) $NO_3^-(aq) \rightarrow NO(g)$ (in acid)
   (d) $MnO_4^-(aq) \rightarrow MnO_2(s)$ (in base)

3. Balance the following redox equations. All occur in acid solution.
   (a) $Ag(s) + NO_3^-(aq) \rightarrow NO_2(g) + Ag^+(aq)$
   (b) $MnO_4^-(aq) + HSO_3^-(aq) \rightarrow Mn^{2+}(aq) + SO_4^{2-}(aq)$
   (c) $Zn(s) + NO_3^-(aq) \rightarrow Zn^{2+}(aq) + N_2O(g)$
   (d) $Cr(s) + NO_3^-(aq) \rightarrow Cr^{3+}(aq) + NO(g)$

4. Balance the following redox equations. All occur in acid solution.

(a) $Sn(s) + H^+(aq) \rightarrow Sn^{2+}(aq) + H_2(g)$

(b) $Cr_2O_7^{2-}(aq) + Fe^{2+}(aq) \rightarrow Cr^{3+}(aq) + Fe^{3+}(aq)$

(c) $MnO_2(s) + Cl^-(aq) \rightarrow Mn^{2+}(aq) + Cl_2(g)$

(d) $CH_2O(aq) + Ag^+(aq) \rightarrow HCO_2H(aq) + Ag(s)$

5. Balance the following redox equations. All occur in basic solution.

(a) $Al(s) + H_2O(\ell) \rightarrow Al(OH)_4^-(aq) + H_2(g)$

(b) $CrO_4^{2-}(aq) + SO_3^{2-}(aq) \rightarrow Cr(OH)_3(s) + SO_4^{2-}(aq)$

(c) $Zn(s) + Cu(OH)_2(s) \rightarrow [Zn(OH)_4]^{2-}(aq) + Cu(s)$

(d) $HS^-(aq) + ClO_3^-(aq) \rightarrow S(s) + Cl^-(aq)$

6. Balance the following redox equations. All occur in basic solution.

(a) $Fe(OH)_3(s) + Cr(s) \rightarrow Cr(OH)_3(s) + Fe(OH)_2(s)$

(b) $NiO_2(s) + Zn(s) \rightarrow Ni(OH)_2(s) + Zn(OH)_2(s)$

(c) $Fe(OH)_2(s) + CrO_4^{2-}(aq) \rightarrow Fe(OH)_3(s) + [Cr(OH)_4]^-(aq)$

(d) $N_2H_4(aq) + Ag_2O(s) \rightarrow N_2(g) + Ag(s)$

Constructing Voltaic Cells

(See Section 19.2 and Examples 19.3 and 19.4.)

7. A voltaic cell is constructed using the reaction of chromium metal and iron(II) ions.

$$2\ Cr(s) + 3\ Fe^{2+}(aq) \rightarrow 2\ Cr^{3+}(aq) + 3\ Fe(s)$$

Complete the following sentences: Electrons in the external circuit flow from the ____ electrode to the ____ electrode. Negative ions move in the salt bridge from the ____ half-cell to the ____ half-cell. The half-reaction at the anode is ____, and that at the cathode is ____.

8. A voltaic cell is constructed using the reaction

$$Mg(s) + 2\ H^+(aq) \rightarrow Mg^{2+}(aq) + H_2(g)$$

(a) Write equations for the oxidation and reduction half-reactions.

(b) Which half-reaction occurs in the anode compartment, and which occurs in the cathode compartment?

(c) Complete the following sentences: Electrons in the external circuit flow from the ____ electrode to the ____ electrode. Negative ions move in the salt bridge from the ____ half-cell to the ____ half-cell. The half-reaction at the anode is ____, and that at the cathode is ____.

9. The half-cells $Fe^{2+}(aq)\,|\,Fe(s)$ and $O_2(g)\,|\,H_2O$ (in acid solution) are linked to create a voltaic cell.

(a) Write equations for the oxidation and reduction half-reactions and for the overall (cell) reaction.

(b) Which half-reaction occurs in the anode compartment, and which occurs in the cathode compartment?

(c) Complete the following sentences: Electrons in the external circuit flow from the ____ electrode to the ____ electrode. Negative ions move in the salt bridge from the ____ half-cell to the ____ half-cell.

10. The half-cells $Sn^{2+}(aq)\,|\,Sn(s)$ and $Cl_2(g)\,|\,Cl^-(aq)$ are linked to create a voltaic cell.

(a) Write equations for the oxidation and reduction half-reactions and for the overall (cell) reaction.

(b) Which half-reaction occurs in the anode compartment, and which occurs in the cathode compartment?

(c) Complete the following sentences: Electrons in the external circuit flow from the ____ electrode to the ____ electrode. Negative ions move in the salt bridge from the ____ half-cell to the ____ half-cell.

11. For each of the following electrochemical cells, write equations for the oxidation and reduction half-reactions and for the overall reaction.

(a) $Cu(s)\,|\,Cu^{2+}(aq)\,||\,Fe^{3+}(aq), Fe^{2+}(aq)\,|\,Pt(s)$

(b) $Pb(s)\,|\,PbSO_4(s)\,|\,SO_4^{2-}(aq)\,||\,Fe^{3+}(aq), Fe^{2+}(aq)\,|\,Pt(s)$

12. For each of the following electrochemical cells, write equations for the oxidation and reduction half-reactions and for the overall reaction.

(a) $Pb(s)\,|\,Pb^{2+}(aq)\,||\,Sn^{4+}(aq), Sn^{2+}(aq)\,|\,C(s)$

(b) $Hg(\ell)\,|\,Hg_2Cl_2(s)\,|\,Cl^-(aq)\,||\,Ag^+(aq)\,|\,Ag(s)$

13. Use cell notation to depict an electrochemical cell based upon the following reaction that is product-favored at equilibrium.

$$Cu(s) + Cl_2(g) \rightarrow 2\ Cl^-(aq) + Cu^{2+}(aq)$$

14. Use cell notation to depict an electrochemical cell based upon the following reaction that is product-favored at equilibrium.

$$Fe^{3+}(aq) + Ag(s) + Cl^-(aq) \rightarrow Fe^{2+}(aq) + AgCl(s)$$

Commercial Electrochemical Cells

(See Section 19.3.)

15. What are the similarities and differences between dry cells, alkaline batteries, and Ni-cad batteries?

16. What reactions occur when a lead storage battery is recharged?

Standard Electrochemical Potentials

(See Section 19.4 and Example 19.5.)

17. Calculate the value of $E°$ for each of the following reactions. Decide whether each is product-favored at equilibrium in the direction written.

(a) $2\ I^-(aq) + Zn^{2+}(aq) \rightarrow I_2(s) + Zn(s)$

(b) $Zn^{2+}(aq) + Ni(s) \rightarrow Zn(s) + Ni^{2+}(aq)$

(c) $2\ Cl^-(aq) + Cu^{2+}(aq) \rightarrow Cu(s) + Cl_2(g)$

(d) $Fe^{2+}(aq) + Ag^+(aq) \rightarrow Fe^{3+}(aq) + Ag(s)$

18. Calculate the value of $E°$ for each of the following reactions. Decide whether each is product-favored at equilibrium in the direction written. [Reaction (d) is carried out in basic solution.]

(a) $Br_2(\ell) + Mg(s) \rightarrow Mg^{2+}(aq) + 2\ Br^-(aq)$

(b) $Zn^{2+}(aq) + Mg(s) \rightarrow Zn(s) + Mg^{2+}(aq)$

(c) $Sn^{2+}(aq) + 2\ Ag^+(aq) \rightarrow Sn^{4+}(aq) + 2\ Ag(s)$

(d) $2\ Zn(s) + O_2(g) + 2\ H_2O(\ell) + 4\ OH^-(aq) \rightarrow 2\ [Zn(OH)_4]^{2-}(aq)$

19. Balance each of the following unbalanced equations; then calculate the standard potential, $E°$, and decide whether each is product-favored at equilibrium as written. (All reactions are carried out in acid solution.)

(a) $Sn^{2+}(aq) + Ag(s) \rightarrow Sn(s) + Ag^+(aq)$

(b) $Al(s) + Sn^{4+}(aq) \rightarrow Sn^{2+}(aq) + Al^{3+}(aq)$

(c) $ClO_3^-(aq) + Ce^{3+}(aq) \rightarrow Cl_2(g) + Ce^{4+}(aq)$

(d) $Cu(s) + NO_3^-(aq) \rightarrow Cu^{2+}(aq) + NO(g)$

20. Balance each of the following unbalanced equations; then calculate the standard potential, $E°$, and decide whether each is product-favored at equilibrium as written. (All reactions are carried out in acid solution.)

(a) $I_2(s) + Br^-(aq) \rightarrow I^-(aq) + Br_2(\ell)$

(b) $Fe^{2+}(aq) + Cu^{2+}(aq) \rightarrow Cu(s) + Fe^{3+}(aq)$

(c) $Fe^{2+}(aq) + Cr_2O_7^{2-}(aq) \rightarrow Fe^{3+}(aq) + Cr^{3+}(aq)$

(d) $MnO_4^-(aq) + HNO_2(aq) \rightarrow Mn^{2+}(aq) + NO_3^-(aq)$

Ranking Oxidizing and Reducing Agents

(See Section 19.4 and Example 19.5. Use a table of standard reduction potentials [Table 19.1 or Appendix M] to answer Study Questions 21–28.)

21. Consider the following half-reactions:

Half-Reaction	$E°$(V)
$Cu^{2+}(aq) + 2\ e^- \rightarrow Cu(s)$	+0.34
$Sn^{2+}(aq) + 2\ e^- \rightarrow Sn(s)$	−0.14
$Fe^{2+}(aq) + 2\ e^- \rightarrow Fe(s)$	−0.44
$Zn^{2+}(aq) + 2\ e^- \rightarrow Zn(s)$	−0.76
$Al^{3+}(aq) + 3\ e^- \rightarrow Al(s)$	−1.66

(a) Based on $E°$ values, which metal is the most easily oxidized?

(b) Which metals on this list are capable of reducing $Fe^{2+}(aq)$ to $Fe(s)$?

(c) Write a balanced chemical equation for the reaction of $Fe^{2+}(aq)$ with $Sn(s)$. Is this reaction product-favored or reactant-favored at equilibrium?

(d) Write a balanced chemical equation for the reaction of $Zn^{2+}(aq)$ with $Sn(s)$. Is this reaction product-favored or reactant-favored at equilibrium?

22. Consider the following half-reactions:

Half-Reaction	$E°$(V)
$MnO_4^-(aq) + 8\ H^+(aq) + 5\ e^- \rightarrow Mn^{2+}(aq) + 4\ H_2O(\ell)$	+1.51
$BrO_3^-(aq) + 6\ H^+(aq) + 6\ e^- \rightarrow Br^-(aq) + 3\ H_2O(\ell)$	+1.47
$Cr_2O_7^{2-}(aq) + 14\ H^+(aq) + 6\ e^- \rightarrow 2\ Cr^{3+}(aq) + 7\ H_2O(\ell)$	+1.33
$NO_3^-(aq) + 4\ H^+(aq) + 3\ e^- \rightarrow NO(g) + 2\ H_2O(\ell)$	+0.96
$SO_4^{2-}(aq) + 4\ H^+(aq) + 2\ e^- \rightarrow SO_2(g) + 2\ H_2O(\ell)$	+0.20

(a) Choosing from among the reactants in these half-reactions, identify the strongest and weakest oxidizing agents.

(b) Which of the oxidizing agents listed is (are) capable of oxidizing $Br^-(aq)$ to $BrO_3^-(aq)$ (in acid solution)?

(c) Write a balanced chemical equation for the reaction of $Cr_2O_7^{2-}(aq)$ with $SO_2(g)$ in acid solution. Is this reaction product-favored or reactant-favored at equilibrium?

(d) Write a balanced chemical equation for the reaction of $Cr_2O_7^{2-}(aq)$ with $Mn^{2+}(aq)$. Is this reaction product-favored or reactant-favored at equilibrium?

23. Which of the following elements is the best reducing agent under standard conditions?
(a) Cu (d) Ag
(b) Zn (e) Cr
(c) Fe

24. From the following list, identify those elements that are easier to oxidize than $H_2(g)$.
(a) Cu (d) Ag
(b) Zn (e) Cr
(c) Fe

25. Which of the following ions is most easily reduced?
(a) $Cu^{2+}(aq)$ (d) $Ag^{+}(aq)$
(b) $Zn^{2+}(aq)$ (e) $Al^{3+}(aq)$
(c) $Fe^{2+}(aq)$

26. From the following list, identify the ions that are more easily reduced than $H^{+}(aq)$.
(a) $Cu^{2+}(aq)$ (d) $Ag^{+}(aq)$
(b) $Zn^{2+}(aq)$ (e) $Al^{3+}(aq)$
(c) $Fe^{2+}(aq)$

27. (a) Which halogen is most easily reduced in acidic solution: F_2, Cl_2, Br_2, or I_2?
(b) Identify the halogens that are better oxidizing agents in acidic solution than $MnO_2(s)$.

28. (a) Which ion is most easily oxidized to the elemental halogen in acidic solution: F^-, Cl^-, Br^-, or I^-?
(b) Identify the halide ions that are more easily oxidized in acidic solution than $H_2O(\ell)$.

Electrochemical Cells Under Nonstandard Conditions

(See Section 19.5 and Examples 19.6 and 19.7.)

29. Calculate the potential delivered by a voltaic cell using the following reaction if all dissolved species are 2.5×10^{-2} M and the pressure of H_2 is 1.0 bar.

$$Zn(s) + 2\ H_2O(\ell) + 2\ OH^-(aq) \rightarrow [Zn(OH)_4]^{2-}(aq) + H_2(g)$$

30. Calculate the potential developed by a voltaic cell using the following reaction if all dissolved species are 0.015 M.

$$2\ Fe^{2+}(aq) + H_2O_2(aq) + 2\ H^+(aq) \rightarrow 2\ Fe^{3+}(aq) + 2\ H_2O(\ell)$$

31. One half-cell in a voltaic cell is constructed from a silver wire electrode in a 0.25 M solution of $AgNO_3$. The other half-cell consists of a zinc electrode in a 0.010 M solution of $Zn(NO_3)_2$. Calculate the cell potential.

32. One half-cell in a voltaic cell is constructed from a copper wire electrode in a 4.8×10^{-3} M solution of $Cu(NO_3)_2$. The other half-cell consists of a zinc electrode in a 0.40 M solution of $Zn(NO_3)_2$. Calculate the cell potential.

33. One half-cell in a voltaic cell is constructed from a silver wire electrode in a $AgNO_3$ solution of unknown concentration. The other half-cell consists of a zinc electrode in a 1.0 M solution of $Zn(NO_3)_2$. A potential of 1.48 V is measured for this cell. Use this information to calculate the concentration of $Ag^+(aq)$.

34. One half-cell in a voltaic cell is constructed from an iron electrode in an $Fe(NO_3)_2$ solution of unknown concentration. The other half-cell is a standard hydrogen electrode. A potential of 0.49 V is measured for this cell. Use this information to calculate the concentration of $Fe^{2+}(aq)$.

Electrochemistry, Thermodynamics, and Equilibrium

(See Section 19.6 and Examples 19.8 and 19.9.)

35. Calculate $\Delta_r G°$ and the equilibrium constant for the following reactions.
(a) $2\ Fe^{3+}(aq) + 2\ I^-(aq) \rightleftharpoons 2\ Fe^{2+}(aq) + I_2(aq)$
(b) $I_2(aq) + 2\ Br^-(aq) \rightleftharpoons 2\ I^-(aq) + Br_2(\ell)$

36. Calculate $\Delta_r G°$ and the equilibrium constant for the following reactions.
(a) $Zn^{2+}(aq) + Ni(s) \rightleftharpoons Zn(s) + Ni^{2+}(aq)$
(b) $Cu(s) + 2\ Ag^+(aq) \rightleftharpoons Cu^{2+}(aq) + 2\ Ag(s)$

37. Use standard reduction potentials (Appendix M) for the half-reactions $AgBr(s) + e^- \rightarrow Ag(s) + Br^-(aq)$ and $Ag^+(aq) + e^- \rightarrow Ag(s)$ to calculate the value of K_{sp} for AgBr.

38. Use the standard reduction potentials (Appendix M) for the half-reactions $Hg_2Cl_2(s) + 2\ e^- \rightarrow 2\ Hg(\ell) + 2\ Cl^-(aq)$ and $Hg_2^{2+}(aq) + 2\ e^- \rightarrow 2\ Hg(\ell)$ to calculate the value of K_{sp} for Hg_2Cl_2.

39. Use the standard reduction potentials (Appendix M) for the half-reactions $[AuCl_4]^-(aq) + 3\ e^- \rightarrow Au(s) + 4\ Cl^-(aq)$ and $Au^{3+}(aq) + 3\ e^- \rightarrow Au(s)$ to calculate the value of $K_{formation}$ for the complex ion $[AuCl_4]^-(aq)$.

40. Use the standard reduction potentials (Appendix M) for the half-reactions $[Zn(OH)_4]^{2-}(aq) + 2\ e^- \rightarrow Zn\ (s) + 4\ OH^-(aq)$ and $Zn^{2+}(aq) + 2\ e^- \rightarrow Zn(s)$ to calculate the value of $K_{formation}$ for the complex ion $[Zn(OH)_4]^{2-}$.

Electrolysis

(See Section 19.7 and Example 19.10.)

41. Diagram the apparatus used to electrolyze molten NaCl. Identify the anode and the cathode. Trace the movement of electrons through the external circuit and the movement of ions in the electrolysis cell.

42. Diagram the apparatus used to electrolyze aqueous $CuCl_2$. Identify the reaction products, the anode, and the cathode. Trace the movement of electrons through the external circuit and the movement of ions in the electrolysis cell.

43. Which product, O_2 or F_2, is more likely to form at the anode in the electrolysis of an aqueous solution of KF? Explain your reasoning.

44. Which product, Ca or H_2, is more likely to form at the cathode in the electrolysis of $CaCl_2$? Explain your reasoning.

45. An aqueous solution of KBr is placed in a beaker with two inert platinum electrodes. When the cell is attached to an external source of electrical energy, electrolysis occurs.

(a) Hydrogen gas and hydroxide ion form at the cathode. Write an equation for the half-reaction that occurs at this electrode.

(b) Bromine is the primary product at the anode. Write an equation for its formation.

46. An aqueous solution of Na_2S is placed in a beaker with two inert platinum electrodes. When the cell is attached to an external battery, electrolysis occurs.

(a) Hydrogen gas and hydroxide ion form at the cathode. Write an equation for the half-reaction that occurs at this electrode.

(b) Sulfur is the primary product at the anode. Write an equation for its formation.

Counting Electrons

(See Section 19.8 and Example 19.11.)

47. In the electrolysis of a solution containing $Ni^{2+}(aq)$, metallic Ni(s) deposits on the cathode. Using a current of 0.150 A for 12.2 minutes, what mass of nickel will form?

48. In the electrolysis of a solution containing $Ag^{+}(aq)$, metallic Ag(s) deposits on the cathode. Using a current of 1.12 A for 2.40 hours, what mass of silver forms?

49. Electrolysis of a solution of $CuSO_4(aq)$ to give copper metal is carried out using a current of 0.66 A. How long should electrolysis continue to produce 0.50 g of copper?

50. Electrolysis of a solution of $Zn(NO_3)_2(aq)$ to give zinc metal is carried out using a current of 2.12 A. How long should electrolysis continue in order to prepare 2.5 g of zinc?

51. A voltaic cell can be built using the reaction between Al metal and O_2 from the air. If the Al anode of this cell consists of 84 g of aluminum, how many hours can the cell produce 1.0 A of electricity, assuming an unlimited supply of O_2?

52. Assume the specifications of a Ni-Cd voltaic cell include delivery of 0.25 A of current for 1.00 hour. What is the minimum mass of the cadmium that must be used to make the anode in this cell?

Corrosion: Redox Reactions in the Environment

(See Section 19.9.)

53. Use $E°$ values to predict which of the following metals, if coated on iron, will provide cathodic protection against corrosion to iron.

(a) Cu

(b) Mg

(c) Ni

(d) Sn

54. Use $E°$ values to predict which of the following metals, if coated on nickel, will provide cathodic protection against corrosion to nickel.

(a) Cu

(b) Mg

(c) Zn

(d) Cr

55. In the presence of oxygen and water, two half-reactions responsible for the corrosion of iron are

$$Fe(s) \rightarrow Fe^{2+}(aq) + 2\ e^-$$

$$O_2(g) + 2\ H_2O(\ell) + 4\ e^- \rightarrow 4\ OH^-(aq)$$

Calculate the the standard potential, $E°$, and decide whether the reaction is product-favored at equilibrium. Will decreasing the pH make the reaction less thermodynamically product-favored at equilibrium?

56. In the presence of oxgyen and acid, two half-reactions responsible for the corrosion of iron are

$$Fe(s) \rightarrow Fe^{2+}(aq) + 2\ e^-$$

$$O_2(g) + 4\ H^+(aq) + 4\ e^- \rightarrow 2\ H_2O(\ell)$$

Calculate the the standard potential, $E°$, and decide whether the reaction is product-favored at equilibrium. Will decreasing the pH make the reaction less thermodynamically product-favored at equilibrium?

General Questions

These questions are not designated as to type or location in the chapter. They may combine several concepts.

57. Write balanced equations for the following half-reactions.

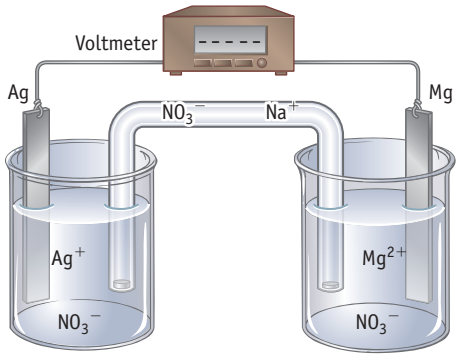
(a) $UO_2^+(aq) \rightarrow U^{4+}(aq)$ (acid solution)

(b) $ClO_3^-(aq) \rightarrow Cl^-(aq)$ (acid solution)

(c) $N_2H_4(aq) \rightarrow N_2(g)$ (basic solution)

(d) $ClO^-(aq) \rightarrow Cl^-(aq)$ (basic solution)

58. Balance the following equations.



(a) $Zn(s) + VO^{2+}(aq) \rightarrow Zn^{2+}(aq) + V^{3+}(aq)$ (acid solution)

(b) $Zn(s) + VO_3^-(aq) \rightarrow V^{2+}(aq) + Zn^{2+}(aq)$ (acid solution)

(c) $Zn(s) + ClO^-(aq) \rightarrow Zn(OH)_2(s) + Cl^-(aq)$ (basic solution)

(d) $ClO^-(aq) + [Cr(OH)_4]^-(aq) \rightarrow Cl^-(aq) + CrO_4^{2-}(aq)$ (basic solution)

59. Magnesium metal is oxidized, and silver ions are reduced in a voltaic cell using $Mg^{2+}(aq, 1\ M)\,|\,Mg$ and $Ag^+(aq, 1\ M)\,|\,Ag$ half-cells.

(a) Label each part of the cell.

(b) Write equations for the half-reactions occurring at the anode and the cathode, and write an equation for the net reaction in the cell.

(c) Trace the movement of electrons in the external circuit. Assuming the salt bridge contains $NaNO_3$, trace the movement of the Na^+ and NO_3^- ions in the salt bridge that occurs when a voltaic cell produces current. Why is a salt bridge required in a cell?

60. You want to set up a series of voltaic cells with specific cell potentials. A $Zn^{2+}(aq, 1.0\ M)\,|\,Zn(s)$ half-cell is in one compartment. Identify several half-cells that you could use so that the cell potential will be close to (a) 1.1 V and (b) 0.50 V. Consider cells in which the zinc cell can be either the cathode or the anode.

61. You want to set up a series of voltaic cells with specific cell potentials. The $Ag^+(aq, 1.0\ M)\,|\,Ag(s)$ half-cell is one of the compartments. Identify several half-cells that you could use so that the cell potential will be close to (a) 1.7 V and (b) 0.50 V. Consider cells in which the silver cell can be either the cathode or the anode.

62. Which of the following reactions is (are) product-favored at equilibrium?

(a) $Zn(s) + I_2(s) \rightarrow Zn^{2+}(aq) + 2\ I^-(aq)$

(b) $2\ Cl^-(aq) + I_2(s) \rightarrow Cl_2(g) + 2\ I^-(aq)$

(c) $2\ Na^+(aq) + 2\ Cl^-(aq) \rightarrow 2\ Na(s) + Cl_2(g)$

(d) $2\ K(s) + 2\ H_2O(\ell) \rightarrow 2\ K^+(aq) + H_2(g) + 2\ OH^-(aq)$

63. In the table of standard reduction potentials, locate the half-reactions for the reductions of the following metal ions to the metal: $Sn^{2+}(aq)$, $Au^+(aq)$, $Zn^{2+}(aq)$, $Co^{2+}(aq)$, $Ag^+(aq)$, $Cu^{2+}(aq)$. Among the metal ions and metals that make up these half-reactions:

(a) Which metal ion is the weakest oxidizing agent?

(b) Which metal ion is the strongest oxidizing agent?

(c) Which metal is the strongest reducing agent?

(d) Which metal is the weakest reducing agent?

(e) Will Sn(s) reduce $Cu^{2+}(aq)$ to Cu(s)?

(f) Will Ag(s) reduce $Co^{2+}(aq)$ to Co(s)?

(g) Which metal ions on the list can be reduced by Sn(s)?

(h) What metals can be oxidized by $Ag^+(aq)$?

64. ▲ In the table of standard reduction potentials, locate the half-reactions for the reductions of the following nonmetals: F_2, Cl_2, Br_2, I_2 (reduction to halide ions), and O_2, S, Se (reduction to H_2X in aqueous acid). Among the elements, ions, and compounds that make up these half-reactions:

(a) Which element is the weakest oxidizing agent?

(b) Which ion or H_2X is the weakest reducing agent?

(c) Which of the elements listed is (are) capable of oxidizing H_2O to O_2?

(d) Which of these elements listed is (are) capable of oxidizing H_2S to S?

(e) Is O_2 capable of oxidizing I^- to I_2, in acid solution?

(f) Is S capable of oxidizing I^- to I_2?

(g) Is the reaction $H_2S(aq) + Se(s) \rightarrow H_2Se(aq) + S(s)$ product-favored at equilibrium?

(h) Is the reaction $H_2S(aq) + I_2(s) \rightarrow 2\ H^+(aq) + 2\ I^-(aq) + S(s)$ product-favored at equilibrium?

65. Four voltaic cells are set up. In each, one half-cell contains a standard hydrogen electrode. The second half-cell is one of the following:

(i) $Cr^{3+}(aq, 1.0\ M)\,|\,Cr(s)$
(ii) $Fe^{2+}(aq, 1.0\ M)\,|\,Fe(s)$
(iii) $Cu^{2+}(aq, 1.0\ M)\,|\,Cu(s)$
(iv) $Mg^{2+}(aq, 1.0\ M)\,|\,Mg(s)$

(a) In which of the voltaic cells does the hydrogen electrode serve as the cathode?

(b) Which voltaic cell produces the highest potential? Which produces the lowest potential?

66. The following half-cells are available:

(i) $Ag^{+}(aq, 1.0\ M)\,|\,Ag(s)$
(ii) $Zn^{2+}(aq, 1.0\ M)\,|\,Zn(s)$
(iii) $Cu^{2+}(aq, 1.0\ M)\,|\,Cu(s)$
(iv) $Co^{2+}(aq, 1.0\ M)\,|\,Co(s)$

Linking any two half-cells makes a voltaic cell. Given four different half-cells, six voltaic cells are possible. These are labeled, for simplicity, Ag-Zn, Ag-Cu, Ag-Co, Zn-Cu, Zn-Co, and Cu-Co.

(a) In which of the voltaic cells does the copper electrode serve as the cathode? In which of the voltaic cells does the cobalt electrode serve as the anode?

(b) Which combination of half-cells generates the highest potential? Which combination generates the lowest potential?

67. The reaction occurring in the cell in which Al_2O_3 and aluminum salts are electrolyzed is $Al^{3+}(aq) + 3\ e^- \rightarrow Al(s)$. If the electrolysis cell operates at 5.0 V and 1.0×10^5 A, what mass of aluminum metal can be produced in a 24-hour day?

68. ▲ A cell is constructed using the following half-reactions:

$$Ag^{+}(aq) + e^- \rightarrow Ag(s)$$

$$Ag_2SO_4(s) + 2\ e^- \rightarrow 2\ Ag(s) + SO_4^{2-}(aq) \qquad E^\circ = 0.653\ V$$

(a) What reactions should be observed at the anode and cathode?

(b) Calculate the solubility product constant, K_{sp}, for Ag_2SO_4.

69. ▲ A potential of 0.142 V is recorded (under standard conditions) for a voltaic cell constructed using the following half reactions:

Cathode: $Pb^{2+}(aq) + 2\ e^- \rightarrow Pb(s)$

Anode: $PbCl_2(s) + 2\ e^- \rightarrow Pb(s) + 2\ Cl^-(aq)$

Net: $Pb^{2+}(aq) + 2\ Cl^-(aq) \rightarrow PbCl_2(s)$

(a) What is the standard reduction potential for the anode reaction?

(b) Calculate the solubility product, K_{sp}, for $PbCl_2$.

70. What is the value of E° for the following half-reaction?

$$Ag_2CrO_4(s) + 2\ e^- \rightarrow 2\ Ag(s) + CrO_4^{2-}(aq)$$

71. The standard potential, E°, for the reaction of $Zn(s)$ and $Cl_2(g)$ is +2.12 V. What is the standard free energy change, $\Delta_r G^\circ$, for the reaction?

72. ▲ An electrolysis cell for aluminum production operates at 5.0 V and a current of 1.0×10^5 A. Calculate the number of kilowatt-hours of energy required to produce 1 metric ton (1.0×10^3 kg) of aluminum. (1 kWh = 3.6×10^6 J and 1 J = 1 C · V)

73. ▲ Electrolysis of molten NaCl is done in cells operating at 7.0 V and 4.0×10^4 A. What mass of Na(s) and $Cl_2(g)$ can be produced in 1 day in such a cell? What is the energy consumption in kilowatt-hours? (1 kWh = 3.6×10^6 J and 1 J = 1 C · V)

74. ▲ A current of 0.0100 A is passed through a solution of rhodium sulfate, causing reduction of the metal ion to the metal. After 3.00 hours, 0.038 g of Rh has been deposited. What is the charge on the rhodium ion, Rh^{n+}? What is the formula for rhodium sulfate?

75. ▲ A current of 0.44 A is passed through a solution of ruthenium nitrate causing reduction of the metal ion to the metal. After 25.0 minutes, 0.345 g of Ru has been deposited. What is the charge on the ruthenium ion, Ru^{n+}? What is the formula for ruthenium nitrate?

76. The total charge that can be delivered by a large dry cell battery before its voltage drops too low is usually about 35 amp-hours. (One amp-hour is the charge that passes through a circuit when 1 A flows for 1 hour.) What mass of Zn is consumed when 35 amp-hours are drawn from the cell?

77. Chlorine gas is obtained commercially by electrolysis of brine (a concentrated aqueous solution of NaCl). If the electrolysis cells operate at 4.6 V and 3.0×10^5 A, what mass of chlorine can be produced in a 24-hour day?

78. Write equations for the half-reactions that occur at the anode and cathode in the electrolysis of *molten* KBr. What are the products formed at the anode and cathode in the electrolysis of *aqueous* KBr?

79. The products formed in the electrolysis of aqueous $CuSO_4$ are Cu(s) and $O_2(g)$. Write equations for the anode and cathode reactions.

80. Predict the products formed in the electrolysis of an aqueous solution of $CdSO_4$.

Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

81. In the electrolysis of $HNO_3(aq)$, hydrogen is produced at the cathode. According to a table of reduction potentials, $NO_3^-(aq)$ is easier to reduce than $H^+(aq)$. Suggest a possible reason why H_2 formed rather than NO. What is the product formed at the anode? Write an equation for the anode reaction.

82. The metallurgy of aluminum involves electrolysis of Al_2O_3 dissolved in molten cryolite (Na_3AlF_6) at about 950 °C. Aluminum metal is produced at the cathode. Predict the anode product and write equations for the reactions occurring at both electrodes.

83. Two half-cells, $Pt\,|\,Fe^{3+}(aq, 0.50\ M), Fe^{2+}(aq, 1.0 \times 10^{-5}\ M)$ and $Hg^{2+}(aq, 0.020\ M)\,|\,Hg$, are constructed and then linked together to form a voltaic cell. Which electrode is the anode? What will be the potential of the voltaic cell at 298 K?

84. A voltaic cell is set up utilizing the reaction

$$Cu(s) + 2\ Ag^+(aq) \rightarrow Cu^{2+}(aq) + 2\ Ag(s)$$

$$Cu(s)\,|\,Cu^{2+}(aq, 1.0\ M)\,||\,Ag^+(aq, 0.001\ M)\,|\,Ag(s)$$

Under standard conditions, the expected potential is 0.45 V. Predict whether the potential for the voltaic cell will be higher, lower, or the same as the standard potential. Verify your prediction by calculating the new cell potential.

85. Calculate the cell potential for the following cell:

$$Pt\,|\,H_2(P = 1\ bar)\,|\,H^+(aq, 1.0\ M)\,||\,Fe^{3+}(aq, 1.0M), Fe^{2+}(aq, 1.0M)\,|\,Pt$$

Will this reaction be more or less favorable at lower pH? To determine this, calculate the cell potential for a reaction in which $[H^+(aq)]$ is 1.0×10^{-7} M.

86. A voltaic cell set up utilizing the reaction

$$Cu(s) + 2\ Ag^+(aq) \rightarrow Cu^{2+}(aq) + 2\ Ag(s)$$

has a cell potential of 0.45 V at 298 K. Describe how the potential of this cell will change as the cell is discharged. At what point does the cell potential reach a constant value? Explain your answer.

87. Two $Ag^+(aq)\,|\,Ag(s)$ half-cells are constructed. The first has $[Ag^+] = 1.0$ M, the second has $[Ag^+] = 1.0 \times 10^{-5}$ M. When linked together with a salt bridge and external circuit, a cell potential is observed. (This kind of voltaic cell is referred to as a *concentration cell.*)

(a) Draw a picture of this cell, labeling all components. Indicate the cathode and the anode, and indicate in which direction electrons flow in the external circuit.

(b) Calculate the cell potential at 298 K.

88. Calculate equilibrium constants for the following reactions at 298 K. Indicate whether the equilibrium as written is reactant- or product-favored at equilibrium.

(a) $Co(s) + Ni^{2+}(aq) \rightleftharpoons Co^{2+}(aq) + Ni(s)$

(b) $Fe^{3+}(aq) + Cr^{2+}(aq) \rightleftharpoons Cr^{3+}(aq) + Fe^{2+}(aq)$

89. Calculate equilibrium constants for the following reactions at 298 K. Indicate whether the equilibrium as written is reactant- or product-favored at equilibrium.

(a) $2\ Cl^-(aq) + Br_2(\ell) \rightleftharpoons Cl_2(aq) + 2\ Br^-(aq)$

(b) $Fe^{2+}(aq) + Ag^+(aq) \rightleftharpoons Fe^{3+}(aq) + Ag(s)$

90. Use the table of standard reduction potentials (Appendix M) to calculate $\Delta_r G°$ for the following reactions at 298 K.

(a) $ClO_3^-(aq) + 5\ Cl^-(aq) + 6\ H^+(aq) \rightarrow 3\ Cl_2(g) + 3\ H_2O(\ell)$

(b) $AgCl(s) + Br^-(aq) \rightarrow AgBr(s) + Cl^-(aq)$

91. Use the table of standard reduction potentials (Appendix M) to calculate $\Delta_r G°$ for the following reactions at 298 K.

(a) $3\ Cu(s) + 2\ NO_3^-(aq) + 8\ H^+(aq) \rightarrow 3\ Cu^{2+}(aq) + 2\ NO(g) + 4\ H_2O(\ell)$

(b) $H_2O_2(aq) + 2\ Cl^-(aq) + 2\ H^+(aq) \rightarrow Cl_2(g) + 2\ H_2O(\ell)$

92. ▲ Write balanced equations for the following reduction half-reactions involving organic compounds.

(a) $HCO_2H \rightarrow CH_2O$ (acid solution)

(b) $C_6H_5CO_2H \rightarrow C_6H_5CH_3$ (acid solution)

(c) $CH_3CH_2CHO \rightarrow CH_3CH_2CH_2OH$ (acid solution)

(d) $CH_3OH \rightarrow CH_4$ (acid solution)

93. ▲ Balance the following equations involving organic compounds.

(a) $Ag^+(aq) + C_6H_5CHO(aq) \rightarrow Ag(s) + C_6H_5CO_2H(aq)$ (acid solution)

(b) $CH_3CH_2OH + Cr_2O_7^{2-}(aq) \rightarrow CH_3CO_2H(aq) + Cr^{3+}(aq)$ (acid solution)

94. A voltaic cell is constructed in which one half-cell consists of a silver wire in an aqueous solution of $AgNO_3$. The other half-cell consists of an inert platinum wire in an aqueous solution containing $Fe^{2+}(aq)$ and $Fe^{3+}(aq)$.

(a) Calculate the cell potential, assuming standard conditions.

(b) Write the net ionic equation for the reaction occurring in the cell.

(c) Which electrode is the anode and which is the cathode?

(d) If $[Ag^+]$ is 0.10 M, and $[Fe^{2+}]$ and $[Fe^{3+}]$ are both 1.0 M, what is the cell potential? Is the net cell reaction still that used in part (a)? If not, what is the net reaction under the new conditions?

95. An expensive but lighter alternative to the lead storage battery is the silver-zinc battery.

$$Ag_2O(s) + Zn(s) + H_2O(\ell) \rightarrow Zn(OH)_2(s) + 2\ Ag(s)$$

The electrolyte is 40% KOH, and silver–silver oxide electrodes are separated from zinc–zinc hydroxide electrodes by a plastic sheet that is permeable to hydroxide ions. Under normal operating conditions, the battery has a potential of 1.59 V.

(a) How much energy can be produced per gram of reactants in the silver-zinc battery? Assume the battery produces a current of 0.10 A.

(b) How much energy can be produced per gram of reactants in the standard lead storage battery? Assume the battery produces a current of 0.10 A at 2.0 V.

(c) Which battery (silver-zinc or lead storage) produces the greater energy per gram of reactants?

96. The specifications for a lead storage battery include delivery of a steady 1.5 A of current for 15 hours.

(a) What is the minimum mass of lead that will be used in the anode?

(b) What mass of PbO_2 must be used in the cathode?

(c) Assume that the volume of the battery is 0.50 L. What is the minimum molarity of H_2SO_4 necessary?

97. Manganese may play an important role in chemical cycles in the oceans. Two reactions involving manganese (in acid solution) are the reduction of nitrate ions (to NO) with Mn^{2+} ions and the oxidation of ammonium ions (to N_2) with MnO_2.

(a) Write balanced chemical equations for these reactions (in acid solution).

(b) Calculate $E°_{cell}$ for the reactions. (One half-reaction potential you need is for the reduction of N_2 to NH_4^+, $E° = -0.272$ V.)

98. ▲ You want to use electrolysis to plate a cylindrical object (radius = 2.50 and length = 20.00 cm) with a coating of nickel metal, 4.0 mm thick. You place the object in a bath containing a salt (Na_2SO_4). One electrode is impure nickel, and the other is the object to be plated. The electrolyzing potential is 2.50 V.

(a) Which is the anode and which is the cathode in the experiment? What half-reaction occurs at each electrode?

(b) Calculate the number of kilowatt-hours (kWh) of energy required to carry out the electrolysis. (1 kWh = 3.6×10^6 J and 1 J = 1 C × 1 V)

99. ▲ Iron(II) ion undergoes a disproportionation reaction to give Fe(s) and the iron(III) ion. That is, iron(II) ion is both oxidized and reduced within the same reaction.

$$3\ Fe^{2+}(aq) \rightleftharpoons Fe(s) + 2\ Fe^{3+}(aq)$$

(a) What two half-reactions make up the disproportionation reaction?

(b) Use the values of the standard reduction potentials for the two half-reactions in part (a) to determine whether this disproportionation reaction is product-favored at equilibrium.

(c) What is the equilibrium constant for this reaction?

100. ▲ Copper(I) ion disproportionates to copper metal and copper(II) ion. (See Study Question 99.)

$$2\ Cu^+(aq) \rightleftharpoons Cu(s) + Cu^{2+}(aq)$$

(a) What two half-reactions make up the disproportionation reaction?

(b) Use values of the standard reduction potentials for the two half-reactions in part (a) to determine whether this disproportionation reaction is product-favored at equilibrium.

(c) What is the equilibrium constant for this reaction? If you have a solution that initially contains 0.10 mol of Cu^+ in 1.0 L of water, what are the concentrations of Cu^+ and Cu^{2+} at equilibrium?

101. The simplest way to write the reaction for discharge in a lithium-ion battery is

$$Li(\text{on carbon})(s) + CoO_2(s) \rightarrow 6\ C(s) + LiCoO_2(s)$$

(a) What are the oxidation numbers for cobalt in the two substances in the battery?

(b) In such a battery, what reaction occurs at the cathode? At the anode?

(c) An electrolyte is needed for ion conduction within the battery. From what you know about lithium chemistry, can the electrolyte in the battery be dissolved in water?

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

102. A lithium-ion camera battery is rated at 7500 mAh. That is, it can deliver 7500 milliamps (mA) or 7.5 amps of steady current for an hour.

(a) How many moles of electrons can the battery deliver in one hour?

(b) What mass of lithium is oxidized under these conditions in 1.0 hour?

103. Can either sodium or potassium metal be used as a sacrificial anode to protect the iron hull of a ship?

104. Galvanized steel pipes are used in the plumbing of many older homes. When copper plumbing is added to a system consisting of galvanized steel pipes it is necessary to place an insulator between the copper and the steel to avoid corrosion. Write a balanced oxidation-reduction equation for the reaction that occurs if the pipes are directly connected. What is the standard potential between the metals?

In the Laboratory

105. Consider an electrochemical cell based on the half-reactions $Ni^{2+}(aq) + 2\ e^- \rightarrow Ni(s)$ and $Cd^{2+}(aq) + 2\ e^- \rightarrow Cd(s)$.

(a) Diagram the cell, and label each of the components (including the anode, cathode, and salt bridge).

(b) Use the equations for the half-reactions to write a balanced, net ionic equation for the overall cell reaction.

(c) What is the polarity of each electrode?

(d) What is the value of $E°_{cell}$?

(e) In which direction do electrons flow in the external circuit?

(f) Assume that a salt bridge containing $NaNO_3$ connects the two half-cells. In which direction do the $Na^+(aq)$ ions move? In which direction do the $NO_3^-(aq)$ ions move?

(g) Calculate the equilibrium constant for the reaction.

(h) If the concentration of Cd^{2+} is reduced to 0.010 M and $[Ni^{2+}] = 1.0$ M, what is the value of E_{cell}? Is the net reaction still the reaction given in part (b)?

(i) If 0.050 A is drawn from the battery, how long can it last if you begin with 1.0 L of each of the solutions and each was initially 1.0 M in dissolved species? Each electrode weighs 50.0 g in the beginning.

106. An old method of measuring the current flowing in a circuit was to use a "silver coulometer." The current passed first through a solution of $Ag^+(aq)$ and then into another solution containing an electroactive species. The amount of silver metal deposited at the cathode was weighed. From the mass of silver, the number of atoms of silver was calculated. Since the reduction of a silver ion requires one electron, this value equaled the number of electrons passing through the circuit. If the time was noted, the average current could be calculated. If, in such an experiment, 0.052 g of Ag is deposited during 450 s, what was the current flowing in the circuit?

107. A "silver coulometer" (Study Question 106) was used in the past to measure the current flowing in an electrochemical cell. Suppose you found that the current flowing through an electrolysis cell deposited 0.089 g of Ag metal at the cathode after exactly 10 min. If this same current then passed through a cell containing gold(III) ion in the form of $[AuCl_4]^-$, how much gold was deposited at the cathode in that electrolysis cell?

108. ▲ Four metals, A, B, C, and D, exhibit the following properties:

(a) Only A and C react with 1.0 M hydrochloric acid to give $H_2(g)$.

(b) When C is added to solutions of the ions of the other metals, metallic B, D, and A are formed.

(c) Metal D reduces B^{n+} to give metallic B and D^{n+}.

Based on this information, arrange the four metals in order of increasing ability to act as reducing agents.

109. ▲ A solution of KI is added dropwise to a pale blue solution of $Cu(NO_3)_2$. The solution changes to a brown color, and a precipitate of CuI forms. In contrast, no change is observed if solutions of KCl and KBr are added to aqueous $Cu(NO_3)_2$. Consult the table of standard reduction potentials to explain the dissimilar results seen with the different halides. Write an equation for the reaction that occurs when solutions of KI and $Cu(NO_3)_2$ are mixed.

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

110. ▲ The amount of oxygen, O_2, dissolved in a water sample at 25 °C can be determined by titration. The first step is to add solutions of $MnSO_4$ and NaOH to the water to convert the dissolved oxygen to MnO_2. A solution of H_2SO_4 and KI is then added to convert the MnO_2 to Mn^{2+}, and the iodide ion is converted to I_2. The I_2 is then titrated with standardized $Na_2S_2O_3$.

(a) Balance the equation for the reaction of Mn^{2+} ions with O_2 in basic solution.

(b) Balance the equation for the reaction of MnO_2 with I^- in acid solution.

(c) Balance the equation for the reaction of $S_2O_3^{2-}$ with I_2.

(d) Calculate the amount of O_2 in 25.0 mL of water if the titration requires 2.45 mL of 0.0112 M $Na_2S_2O_3$ solution.

Summary and Conceptual Questions

The following questions may use concepts from this and previous chapters.

111. Fluorinated organic compounds are used as herbicides, flame retardants, and fire-extinguishing agents, among other things. A reaction such as

$$CH_3SO_2F + 3\ HF \rightarrow CF_3SO_2F + 3\ H_2$$

is carried out electrochemically in liquid HF as the solvent.

(a) If you electrolyze 150 g of CH_3SO_2F, what mass of HF is required, and what mass of each product can be isolated?

(b) Is H_2 produced at the anode or the cathode of the electrolysis cell?

(c) A typical electrolysis cell operates at 8.0 V and 250 A. How many kilowatt-hours of energy does one such cell consume in 24 hours?

112. ▲ The free energy change for a reaction, $\Delta_r G°$, is the maximum energy that can be extracted from the process as work, whereas $\Delta_r H°$ is the total chemical potential energy change. The efficiency of a fuel cell is the ratio of these two quantities.

$$\text{Efficiency} = \frac{\Delta_r G°}{\Delta_r H°} \times 100\%$$

Consider the hydrogen-oxygen fuel cell, where the net reaction is

$$H_2(g) + \tfrac{1}{2}\ O_2(g) \rightarrow H_2O(\ell)$$

(a) Calculate the efficiency of the fuel cell under standard conditions.

(b) Calculate the efficiency of the fuel cell if the product is water vapor instead of liquid water.

(c) Does the efficiency depend on the state of the reaction product? Why or why not?

113. A hydrogen-oxygen fuel cell operates on the simple reaction

$$H_2(g) + \tfrac{1}{2}\ O_2(g) \rightarrow H_2O(\ell)$$

If the cell is designed to produce 1.5 A of current and if the hydrogen is contained in a 1.0-L tank at 200 atm pressure at 25 °C, how long can the fuel cell operate before the hydrogen runs out? (Assume there is an unlimited supply of O_2.)

114. ▲ (a) Is it easier to reduce water in acid or base? To evaluate this, consider the half-reaction

$$2\ H_2O(\ell) + 2\ e^- \rightarrow 2\ OH^-(aq) + H_2(g) \qquad E° = -0.83\ V$$

(b) What is the reduction potential for water for solutions at pH = 7 (neutral) and pH = 1 (acid)? Comment on the value of $E°$ at pH = 1.

115. ▲ Living organisms derive energy from the oxidation of food, typified by glucose.

$$C_6H_{12}O_6(aq) + 6\ O_2(g) \rightarrow 6\ CO_2(g) + 6\ H_2O(\ell)$$

Electrons in this redox process are transferred from glucose to oxygen in a series of at least 25 steps. It is instructive to calculate the total daily current flow in a typical organism and the rate of energy expenditure (power). (See T. P. Chirpich: *Journal of Chemical Education*, Vol. 52, p. 99, 1975.)

(a) The molar enthalpy of combustion of glucose is −2800 kJ/mol-rxn. If you are on a typical daily diet of 2400 Cal (kilocalories), what amount of glucose (in moles) must be consumed in a day if glucose is the only source of energy? What amount of O_2 must be consumed in the oxidation process?

(b) How many moles of electrons must be supplied to reduce the amount of O_2 calculated in part (a)?

(c) Based on the answer in part (b), calculate the current flowing, per second, in your body from the combustion of glucose.

(d) If the average standard potential in the electron transport chain is 1.0 V, what is the rate of energy expenditure in watts?

CHAPTER OUTLINE

20.1 The Atmosphere

20.2 The Aqua Sphere (Water)

20.3 Energy

20.4 Fossil Fuels

20.5 Alternative Sources of Energy

20.6 Environmental Impact of Fossil Fuels

20.7 Green Chemistry and Sustainability

20.1 The Atmosphere

Goal for Section 20.1

- Know the important chemical components of Earth's atmosphere, how those components affect the Earth, and how they can be affected by pollutants.

The composition of the atmosphere is being changed by human activities, and the resulting effects on climate are well established. It may be the least weighty part of the environment, but it is complex and has a disproportionately large influence on our planet.

The major components of the atmosphere are listed in Table 20.1. These values are for dry air at sea level, but air also contains water vapor, which can vary considerably from place to place and from day to day. It can be as high as 40,000 ppm (parts per million) but is generally about half this value or less.

There are many more components of the atmosphere than those listed in the table. These include trace amounts of chemicals emitted by plants, animals, and microbes, as well as from burning coal, oil, and natural gas to generate electricity, from vehicle exhausts, from industry, and from our day-to-day activities.

TABLE 20.1 The Gases of the Atmosphere*

Gases	Concentration (ppm)
Nitrogen (N_2)	780,840
Oxygen (O_2)	209,460
Argon (Ar)	9,340
Carbon dioxide (CO_2)	397
Neon (Ne)	18
Helium (He)	5.2
Methane (CH_4)	1.8
Krypton (Kr)	1.1
Hydrogen (H_2)	0.5
Ozone (O_3)	0.4
Dinitrogen monoxide (nitrous oxide, N_2O)	0.3
Carbon monoxide (CO)	0.1
Xenon (Xe)	0.09
Radon (Rn)	traces

*Data on gas concentrations refer to relative numbers of particles (in parts per million) in dry air.

◀ **Alligators, a Sentinel Species for the Environment.** A team of chemists and biologists has been studying crocodiles in southern Africa and alligators along the southeastern coast of the United States to determine the impact of long-lived chemicals in the environment. Alligators live to 50 or more years and, once they reach sexual maturity, can reproduce for most of their lives. Therefore, scientists can observe the effect of pollutants on their health and on their environment over a long period of time. (The alligator in this photo is relatively young. It was caught in a snare and, after taking a blood and urine sample for analysis, was returned to its home.)

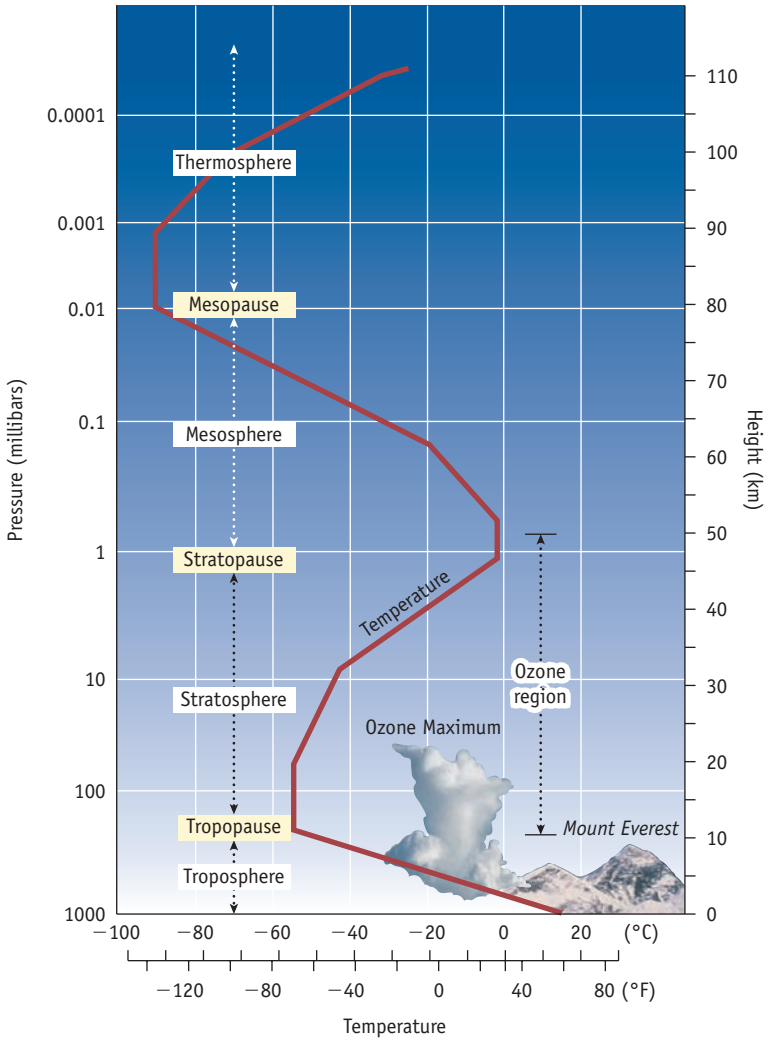
You might imagine that air is a homogeneous mixture of gases that is constantly being stirred by the motion of the planet and the heat of the Sun. In fact, mixing is far from complete. There is relatively little exchange of air between the north and south regions of the planet, and there are distinct layers in the atmosphere (*A Closer Look: The Earth's Atmosphere*). For humans, the most important layer is the lower layer—the troposphere, which goes up to about 7 km at the poles and 17 km at the equator. Above the troposphere is the stratosphere, which extends to about 30 km, getting less dense as altitude increases. There are even higher regions, but in this chapter we concern ourselves only with the troposphere and the stratosphere.

Gigatons are often used in environmental studies because the masses involved are so large. A *metric ton* is 1000 kg, but a gigaton is a billion metric tons, that is, 10^9 metric tons.

The total mass of the atmosphere is estimated to be around 5.15×10^{18} kg (5.15×10^{15} metric tons, or 5.15×10^6 gigatons). Three quarters of the mass of the atmosphere is in the troposphere, and there its average temperature is 14 °C. It can

A CLOSER LOOK

The Earth's Atmosphere



Earth's atmosphere is a mixture of gases in more or less distinct layers with widely differing temperatures.

Up through the troposphere, there is a gradual decline in temperature (and pressure) with altitude. The temperature climbs again in the stratosphere due to the absorption of energy from the Sun by stratospheric ozone, O_3.

The pressure drops steadily as altitude increases while the temperature varies dramatically. This is an illustration of the difference between *temperature* and *thermal energy*. The temperature of a gas reflects the average kinetic energy of the molecules of the gas, whereas the thermal energy present in an object is the *total* kinetic energy of the molecules. In the thermosphere, the molecules present have a very high temperature, but the thermal energy is exceedingly small because there are so few molecules.

Gases within the troposphere are well mixed by convection. Pollutants that are produced on Earth's surface can rise to the stratosphere, but the stratosphere acts as a "thermal lid" on the troposphere and prevents significant mixing of polluting gases into the stratosphere and beyond. Nonetheless, small amounts of pollutants such as chlorofluorocarbons do enter the stratosphere and contribute to destruction of ozone.

The pressure of the atmosphere declines with altitude, and so the partial pressure of O_2 declines. The figure shows why climbers have a hard time breathing on Mount Everest, where the altitude is 29,028 ft (8848 m) and the O_2 partial pressure is only 29% of the sea level partial pressure. With proper training, a climber could reach the summit without supplemental oxygen. However, this same feat would not be possible if Everest were farther north. Earth's atmosphere thins toward the poles, and so the O_2 partial pressure would be even less if Everest's summit were in the northern part of North America, for example.

be as low as −89 °C (the lowest temperature ever recorded, in Antarctica in 1983) or as high as 58 °C (the highest temperature ever recorded, in North Africa in 1922).

After temperature, the next most obvious property of the atmosphere is the pressure it exerts, which at sea level is around 101 kPa (1 atmosphere) and about 25 kPa (0.25 atm) at 11 km (about 35,000 feet), the altitude used by passenger aircraft.

Some of the gases of the atmosphere are unreactive, notably the noble gases: helium, neon, argon, krypton, and xenon. Helium and argon are added continuously to the atmosphere because they are products of radioactive decay—helium comes from alpha particles emitted by naturally occurring elements such as uranium, and argon is produced by decay of ^{40}K, a long-lived radioactive isotope of potassium.

The other gases of the atmosphere, particularly oxygen, nitrogen, and carbon dioxide, are chemically reactive and can be changed into other molecules by reactions driven by lightning, ultraviolet rays from the Sun, or the influence of living things.

The atmosphere has undergone significant changes over the lifetime of our planet, and it is still changing. The well-publicized increase of CO_2 in the atmosphere and the decrease of ozone in the stratosphere are probably the best-known changes, but human activity is contributing new chemicals to the environment as well. We need to understand what these changes mean for the future.

Nitrogen and Nitrogen Oxides

Nitrogen in the atmosphere, N_2, arose from the out-gassing of Earth when it was simply a molten mass. Even today, some nitrogen escapes when volcanoes erupt. Every living thing on the planet has nitrogen in its cells in the form of proteins and in DNA and RNA, among other compounds. Gaseous N_2 is not the direct source of this element in living beings, however; to be taken up by plants, nitrogen must be in the form of a usable nitrogen compound, such as ammonia or ammonium or nitrate ions.

In the environment, atmospheric N_2 molecules are converted to other compounds by a number of natural processes. Some of this conversion is carried out within the nitrogen cycle, shown in Figure 20.1, which charts the processes that convert between various N-containing molecules and ions in nature.

Humans also influence the nitrogen cycle. On a global scale, the conversion of nitrogen to its various compounds is accomplished to the extent of around 50% by biological processes and 10% by lightning. Another 30% comes from burning fossil fuels and 10% from manufactured fertilizers. Indeed, according to recent

Sustainability "Sustainability" or "sustainable development," is an important aspect of this chapter. In 1987 a commission of the United Nations defined sustainable development as "development that meets the needs of the present without compromising the ability of future generations to meet their own needs." This is a complex topic, but there appears to be a consensus that achieving sustainable development requires the interaction of scientific, environmental, societal, and economic factors.

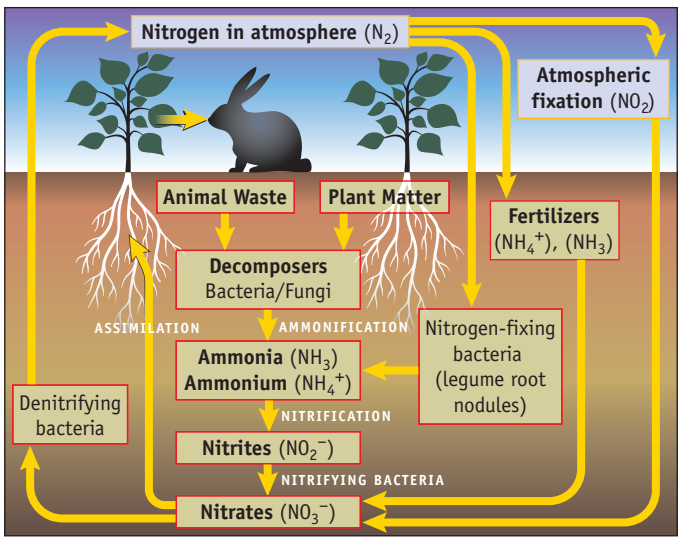

Figure 20.1 The nitrogen cycle The nitrogen cycle involves nitrogen fixation by soil bacteria or, in aquatic environments, by cyanobacteria. The NH_4^+ ions produced are converted to nitrate ions, the main form of nitrogen absorbed by plants. Nitrogen is returned to the atmosphere by denitrifying bacteria, which convert nitrate ions to N_2.

research, nitrogen inputs to the environment from fossil fuel combustion and large-scale biomass burning accelerated greatly beginning about 1895, and another shift was seen beginning about 1970 with significant increases in nitrogen fertilizer production.

Various nitrogen oxides are also present in the atmosphere, among them dinitrogen monoxide (nitrous oxide, N_2O), nitrogen monoxide (nitric oxide, NO), and nitrogen dioxide (NO_2). Collectively, nitrogen oxides are referred to as NO_x compounds. Although the nitrogen cycle does produce some of these oxides in the atmosphere, the majority of NO_x molecules are produced by human activities.

The most abundant nitrogen oxide in the atmosphere is the least reactive one, dinitrogen monoxide, N_2O. Its current average abundance is 0.3 ppm; however, the percent of this gas in the atmosphere has been increasing slowly for 250 years. The other nitrogen oxides make up only 0.00005 ppm of the atmosphere. Although 100 million tons of NO and NO_2 are generated by human processes annually, the concentration of these materials in the atmosphere is low because they are quickly washed out of the atmosphere by rain (where they contribute to "acid rain"). But, NO_x compounds can linger in certain situations, particularly over cities in sunny climates. There they can react with hydrocarbons in the atmosphere, such as traces of unburned fuel, to produce irritating photochemical smog. Among the components of smog are PANs, peroxyacyl nitrates. PANs are formed by photochemical (light-induced) reactions in smog involving organic compounds, O_3, and NO_x. They are toxic and irritating. At low concentrations, they irritate the eyes, but at higher concentrations they can cause more serious damage to both animals and vegetation. They are relatively stable; thus, it is possible they can persist for some time and travel considerable distance from where they are formed.

Peroxyacetyl nitrate (PAN), an air pollutant. It is an oxidant more powerful than ozone and is a lachrymator (it makes your eyes tear). It is formed in the atmosphere when ethanol is used as a fuel, so the more ethanol is used, the more its formation could be a problem.

Oxygen

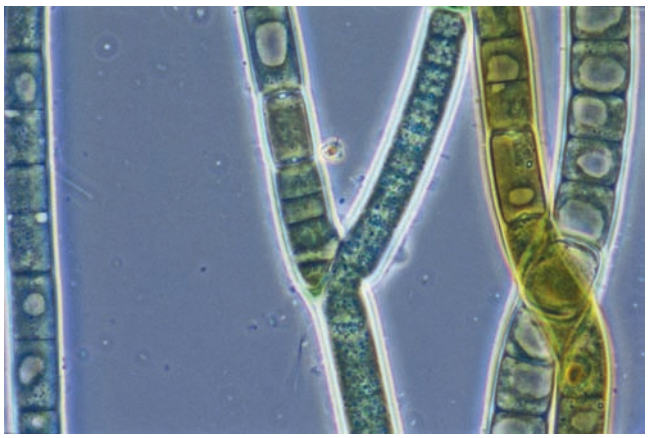
Over the lifetime of our planet, plant life has had a dramatic effect on the atmosphere, changing it from a reducing to an oxidizing one, that is, from there being no oxygen present to one where O_2 is the second most abundant species present in the atmosphere. This change meant that life had to change. Those species that could not live in the presence of oxygen either died out or were relegated to regions where oxygen is blocked out. The concentration of oxygen in the air is now midway between two extremes that would make life on Earth impossible for humans: below 17% we would suffocate, and above 25% all organic material would burn easily.

The total mass of oxygen in the atmosphere is a million gigatons. Even though the burning of 7 gigatons of fossil fuel carbon per year consumes 18 gigatons of oxygen, this makes almost no discernible difference to the amount of oxygen in the atmosphere.

Oxygen is a by-product of plant **photosynthesis**. Carbon dioxide is the source of the carbon that plants need and that they capture from the air and turn into carbohydrates such as glucose ($C_6H_{12}O_6$) by photosynthesis. The overall chemical reaction is

$$6\ CO_2 + 6\ H_2O \rightarrow C_6H_{12}O_6 + 6\ O_2$$

and the net result is the release of an oxygen molecule into the atmosphere for each CO_2 absorbed. Oxygen molecules released by photosynthesis remain in the atmosphere, on average, around 3000 years before being consumed through respiration in living beings or through other oxidation reactions.



Blue-green algae, or cyanobacteria (Figure 20.2), first began producing oxygen as long ago as 3.5 billion years. But, mysteriously, hundreds of millions of years elapsed before a significant amount of oxygen was present in the atmosphere. Astrobiologists are not certain why this occurred, but it does seem plausible that the oxygen first produced did not remain in the atmosphere because it reacted with metals, especially converting abundant iron to iron(II) and iron(III) oxides. (Iron is the fourth most abundant element in the Earth's crust, where it is found primarily in the

form of iron(III) oxides.) The concentration of oxygen remained low until about 2 billion years ago when it rose relatively rapidly to around 20% and the first land plants started to appear.

There are three naturally occurring isotopes of oxygen: oxygen-16 accounts for 99.76% of O atoms, oxygen-17 for a mere 0.04%, and oxygen-18 for 0.2%. The ratio of oxygen-18 to oxygen-16 in the world's oceans has varied slightly over geological time, and this has left an imprint on parts of the environment, providing evidence of past climates. When the world is in a cooler period, water molecules with the lighter isotope, oxygen-16, evaporate more readily from the oceans than their heavier oxygen-18 counterpart. Thus, precipitation in the form of snow is slightly richer in oxygen-16, and the water that remains in the oceans is slightly richer in oxygen-18. Marine creatures during such periods lay down shells that have more oxygen-18 than expected, and these are preserved in sediments. Analyzing the ratio of the two isotopes in such deposits reveals the cycle of global cooling and warming that has characterized the past half million years with its five ice ages.

Figure 20.2 Cyanobacteria. The importance of cyanobacteria, also known as blue-green algae, lies in their production of oxygen by photosynthesis and their participation in the nitrogen cycle.

Ozone

Ozone (O_3) plays a key role in life on this planet, but it is also a threat. In the troposphere, it is a pollutant, whereas in the stratosphere it acts as a shield, protecting the planet from damaging ultraviolet rays from the Sun. This shield is known as the **ozone layer (**Figure 20.3).

Ozone is formed in lightning storms, so there is a natural low level of ozone in the air we breathe, about 0.02 ppm. In summer, however, the level can increase to 0.1 ppm or more as a result of sunlight acting on the nitrogen dioxide emitted by vehicles. The ultraviolet component of sunlight causes the dissociation of NO_2 to NO and O atoms. The resulting O atoms then react with O_2 (in the presence of a third molecule acting as an energy "sink") to produce ozone.

$$NO_2 + \text{energy } (\lambda < 240 \text{ nm}) \rightarrow NO + O$$

$$O + O_2 \rightarrow O_3$$

Because ozone damages the lungs, a legal limit for exposure to ozone in the workplace, 0.1 ppm, has been established. Some growing plants are also susceptible to the gas, and even though they do not show visible signs of stress, their growth is reduced in proportion to the level of ozone in the air.

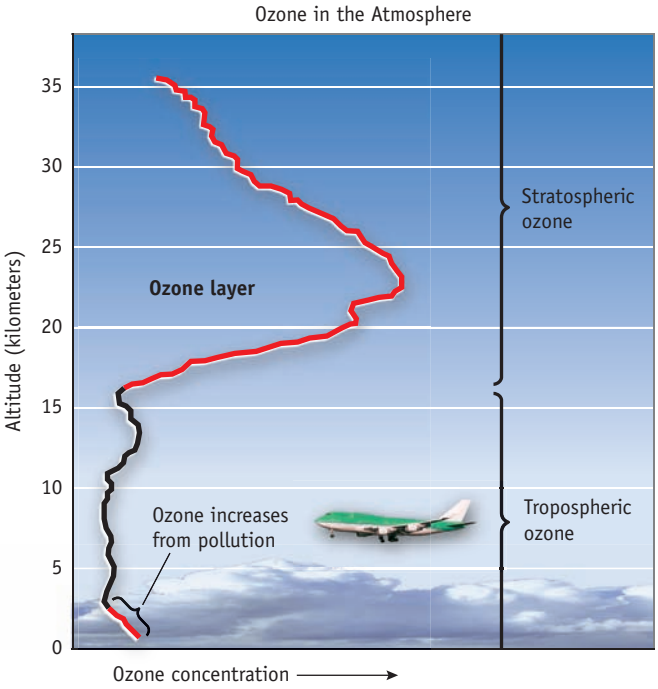

Figure 20.3 The ozone layer. About 90% of the ozone in the atmosphere is contained in the stratosphere (roughly 15–50 km above the surface). Concentrations there range from 2 to 8 ppm.

In contrast to ozone in the troposphere, O_3 in the stratosphere is vital to the planet because the molecules absorb high-energy ultraviolet radiation before it reaches Earth's surface. Ozone is formed in the stratosphere when radiation with wavelengths shorter than 240 nm interacts with O_2 molecules and cleaves them into two O atoms. Each O atom combines with another O_2 molecule to produce an ozone molecule.

$$O_2 + \text{energy} \rightleftharpoons O + O$$

$$O + O_2 \rightarrow O_3$$

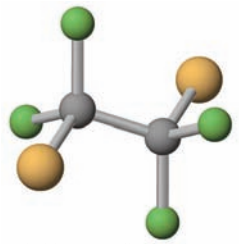
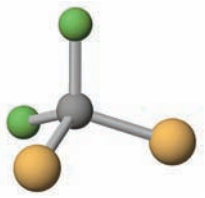
Ozone in turn absorbs ultraviolet radiation with wavelengths less than 320 nm, and the O_3 is decomposed to O_2 and O atoms.



$$O_3 + \text{energy } (\lambda < 320 \text{ nm}) \rightleftharpoons O_2 + O$$

$$O + O_3 \rightarrow 2\ O_2$$



Without the ozone layer, higher energy radiation capable of harming living cells would penetrate to Earth's surface. An increase in radiation could lead to an increased incidence of skin cancer and cataracts and suppression of the human immune response system. Damage to crops and marine phytoplankton and weathering of plastics can also result from increased levels of ultraviolet radiation.

The "Ozone Hole"

From the late 1800s until about 1930, ammonia (NH_3), chloromethane (CH_3Cl), and sulfur dioxide (SO_2) were widely used as refrigerants. However, leakage from refrigerators caused several fatal accidents in the 1920s, so three American corporations, Frigidaire, General Motors, and DuPont, collaborated on the search for a less dangerous fluid. In 1928, Thomas Midgley, Jr., and his coworkers discovered a "miracle compound" as a substitute. This compound, dichlorodifluoromethane (CCl_2F_2), is a member of a large family of compounds called chlorofluorocarbons (CFCs). The two compounds shown here are CFC-114 ($C_2Cl_2F_4$) and CFC-12 (CCl_2F_2).

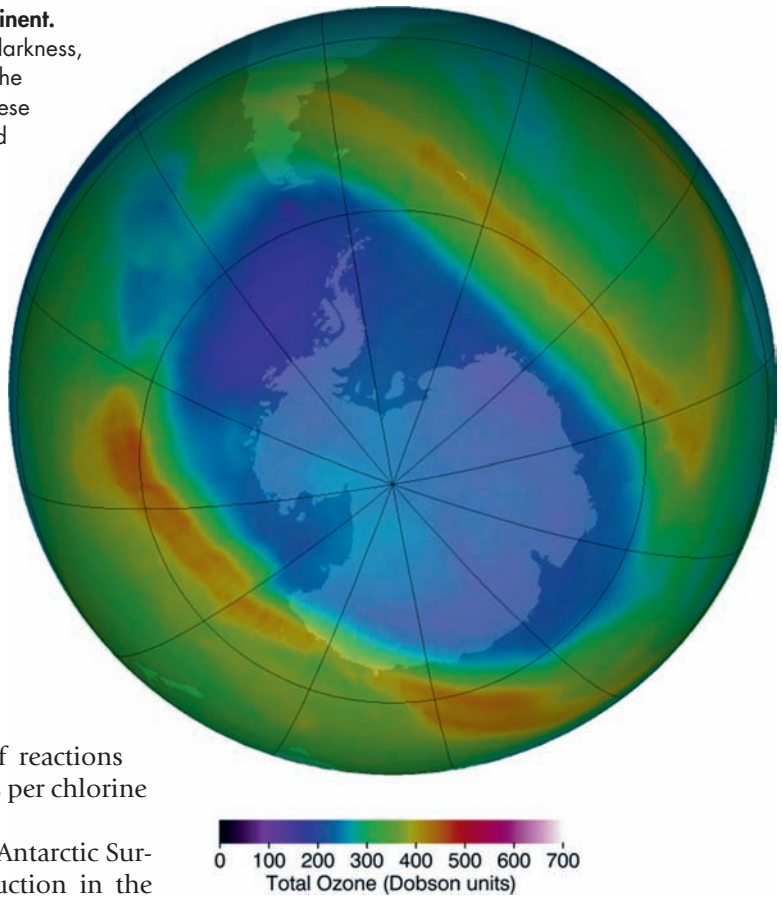
dichlorotetrafluoroethane

dichlorodifluoromethane

These compounds had exactly the physical and chemical properties needed for a refrigerant: appropriate critical temperatures and pressures, no toxicity, and apparent chemical inertness.

The uses of CFCs grew dramatically, not only in air conditioning and refrigeration equipment but also in applications such as propellants for aerosol cans, foaming agents in the production of expanded plastic foams, and inhalers for asthma sufferers.

Unfortunately, the properties that made CFCs so useful also led to environmental problems. CFCs are unreactive in Earth's troposphere, which allows them to remain there for hundreds of years. Over time, however, they slowly diffuse into the stratosphere, where they are decomposed by solar radiation.



$$CF_2Cl_2(g) + \text{UV radiation} \rightarrow \cdot CF_2Cl(g) + \cdot Cl(g)$$

The Cl atoms released in the decomposition of CFCs and other chlorine-containing compounds can then destroy large numbers of ozone molecules. This occurs because Cl atoms catalyze the decomposition of O_3 molecules and produce the radical species ClO (Step 1). The ClO radical in turn intercepts O atoms (Step 2) from the radiation-driven decomposition of O_3 molecules (Step 3).

Step 1	$O_3(g) + \cdot Cl(g) \rightarrow \cdot ClO(g) + O_2(g)$
Step 2	$\cdot ClO(g) + O(g) \rightarrow \cdot Cl(g) + O_2(g)$
Step 3	$O_3(g) + \text{solar radiation} \rightarrow O(g) + O_2(g)$
Net reaction:	$2\ O_3(g) \rightarrow 3\ O_2(g)$

Courtesy of NASA Ozone Watch

Figure 20.4 The "ozone hole" over the Antarctic continent. During the Antarctic winter, when there are 24 hours of darkness, aerosols of HCl and $ClONO_2$ freeze and accumulate in the polar stratospheric clouds. During the Antarctic spring, these crystals melt, and Cl and ClO radicals are rapidly formed and lead to a depletion of stratospheric ozone over the continent. Depletion is greatest in the blue zones. Note that the depletion of ozone extends from the South Pole to the tip of South America. [The numbers on the color scale are Dobson units (DU). This is a unit of measurement for the total amount of ozone in the atmosphere above a point on the Earth's surface. One DU is equivalent to a layer of pure ozone 0.01 mm thick at standard temperature and pressure.]

When repeated over and over, this sequence of reactions leads to the destruction of many ozone molecules per chlorine atom.

In 1985 three British scientists of the British Antarctic Survey discovered that there was a significant reduction in the ozone concentration over the Antarctic continent in the late winter and early spring, which has since been referred to as the "ozone hole" (Figure 20.4). In 1986, a team from the U.S. National Center for Atmospheric Research went to Antarctica to investigate the "hole" and found that it had higher levels of the reaction intermediate, $\cdot ClO$, than expected in the stratosphere.

The "ozone hole" occurrence is tied not only to $\cdot Cl$ and $\cdot ClO$ radicals, but also to NO_x chemistry. Ozone destruction over Antarctica is partly affected in certain seasons by the combination of $\cdot ClO$ and $\cdot NO_2$ to give the compound $ClONO_2$.

$$\cdot ClO(g) + \cdot NO_2(g) \rightarrow ClONO_2(g)$$

In the Antarctic winter this compound and others such as HCl are frozen in stratospheric clouds. In the spring, at warmer temperatures, the problem begins when reactions such as the following occur:

$$ClONO_2(g) + H_2O(g) \rightarrow HOCl(g) + HNO_3(g)$$

$$ClONO_2(g) + HCl(g) \rightarrow Cl_2(g) + HNO_3(g)$$

Both HOCl and Cl_2 can be decomposed by solar radiation to give $\cdot Cl$ atoms, which then lead to ozone destruction.

Because of the damage caused to the stratospheric ozone layer by CFCs and related compounds, the United States banned the use of CFCs as aerosol propellants in 1978, and 68 nations had followed suit by 1987. In 1990, the United States and 140 other countries agreed to a complete halt in CFC manufacture as of December 31, 1995.

Carbon Dioxide and Methane

Carbon is essential to life as we know it because only carbon has the ability to form stable compounds consisting of long chains and rings of atoms. This is the basis of

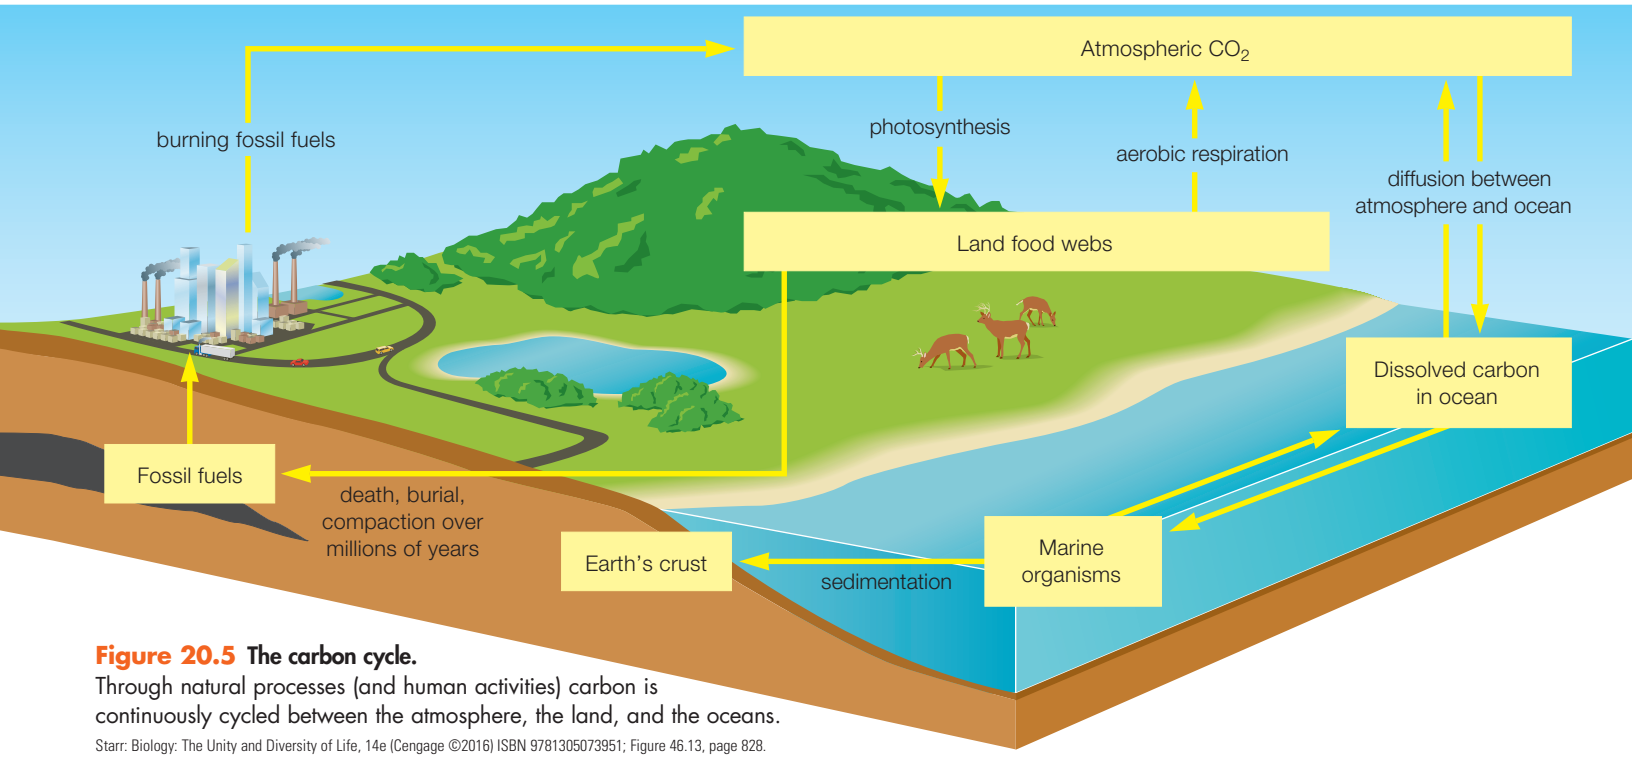

Figure 20.5 The carbon cycle.
Through natural processes (and human activities) carbon is continuously cycled between the atmosphere, the land, and the oceans.
Starr: Biology: The Unity and Diversity of Life, 14e (Cengage ©2016) ISBN 9781305073951; Figure 46.13, page 828.

the structures for many compounds that comprise living cells. The food we eat—carbohydrates, oils, proteins, and fiber—is made up of carbon compounds, and this carbon eventually returns to the atmosphere as CO_2 as part of the natural carbon cycle (Figure 20.5). This cycle moves over 200 gigatons of carbon every year between various compartments of the terrestrial ecosphere and so rules the tempo of life on Earth.

Climate Change Carbon dioxide and methane have significant effects on the environment (Section 20.6).

Some years ago scientists began to notice increasing levels of CO_2 in the atmosphere, so the *Intergovernmental Panel on Climate Change* (IPCC) was set up in 1988 by members of the United Nations Environment Program and the World Meteorological Organization. In the five IPCC Assessment Reports issued to date, a significant increase in the atmospheric carbon dioxide concentration has been reported, from around 280 ppm in 1750 to 408.84 in June 2017. (Figure 20.6 shows the increase in atmospheric CO_2 over a 50-year period and the seasonal variation.) The fourth IPCC report stated that "Today's CO_2 concentration has not been exceeded during the past 420,000 years and likely not during the past 20 million years. The rate of increase over the past century is unprecedented, at least during the past

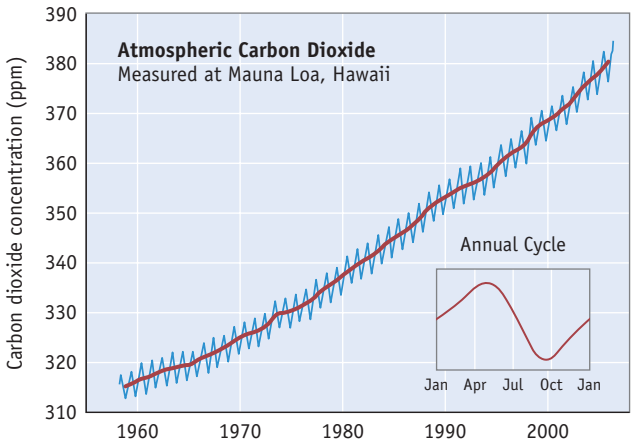

Figure 20.6 Mean monthly concentrations of CO_2 at Mauna Loa, Hawaii, over a 50-year period. Notice the yearly cycle of CO_2 concentration. It declines in the summer when photosynthesis is at its peak. In June 2017, the atmospheric concentration of CO_2 was 408.84 ppm (an increase of almost 9 ppm from 400.24 ppm in November 2015).

20,000 years." As described in Section 20.6, there has been significant debate about the origin of this increase and its effects on the planet's climate.

Methane is formed and released into the atmosphere in enormous amounts by biological processes. Some methane is produced in nature by anaerobic bacteria (that is, those that do not use oxygen) at the bottom of lakes and swamps, in termite mounds, and in the guts of animals such as cows and humans. Landfill sites are also contributors of methane from the decomposition of organic materials in the absence of significant oxygen. The release of methane as the result of human activities such as coal mining or the processing and use of natural gas also contributes to CH_4 in the atmosphere. Finally, the increasing use of "fracking" (more on hydraulic fracturing in *A Closer Look: Fracking*) to obtain poorly accessible gas and oil has also led to a significant release of CH_4 to the atmosphere.

Methane hydrates are another source of methane (page 936). There are vast amounts of methane hydrates in the depths of the ocean, but they may be too expensive to "mine" as a fuel source. The hydrates are also found in the Arctic, locked in the permafrost. There is also some concern that these deposits could release more methane directly into the atmosphere if warming of these regions continues.

The methane concentration in the atmosphere is now around 1.8 ppm. Based on studies of air bubbles trapped in ice sheets, we know that methane is now more abundant in Earth's atmosphere than at any time in the last 400,000 years. Concerns about methane in the atmosphere arise because it is a powerful greenhouse gas (page 944). In fact, CH_4 is about 21 times better at atmospheric warming than CO_2 by weight.

20.2 The Aqua Sphere (Water)

Goal for Section 20.2

- Know the basic steps in water purification and be aware of common water pollutants.

There is an abundance of water on our planet, in the oceans, lakes, rivers, and underground aquifers, locked in minerals, in ice and snow in arctic regions, and water vapor in the atmosphere. This is fortunate because life as we know it cannot exist without water. Right now, however, there are serious problems associated with this valuable resource. Some locations are deprived of sufficient water, whereas there is an overabundance in other places. There are huge variations in the purity and quality of available water supplies, and evidence suggests these problems will continue to increase in the future.

People need water for drinking and for their everyday needs, but agriculture and industry require even larger amounts of water. Currently, most water we use comes from available groundwater, rivers, lakes, underground aquifers, and rainwater collected and stored in reservoirs above or below ground. However, we need to recognize that climate change can change the amount and distribution of water resources around the world.

The amount of water used will increase with continuing growth in global population. Already 500 million people worldwide are affected at some level by water shortages, although most of these problems have not yet seriously affected people in the United States. However, in the Great Plains underground aquifers are becoming seriously depleted, and some lakes and rivers are drying up. For example, Lake Mead, which was created by the Hoover Dam (on the Colorado River on the border between Nevada and Arizona) is now around 20 meters (60 feet) or more below the level of water it held in the 1980s (Figure 20.7). The Colorado River no longer reaches the sea; much of its water is being drawn off for use in surrounding communities, especially for agriculture to irrigate crops.

AP Images/Kyodo

Microplastics in the oceans. When a plastic grocery bag or water bottle goes into a river or ocean, it eventually degrades to tiny bits or microplastics, pieces less than 5 mm in size. Biologists have found that these plastics profoundly affect aquatic life, especially filter feeders (such as oysters and shrimp). Especially bad are microbeads used in some cleaners and toothpaste. Microbeads are now banned in personal care products, but thousands of tons were used over a number of years.

Figure 20.7 Lake Mead, a symbol of a crisis in water supply. Lake Mead is the largest man-made lake and reservoir in the United States. It is located on the Colorado River in the states of Nevada and Arizona. Aqueducts carry the water to Las Vegas, Los Angeles, San Diego, and other communities in the Southwest. This view of the lake from Hoover Dam shows the drop in the lake level, which used to cover the white rocks on the mountainsides. The Scripps Institute of Oceanography set the odds of Lake Mead drying up by 2021 at 50-50.

Water Use In the United States, the average daily indoor per capita water use is about 70 gallons, which is much greater than in any other country. In some developing countries, the per capita use is one tenth of this amount or less.

Water quality is always an underlying issue when talking about water. There is a lot of water on Earth, but 97% of it is in the oceans and unsuitable for most uses until it is separated from dissolved salts. Much of the remaining 3% is also unsuitable for human consumption.

We contribute to pollution of water resources in much of what we do. For centuries humans have treated lakes, rivers, and oceans as the easiest place to dump waste. All too often, what appear to be benign human activities have unintended consequences for water supplies. For example, agricultural and industrial chemicals and drugs from discarded medications are now found in water supplies. The presence of dissolved materials in water supplies then requires complex and expensive purification processes if the water is to be used.

The Oceans

Oceans cover 71% of the area of the planet, contain about 1.3×10^9 km^3 of seawater, and have an average depth of 3790 m. A multitude of life forms is known to exist in the oceans and, because the depths have barely been explored, the number is likely to increase.

The quantity of minerals dissolved in the oceans is vast (Table 20.2). Sodium chloride (sodium and chloride ions) is found in the largest amount, and there are sizable quantities of magnesium ions, calcium ions, potassium ions, and carbonate/bicarbonate ions. Many other elements are present in seawater in concentrations less than one ppm but because of the huge amounts of seawater, the amounts of these elements potentially available in seawater is striking. The lure of obtaining dissolved metals from seawater has tantalized people through the ages. Gold, for example, is present in seawater at a concentration of 10 parts per trillion (10 g in 1 trillion g of water), so the total amount in the world's oceans is more than 13 million tons. Although some have tried, no method has been found to extract gold profitably from the oceans.

TABLE 20.2 Concentrations of Some Cations and Anions in Seawater

Element	Dissolved Species	Concentrations (mmol/L)
Chlorine	Cl^-	550
Sodium	Na^+	460
Magnesium	Mg^{2+}	52
Calcium	Ca^{2+}	10
Potassium	K^+	10
Carbon	HCO_3^-, CO_3^{2-}	30
Phosphorus	HPO_4^{2-}	<1

Concerns have been expressed about the effect on sea levels caused by global warming. Warming leads to expansion of the volume of water in the oceans, but it also melts ice now stacked on land (such as that in Greenland). Both would cause an increase in sea level. (Melting of Arctic sea ice, which is occurring, will not raise the sea level because the volume of liquid water formed is smaller than the volume of ice.)

Sea Level Rise The U.S. National Research Council reported in June 2012 that the sea level will rise between 8 and 23 cm by 2030 (relative to the 2000 level). "Global mean sea level is rising primarily because global temperatures are rising, causing ocean water to expand and land ice to melt. However, sea-level rise is not uniform; it varies from place to place." (*Sea-Level Rise for the Coasts of California, Oregon, and Washington: Past, Present, and Future.* National Academies Press, 2012.)

Water Purification

Water is as vital to life as food: You would not survive a week if you had no water to drink. Most people in developed countries have clean, safe water supplied to their homes (although curiously many prefer to buy it in small bottles). Sadly, a large number of our fellow humans, generally in less-developed countries, have to make do with whatever water they can find, taking it from a well or even from a river, and then they are at risk of contracting a water-borne disease such as cholera, typhoid, gastroenteritis, or meningitis. Worldwide, more than 5000 people a day are thought to die of diseases contracted from the water they drink.

Water purification began with the ancient Egyptians 3500 years ago. They discovered that when alum—potassium aluminum sulfate, $KAl(SO_4)_2$—was dissolved in water visible impurities were removed. In mildly basic conditions, this salt forms a voluminous precipitate of aluminum hydroxide, $Al(OH)_3$, which carries down any cloudiness from suspended particles as it settles. Modern water treatment plants (Figure 20.8) add a small amount of slaked lime [$Ca(OH)_2$] to raise the pH slightly and then a solution of aluminum sulfate or alum to create solid $Al(OH)_3$, which removes many impurities as it settles. The water is then filtered through sand to remove any trace of the aluminum hydroxide.

After treatment with alum and subsequent settling and filtration, water is crystal clear and ready to be disinfected to destroy any pathogens still present. This can be done with a powerful oxidizing agent such as chlorine, sodium hypochlorite (NaClO), or ozone. Chlorine gas and hypochlorite ions have an advantage over ozone in that they are more persistent, meaning that the water will still be fit to drink even when it has been standing in a pipe for a long time. For those areas where the water supply cannot be assumed drinkable, purification tablets are available. These react with the water to form a solution of hypochlorite ions (ClO^-) strong enough to kill off pathogens and make the water safe to drink. Boiling water also makes it potable.

Chlorine in Water Treatment See *Applying Chemical Principles: 20.1. Chlorination of Water Supplies* in this chapter for details on using chlorine and hypochlorite salts in water treatment.

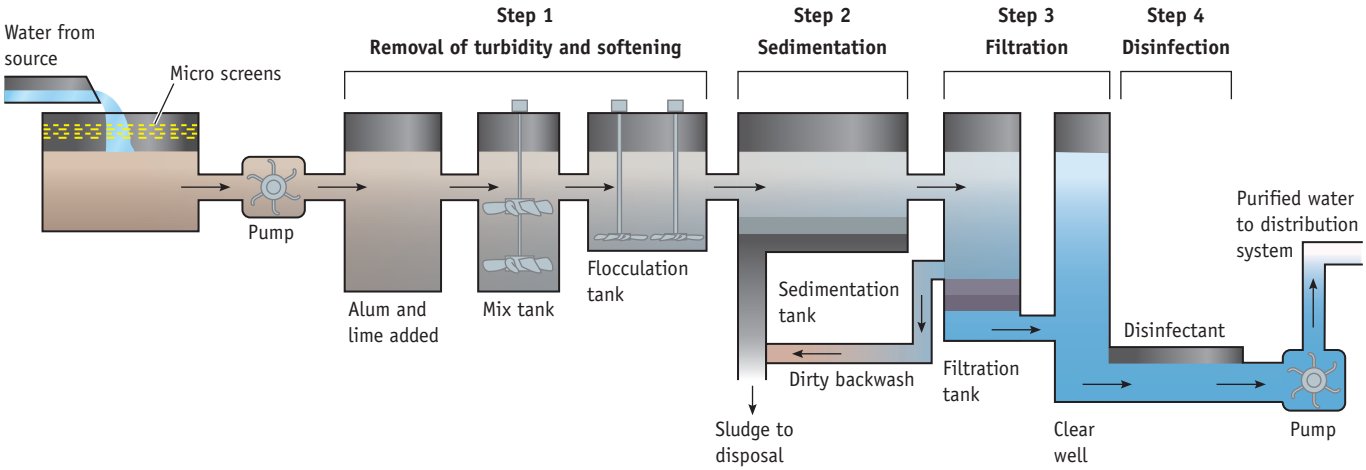

Figure 20.8 A municipal water treatment plant. The general steps in this process are the removal of turbidity, softening, sedimentation and filtration, and disinfection. The removal of turbidity (by addition of alum) and the disinfection of water are discussed in the text.

Ozone (O_3) is the most commonly used water supply disinfectant in Europe. It is also currently used in Los Angeles and some smaller communities in the United States. One advantage is that it does not produce toxic trihalomethanes (such as $CHCl_3$), the by-products of chlorine treatment. Furthermore, it is more effective than chlorine at killing *Cryptosporidium* bacteria and destroying viruses, and it does not leave a residual "chlorine" taste. However, due to its reactivity, ozone must be generated on site, and it is more expensive. Also, it does not provide residual disinfection in the distribution system.

Potable water can also be obtained from contaminated water by **reverse osmosis** (*A Closer Look: Reverse Osmosis for Pure Water,* page 585). This technique is most often used with seawater, but waste water from any suspect source can be treated by this technique. Osmosis is the process whereby water moves across a membrane in such a way as to dilute a solution with a higher solute concentration (Section 13.4). However, if a high enough pressure is applied to the solution with the higher solute concentration, the process of osmosis can be reversed and pure water can be obtained.

Chemistry is an important part of the reverse osmosis desalination apparatus because of the membranes that allow the passage of water molecules but not of dissolved salts. The membranes are made of polymers such as polyvinylidene fluoride and polypropylene with ultrafine pores. They have to withstand the high pumping pressures that are needed to force water against the osmotic pressure gradient. Despite the equipment and energy requirements, the cost of water obtained by reverse osmosis is not excessive; a cubic meter of water (1000 L) produced this way can cost only about $1. Desalination systems are now a $1 billion per year industry and growing at a rate of 7% per year.

Water Pollution: Treatment and Avoidance

Water pollution arises mainly from activities such as farming, mining, papermaking, inadequate or nonexistent sewage treatment facilities, and waste disposal from the chemical and other industies. Protecting natural bodies of water is now high on the agenda of most developed societies, and this has been achieved mainly by controlling the handling and use of substances that may be harmful and by installing better sewage treatment facilities.

John C. Kotz

Figure 20.9 Algae bloom from excess phosphate in a pond. In this pond, which borders the fairway of a golf course, algae blooms have occurred because of the phosphate-containing fertilizers used on the course.

Phosphates

Phosphate pollution was a significant environmental problem in the recent past. One example occurred in Lake Erie, one of the Great Lakes. In the 1960s it appeared Lake Erie was no longer capable of supporting life because of a lack of dissolved oxygen. This was due in part to an excess of nutrients, primarily phosphates, supplied by the rivers that drained into the lake. These nutrients caused a great increase in the amount of algae present, which in turn used up the dissolved oxygen and made it so that no other life could survive. Where did the phosphates come from? Although sewage treatment plants draining into the rivers removed most pollutants, they were not removing phosphates that had become a major component of household detergents. Phosphate from fertilizers also found its way into surface water (Figure 20.9). Similar problems have been experienced in other parts of the world, notably in Europe.

Campaigns to control the use of phosphates have been largely successful. Reduced use of phosphates in fertilizers and improved fertilizer application methods have generally decreased phosphate runoff into waterways. These chemicals were also taken out of household products, and phosphate was extracted at sewage plants before the waste water was released to rivers. As a result, Lake Erie and other lakes slowly began to recover.

Heavy Elements

"Heavy elements" are those that have densities substantially greater than about 5 g/cm^3; these include cadmium, copper, iron, mercury, lead, and chromium as well as the metalloid arsenic. Many heavy elements are found in our environment and

A CLOSER LOOK

The Flint, Michigan Water Treatment Problem

An estimated 22% of the water distribution pipes in the United States are more than 50 years old. Further, many of the pipes supplying water in homes are lead. This is true in at least portions of Flint, Michigan, and this and other factors led to significant health problems in the community.

In April 2014, in order to save money, the city of Flint switched from obtaining treated water from Detroit to pumping it from a nearby river and treating the water in their treatment facility. However, very shortly after, they found unsafe levels of E. coli, coliform bacteria, and trihalomethanes in the water. In early 2015 further investigation also found dangerously high levels of lead. The Environmental Protection Agency specifies that action must be taken if lead exceeds 15 ppb (parts per billion) in more than 10% of the water taps investigated. In one home in Flint, however, investigators found 13,200 ppb lead, and the problem was widespread in the community. It is well known that lead is neurotoxic, particularly in children, and can impair their development. Reducing the lead levels in drinking water was critical.

Because of the problems with its drinking water, the City of Flint switched back to obtaining drinking water from Detroit. Lead levels are now dropping in the system, but the level is still too high in some homes.

Why did switching to a new water source lead to high lead levels? In part, it was because the city decided to save money by not adding phosphate salts to the system. Phosphate salts act as corrosion inhibitors. For example, in a lead pipe, they form insoluble $Pb_3(PO_4)_2$ with any Pb^{2+} ions in the system. The precipitate forms a crust on the pipe walls and prevents additional Pb^{2+} ions from entering the system. Without this corrosion inhibitor, and protective coating, oxygen and added chlorine oxidize the lead in the pipes, and lead ions enter the water system.

There are also iron pipes in the water system. If they are also not protected by a corrosion inhibitor, Fe^{2+} ions also enter the sytem, and households see muddy, brown water.

As one investigator, Marc Edwards, said, "The entire Flint water crisis could have been avoided if the city had just added orthophosphate." (*Chemical & Engineering News*, February 15, 2016, pages 26–29)

Mark Wilson/Getty Images

This image of rust-colored water became a symbol of the problems with the Flint, Michigan, water debacle.

some, such as iron and copper, are essential to life and are present in most living organisms. However, even these elements are toxic in sufficient amounts, and many other metals are highly toxic even in very small amounts. Heavy elements can impair mental and central nervous function and damage lungs, kidneys, liver, and other organs. The effects are best described by the German chemist Alfred Stock, who contracted mercury poisoning early in the 20th century. He said "[It] first reveals itself only as an affection of the nerves, causing headaches, numbness, mental lassitude, depression, and the loss of memory; such are very disturbing to one engaged in an intellectual occupation."

Because of the consequences of heavy elements on health, the United States Environmental Protection Agency (EPA) places limits on the amount of many heavy elements allowed in drinking water and in foods. For example, lead levels in water in the United States are currently required to be no more than 15 μg/L (15 ppb) (*A Closer Look: The Flint, Michigan Water Treatment Problem*). Lead is a cumulative poison that has been linked to learning disabilities, but it may still be found in the water of older houses due to leaching from lead plumbing and in older paints, which used "white lead" (PbO and $PbCO_3$) as a pigment.

Knowledge of heavy element toxicity even made its way to Hollywood in 2000. The movie *Erin Brockovich* is centered around water pollution from chromium(VI) (generally in the form of ions such as CrO_4^{2-} or $Cr_2O_7^{2-}$). For chemists, chromium is a good example of the importance of knowing the oxidation state of an element; chromium(VI) compounds are toxic whereas chromium(III) is an essential trace element that plays a role in human metabolism.

Heavy Metals and ATSDR The federal Agency for Toxic Substances and Disease Registry (ATSDR) lists a number of heavy elements of concern, such as arsenic, cadmium, chromium, lead, mercury, nickel, vanadium, and zinc (among over 15 others). The ATSDR lists four heavy elements in the top 10 on its "Substance Priority List": 1, arsenic; 2, lead; 3, mercury; and 7, cadmium.

Arsenic in Drinking Water

Arsenic is number one on the "Substance Priority List" of the U.S. Agency for Toxic Substances and Disease Registry. Various compounds containing this element are used for wood preservation, in pesticides, and as a component in electronic devices.

Arsenic is also found in several naturally occurring minerals and so can find its way into water supplies.

One well-documented example of arsenic in water supplies is in the West Bengal region of India and the neighboring country of Bangladesh. Unfortunately, the contamination went unnoticed for many years. Drinking water came mainly from tube wells drilled in the 1970s by the United Nations Children's Fund (UNICEF). The goal was to provide safe drinking water for a population that had traditionally taken its water from contaminated streams, rivers, and ponds and which had suffered accordingly from water-borne diseases such as gastroenteritis, typhoid, and cholera. Eventually, 5 million such wells were drilled, and they indeed served the purpose of bringing cholera under control. In its place, however, they unknowingly brought low-level arsenic poisoning to large areas of Bangladesh.

NurPhoto/NurPhoto/Getty Images

Figure 20.10 A villager in West Bengal, India shows her hands affected by arsenic contamination in the water supply.

UNICEF continued to support the well-drilling program after Bangladesh independence, and by 1997 it could report that it had already surpassed its goal of providing 80% of the population in those regions with "safe" water. Such had been the success of the program that many villagers installed private wells. Then doctors began to notice a worrying increase in skin cancer and suspected that arsenic was the cause. Analysis of the water from the wells showed that more than 20 million people were drinking water containing arsenic at the 50 ppb (parts per billion) level, and as many as 5 million people were drinking water containing 300 ppb arsenic. (The U.S. EPA has set the safe level for arsenic in drinking water at 10 ppb.) A team from the Dhaka Community Hospital visited 18 affected areas and examined 2000 adults and children; they concluded that more than half had skin lesions due to arsenic (Figure 20.10).

When drinking water is contaminated the problem can be costly to solve. For example, when half a million people in New Mexico were exposed to high arsenic levels in their drinking water, action was taken, but at a cost of $100 million. For Bangladesh this level of spending is not possible, so chemists have sought simple and inexpensive ways to remove arsenic from water. One method passes the water through layers of sand, pieces of iron, and charcoal. The inorganic arsenic, which is present as arsenite ions, AsO_3^{3-}, sticks to the pieces of iron while the organic forms of arsenic are absorbed into the charcoal.

20.3 Energy

Goal for Section 20.3

- Be aware of the general trends in energy use and energy sources.

Look around you—energy is involved in anything that is moving or emitting light, sound, or heat. Heating and lighting your home, moving your automobile, powering your laptop computer—all are commonplace examples in which energy is used, and all are, at their origin, primarily based on chemical processes. In this section, we examine how chemistry is fundamental to understanding and addressing current energy issues.

Supply and Demand: The Balance Sheet on Energy

We take for granted that energy is available and that it will always be there to use. But will it? Richard Smalley (1943–2005), a chemist and Nobel Prize winner, stated that among the top 10 problems humanity will face over the next 50 years, the energy supply ranks as number one. What is the source of this prediction? Information such as the following is often quoted in the popular press:

- Global demand for energy has almost tripled in the past 40 years and may triple again in the next 50 years. Most of the demand comes from industrialized nations, but most of the increase in demand is coming from developing countries.

- In 2011 fossil fuels accounted for 80% of the total energy used in the United States (Figure 20.11). (Of this total, petroleum accounts for 35%, natural gas 25%, and coal 20%.) Nuclear, biomass, and hydroelectric power contribute about 17% of the total energy budget. The remaining 3% derives from solar, wind, and geothermal energy-generating facilities.
- With only about 5% of the world's population, the United States consumes over 20% of all the energy used in the world. This usage is equivalent to the consumption of 7 gallons of oil or 70 pounds of coal per person per day.
- China and India, with rapidly growing economies, are increasing their energy usage by about 8% per year. In 2007, China passed the United States as the number one emitter of greenhouse gases in the world, and in 2009 China became the largest consumer of energy.

Two basic issues, *energy resources* and *energy usage*, emerge from these statistics and form the basis for this discussion of energy.

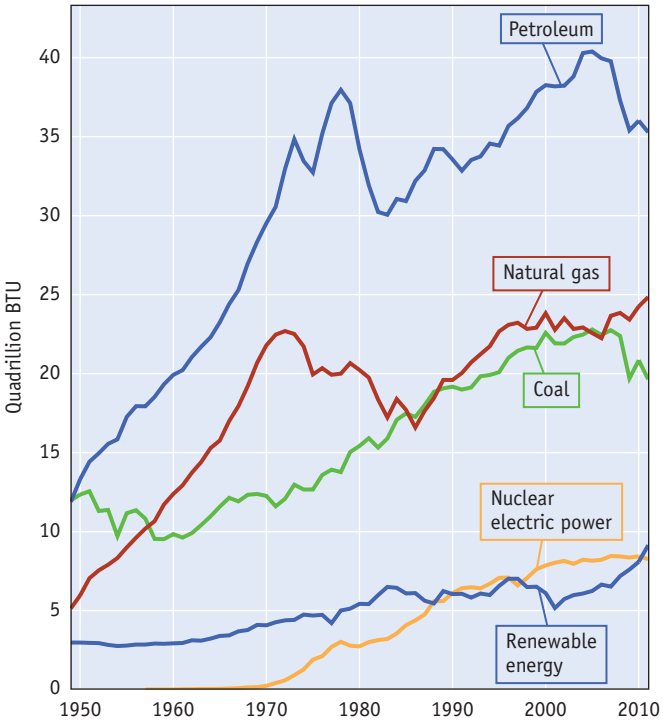

Figure 20.11 Changes in U.S. energy usage by source, 1949–2011. The vertical axis is in units of BTU (units of energy called British thermal units). Extended to 2015, there is little change in these trends. Graph taken from www.eia.gov. The U.S. Energy Information Administration (EIA) is an excellent source of energy information.

Energy Resources

The world is hugely dependent on fossil fuels as a source of energy (Section 20.4). About 65% of the electricity in the United States is generated using fossil fuels, mostly coal and natural gas (Figure 20.12).

Why is there such a dominance of fossil fuels on the resource side of the equation? An obvious reason is that energy derived from burning fossil fuels is cheaper than

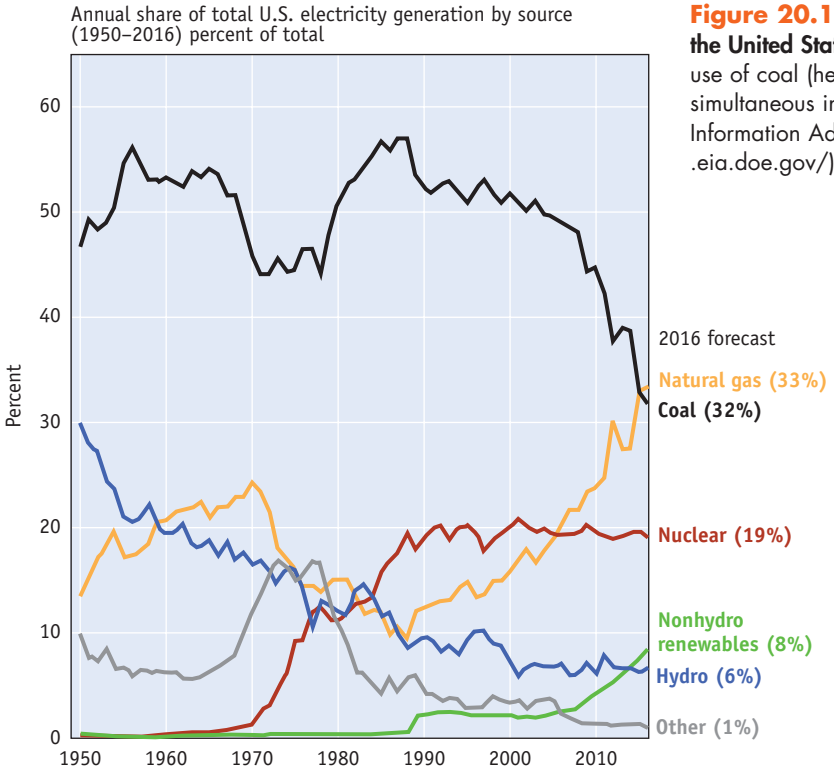

Figure 20.12 Fuel used in the electric power industry in the United States, 1950–2016. Notice the recent decline in use of coal (here and in Figure 20.11), which is matched by a simultaneous increase in use of natural gas. Source: U.S. Energy Information Administration, *Electric Power Annual* (2010) (www.eia.doe.gov/).

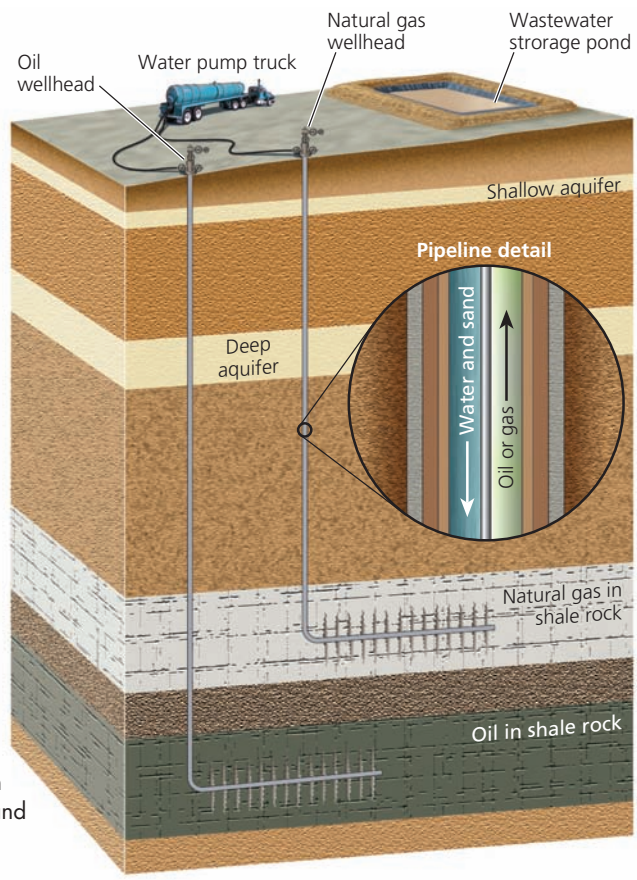
energy from other sources. In addition, societies have made an immense investment in the infrastructure needed to distribute and use this energy. Power plants using coal or natural gas cannot be converted readily to accommodate another fuel. The infrastructure for the distribution of energy—gas pipelines, service stations for cars, and the grid distributing electricity to users—is already in place. The system works well.

Because the system using fossil fuels works well, why do we worry about using fossil fuels? One major problem is that fossil fuels are *nonrenewable energy sources*. Nonrenewable sources are those for which the energy source is used and not concurrently replenished. Fossil fuels are the obvious example, and nuclear energy is in this category as well. Conversely, energy sources that involve using the Sun's energy are examples of *renewable resources*. These include solar energy and energy derived from wind, biomass, and moving water. Likewise, geothermal energy is a renewable resource.

There is a limited supply of fossil fuels, so we must ask how long our fossil fuels will last. Regrettably, there is not an exact answer. One estimate suggests that at current consumption rates and using current technology the world's oil reserves will be depleted in 30–80 years. Natural gas and coal supplies are projected to last longer: 60–200 years for natural gas and from 150 to several hundred years for coal. These numbers are uncertain, however, because assumptions must be made about the future rate of consumption and because estimates are based on guesses regarding reserves. The latter has become especially apparent recently because of the rapid rise in natural gas supply and use owing to the development of hydraulic fracturing or "fracking" (Figure 20.12) (*A Closer Look: Fracking*). In 2015, about 1.7 million wells



A CLOSER LOOK

Fracking

In April 2012 *Chemical & Engineering News* said that "The U.S. is on a natural gas binge. In a mere half-dozen years, natural gas production and prices have been transformed. Thanks to a new unconventional natural gas technology—hydraulic fracturing—the nation has seen natural gas production go from a trickle to a flood."

What is hydraulic fracturing or "fracking" as it is often called? It is a technique to release gas and oil from geological formations that contain hydrocarbons but that have been previously impervious to standard drilling techniques. In fracking, several million gallons of water, sand, and a cocktail of chemicals are forced under pressure into a shale or tight rock formation. This mixture opens fissures in the formation and allows the oil and gas to escape.

One problem with fracking is that other organic compounds, sulfur dioxide, and other waste materials come to the surface as well. Another is that enormous amounts of water are required. And finally, although methane is usually the desired product, some of it escapes capture and diffuses to the troposphere where it contributes significantly to the greenhouse effect.

Fracking. A mixture of water, other liquids, and sand is injected into a geological formation that may contain oil and gas (such as gas-rich shale). The fracking mixture opens fissures in the formation and gas and oil are released.

were producing oil and gas in the United States. With the development of hydraulic fracturing, it is likely that a number of new oil and natural gas wells will be drilled in the near future.

We cannot ignore the fact that a change away from fossil fuels must occur someday. As supply diminishes and demand increases, expansion to other fuel types will inevitably occur. Increased cost of energy based on fossil fuels will encourage these changes. The technologies to facilitate change, and the answers regarding which alternative fuel types will be the most efficient and cost-effective, can be aided by research in chemistry.

One energy source that has been exploited extensively in some countries is nuclear power (Table 20.3), and several European countries and South Korea generate more than 30% of their electricity this way. Certain countries (such as Iceland and New Zealand) are also able to exploit geothermal power as an energy source, and Germany and Spain plan on meeting 25% of their electrical energy needs with wind power by the year 2020.

Data for 2015 from www.nei.org

Energy Usage

Energy usage is related to the degree to which a country has industrialized: the more industrialized a country, the more energy is used on a per capita basis (Figure 20.13). This means that, as developing nations become more industrialized, personal energy usage worldwide will surely increase proportionally. There has been rapid growth in energy usage over the past two decades, and it is predicted rapid growth will continue in the next half-century.

Conservation and improving energy efficiency can alter energy consumption. This can mean consciously using less energy (such as driving less, turning off lights when not in use, and turning the thermostat down [for heating] or up [for cooling]). It can also mean using energy more efficiently. Some examples of more efficient energy use are:

- Recycling aluminum is now a common practice because it requires only one third of the energy needed to produce the metal from its ore.
- Light-emitting diodes (LEDs) are now used in streetlights, and compact fluorescent lights and LEDs are finding wider use in homes. Both use a fraction of the energy required by incandescent bulbs (in which only 5% of the energy used is delivered in the form of light; the remaining 95% is wasted as heat).
- Hybrid cars offer up to twice the gas mileage of conventional cars.
- Many newer appliances (from refrigerators to air conditioners) are designed to use less energy per delivered output.

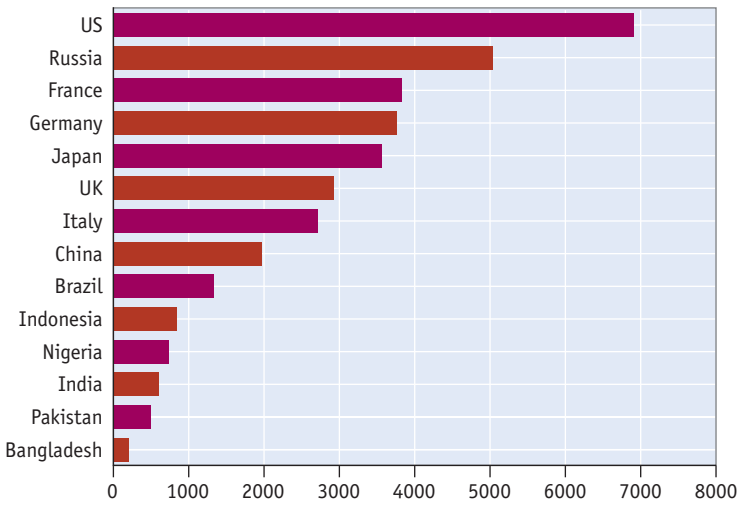

Figure 20.13 Energy use per capita. Usage from all sources is expressed in terms of their equivalent in kilograms of oil.

20.4 Fossil Fuels

Goal for Section 20.4

- Calculate and use enthalpy changes associated with burning of fossil fuels or with other reactions in the environment.

Fossil fuels originate from organic matter that was trapped under the Earth's surface for many millennia. Due to the particular combination of temperature, pressure, and available oxygen, the decomposition of organic matter resulted in the hydrocarbons we extract and use today: coal, crude oil, and natural gas—the solid, liquid, and gaseous forms of fossil fuels, respectively. These fuels are simple to use and are relatively inexpensive, compared with the current cost requirements of other sources for the equivalent amount of energy.

The hydrocarbons of fossil fuels have varying ratios of carbon to hydrogen, and their energy output from burning is related to that ratio (Table 20.4) . You can analyze this relationship using data on enthalpies of formation and by looking at the combustion of a fuel that is 100% carbon and another that is 100% hydrogen. For example, oxidation of 1.0 mol (12.01 g) of pure carbon produces 393.5 kJ of energy or 32.8 kJ/g.

$$C(s) + O_2(g) \rightarrow CO_2(g)$$

$$\Delta_r H° = -393.5 \text{ kJ/mol-rxn or } -32.8 \text{ kJ/g C}$$

In contrast, burning hydrogen to form water is much more exothermic on a per-gram basis, with about 120 kJ evolved per gram of hydrogen consumed.

$$H_2(g) + \tfrac{1}{2}\, O_2(g) \rightarrow H_2O(g)$$

$$\Delta_r H° = -241.8 \text{ kJ/mol-rxn or } -119.9 \text{ kJ/g } H_2$$

Coal is mostly carbon, so the amount of heat transferred is similar to that of pure carbon. On the other hand, methane is 25% hydrogen (by mass), and the higher molecular weight hydrocarbons in petroleum and products refined from petroleum average 16–17% hydrogen content. Therefore, the energy transferred as heat on a per-gram basis is greater than that of pure carbon but less than that of hydrogen itself.

While the basic chemical principles for extracting energy from fossil fuels are simple, there are complications in practice. Let us look at each of these fuels in turn.

TABLE 20.4

Energy Released by Combustion of Fossil Fuels

Substance	Energy Released (kJ/g)
Coal	29–37
Crude petroleum	43
Gasoline (refined petroleum)	47
Natural gas (methane)	50

Coal

The solid rock-like substance we call *coal* began to form almost 290 million years ago. Decomposition of plant matter occurred to a sufficient extent that the primary component of coal is carbon. However, coal samples vary considerably in their composition and characteristics. Carbon content may range from 60% to 95%, with variable amounts of hydrogen, oxygen, sulfur, and nitrogen present in various forms.

Sulfur, a common constituent in some coals, was incorporated into the mixture partly from decaying plants and partly from hydrogen sulfide, H_2S, a waste product from certain bacteria. In addition, coal may contain traces of many other elements, including some that are toxic (such as arsenic, mercury, cadmium, and lead) or radioactive (uranium and thorium).

Mercury from Coal "Coal-fired power plants are the largest source of human-generated mercury in the atmosphere. Mercury is neurotoxic and, in its elemental form, can stay in the atmosphere for a year or more." *Chemical & Engineering News*, January 30, 2017, page 5.

When coal is burned, some of the impurities are dispersed into the air, and some end up in the ash that remains. In the United States, coal-fired power plants are responsible for over 70% of the emissions of SO_2 and 33% of mercury emissions into the environment. (Power plants in the United States emit about 50 tons of mercury per year; worldwide, about 5500 tons are emitted.) Sulfur dioxide reacts with water and oxygen in the atmosphere to form sulfuric acid, which contributes (along with nitric acid) to *acid rain*.

$$2\ SO_2(g) + O_2(g) \rightarrow 2\ SO_3(g)$$

$$SO_3(g) + H_2O(\ell) \rightarrow H_2SO_4(aq)$$

TABLE 20.5 Types of Coal

Type	Consistency	Sulfur Content	Energy Released (kJ/g)
Lignite	Very soft	Very low	28–30
Bituminous coal	Soft	High	29–37
Anthracite	Hard	Low	36–37

Because these acids are harmful to the environment, legislation limits the extent of sulfur dioxide emissions from coal-fired plants. The combustion gases are passed through a water spray with chemicals such as limestone (calcium carbonate) to form solids that can be removed:

$$2\ SO_2(g) + 2\ CaCO_3(s) + O_2(g) \rightarrow 2\ CaSO_4(s) + 2\ CO_2(g)$$

These devices are expensive and increase the cost of energy produced. That, combined with the fact that natural gas is now much less expensive, means that coal is declining rapidly as a source of power in the United States (Figure 20.12).

Coal Declining in Use Figures 20.11 and 20.12 point to the significant decline in the use of coal for power generation since about 2000.

There are three categories of coal (Table 20.5 and Figure 20.14). *Anthracite*, or hard coal, is the highest-quality coal. Among the forms of coal, anthracite provides the largest amount of energy per gram and has a low sulfur content. Unfortunately, anthracite coal is uncommon, with only 2% of the U.S. coal reserves occurring in this form. *Bituminous coal*, also referred to as *soft coal*, accounts for about 45% of the U.S. coal reserves and is the coal most widely used in electric power generation. Soft coal typically has the highest sulfur content. *Lignite*, also called brown coal because of its paler color, is geologically the "youngest" form of coal. It releases a smaller amount of energy per gram than the other forms of coal, often contains a significant amount of water, and is the least satisfactory as a fuel.

Heating coal in the absence of air converts it to *coke*, which is almost pure carbon and is an excellent fuel. In the process of coke formation, a variety of organic compounds are driven off. These are used as raw materials in the chemical industry to produce polymers, pharmaceuticals, synthetic fabrics, waxes, tar, and numerous other products.

Technology to convert coal into gaseous fuels (coal gasification) or liquid fuels (liquefaction) is well known, but the extent to which these processes are used is limited by cost. They can provide fuels that burn more cleanly than coal, but

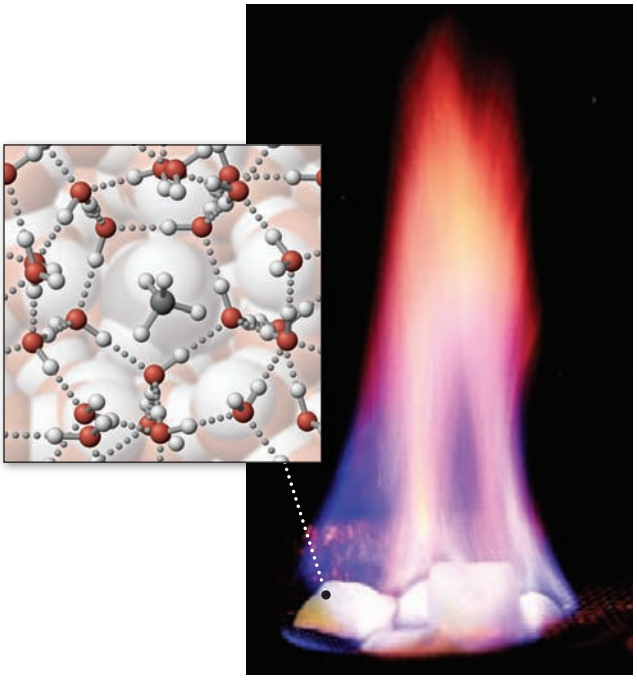
Figure 20.15 **Passenger bus powered by natural gas.**

30–40% of the available energy is lost in the process of generating these fuels. However, as petroleum and natural gas reserves dwindle and the costs of these fuels increase, liquid and gaseous fuels derived from coal could become more important.



Methane/Natural Gas

Natural gas is found deep under the Earth's surface. There is some debate as to how the gas formed, but one major theory is that it was produced by bacteria decomposing organic matter in an anaerobic environment (in which no O_2 is present). The major component of natural gas (70–95%) is methane (CH_4). Lesser quantities of ethane (C_2H_6), propane (C_3H_8), and butane (C_4H_{10}) may also be present, along with other gases including N_2, He, CO_2, and H_2S. The impurities and higher-molecular-weight components of natural gas are separated out during the refining process, so the gas piped into our homes is primarily methane.

Natural gas emits fewer pollutants when burned and produces relatively more energy than other fossil fuels. For this reason it is gaining increased use in municipal vehicles such as buses and trucks (Figure 20.15). It can be transported by pipelines and piped into buildings, where it is burned to heat ambient air, and to heat water for washing, bathing, and cooking. It is also a popular choice for new electrical power plants. Gas-fired power plants emit 40% less carbon dioxide than coal-burning plants and, in contrast to coal-fired power plants, there is no mercury pollution. In addition, the disposal of the solids left from coal combustion (called *fly ash*) is not an issue.

Just as importantly, prices of natural gas are less than half of what they were before 2010, in part because of the discovery of new sources such as hydraulic fracturing or "fracking" (*A Closer Look: Fracking*, page 932).

Finally, methane hydrates are a potential new source of methane (Figure 20.16). In 1970, oceanographers drilling into the seabed off the coast of South Carolina pulled up samples of a whitish solid that fizzed and oozed when it was removed from the drill casing. They quickly realized it was methane hydrate. Since this original discovery, methane hydrate has been found in many parts of the oceans as well as under permafrost in the Arctic. (The latter may be the source of the methane bubbles seen in ice in the Arctic and pictured on the cover of this book.) It is estimated that 1.5×10^{13} tons of methane hydrate are buried under the sea floor around the world. In fact, the energy available from this source may surpass that of all the other known fossil fuel reserves by as much as a factor of 2! Clearly, this is a potential source of an important fuel in the future.

J. Pinkston and L. Stern, U. S. Geological Survey https://www.sciencedaily.com/releases/2009/03/090323143858.htm

Figure 20.16 **Methane hydrate.** When a sample is brought to the surface from the depths of the ocean, the methane oozes out of the solid and can be burned. The structure of solid methane hydrate consists of methane trapped in a lattice of water. The lattice shown here is a common structural unit of a more complex structure. Each point of the lattice is an O atom of an H_2O molecule. The edges consist of an O···H—O series of atoms connected by a hydrogen bond and covalent bond. (Other, more complex structural units are known.) Such structures are often called "clathrates."

Figure 20.17 Tar sands. Tar sands are deposits of oil-rich bitumen mixed with clay and sand embedded in rocks often buried beneath the surface. Several tons of top soil must be removed for each barrel of bitumen, and large open-pit mines result. The largest tar sands reserves are in Alberta, Canada. The tar sands are an increasingly important source of petroleum, and Canada is planning a large increase in production.

Petroleum

Petroleum, a complicated mixture of hydrocarbons whose molar masses range from low to very high, is often found in porous rock formations that are bounded by impermeable rock (*A Closer Look: Petroleum Chemistry*, page 938). The hydrocarbons may have anywhere from one to 20 or more carbon atoms in their structures, and compounds containing sulfur, nitrogen, and oxygen may also be present, usually in small amounts.

Petroleum goes through extensive processing at refineries to separate the various components and convert less valuable compounds into more valuable ones. Nearly 85% of the crude petroleum pumped from the ground ends up being used as a fuel, either for transportation (gasoline and diesel fuel) or for heating (fuel oils).

Tar sands (also called **oil sands**) are another source of petroleum (Figure 20.17). They contain a very viscous organic liquid called *bitumen*. This is chemically similar to the highest-molecular-weight fraction obtained by distillation of crude oil. The largest source of tar sands in the world is in Alberta, Canada (the Athabasca sands), followed closely by those in Venezuela. Resources approaching 3.5 trillion barrels of oil—twice the world's known reserves of petroleum—are estimated in these two locations. The United States imports more oil from Canada than any other country (about 1 million barrels per day), and most of this is from the Athabasca oil sands.

Extracting the oil from sands is quite costly. Essentially, the sands must be mined and then mixed with hot water or steam to extract the bitumen. Once extraction is completed, the mined land must be restored (reclaimed), which adds to the cost of the process. Because most of the Canadian oil sands are located in dry areas, obtaining an adequate water supply for extraction is a significant constraint on increased production.

20.5 Alternative Sources of Energy

Goal for Section 20.5

- Know the various forms of alternative energy sources and some of their advantages and disadvantages.

At the present time the world economy is built on the use of fossil fuels. However, there will surely be a time when these fuels will become scarce, so chemists and engineers are looking for alternatives.

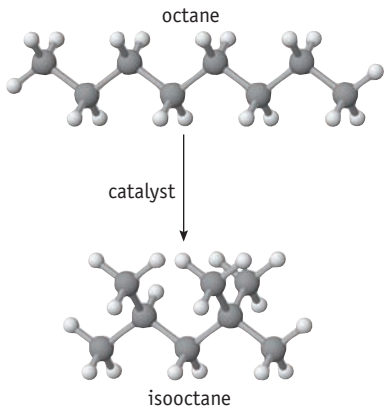
A CLOSER LOOK

Petroleum Chemistry

Much of the world's current technology relies on petroleum. Burning fuels derived from petroleum provides by far the largest amount of energy in the industrial world. Petroleum and natural gas are also the chemical raw materials used in the manufacture of many plastics, pharmaceuticals, and a vast array of other compounds.

The petroleum that is pumped out of the ground is a complex mixture whose composition varies greatly, depending on its source. The primary components of petroleum are always alkanes (hydrocarbons with the formula C_nH_{2n+2}), but, to varying degrees, nitrogen- and sulfur-containing compounds are also present. Aromatic compounds (such as benzene, C_6H_6) are present as well, but more reactive compounds with double and triple carbon–carbon bonds such as alkenes and alkynes are not.



©iStockphoto.com/Olivier Lantzendörffer

A modern petrochemical plant.

An early step in the petroleum refining process is distillation, in which the crude mixture is separated into a series of fractions based on boiling point: first a gaseous fraction (mostly alkanes with one to four carbon atoms; this fraction is often burned off), and then gasoline, kerosene, and fuel oils. After distillation, considerable material, in the form of a semisolid, tar-like residue, remains.

The petrochemical industry seeks to maximize the amounts of the higher-valued fractions of petroleum produced and to make specific compounds for which a particular need exists. This means carrying out chemical reactions involving the raw materials on a huge scale. One process to which petroleum is subjected is known as *cracking*. At very high temperatures, bond breaking or "cracking" can occur, and hydrocarbons with longer carbon chains fragment into smaller molecular units. These reactions are carried out using a wide array of catalysts, materials that speed up reactions and direct them toward specific products. Among the important products of cracking is ethylene (C_2H_4), which serves as the raw material for the formation of materials such as polyethylene. Cracking also produces other reactive hydrocarbons and gaseous hydrogen, both widely used raw materials.

Other important reactions involving petroleum are run at elevated temperatures and in the presence of specific catalysts. Such reactions include *isomerization* reactions, in which the carbon skeleton of an alkane rearranges to form a new isomeric species, and *reformation* processes, in which naphthas (petroleum distillates, mostly straight chain hydrocarbons) form more valuable products including cyclic and branched chain hydrocarbons. Each process is directed toward achieving a specific goal, such as increasing the proportion of branched-chain hydrocarbons in gasoline to obtain higher octane ratings.

Producing gasoline. Branched hydrocarbons have a higher octane rating in gasoline. Therefore, an important process in producing gasoline is the isomerization of octane to a branched hydrocarbon such as isooctane, 2,2,4-trimethylpentane.

Fuel Cells

In the United States in 2015, roughly equal amounts of electricity came from coal-fired power plants and from natural gas units (Figure 20.12). The heat of combustion from these fuels is used to produce high-pressure steam, which spins a turbine in a generator. Unfortunately, not all of the energy from the combustion can be converted to usable work. Some of the energy stored in the fuel is transferred as heat to the surroundings, making this an inherently inefficient process. The efficiency is about 35–40% for a coal-fired steam turbine and 50–55% for the newer natural gas turbines.

A much more efficient process is possible if electrons, the carriers of electricity, could be generated directly from chemicals, rather than going through an energy conversion process from heat to mechanical work to electricity. Fuel cell technology makes this direct conversion to electricity possible.

The electrochemistry of fuel cells was described in Section 19.3, and you saw that they are similar to batteries, except that fuel is supplied from an external source (Figure 20.18). They are more efficient than combustion-based energy production, with up to 60% energy conversion.

The net reaction in fuel cells is the oxidation of the fuel and the consumption of the oxidizing agent. Because the fuel and the oxidant never come directly in

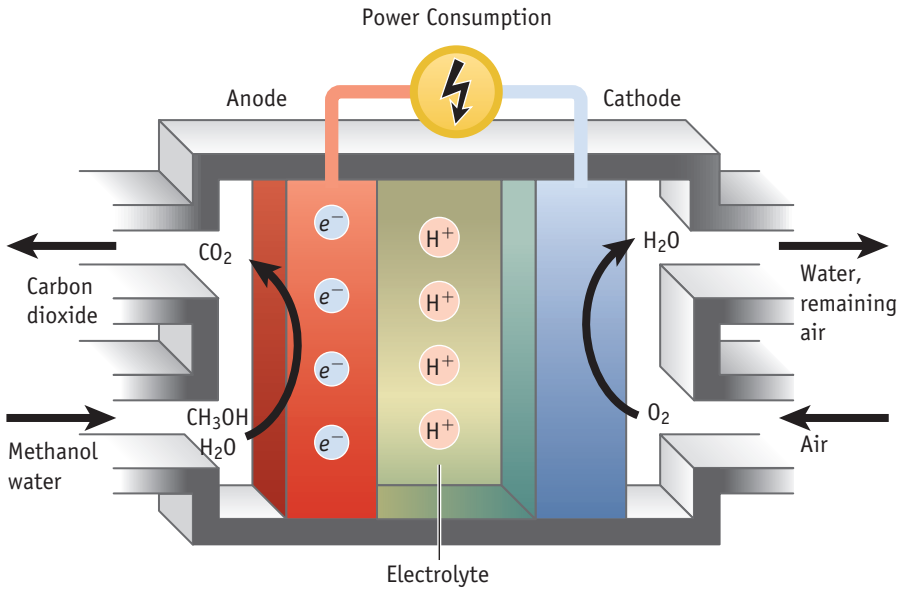

Figure 20.18 Fuel cell. This fuel cell uses methanol and oxygen as reactants (see Section 19.3 for the electrochemistry of fuel cells).

contact with each other, there is no combustion and thus minimal loss of energy as heat. The energy evolved in the reaction is converted directly to electricity.

Hydrogen fuel cells have been used on the Space Shuttle and in some prototype automobiles and buses. The overall reaction in these fuel cells is the combination of hydrogen and oxygen to form water. Hydrocarbon-based fuels such as methanol (CH_3OH) are also candidates for use as the fuel in fuel cells, where the net reaction in the cell is

$$CH_3OH(\ell) + {}^3/_2\ O_2(g) \rightarrow CO_2(g) + 2\ H_2O(\ell)$$

$$\Delta_r H° = -727\ \text{kJ/mol-rxn or } -23\ \text{kJ/g } CH_3OH$$

Using enthalpies of formation data (Section 5.7), you can confirm that the energy generated from this reaction is 727 kJ/mol-rxn (or 23 kJ/g) of liquid methanol. That is equivalent to 200 watt-hours (W-h) of energy per mole of methanol (1 W = 1 J/s), or 5.0 kW-h per liter of methanol.

Hydrogen

Predictions about the diminished supply of fossil fuels have led to speculation about alternative fuels, and hydrogen has been widely suggested as a possible choice. The term *hydrogen economy* has been used to describe the combined processes of producing, storing, and using hydrogen as a fuel.

There are reasons to consider hydrogen an attractive option. Oxidation of hydrogen yields several times as much energy per gram as the oxidation of fossil fuels. Comparing the combustion of hydrogen with that of propane, a fuel used in some cars, you can calculate that H_2 produces about 2.6 times more energy per gram than propane.

$$H_2(g) + {}^1/_2\ O_2(g) \rightarrow H_2O(g)$$

$$\Delta_r H° = -241.83\ \text{kJ/mol-rxn or } -119.95\ \text{kJ/g } H_2$$

$$C_3H_8(g) + 5\ O_2(g) \rightarrow 3\ CO_2(g) + 4\ H_2O(g)$$

$$\Delta_r H° = -2043.15\ \text{kJ/mol-rxn or } -46.37\ \text{kJ/g } C_3H_8$$

Another advantage of using hydrogen instead of a hydrocarbon fuel is that the only product of H_2 oxidation is H_2O.

The Linde Group

Figure 20.19 An industrial steam reforming plant.

Some have proposed that hydrogen might be able to replace gasoline in automobiles and natural gas to heat homes and even that it could be used as a fuel to generate electricity or to run industrial processes. Before this can happen, however, there are many practical problems to be solved, including the following as-yet unmet needs:

- An inexpensive method of producing hydrogen
- A practical means of storing hydrogen
- A distribution system (hydrogen refueling stations)

Perhaps the most serious problem is the task of producing hydrogen. Hydrogen is abundant on Earth, but not as the free element. Elemental hydrogen has to be obtained from its compounds. Currently, most hydrogen is produced industrially from the reaction of natural gas and water by *steam reforming* at high temperature (Figure 20.19).

$$\textit{Steam reforming}\quad CH_4(g) + H_2O(g) \rightarrow 3\ H_2(g) + CO(g)$$

$$\Delta_r H^\circ = +206.2\ \text{kJ/mol-rxn}$$

Hydrogen can also be obtained from the reaction of coal and water at high temperature (the so-called *water–gas reaction*).

$$\textit{Water–gas reaction}\quad C(s) + H_2O(g) \rightarrow H_2(g) + CO(g)$$

$$\Delta_r H^\circ = +131.3\ \text{kJ/mol-rxn}$$

Both steam reforming and the water–gas reaction are highly endothermic, and both rely on fossil fuels as raw materials. This, of course, makes no sense if the overriding goal is to replace fossil fuels.

If the hydrogen economy is ever to take hold, the logical source of hydrogen is water.

$$H_2O(\ell) \rightarrow H_2(g) + \tfrac{1}{2}\ O_2(g)$$

$$\Delta_r H^\circ = +285.83\ \text{kJ/mol-rxn}$$

The electrolysis of water provides hydrogen (Section 21.3) but also requires considerable energy. The first law of thermodynamics tells us that we can get no more energy from the oxidation of hydrogen than we expended to obtain H_2 from H_2O. In fact, we cannot even reach this break-even point because some of the energy will inevitably be dispersed (Chapter 18). Hence, the only way to obtain hydrogen from water in amounts that would be needed and in an economically favorable way is to use a cheap and abundant source of energy to drive this process. A logical candidate is solar energy, but, unfortunately, using solar energy in this way has yet to become practical. This is yet another problem for chemists and engineers to solve!

No matter how hydrogen is produced, it has to be delivered to vehicles and homes in a safe and practical manner. Again, problems remain to be solved. European researchers have found that a tanker truck that can deliver 2400 kg of compressed natural gas (mostly methane) can deliver only 288 kg of H_2 at the same pressure. Although hydrogen oxidation delivers about 2.4 times more energy per gram (119.95 kJ/g) than methane, the tanker can carry about eight times more methane than H_2. That is, it will take more tanker trucks to deliver the hydrogen needed to power the same number of cars or homes running on hydrogen than those running on methane.

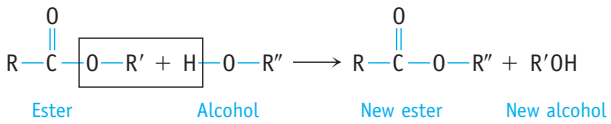
Biofuels

Biofuels now supply only about 2% of the fuel used worldwide for transportation, but some people predict that they may contribute much more to U.S. transportation needs by 2030. Biofuels include substances ranging from solids such as wood to bioethanol and biodiesel.

Gasoline sold today often contains ethanol, C_2H_5OH. If the ethanol is derived from fermentation of materials derived from biological sources, then it is sometimes referred to as **bioethanol**. In addition to being a fuel, ethanol improves the burning characteristics of gasoline. Every state in the United States now has available a blend of ethanol and gasoline, the most common being 10% ethanol and 90% petroleum-based fuels (*Applying Chemical Principles: The Fuel Controversy—Alcohol and Gasoline,* page 259).

Ethanol can be made readily by fermentation of sugars derived from renewable resources such as corn, sugar cane, sugar beets, or agricultural residues. It can also be derived from cellulosic materials such as trees and grasses, but the process is more complicated and is not now economically viable.



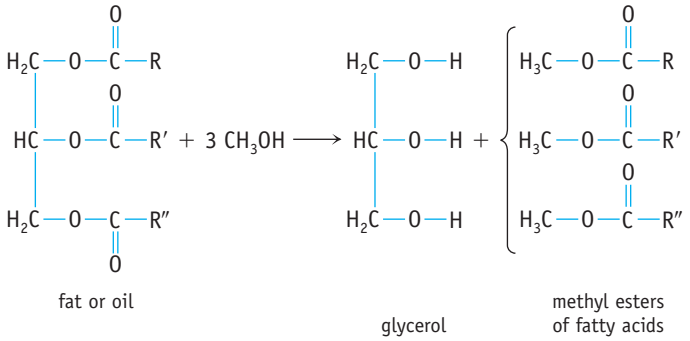
Brazil has made the production of ethanol from sugar cane a top priority. About 40% of the motor fuel sold in Brazil is ethanol, and most new cars sold in Brazil are "flex-fuel" cars that run on either gasoline or ethanol. The United States and Brazil produce 70% of the world's ethanol.

One significant problem with bioethanol is that the energy content of a liter of ethanol is only about two thirds that of a liter of gasoline. Unless the ethanol industry is subsidized, the cost of ethanol for transportation would be greater than the cost of using gasoline at current prices.

There are several points to be made about the use of ethanol as a fuel.

- Green plants use the Sun's energy to make biomass from CO_2 and H_2O by photosynthesis. The Sun is a renewable resource and so, in principle, is the ethanol derived from biomass.
- The process recycles CO_2. Plants use CO_2 to create biomass, which in turn is used to make ethanol. In the final step in this cycle, oxidation of ethanol returns CO_2 to the atmosphere.
- One serious issue concerning the use of corn-derived ethanol is the net energy balance. You have to consider the energy expended to run tractors and trucks, harvest corn, and make fertilizer, among other things, versus the energy available in the ethanol produced as the end product. Recent analyses and improvements in corn-to-ethanol technology seem to indicate more energy is available than is used in production, but not by much.

Biodiesel, promoted as an alternative to petroleum-based fuels used in diesel engines, is made from plant and animal oils. Chemically, biodiesel is a mixture of esters of long-chain fatty acids prepared from plant and animal fats and oils by *trans-esterification*. This is a reaction between an ester and an alcohol in which the —OR″ on the alcohol exchanges with the OR′ group of the ester (where R′ and R″ are organic groups):



Fats and oils are esters, derived from glycerol [$HOCH_2CH(OH)CH_2OH$] and high-molar-mass organic acids with at least 12 carbon atoms in the chain. Common fatty acids found in fats and oils are

lauric acid	$CH_3(CH_2)_{10}CO_2H$
myristic acid	$CH_3(CH_2)_{12}CO_2H$
palmitic acid	$CH_3(CH_2)_{14}CO_2H$
stearic acid	$CH_3(CH_2)_{16}CO_2H$
oleic acid	$CH_3(CH_2)_7CH{=}CH(CH_2)_7CO_2H$

The reaction of fats and oils with methanol (in the presence of a catalyst to speed up the reaction) produces a mixture of the methyl esters of the fatty acids and glycerol.

Jeff Greenberg/AGE Fotostock

Figure 20.20 The biodiesel bus. Buses at the University of California-San Diego are fueled by biodiesel.

Glycerol, a by-product of the reaction, is a valuable commodity for the health care industry, so it is separated and sold. The mixture of esters that remains can be used directly as a fuel in existing diesel engines, or it can be blended with petroleum products. In the latter case, the fuel mixture is identified by a designation such as B20 (B = biodiesel, 20 refers to 20% by volume). Biodiesel has the advantage of being clean burning with fewer environmental problems associated with exhaust gases than for petroleum-based diesel fuels (Figure 20.20). In particular, there are no SO_2 emissions, one of the common problems associated with petroleum-based diesel fuels.

20.6 Environmental Impact of Fossil Fuels

Goal for Section 20.6

- Know the identity of chemical pollutants in air and water and their effects on human life and on the global climate.

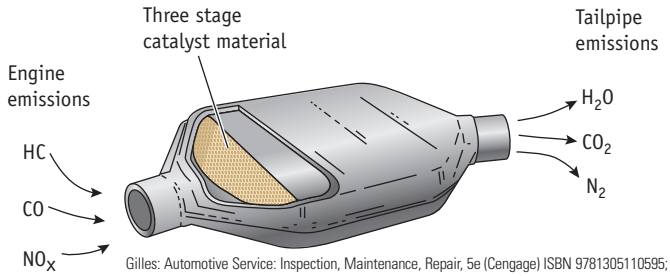
We are a carbon-based society—about 85% of the energy used in the world today comes from fossil fuels. Because of this, Earth's inhabitants have added gaseous compounds based on carbon, nitrogen, and sulfur to the environment, and, as their energy needs increase, will likely continue to do so. These compounds include mainly CO_2 but also CH_4, NO_x, and SO_2, which all have a significant impact on the environment.

Air Pollution

Local and international air pollution is one impact of the use of fossil fuels. The high temperature and pressure used in the combustion process in automobile engines have the unfortunate consequence of also causing a reaction between atmospheric nitrogen and oxygen that results in some NO formation. The NO can then react further with oxygen to produce nitrogen dioxide. This poisonous brown gas is further oxidized to form nitric acid, HNO_3, in the presence of water.

$$N_2(g) + O_2(g) \rightarrow 2\ NO(g) \qquad \Delta_r H° = 180.58\ kJ/mol\text{-}rxn$$

$$2\ NO(g) + O_2(g) \rightarrow 2\ NO_2(g) \qquad \Delta_r H° = -114.4\ kJ/mol\text{-}rxn$$



$$3\ NO_2(g) + H_2O(\ell) \rightarrow 2\ HNO_3(aq) + NO(g) \qquad \Delta_r H° = -71.4\ kJ/mol\text{-}rxn$$

Atmospheric NO The reaction between N_2 and O_2 is strongly disfavored at low temperatures, but it becomes more favorable at the high temperatures in an internal combustion engine (Reaction type 3 in Table 18.1).

Internal combustion engines in vehicles can add further to air pollution if they do not run at optimum efficiency. If an engine is not getting enough oxygen to effect complete combustion, exhaust emissions may also contain unburned hydrocarbons and carbon monoxide.

Gilles: Automotive Service: Inspection, Maintenance, Repair, 5e (Cengage) ISBN 9781305110595; Science Figure 43.1

Figure 20.21 Catalytic Converter. Currently automobiles use three-stage converters to convert combustion gases from the engine to water, CO_2, and N_2. In the first stage nitrogen oxides are reduced to N_2. In the second, unburned hydrocarbons and CO are oxidized to water and CO_2. The third stage is an oxygen sensor. Its function is to ensure there is enough oxygen in the exhaust stream to oxidize unburned hydrocarbons and CO. In addition, it adjusts the fuel injection system to make sure the engine is running close to the oxygen-to-fuel stoichiometric point. The catalyst in the converter is a mixture of noble metals (Pt, Pd, Rh) suspended in a ceramic honeycomb or on ceramic beads.

To some extent, the amounts of pollutants released can be limited by use of automobile catalytic converters. Catalytic converters are high-surface-area metal grids that are coated with platinum, palladium, or rhodium (Figure 20.21). These very expensive metals catalyze complete combustion, helping to combine oxygen in the air with unburned hydrocarbons or other by-products in the vehicle exhaust. As a result, the products of incomplete combustion can be converted to water and carbon dioxide (or other oxides). In addition, nitrogen oxides can be decomposed to N_2 and O_2. However, some nitric acid and NO_2 inevitably remain in automobile exhaust, and these compounds are major contributors to environmental pollution in the form of acid rain and smog. The brown acidic haze in highly congested cities such as Beijing, Los Angeles, Mexico City, and Houston results largely from automobile emissions. Such pollution problems have led to stricter emission standards for automobiles, and the development of low-emission or emission-free vehicles is a high priority in the automobile industry (motivated in part by emission standards of states such as California).

Greenhouse Effect and Global Warming/ Climate Change

The **greenhouse effect** is a name given to the trapping of energy in Earth's atmosphere by a process very similar to that occurring in glass-enclosed greenhouses in which plants are grown (Figure 20.22). The atmosphere, acting like glass in a greenhouse, is transparent to incoming solar radiation. This is absorbed by the Earth and re-emitted as infrared radiation. Gases in the atmosphere, like window glass, trap

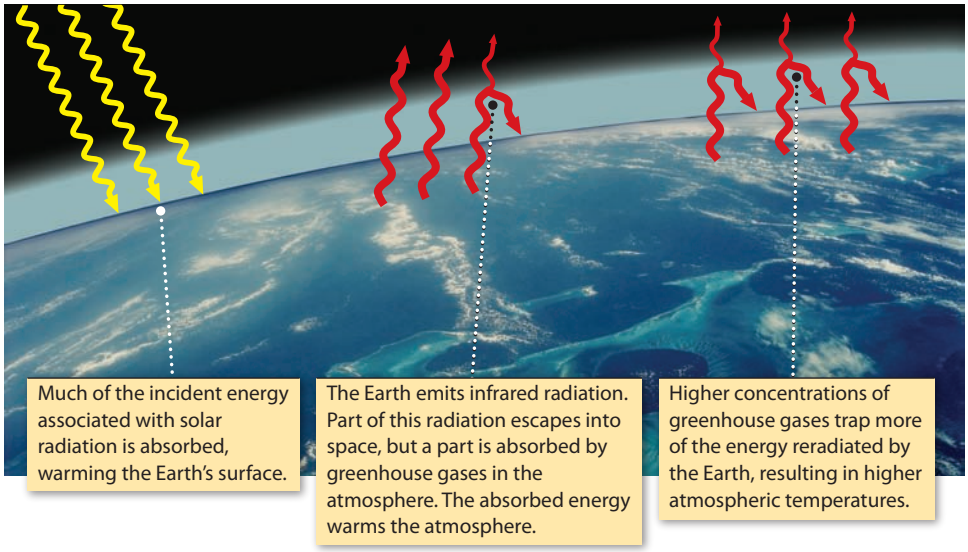
A CLOSER LOOK

The Clean Air Act

The Clean Air Act was enacted by the U.S. Congress in 1970 and amended twice since then. The act requires the Environmental Protection Agency (EPA) to set standards for air quality (NAAQS, National Ambient Air Quality Standards) for six common pollutants: particulates, ozone (ground level), CO, sulfur oxides, nitrogen oxides, and lead. Standards are set at two levels, a primary standard being health related and a secondary standard pertaining to environmental and property damage. For example:

Lead, primary and secondary, cannot exceed 0.15 $\mu g/m^3$.

Ozone, primary and secondary, 0.075 ppm, daily maximum 8-hour concentration averaged over 3 years.



The EPA monitors pollutant concentrations at sites throughout the country and determines whether or not the standards are attained. If standards are not met, states are required to develop a general plan to attain and maintain NAAQS.

See https://www.epa.gov/laws-regulations/summary-clean-air-act. This site provides links to sections of the U.S. Code containing the amended text of the Clean Air Act.

Figure 20.22 The greenhouse effect.

some of these longer infrared rays, keeping the Earth warmer than it would otherwise be.

The greenhouse effect is caused by certain gases in the troposphere. These gases are small molecules whose bonds vibrate with frequencies in the infrared region of the electromagnetic spectrum. Such a gas can trap infrared radiation, thus retaining energy that would otherwise be radiated into space.

Which gases can act as greenhouse gases depends solely on their composition. Gases that are single atoms, like argon, have no chemical bonds and so cannot interact with infrared light. Homonuclear diatomic molecules such as nitrogen (N_2) and oxygen (O_2) also do not absorb infrared radiation. Because these three gases make up 99% of the atmosphere, it is clearly beneficial that they are not greenhouse gases.

On the other hand, diatomic molecules with bonds between different atoms, such as HCl, and any molecules with three or more atoms, such as water (H_2O), carbon dioxide (CO_2), dinitrogen monoxide (N_2O), and methane (CH_4), are greenhouse gases. (Water vapor is the main greenhouse gas and accounts for most of the observed effect.) They allow Earth to warm more than it would based solely on its distance from the Sun. In this respect, these gases are vital. If Earth did not retain some energy supplied by the Sun, the average temperature would be too cold. Life would be impossible.

Much of the concern about global warming surrounds the use of fossil fuels and one of the products of their combustion, CO_2. As our society has increased its use of fossil fuels, the concentration of CO_2 in the air has increased. (The increase in CO_2 has been from about 280 ppm prior to the industrial revolution to about 410 ppm today.) Scientists are concerned that this increased concentration will enhance the natural greenhouse effect, causing the planet's temperature to rise.

The *Intergovernmental Panel on Climate Change* (IPCC, a scientific body under the auspices of the United Nations) has issued five Assessment Reports describing climate change. This term refers to the gradual warming of the surface air and oceans of the Earth and the consequences of that warming. The best estimate is that the surface temperature of the Earth has increased 0.6–0.9 °C during the last century and that it is continuing to increase (Figure 20.23).

Earth began to emerge from a cold period around 150 years ago. Will the natural cycle of temperature change create a warm period like those at the time of the Roman Empire and during the Middle Ages? Or has the increase in human population and the use of fossil fuels, both of which increase the level of CO_2 in the atmosphere, made an additional contribution that will result in a much warmer period than those earlier ages experienced?

Atmospheric CO_2 Levels The atmospheric level of CO_2 has risen over 80 ppm in the last 55 years to its current level (almost 409 ppm in June 2017). For more on CO_2 levels and the influence on ocean waters see the section on "Ocean Acidification" below. See also http://www.co2.earth.

Other Greenhouse Gases Industry has added new greenhouse gases to the atmosphere such as CFCs (chlorofluorocarbons) and volatile organic compounds (VOCs). Although some VOCs (e.g., isoprene and terpenes) are given off by trees, VOCs are also given off by paints, adhesives, plastics, air fresheners, and cosmetics. The family of CFCs has been replaced by a new generation of hydrofluorocarbon (HFC) compounds such as $F_3C—CH_2F$, also called HFC-134a, a compound now commonly used in air conditioners and refrigerators. While HFCs are better for the ozone layer than CFCs, they, like CFCs, are still greenhouse gases.

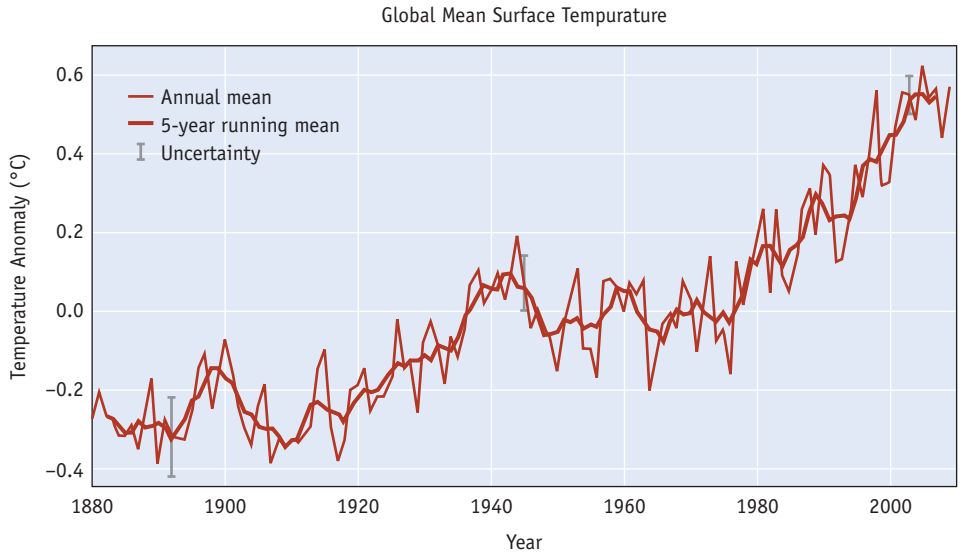

Figure 20.23 Variation in global mean surface temperatures for about 125 years. This plot from the NASA Earth Observatory shows that Earth's average surface temperature has increased by about 0.6–0.9 °C between 1905 and 2005. This also shows the *rate* of temperature change has nearly doubled in the last 50 years. This increase in surface temperarture shows no sign of abating.

In the first three of the IPCC Assessment Reports (1990), the authors warned that human activity might be partly responsible for raising the global temperature. Although some heeded the IPCC warnings, little was done to curtail the use of fossil fuels. However, some effort is now being directed into generating electricity by sustainable means such as wind power and solar panels. In 2007, the *Fourth Assessment Report* from IPCC went further by saying there is now little doubt that the planet is warming and that additions of greenhouse gases to the atmosphere by humans are having a measureable effect. (For the latest reports, see www.ipcc.ch.)

Ocean Acidification

Ocean acidification is one consequence of the increasing atmospheric concentration of CO_2. Oceanographers now believe that the planet's oceans have absorbed so much CO_2 from the atmosphere that the resulting levels of carbonic acid could fundamentally change the oceans.

As illustrated in Figure 20.24, the concentration of atmospheric CO_2 has been steadily increasing over the past several decades. In this regard, it is important to recall that the solubility of gases, and specifically CO_2, is directly related to the gas partial pressure (Section 13.3). An increase in concentration of CO_2 in the atmosphere will lead to a greater concentration of dissolved CO_2 and, because CO_2 is an acidic oxide, to a greater concentration of carbonic acid, H_2CO_3.

$$CO_2(aq) + H_2O(\ell) \rightleftharpoons H_2CO_3(aq) \qquad K = 650$$

The carbonic acid ionizes to produce low concentrations of bicarbonate and carbonate ions as well as hydronium ions.

$$H_2CO_3(aq) + H_2O(\ell) \rightleftharpoons H_3O^+(aq) + HCO_3^-(aq) \qquad K_{a1} = 4.2 \times 10^{-7}$$

$$HCO_3^-(aq) + H_2O(\ell) \rightleftharpoons H_3O^+(aq) + CO_3^{2-}(aq) \qquad K_{a2} = 4.8 \times 10^{-11}$$

Most importantly, as Figure 20.25 shows, these equilibria are a function of the pH of the solution. The most obvious effect, and an effect with environmental consequences, is that raising the CO_2 concentration will lead to a lower pH in lakes and oceans and thus to a decrease in the concentration of carbonate ion.

A result of the absorption of ever-increasing amounts of CO_2 has been that the pH of the oceans has declined from about 8.2 in the 18th century to about 8.07 presently. Data obtained in Hawaii since the late 1980s clearly shows the downward trend in pH (Figure 20.24).

The trends in CO_2 concentration and pH are clear, and there are at least two major consequences. The first is that sea organisms without shells, such as anemones

Reconstruction of Regional and Global Temperature for the Past 11,300 Years S. Marcott, J. D. Shakun, P. U. Clark, and A. C. Mix, *Science*, **2013,** *339*, 1198–1201. This paper showed there was a period from about 11,300 years ago to about 4000 years ago when the climate was warmer than in the period from about 2000 years ago to several hundred years ago. The very rapid, more recent rise in temperature shown in Figure 20.23 was confirmed. The authors state that "Global temperature . . . has risen from near the coldest to the warmest levels of the Holocene within the past century, reversing the long-term cooling trend that began about 5000 [years ago]."

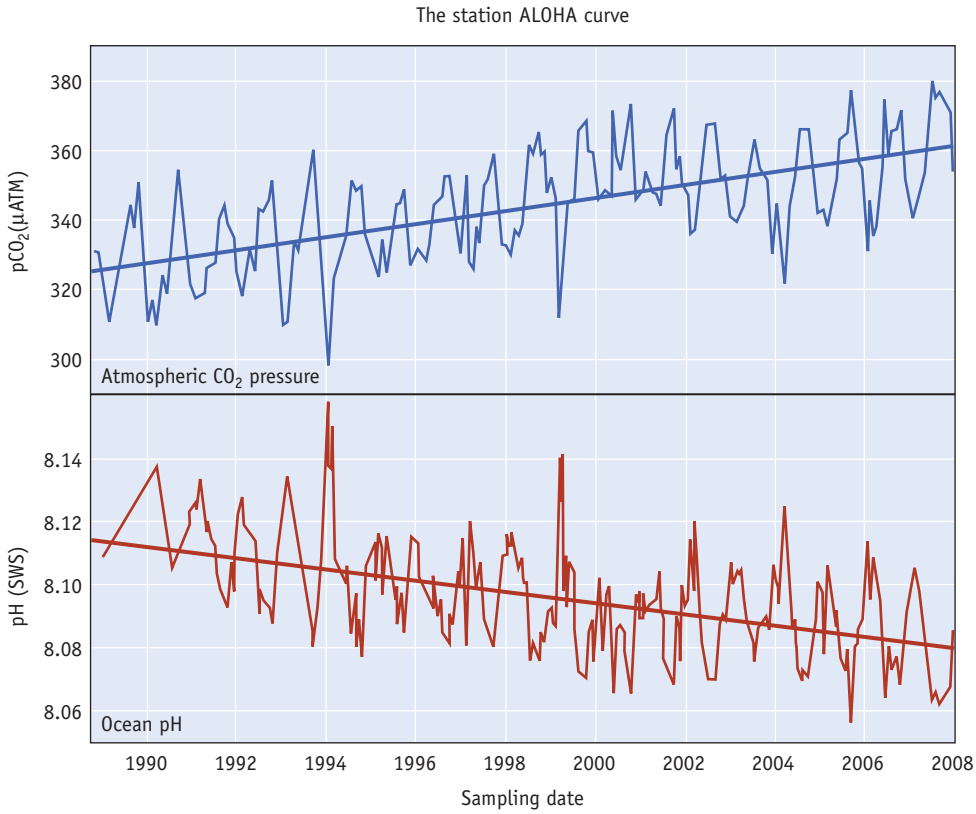

Figure 20.24 Changes in atmospheric and ocean CO_2 concentration and ocean pH at a station in Hawaii. There are seasonal variations in CO_2 concentration and pH, but the overall trends are clear.

Ocean Acidification ". . . the rate of ocean acidification is faster than at any time in the past 300 million years." B. Hönisch, *et al.*, *Science*, 2012, **335**, 1058–1063.

and jellyfish, will find it particularly difficult to regulate their functions. Many biochemical reactions are dependent on hydronium ion concentration, and, for creatures without shells, their internal pH is that of the surroundings. These organisms evolved over millennia to live in water with a pH of about 8.1–8.2. Because a drop of pH to 7.9 represents a doubling of the hydronium ion concentration, these organisms will surely be affected, likely adversely.

The second major consequence of the trend in CO_2 concentration is that the natural equilibrium involving calcium carbonate is upset.

$$CaCO_3(s) \rightleftharpoons Ca^{2+}(aq) + CO_3^{2-}(aq) \qquad K_{sp} \text{ for calcite} = 3.4 \times 10^{-9}$$

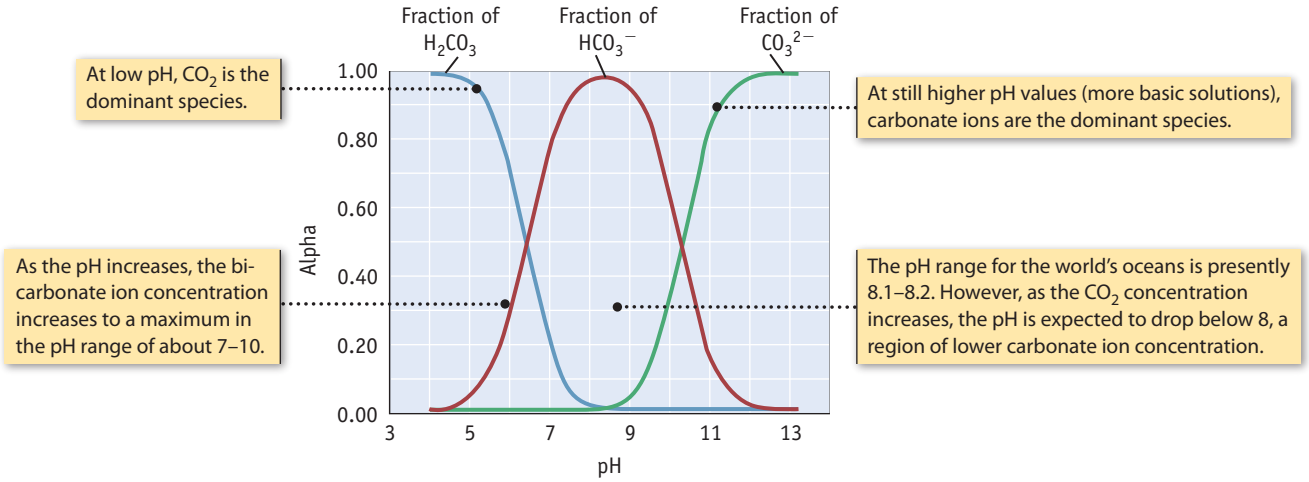

Figure 20.25 Distribution of species for a solution of CO_2 in water. This plot, called an alpha (α) plot, shows how the species in solution change as the pH changes.

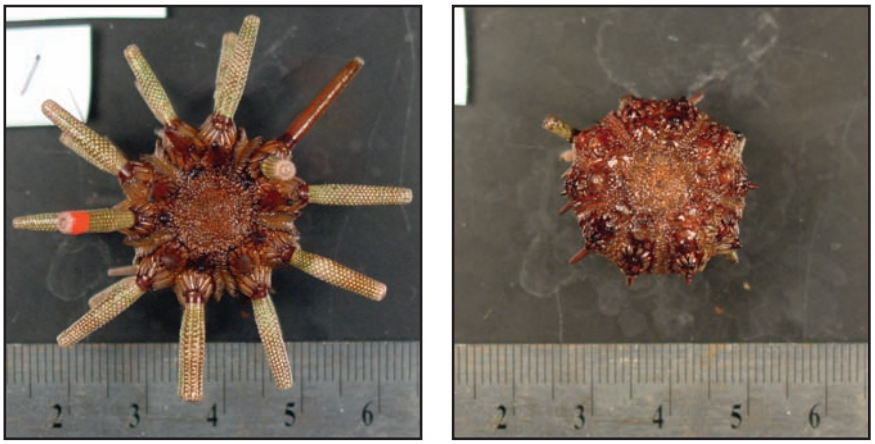

Figure 20.26 Sea urchins. The growth of spines by sea urchins depends on the level of CO_2 in the water.

When the pH of sea water drops, excess hydronium ions capture carbonate ions to produce bicarbonate ions,

$$H_3O^+(aq) + CO_3^{2-}(aq) \rightleftharpoons HCO_3^-(aq) + H_2O(aq) \qquad K = 1/4.8 \times 10^{-11} = 2.1 \times 10^{10}$$

thus reducing the carbonate ion concentration. Le Chatelier's principle tells us that additional calcium carbonate will dissolve to compensate for this disturbance. This has serious consequences for corals, which are built of calcium carbonate or for the shells of creatures with calcium carbonate exoskeletons such as oysters, clams, mussels, snails, and a wide variety of seashells (Figure 20.26).

Oceanographers often discuss the potential for calcium carbonate to form in terms of the saturation state, Ω (omega),

$$\Omega = \frac{[Ca^{2+}][CO_3^{2-}]}{K_{sp}}$$

Q* and *K This expression for Ω is equivalent to comparing the reaction quotient and equilibrium constant (Chapters 15–17).

where the product of the ion concentration in a given solution is divided by the solubility product constant, K_{sp}, for the mineral. If Ω is greater than 1, then the shell of an organism will not dissolve. If it is less than 1, then the mineral will dissolve.

It is relevant to this discussion of dissolving calcium carbonate to note that there are two forms of the mineral: aragonite (page 958) and calcite (page 810). Their solid-state structures are slightly different and so are their K_{sp} values

Aragonite and Calcite in Seawater The K_{sp} values for these minerals are more than 100 times larger in seawater than in freshwater. W. Stumm and J. Morgan, *Aquatic Chemistry,* 2nd edition, John Wiley, New York, 1981, page 243.

$$K_{sp} \text{ for aragonite in sea water} = 8.9 \times 10^{-7}$$

$$K_{sp} \text{ for calcite in sea water} = 6.3 \times 10^{-7}$$

Aragonite is slightly more soluble in sea water (at 25 °C) than is calcite. The importance of this is that most shells are made of aragonite, with possibly some parts made of calcite. The result is that organisms that produce aragonite are more vulnerable to changes in seawater pH.

20.7 Green Chemistry and Sustainability

Goal for Section 20.7

- Recognize the principles of green chemistry.

One goal of this book has been to introduce you to the practice of **green chemistry**, which is also called "sustainable chemistry." You first learned about green chemistry

Anastas, P. T.; Warner, J. C. *Green Chemistry: Theory and Practice*, Oxford University Press: New York, 1998, p. 30. Oxford University Press.

in Chapter 1, and you have seen examples of it throughout the book. Now that you are nearing the end of this book, you may better appreciate the complete *Twelve Principles of Green Chemistry.*

- **Prevention:** It is better to prevent waste than to treat or clean up waste after it has been created.
- **Atom Economy:** Synthetic methods should be designed to maximize the incorporation of all materials used in the process into the final product.
- **Less Hazardous Chemical Syntheses:** Wherever practicable, synthetic methods should be designed to use and generate substances that possess little or no toxicity to human health and the environment.
- **Designing Safer Chemicals:** Chemical products should be designed to effect their desired function while minimizing their toxicity.
- **Safer Solvents and Auxiliaries:** The use of auxiliary substances (e.g., solvents, separation agents, etc.) should be made unnecessary wherever possible and innocuous when used.
- **Design for Energy Efficiency:** Energy requirements of chemical processes should be recognized for their environmental and economic impacts and should be minimized. If possible, synthetic methods should be conducted at ambient temperature and pressure.
- **Use of Renewable Feedstocks:** A raw material or feedstock should be renewable rather than depleted whenever technically and economically practicable.
- **Reduce Derivatives:** Unnecessary derivatization (use of blocking groups, protection/deprotection, temporary modification of physical/chemical processes) should be minimized or avoided if possible, because such steps require additional reagents and can generate waste.
- **Catalysis:** Catalytic reagents (as selective as possible) are superior to stoichiometric reagents.
- **Design for Degradation:** Chemical products should be designed so that at the end of their function they break down into innocuous degradation products and do not persist in the environment.
- **Real-time Analysis for Pollution Prevention:** Analytical methodologies need to be further developed to allow for real-time, in-process monitoring and control prior to the formation of hazardous substances.
- **Inherently Safer Chemistry for Accident Prevention:** Substances and the form of a substance used in a chemical process should be chosen to minimize the potential for chemical accidents, including releases, explosions, and fires.

Green Chemistry Awards. The EPA (Environmental Protection Agency) makes annual awards for developments in Green Chemistry. https://www.epa.gov/greenchemistry/presidential-green-chemistry-challenge-winners

Examples of Green Chemistry in this book:

(a) Atom Economy, page 207
(b) Green Chemistry, Safe Dyes, and Molecular Orbitals, page 439
(c) Supercritical CO_2, page 514
(d) Polylactic acid, page 1100

If we assume the word "green" means environmentally sound or friendly, how can chemistry be green? People have many different opinions concerning chemistry and chemicals. Some use the word "chemical" as a synonym for a toxic substance. Others believe that all our problems can be solved through research in chemistry and other sciences. Chemists realize that all *matter*, including our food, water, and bodies as well as toxic compounds, is composed of chemicals. The practice of chemistry, like most aspects of life, has created problems at times, but chemistry has also solved many others.

20.1 Chlorination of Water Supplies

Chlorination is the oldest and most commonly used water disinfection method in the United States. Originally, chlorine gas was dissolved in water to yield hypochlorous acid (HClO),

$$Cl_2(g) + 2\ H_2O(\ell) \rightarrow HClO(aq) + H_3O^+(aq) + Cl^-(aq)$$

which partially ionizes to yield the hypochlorite ion (ClO^-).

$$HClO(aq) + H_2O(\ell) \rightleftharpoons H_3O^+(aq) + ClO^-(aq) \qquad K_a = 3.5 \times 10^{-8}$$

Two of the chemical species formed by chlorine in water—hypochlorous acid and the hypochlorite ion—are known to environmental engineers as **free available chlorine**, meaning they are available for disinfection. Because chlorine gas is quite toxic and can easily escape from damaged containers, many water treatment facilities have switched to solid hypochlorite salts such as sodium or calcium hypochlorite [NaClO and $Ca(ClO)_2$, respectively].

© Cengage Learning/Charles D. Winters

Chlorine tanks in the water treatment plant of a small city.

Hypochlorous acid and hypochlorite ion are effective in killing bacteria. However, they will also oxidize ions such as iron(II), manganese(II), and nitrite ion, as well as organic impurities. These substances are collectively known as the chlorine demand. To be available to kill bacteria, sufficient chlorine must be added to exceed the chlorine demand.

The advantages of chlorination include its relatively low cost and simple application as well as its ability to maintain residual disinfection throughout the distribution system. However, there are also disadvantages. Chlorine reacts with dissolved, naturally occurring organic compounds in the source water to form carcinogenic compounds such as trihalomethanes (of which chloroform, $CHCl_3$, is one example). Chlorination has also been blamed for causing an unpleasant taste and odor in some drinking water.

In 1998, the Disinfection Byproducts Rule (DBR), which limits the amount of chlorinated organic compounds in water, was implemented in the United States. One way to comply with the DBR is to add ammonia to the water, and about 30% of major U.S. water companies currently use this technique. Ammonia and hypochlorous acid (or hypochlorite ions) react to form chloramines such as NH_2Cl:

$$HClO(aq) + NH_3(aq) \rightarrow NH_2Cl(aq) + H_2O(\ell)$$

Chloramines are called **combined available chlorine**. Like free available chlorine, combined available chlorine is retained as a disinfectant throughout the water distribution system, but it is a weaker disinfectant overall. Combined available chlorine, however, has the advantage that it is less likely to lead to chlorinated organic compounds.

Questions:

1. Consider the reaction of Cl_2 in water to form aqueous HClO and HCl.
   a. This reaction is often referred to as a "disproportionation" reaction because an element increases and decreases in oxidation number in the reaction. How does that apply to this reaction?
   b. Calculate the value of E° and the equilibrium constant for the reaction of Cl_2 in water. [The required reduction half-reaction potentials are in Appendix M (Table 21).]
   c. How is E for the reaction affected by changing pH?
2. What is the overall equilibrium constant for the disproportionation reaction of Cl_2 in water?
3. What is the concentration of HClO in a 0.010 M solution of ClO^-? What is the pH of this solution?
4. Hypochlorite salts are often added to swimming pools and spas to kill microorganisms. At the Summer Olympics in 2016, several swimming pools turned green from an algae bloom. It seemed a mystery at first, but it was soon discovered that a technician had mistakenly added H_2O_2 and that it destroyed the hypochlorite ions, which allowed algae to flourish. Write a balanced equation for this reaction if the products are Cl^- and O_2.
5. As described above, ammonia and hypochlorous acid are used to produce "combined available chlorine" in water treatment. Ammonia and bleach are common household chemicals, but there have long been warnings about mixing the two to clean bathroom fixtures, for example. Is this warning valid? Why? Use the internet to research the main product of this reaction.

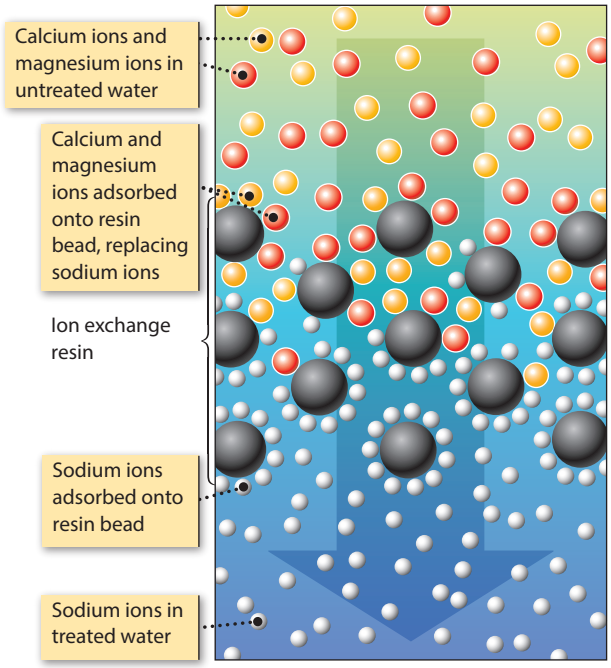
No, hard water doesn't refer to ice. It is the name given to water containing high concentrations of $Ca^{2+}(aq)$ and, in some instances, $Mg^{2+}(aq)$ and other divalent metal cations. Accompanying these cations will be various anions, including in particular the hydrogen carbonate anion, $HCO_3^-(aq)$.

Rainwater does not usually contain high concentrations of these ions, and so is not classified as "hard water." In many parts of the country, however, the municipal water supply comes from aquifers deep underground. If rainwater, containing some dissolved CO_2, has to percolate down through layers of limestone ($CaCO_3$) to get into the aquifer, a small amount of the solid will dissolve because of the following equilibrium:

$$CaCO_3(s) + CO_2(aq) + H_2O(\ell) \rightleftharpoons Ca^{2+}(aq) + 2\ HCO_3^-(aq)$$

If hard water containing $Ca^{2+}(aq)$ and $HCO_3^-(aq)$ is heated, or even if it is left to stand in an open vessel, CO_2 will be expelled, and the equilibrium will shift, precipitating $CaCO_3(s)$ (Section 15.1). This can be a small problem in a teakettle but a bigger problem in an industrial setting, where the solid $CaCO_3$ can clog pipes. Another consequence of hard water is that scum forms when soap is added. Soap is made by hydrolysis of fats, which produces long chain carboxylic acids. Soap scum is a precipitate of the calcium salt of these acids.



To avoid the problems associated with hard water, chemists and engineers have devised ways to "soften" water, that is, to decrease the concentration of the offending cations. In a water treatment plant for a municipality or a large industrial facility, most of the water hardness will be removed chemically, mainly by treatment with calcium oxide (lime, CaO). If HCO_3^- ions are present along with Ca^{2+} and/or Mg^{2+}, the following reactions occur:

$$Ca^{2+}(aq) + 2\ HCO_3^-(aq) + CaO(s) \rightarrow 2\ CaCO_3(s) + H_2O(\ell)$$

$$Mg^{2+}(aq) + 2\ HCO_3^-(aq) + CaO(s) \rightarrow CaCO_3(s) + MgCO_3(s) + H_2O(\ell)$$

Although it seems odd to add CaO to remove calcium ions, notice that adding one mole of CaO leads to the precipitation of two moles of Ca^{2+} as $CaCO_3$.

On a smaller scale, most home water purification systems use *ion exchange* to soften water (Figure). This process involves the replacement of an ion adsorbed onto a solid ion exchange resin by an ion in solution. Synthetic organic polymers with negatively charged functional groups (such as carboxylate groups, $—CO_2^-$) are the most commonly used resins for this purpose. Sodium ions, Na^+, are present in the resin to balance the negative charges of the carboxylate groups. The affinity of a surface for multi-charged cations is greater than for monovalent cations. Therefore, when a solution of hard water is passed

The general operation of an ion-exchange resin. The ion exchange material is usually a polymeric material formed into small beads.

over the surface of the ion exchange resin, Ca^{2+} and Mg^{2+} (and other divalent ions if present) readily replace Na^+ ions. This process can be illustrated in a general way by the equilibrium

$$2\ NaX + Ca^{2+}(aq) \rightleftharpoons CaX_2 + 2\ Na^+(aq)$$

where X represents an adsorption site on the ion exchange resin. The equilibrium favors adsorption of Ca^{2+} and release of Na^+. However, the equilibrium is reversed if $Na^+(aq)$ ions are present in high concentration, and this allows regeneration of the ion exchange resin. A solution containing a high concentration of Na^+ (usually from salt, NaCl) is passed through the resin to convert the resin back to its initial form.

Questions:

1. Assume that a sample of hard water contains 50. mg/L of Mg^{2+} and 150 mg/L of Ca^{2+}, with HCO_3^- as the accompanying anion. What mass of CaO should be added to 1.0 L of this aqueous solution to precipitate all the Mg^{2+} and Ca^{2+} as $CaCO_3$ and $MgCO_3$? What is the total mass of the two solids formed?
2. One way to remove the calcium carbonate residue in a teakettle is to add vinegar (a dilute solution of acetic acid). Write a chemical equation to explain this process. What kind of a reaction is this?

CHAPTER GOALS REVISITED

The goals of this chapter are keyed to specific Study Questions to help you organize your review.

20.1 The Atmosphere

- Know the important chemical components of Earth's atmosphere, how those components affect the Earth, and how they can be affected by pollutants. **1, 2, 5, 6, 43, 52, 58, 59.**

20.2 The Aqua Sphere (Water)

- Know the basic steps in water purification and be aware of common water pollutants. **7–9, 15, 46, 54.**

20.3 Energy

- Be aware of the general trends in energy use and energy sources. **17, 18, 21, 26.**

20.4 Fossil Fuels

- Calculate and use enthalpy changes associated with burning of fossil fuels or with reactions in the environment. **21, 23, 26, 29, 32.**

20.5 Alternative Sources of Energy

- Know the various forms of alternative energy sources and some of their advantages and disadvantages. **33, 35, 47, 51, 56.**

20.6 Environmental Impact of Fossil Fuels

- Know the identity of chemical pollutants in air and water and their effects on human life and on the global climate. **37–39.**

20.7 Green Chemistry and Sustainability

- Recognize the principles of green chemistry. **41.**

STUDY QUESTIONS

▲ denotes challenging questions. **Blue-numbered questions** have answers in Appendix N and fully worked solutions in the *Student Solutions Manual.*

Practicing Skills

The Atmosphere

(See Section 20.1.)

1. Which of the following atmospheric gases is present in highest concentration in dry air?
   (a) N_2O
   (b) CH_4
   (c) O_3
   (d) CO

2. Many chemical reactions that occur in the atmosphere and stratosphere involve free radicals. Free radical formation occurs when a photon of light is absorbed and the energy of the radiation being absorbed causes a chemical bond in the compound to break. Which of the following bonds requires the most energy (and the most energetic radiation) to be broken?
   (a) The oxygen-oxygen bond in O_2
   (b) The chlorine-carbon bond in CCl_2F_2
   (c) The oxygen-oxygen bond in O_3

Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

3. In the discussion on the composition of air, mention is made of the fact that water vapor may have a concentration as high as 40,000 ppm. Calculate the partial pressure exerted by water vapor at this concentration. Assume that this represents a situation with 100% humidity. What temperature would be needed to achieve this value? (See Appendix G.)

4. Assume the average CO_2 concentration in the atmosphere is 406 ppm (as of January 2017). The actual concentration of CO_2 at different sites will vary. Speculate on whether the concentration of CO_2 would be expected to be higher, lower, or the same as this average value in a typical large city.

5. A 2011 article in *Science* magazine stated that "Public discussion of climate change . . . is just beginning to reflect an awareness of the important role played by the global nitrogen cycle." (Figure 20.1.) As part of this cycle it was recently found that nitrite ions in soil can produce nitrous acid, HONO. [M. Kulmala and T. Petaja, *Science*, Vol. 333, pp. 1586–1587, 2011.]
   (a) Draw the Lewis electron dot structure for HONO and indicate the electron-pair geometry around the O and N atoms.
   (b) HONO is a source of hydroxyl radicals, $\cdot OH$, in the atmosphere because enough energy is supplied by sunlight to break the N—O bond. Use the bond dissociation enthalpy of the N—O bond (Table 8.8) to calculate the wavelength of light that could cause HONO to dissociate to the radicals $\cdot NO$ and $\cdot OH$.

6. Suppose you find the CO concentration in your home is 10. ppm by volume at 1.00 atm pressure and 25 °C. What is the CO concentration in mg/L and in ppm by mass. (The average molar mass for dry air is 28.96 g/mol at 1.00 atm pressure and 25 °C.)

The Aqua Sphere

(See Section 20.2.)

7. Various reagents are added to water supplies to kill pathogens and make the water safe to drink. Among the substances listed below, which does not serve that function?
   (a) Cl_2
   (b) O_3
   (c) $Ca(ClO)_2$
   (d) $Al_2(SO_4)_3$

8. Which of the following statements is not correct?
   (a) Phosphates enhance the growth of algae in surface water.
   (b) Melting of the polar ice cap will result in a rise in sea levels.
   (c) Heavy metal toxicity can result from the presence of metal compounds of lead, cadmium, and mercury in water supplies.
   (d) Reverse osmosis is a good way to effect desalination.

9. The carbon content in seawater is 30 mmol/L (Table 20.2). This includes both HCO_3^- and CO_3^{2-} ions. Knowing the pH of seawater is 8.1, what is the ratio of concentrations of these two ions in seawater? (Figure 20.25.)

10. Using the data in Table 20.2, estimate the minimum mass of solid that would remain after evaporation of 1.0 L of seawater.

11. What mass of NaCl could be obtained by evaporating 1.0 L of seawater? (*Note:* The amount of Na^+ ions in seawater limits the amount of NaCl that can be obtained.)

12. In any solution, there must be a balance between the positive and negative charges of the ions that are present. Use the data in Table 20.2 to determine how close to a balance of charge is achieved for the ions in seawater. (The table lists only the major ions in seawater, and the balance between positive and negative charge will only be approximate.)

13. Although there are a number of magnesium-containing minerals, the commercial source of this metal is seawater. Treatment of seawater with $Ca(OH)_2$ gives insoluble $Mg(OH)_2$. This reacts with HCl to produce $MgCl_2$, which is dried, and the metal is obtained by electrolysis of the molten salt. Write balanced net ionic equations for the three reactions described here.

14. Calculate the mass of Mg that could be obtained by the process described in Study Question 13 from 1.0 L of seawater. To prepare 100. kg of Mg, what volume of seawater would be needed? (The density of seawater is 1.025 g/cm^3.)

15. A 2010 article in *Science* magazine described "Sewage Treatment with Anammox." [B. Kartal, J. G. Kuenen, and M. C. M. van Loosdrecht, *Science*, Vol. 328, pp. 702-703, 2010.] The authors noted that "Fixed nitrogen such as ammonium and nitrate [ions] must be removed [from sewage] to avoid toxic algal blooms in the environment." One approach to removing ammonium ions is to use ammonium-oxidizing (anammox) bacteria. Two (unbalanced) reactions that are involved are:

$$NH_4^+(aq) + NO_2^-(aq) \rightarrow N_2(g) + H_2O(\ell)$$

$$NH_4^+(aq) + O_2(g) \rightarrow NO_2^-(aq) + H_2O(\ell)$$

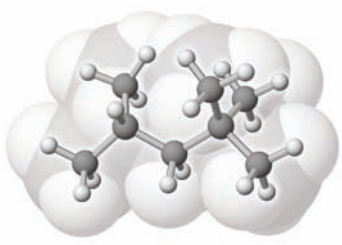
Balance these two equations in acid solution.

16. Silver ions have long been known to have biocidal properties. The increasing use of silver for this purpose has led to greater silver concentrations in waste water, and there has been some concern about it. However, recent studies found that the silver was largely put back into the environment as Ag_2S. The solubility of this sulfide is 1.4×10^{-4} g/L.
    (a) Estimate the K'_{sp} for Ag_2S. (See Table 18b in Appendix J.)
    (b) How does the solubility of Ag_2S change as the pH decreases?

Energy and Fossil Fuels

(See Sections 20.3 and 20.4.)

17. Which of the following is a renewable energy resource?
    (a) nuclear fusion
    (b) hydroelectric power
    (c) natural gas
    (d) coal



18. In the United States (and worldwide), fossil fuels provide the larger source of energy. What is the second largest energy source?
    (a) hydroelectric
    (b) solar
    (c) nuclear
    (d) geothermal

19. Hydrogen can be produced using the reaction of steam (H_2O) with various hydrocarbons. Compare the mass of H_2 expected from the reaction of steam with 100. g each of methane, petroleum, and coal. (Assume complete reaction in each case. Use CH_2 and C as the representative formulas for petroleum and coal, respectively.)

20. Use the value for "energy released" in kilojoules per gram from gasoline listed in Table 20.4 to estimate the percentage of carbon, by mass, in gasoline. (*Hint*: Compare the value for gasoline to the $\Delta_r H°$ values for burning pure C and H_2.)

21. Per capita energy consumption in the United States has been equated to the energy obtained by burning 70. lb of coal per day. Use enthalpy of formation data to calculate the energy transferred as heat, in kilojoules, when 70. lb of coal is burned. (Assume the enthalpy of combustion of coal is 33 kJ/g.)

22. The enthalpy of combustion of isooctane (C_8H_{18}), one of the many hydrocarbons in gasoline, is 5.45×10^3 kJ/mol. Calculate the enthalpy change per gram of isooctane and per liter of isooctane (d = 0.688 g/mL).

isooctane
C_8H_{18}

23. Energy consumption in the United States amounts to the equivalent of the energy obtained by burning 7.0 gal of oil or 70. lb of coal per day per person. Using data in Table 20.4, carry out calculations to show that the energy evolved from these quantities of oil and coal is approximately equivalent. The density of fuel oil is approximately 0.8 g/mL. (1.00 gal = 3.785 L and 1.00 lb = 454 g)

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

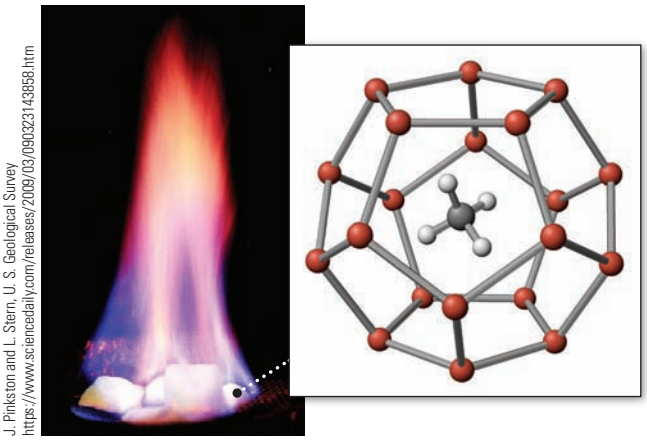
24. Calculate the energy used, in kilojoules, to power a 100-watt lightbulb continuously over a 24-hour period. How much coal would have to be burned to provide this quantity of energy, assuming that the enthalpy of combustion of coal is 33 kJ/g and the power plant has an efficiency of 35%? [Electrical energy for home use is measured in kilowatt hours (kW-h). One watt is defined as 1 J/s, and 1 kW-h is the quantity of energy transferred when 1000 watt is dispensed over a 1.0-hour period.]

25. Confirm the statement in the text that oxidation of 1.0 L of methanol to form $CO_2(g)$ and $H_2O(\ell)$ in a fuel cell will provide at least 5.0 kW-h of energy. (The density of liquid methanol is 0.787 g/mL. See Study Question 24 for definition of kW-h.)

26. List the following substances in order of energy released by combustion per gram: C_8H_{18}, H_2, C(s), CH_4. (See Study Question 22 for the enthalpy of combustion of isooctane, C_8H_{18}.) Which is the best fuel based on a comparison of kJ/g of fuel?

27. A parking lot in Los Angeles receives an average of 2.6×10^7 J/m^2 of solar energy per day in the summer.

(a) If the parking lot is 325 m long and 50.0 m wide, what is the total quantity of energy striking the area per day?



(b) What mass of coal would have to be burned to supply the quantity of energy calculated in (a)? (Assume the enthalpy of combustion of coal is 33 kJ/g.)

28. Your home loses energy in the winter through doors, windows, and any poorly insulated walls. A sliding glass door (6 ft $\times$ 6.5 ft with 0.5 inch of insulating glass) allows 1.0×10^6 J/h to pass through the glass if the inside temperature is 22 °C (72 °F) and the outside temperature is 0 °C (32 °F). What quantity of energy, expressed in kilojoules, is lost per day? Assume that your house is heated by electricity. How many kilowatt-hours of energy are lost per day through the door? (See Study Question 24 for the definition of a kilowatt-hour.)

29. Some fuel-efficient hybrid cars are rated at 55.0 miles per gallon of gasoline. Calculate the energy used to drive 1.00 mile if gasoline produces 48.0 kJ/g and the density of gasoline is 0.737 g/cm^3. (1.00 gal = 3.785 L)

30. Microwave ovens are highly efficient, compared to other cooking appliances. A 1100-watt microwave oven, running at full power for 90 seconds, will raise the temperature of 1 cup of water (225 mL) from 20 °C to 67 °C. As a rough measure of the efficiency of the microwave oven, compare its energy consumption with the energy required to raise the water temperature.

31. In methane hydrate the methane molecule is trapped in a cage of water molecules. Describe the structure: (a) how many water molecules make up the cage, (b) how many hydrogen bonds are involved, and (c) how many faces does the cage have? (Figure 20.16.)

J. Pinkston and L. Stern, U. S. Geological Survey
https://www.sciencedaily.com/releases/2009/03/090323143858.htm

(a) Methane hydrate burns as methane gas escapes from the solid hydrate.

(b) Methane hydrate consists of a lattice of water molecules with methane molecules trapped in the cavity.

32. One cubic meter of methane hydrate has 164 m^3 of CH_4 (at STP). If you burn the methane in 1.00 m^3 of hydrate [to give $CO_2(g)$ and $H_2O(g)$], how much energy, as heat, can be obtained?

Alternative Fuels

(See Section 20.5.)

33. Which of the following is not a limitation for the use of hydrogen as a fuel?

(a) An inexpensive method of producing hydrogen

(b) A practical means of storing hydrogen

(c) Hydrogen is explosive

(d) A distribution system (hydrogen refueling stations)

34. Which of the following statements is true?

(a) Fuel cells are widely used in automobiles.

(b) H_2 is readily available as a transportation fuel.

(c) Petroleum is a mixture of hydrocarbons.

(d) Methane hydrate can never be developed as a commercial energy resource.

35. Methyl myristate, $C_{13}H_{27}CO_2CH_3(\ell)$, can be used as a biofuel.

(a) Write a balanced chemical equation for the reaction that occurs when 1 mol of methyl myristate, $C_{13}H_{27}CO_2CH_3(\ell)$, is burned, forming $CO_2(g)$ and $H_2O(g)$.

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

(b) Using enthalpy of formation data, calculate the standard enthalpy change for the oxidation of 1.00 mol of methyl myristate ($\Delta_f H°$ = −771.0 kJ/mol) to form $CO_2(g)$ and $H_2O(g)$.

(c) Which compound, methyl myristate [$C_{13}H_{27}CO_2CH_3(\ell)$] or hexadecane ($C_{16}H_{34}$, one of many hydrocarbons in petroleum based diesel fuel), is predicted to provide the greater energy per mole of fuel? Per liter? ($\Delta_f H°$ for $C_{16}H_{34}$ = −456.1 kJ/mol) [d(methyl myristate) = 0.86 g/mL, and $d(C_{16}H_{34})$ = 0.77 g/mL].

36. Generating hydrogen gas using the least amount of energy possible is very desirable. One proposed scheme is the catalyzed decomposition of formic acid, HCO_2H. [S. Ott, *Science*, Vol. 333, pp. 1714–1715, 2011.]

$$HCO_2H(g) \rightleftharpoons CO_2(g) + H_2(g)$$

A particularly interesting aspect of this reaction is that it can be run in reverse and so serve as a way of storing hydrogen. Calculate the equilibrium constant (at 298 K) for the decomposition reaction using thermodynamic data. Is the decomposition reaction product-favored at equilibrium at 298 K? (For $HCO_2H(g)$, $\Delta_f H°$ = −378.6 kJ/mol and $S°$ = 248.70 J/K·mol.)

Environmental Impact of Fossil Fuels

(See Section 20.6.)

37. Which of the species listed below is not a greenhouse gas?

(a) H_2O (c) CO_2

(b) CH_4 (d) O_2

38. What is the correlation between ocean pH and atmospheric CO_2?

(a) As CO_2 increases, the pH decreases.

(b) As CO_2 increases, the pH also increases.

(c) As CO_2 increases, the pH does not change.

39. Dinitrogen monoxide, N_2O (commonly called nitrous oxide), is prepared by the careful decomposition of ammonium nitrate and is used as an oxidizing agent in rocket engines as well as a weak general anesthetic (where you may know it as "laughing gas"). However, it is also known to be a powerful greenhouse gas. In a *Science* magazine article, it was stated that "Human activities may be causing an unprecedented rise in the terrestrial N_2O source. Marine N_2O production may also rise substantially as result of eutrophication, warming, and ocean acidification." [L. A. Codispoti, *Science*, Vol. 327, pp. 1339-1340, 2010.]

© Cengage Learning/Charles D. Winters

The powerful greenhouse gas N_2O is used as a propellant in cans of instant whipped cream.

(a) Draw a Lewis electron dot structure for N_2O, and specify the formal charge on each atom and the molecular geometry.

(b) The atom connections are N—N—O. Why is the connection N—O—N not likely?

(c) The highest N_2O concentration observed in the ocean is about 800 nM (nanomolar). At this concentration, what is the mass of N_2O per liter?

40. In 2005, global SO_2 emission was estimated to be 12.83 Gg (gigagrams). According to the EPA, 71% of SO_2 emissions into the atmosphere is from coal-fired power plants. How much coal (in metric tons) must have been burned to produce this much SO_2, assuming that coal is 2.0% sulfur?

Green Chemistry

(See Section 20.7.)

41. Acetonitrile, CH_3CN, is an important solvent. The chemical is normally available as a by-product of the manufacture of acrylonitrile, CH_2=CHCN, the building block of polyacrylonitrile, a widely used polymer. Recently, however, the demand for acrylonitrile dropped, so the supply of acetonitrile diminished to a point where users of the solvent were concerned. For that reason new methods were sought for the synthesis of CH_3CN, and a new "green" method was reported.

Step 1: reaction of ethanol (C_2H_5OH) with ammonia to give ethylamine ($C_2H_5NH_2$) and water.

Step 2: reaction of ethylamine and oxygen (over a ruthenium oxide/aluminum oxide catalyst) to give acetonitrile and water.

(a) Draw Lewis electron dot structures for ethanol, ethylamine, acetonitrile, and acrylonitrile. Specify the molecular geometry around each C atom and, as appropriate, around the O or N atoms.

(b) Write balanced equations for each step in the synthesis of acetonitrile from ethanol.

(c) Calculate the atom economy for the synthesis of acetonitrile from ethanol. (Atom economy is discussed in *Applying Chemical Principles, 4.1, Green Chemistry and Atom Economy*, page 207.)

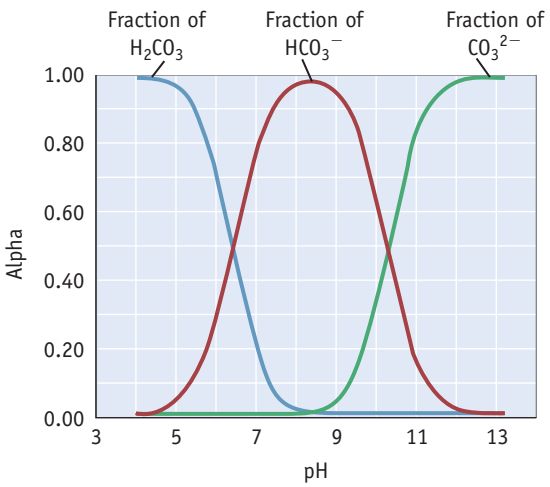
Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

42. The refrigerating liquids in air conditioners and refrigerators are largely chlorofluorocarbons (CFCs) and hydrochlorofluorocarbons (HCFCs). Among the latter family of compounds is the refrigerant HCFC-22 ($HCClF_2$). A problem with the use of HCFC-22 is that HFC-23 (trifluoromethane, HCF_3), a gas with high-global-warming potential, is a by-product of its production (and also from the production of the widely used polymer Teflon). Discarding HFC-23 safely can be a problem. However, recently a method has been developed to convert it to the valuable catalyst trifluoromethanesulfonic acid, CF_3SO_3H. Draw an electron dot structure for the acid (which you can think of as sulfuric acid with a CF_3 group in place of one OH group). Indicate the geometry around the C and S atoms. What is the hybridization of these two atoms?

General Questions

These questions are not designated as to type or location in the chapter. They may combine several concepts.

43. Chlorine atoms are formed by photochemical reactions of chlorofluorocarbons in the upper atmosphere. Using the average bond energy of the C—Cl bond in Table 8.8, calculate the wavelength of radiation with sufficient energy to break the C—Cl bond. In what region of the electromagnetic spectrum does this fall?



44. The formation of NO from N_2 and O_2 is unfavorable at 298 K, but it becomes increasingly favored at high temperatures such as those in an automobile cylinder. Using data ($\Delta_f H°$, $S°$ and $\Delta_f G°$) in Appendix L, calculate the equilibrium constant for the reaction $\frac{1}{2}\ N_2(g) + \frac{1}{2}\ O_2(g) \rightarrow NO(g)$ at 298 K and at 1000 K.

45. The nitrogen cycle (Figure 20.1) shows the oxidation of NH_4^+, first to NO_2^- and then the subsequent oxidation of NO_2^- to NO_3^-. Write balanced equations for each of these half-reactions (in acid solution).

46. Steps have been taken to limit phosphorus in surface water. However, the amounts of nitrogen-containing species in surface water can also be a problem because they also promote excessive growth of algae and water plants. What are likely sources of this nitrogen? What nitrogen compounds are likely to be present in surface water?

47. Here we want to compare ethanol (C_2H_5OH) and gasoline as fuels. We will use isooctane (C_8H_{18}) as a substitute for gasoline. (Isooctane is one of the many hydrocarbons in gasoline, and its enthalpy of combustion will approximate the energy obtained when gasoline burns. See Study Question 22.)
    (a) Calculate $\Delta_r H°$ for the combustion of 1.00 kg each of liquid ethanol and liquid isooctane. Which fuel releases more energy per kilogram? [$\Delta_f H° = -259.3$ kJ/mol for liquid isooctane at 298 K.] (Assume $H_2O(\ell)$ is one product of combustion.)
    (b) Compare the two fuels on the basis of the release of CO_2, a common greenhouse gas. Which fuel produces more CO_2 per kilogram?
    (c) On the basis of this simple comparison and neglecting the energy costs involved in producing 1.00 kg each of ethanol and isooctane, which is the better fuel in terms of energy production and greenhouse gases?

48. Refer to the figure below and Figure 20.25, which show the fraction of species in solution [alpha (α)] as a function of pH. The following questions are in regard to the equilibria involved in an aqueous solution of H_2CO_3 (dissolved CO_2) in fresh water at 25 °C.
    (a) At what pH does $[H_2CO_3(aq)] = [HCO_3^-]$?
    (b) At what pH does $[HCO_3^-] = [CO_3^{2-}]$?
    (c) What is the predominant species in solution when the solution has a pH of 8?
    (d) What species are in solution when the solution has a pH of 7?

In the Laboratory

49. Imagine the following experiment: You have a large graduated cylinder containing 100. mL of liquid water at 0 °C. You drop an ice cube with a volume of 25 cm^3 into the cylinder. Ice has a density of 0.92 g/cm^3, less than the density of liquid water, so it floats with 92% being under water.
    (a) To what level will the water in the graduated cylinder rise after adding the ice?
    (b) Allow the ice to melt. What volume will now be occupied by the liquid water? (One consequence of global warming will be a rise in sea level as ice in the northern and southern regions of the planet melts. However, the effect relates only to melting of ice on land. Melting of floating ice will have no effect on sea levels.)

50. The mineral claudetite contains the element arsenic in the form of arsenic(III) oxide, As_2O_3. The As_2O_3 in a 0.562-g sample of the impure mineral was converted first to H_3AsO_3 and then titrated with a 0.0480 M solution of I_3^-, which reacts with H_3AsO_3 according to the following balanced net ionic equation

$$H_3AsO_3(aq) + 3\ H_2O(\ell) + I_3^-(aq) \rightarrow H_3AsO_4(aq) + 2\ H_3O^+(aq) + 3\ I^-(aq)$$

    If the titration required 45.7 mL of the I_3^- solution, what is the percentage of As_2O_3 in the mineral sample?

Summary and Conceptual Questions

The following questions may use concepts from this and previous chapters.

51. Define the terms *renewable* and *nonrenewable* as applied to energy resources. Which of the following energy resources are renewable: solar energy, coal, natural gas, geothermal energy, wind power?

52. What are the three most abundant gases in the atmosphere? Are any of these greenhouse gases?

53. What are the environmental consequences of ozone in the troposphere? In the stratosphere?

54. Compare the advantages and disadvantages of the different methods used to disinfect drinking water.

55. Mercury, lead, and arsenic in the environment are major concerns. Identify the main source or sources of these pollutants.

56. What is the likelihood that hydrogen (H_2) will become a widely used fuel and that the "hydrogen economy" will become a reality? In particular, what are the advantages and disadvantages of H_2 as a fuel? What would be necessary for a significant conversion to a "hydrogen economy"?

57. An understanding of most environmental issues requires one to consider a range of factors—economic, political, sociological, as well as scientific. Bearing this in mind, discuss each of the issues below.
    (a) Fracking is now in wide use, allowing us to access large quantities of natural gas. What are the positive factors that argue for continued and expanded use of this technique, and what are the concerns?
    (b) Most gasoline now sold contains ethanol. Is production of ethanol for use as a fuel a wise choice? List arguments for and against this policy.
    (c) Two types of vehicles, electric cars and cars using natural gas, are in early stages of development in the United States. Should their development be encouraged? What are the advantages and disadvantages to owning these cars now?

58. Refer to Figure 20.6. What is the average rate of increase in atmospheric CO_2 per year? Assuming the rate of increase continues at the same pace, predict the approximate concentration of CO_2 in the atmosphere in 2020.

59. Which sulfur compounds are atmospheric pollutants? What is their origin? Describe steps being taken to prevent sulfur compounds from entering the atmosphere.

CHAPTER OUTLINE

21.1 Abundance of the Elements

21.2 The Periodic Table: A Guide to the Elements

21.3 Hydrogen

21.4 The Alkali Metals, Group 1A

21.5 The Alkaline Earth Elements, Group 2A

21.6 Boron, Aluminum, and the Group 3A Elements

21.7 Silicon and the Group 4A Elements

21.8 Nitrogen, Phosphorus, and the Group 5A Elements

21.9 Oxygen, Sulfur, and the Group 6A Elements

21.10 The Halogens, Group 7A

21.11 The Noble Gases, Group 8A

21.1 Abundance of the Elements

Goal for Section 21.1

- Recognize patterns in element abundance.

Let's begin our discussion of main group elements by looking at Figure 21.1, a plot of the abundance in the solar system of the elements of the first three periods.

Hydrogen and helium are the most abundant elements in the solar system by a wide margin because most of the mass resides in the Sun, and these elements are the Sun's primary components. Beyond helium, the light elements lithium, beryllium, and boron are low in abundance, but carbon's abundance is very high. From this point on, with the exception of the transition elements iron and nickel, elemental abundances gradually decline as the atomic number increases.

Ten of the elements in Figure 21.1 account for 99% of the aggregate mass of the Earth's crust (Table 21.1), and oxygen, silicon, and aluminum represent more than 80% of this mass. Oxygen and nitrogen are the primary components of the atmosphere, and oxygen-containing water is highly abundant on the surface, underground, and as a vapor in the atmosphere. Yet other elements such as calcium, aluminum, and silicon in Figure 21.1 are found in some of the most common minerals on the Earth.

TABLE 21.1

The 10 Most Abundant Elements in Earth's Crust

Rank	Element	Abundance (ppm)*
1	Oxygen	474,000
2	Silicon	277,000
3	Aluminum	82,000
4	Iron	56,300
5	Calcium	41,000
6	Sodium	23,600
7	Magnesium	23,300
8	Potassium	21,000
9	Titanium	5,600
10	Hydrogen	1,520

*ppm = g per 1000 kg. Data taken from J. Emsley: *The Elements*, New York, Oxford University Press, 3rd edition, 1998.

◀ **Aragonite, $CaCO_3$.** This form of calcium carbonate is less stable than the calcite form and is slightly more water-soluble (page 947). It is a component of sea shells and pearls.

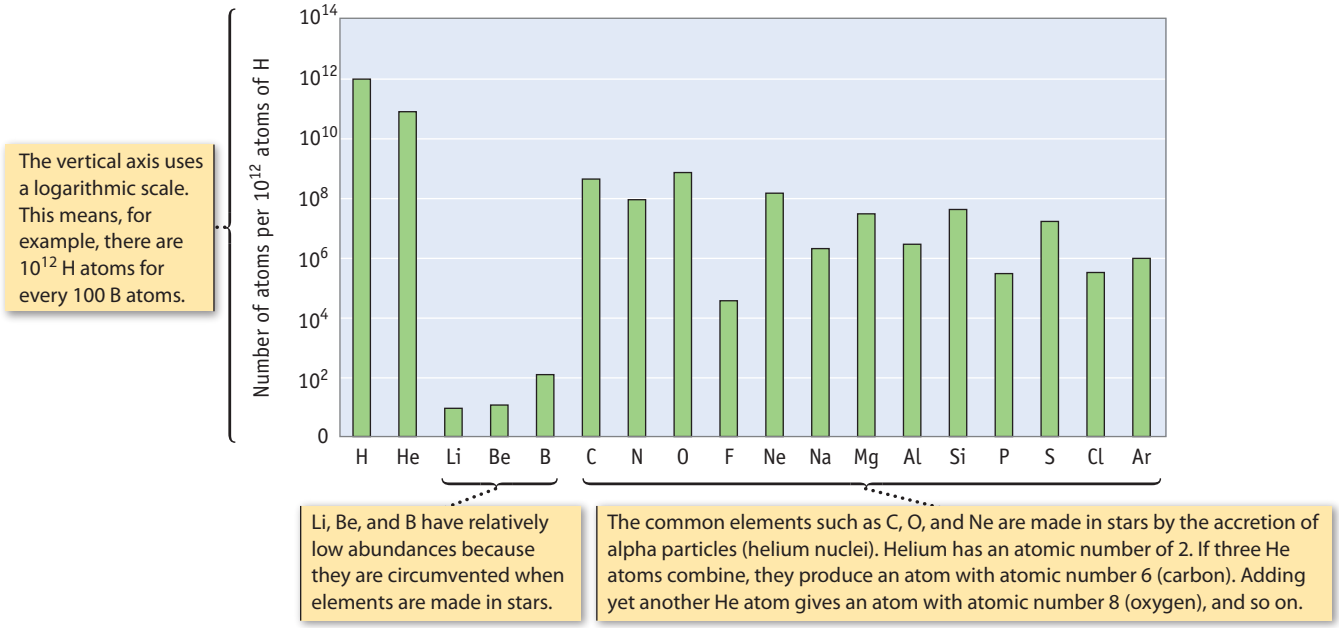

Figure 21.1 **Abundance of elements 1–18 in the solar system.**

Finally, as noted in Figure 21.1, elements with even atomic numbers are more abundant that their neighbors with odd numbers (Si and Al, for example). The reason is that elements are formed in the stars by accretion of helium nuclei (alpha particles, with an atomic number of 2). Elements of odd atomic number are formed from those of even number by some other process.

21.2 The Periodic Table: A Guide to the Elements

Goal for Section 21.2

- Know the general features of the chemistry of main group elements.

The similarities in the chemical and physical properties of certain elements guided Mendeleev when he created the first periodic table (described in Section 2.3). He placed elements in groups based partly on the composition of their common compounds with oxygen and hydrogen (Table 21.2). With some discrepancies, this worked well at the time, but we know now that the elements are grouped according to the arrangements of their valence electrons.

TABLE 21.2 **Similarities Within Periodic Groups***

Group	1A	2A	3A	4A	5A	6A	7A
Common oxide	M_2O	MO	M_2O_3	EO_2	E_4O_{10}	EO_3	E_2O_7
Common hydride	MH	MH_2	MH_3	EH_4	EH_3	EH_2	EH
Highest oxidation state	+1	+2	+3	+4	+5	+6	+7
Common oxoanion			BO_3^{3-}	CO_3^{2-}	NO_3^-	SO_4^{2-}	ClO_4^-
				SiO_4^{4-}	PO_4^{3-}		

*M denotes a metal and E denotes a nonmetal or metalloid.

Recall that the metallic character of the elements declines on moving from left to right in the periodic table. Thus, elements in Group 1A, the alkali metals, are the most metallic elements in the periodic table. Elements on the far right are nonmetals, and in between are the metalloids. Metallic character also increases from the top of a group to the bottom, a feature well illustrated by Group 4A. Carbon, at the top of the group, is a nonmetal; silicon and germanium are metalloids; and tin and lead are metals (Figure 21.2).

It is useful to be aware of the metallic character of an element or group of elements because we know metals typically form ionic compounds, whereas compounds composed only of nonmetals are covalent. We also know that ionic compounds are typically crystalline solids that have high melting points and conduct electricity in the molten state. Covalent compounds, on the other hand, can be gases, liquids, or solids and often have low melting and boiling points.

© Cengage Learning/Charles D. Winters

Figure 21.2 Group 4A elements-from nonmetals to metals. A nonmetal, carbon (graphite crucible); a metalloid, silicon (round, lustrous bar); and metals tin (chips of metal) and lead (bullets, a toy, and a sphere).

Valence Electrons for Main Group Elements

The chemical behavior of an element is determined by the valence electrons, and we know that the valence electrons for main group elements are the *ns* and *np* electrons (where *n* is the period in which the element is found) (Section 7.3).

When considering electronic structure, a useful reference point is the noble gases (Group 8A). Helium has an electron configuration of $1s^2$; the other noble gases have ns^2np^6 valence electron configurations. The dominant characteristic of the noble gases is their lack of reactivity. Indeed, the first two elements in the group do not form any compounds that can be isolated. The other four elements are now known to have limited chemistry, however, and the discovery of xenon compounds in the 1960s ranks as one of the most interesting developments in modern chemistry.

Ionic Compounds of Main Group Elements

Ions of main group elements having filled *s* and *p* subshells are common—justifying the often-seen statement that elements react in ways that achieve a "noble gas configuration." The elements in Groups 1A and 2A form 1+ and 2+ ions with electron configurations that are the same as those for the previous noble gases. All common compounds of these elements (e.g., NaCl, $CaCO_3$) are ionic. The metallic elements in Group 3A (aluminum, gallium, indium, and thallium) form compounds containing 3+ ions.

Elements of Groups 6A and 7A can achieve a noble gas configuration by adding electrons. The Group 7A elements (halogens) form anions with a 1− charge (the halide ions, F^-, Cl^-, Br^-, I^-), and the Group 6A elements form anions with a 2− charge (O^{2-}, S^{2-}, Se^{2-}, Te^{2-}). In Group 5A chemistry, 3− ions with a noble gas configuration (such as the nitride ion, N^{3-}) are also known. The energy required to form highly charged anions is large, however, which means that other types of chemical behavior will usually take precedence.

EXAMPLE 21.1

Reactions of Main Group Elements

Problem Give the formula and name for the product in each of the following reactions. Write a balanced chemical equation for the reaction.

(a) $Ca(s) + S_8(s)$

(b) $Rb(s) + I_2(s)$

(c) lithium and chlorine

(d) aluminum and oxygen

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

What Do You Know? The reactions listed are between metals in periodic groups 1A, 2A, and 3A and nonmetals in periodic groups 6A and 7A. The products formed will be ionic compounds made up of cations formed from metals by loss of electrons and anions formed from nonmetals by the gain of electrons.

Strategy Predictions are based on the assumption that ions are formed with the electron configuration of the nearest noble gas. Group 1A elements form 1+ ions; Group 2A elements form 2+ ions; and metals in Group 3A form 3+ ions. In their reactions with metals, halogen atoms add a single electron to give anions with a 1− charge; Group 6A elements add two electrons to form anions with a 2− charge. For names of products, refer to the nomenclature discussion in Sections 2.4 and 2.5.

SOLUTION

Balanced Equation	Product Name
(a) $8\ Ca(s) + S_8(s) \rightarrow 8\ CaS(s)$	calcium sulfide
(b) $2\ Rb(s) + I_2(s) \rightarrow 2\ RbI(s)$	rubidium iodide
(c) $2\ Li(s) + Cl_2(g) \rightarrow 2\ LiCl(s)$	lithium chloride
(d) $4\ Al(s) + 3\ O_2(g) \rightarrow 2\ Al_2O_3(s)$	aluminum oxide

Think about Your Answer It will be useful to review the formulas and names of common ions in Section 2.5.

Check Your Understanding

Write balanced chemical equations for the reactions forming the following compounds from the elements.

(a) NaBr (c) PbO

(b) CaSe (d) $AlCl_3$

© Cengage Learning/Charles D. Winters

Figure 21.3 Boron halides—molecular compounds. Liquid BBr_3 (left) and solid BI_3 (right). Formed from a metalloid and a nonmetal, both are molecular compounds. The two compounds are sealed in glass ampules to prevent them from reacting with water in the air.

Molecular Compounds of Main Group Elements

Many avenues of reactivity are open to nonmetallic main group elements. When they react with metals, the usual result is the formation of an ionic compound, whereas compounds containing only metalloids and nonmetallic elements are generally molecular in nature.

Molecular compounds are encountered with the Group 3A element boron (Figure 21.3), and the chemistry of carbon in Group 4A is dominated by molecular compounds with covalent bonds (*Carbon—Not Just Another Element*, Chapter 23). Similarly, nitrogen chemistry is dominated by molecular compounds. Consider ammonia, NH_3; the various nitrogen oxides (such as "laughing gas," N_2O); and nitric acid, HNO_3. In each of these compounds, nitrogen bonds covalently to another nonmetallic element. Also in Group 5A, phosphorus reacts with chlorine to produce the molecular compounds PCl_3 (Figure 3.1) and PCl_5.

The valence electron configuration of an element determines the composition of its molecular compounds. Involving all the valence electrons is a frequent occurrence in main group element chemistry, and you should not be surprised to discover compounds in which the central element has the highest possible oxidation number (such as P in PF_5). The highest oxidation number is readily predictable: it equals the group number. Thus, the highest (and only) oxidation number of sodium in its compounds is +1; the highest oxidation number of C is +4; and the highest oxidation number of phosphorus is +5 (Tables 21.2 and 21.3).

TABLE 21.3

Fluorine Compounds Formed by Main Group Elements

Group	Compound	Bonding
1A	NaF	Ionic
2A	MgF_2	Ionic
3A	AlF_3	Ionic
4A	SiF_4	Covalent
5A	PF_5	Covalent
6A	SF_6	Covalent
7A	IF_7	Covalent
8A	XeF_4	Covalent

EXAMPLE 21.2

Predicting Formulas for Molecular Compounds of Main Group Elements

Problem Predict the formula for each of the following:

(a) The product of the reaction between germanium and excess oxygen

(b) The product of the reaction of arsenic and excess fluorine

(c) A compound formed from phosphorus and excess chlorine

(d) The fully deprotonated anion of selenic acid

What Do You Know? You know the symbol and location of each of the elements in the periodic table.

Strategy You can predict that in each reaction the element bonded to the halogen or oxygen in the product will achieve its most positive oxidation number, a value equal to the number of its periodic group.

SOLUTION

(a) The Group 4A element germanium should have a maximum oxidation number of +4. Thus, its oxide has the formula GeO_2.

(b) Arsenic, in Group 5A, reacts vigorously with fluorine to form AsF_5, in which arsenic has an oxidation number of +5.

(c) PCl_5 is formed when the Group 5A element phosphorus reacts with excess chlorine.

(d) The chemistries of the Group 6A elements S and Se are similar. Sulfur has a maximum oxidation number of +6, so it forms SO_3 and sulfuric acid, H_2SO_4. Selenium has analogous chemistry, forming SeO_3 and selenic acid, H_2SeO_4. The fully deprotonated anion of this acid is the selenate ion, SeO_4^{2-}.

Think about Your Answer Notice that in several questions the use of excess oxidizing agent was specified. This is important because, for some of the nonmetals, several different products were possible. For example, the oxidation of carbon can produce either CO_2 or CO depending on whether there is an excess or a deficiency of oxygen. You will encounter other examples in later sections of this chapter.

Check Your Understanding

Write the formula for each of the following:

(a) hydrogen telluride

(b) sodium arsenate

(c) selenium hexachloride

(d) perbromic acid

Using Group Similarities

There are many similarities among elements in the same periodic table group. This means you can use compounds of more common elements as examples when you encounter compounds of elements with which you are less familiar. For example, water, H_2O, is the simplest hydrogen compound of oxygen. You can reasonably expect the hydrogen compounds of other Group 6A elements to be H_2S, H_2Se, and H_2Te; all are well known.

Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

EXAMPLE 21.3

Predicting Formulas

Problem Predict the formula for each of the following:

(a) A compound of hydrogen and phosphorus

(b) The hypobromite ion

(c) Germane (the simplest hydrogen compound of germanium)

(d) Two oxides of tellurium

What Do You Know? We expect the elements in a periodic group to behave similarly in their chemistry, in most instances. Thus, we can use known examples from the more common elements found early in the periodic table and extrapolate to predict the behavior of the less common elements found in the same group.

Strategy Recall as examples some of the compounds of lighter elements in a group, and then assume other elements in that group will form analogous compounds.

SOLUTION

(a) Phosphine, PH_3, has a composition analogous to ammonia, NH_3.

(b) Hypobromite ion, BrO^-, is similar to the hypochlorite ion, ClO^-, the anion of hypochlorous acid (HClO).

(c) GeH_4 (germane) is analogous to CH_4 (methane) and SiH_4 (silane), two other Group 4A hydrogen compounds.

(d) Te and S are in Group 6A. TeO_2 and TeO_3 are analogs of the oxides of sulfur, SO_2 and SO_3.

Think about Your Answer Keep in mind there can be differences between elements within a periodic group. One difference is that second-period elements generally obey the octet rule, whereas in the third period and below, compounds with expanded octets can form (Section 8.5). For example, in reactions with fluorine, nitrogen reacts with F_2 to form only NF_3 whereas phosphorus forms both PF_3 and PF_5.

Check Your Understanding

Identify a compound or ion of a second-period element that has a formula and Lewis structure analogous to each of the following:

(a) PH_4^+ (b) S_2^{2-} (c) P_2H_4 (d) PF_3

EXAMPLE 21.4

Recognizing Incorrect Formulas

Problem One formula is incorrect in each of the following groups. Find the incorrect formula, and indicate why it is incorrect.

(a) $CsSO_4$, KCl, $NaNO_3$, Li_2O

(b) MgO, CaI_2, $BaPO_4$, $CaCO_3$

(c) CO, CO_2, CO_3

(d) PF_5, PF_4^+, PF_7, PF_6^-

What Do You Know? You know the highest oxidation state for a main group element is equal to its group number.

Strategy Look for errors such as incorrect charges on ions or an oxidation number exceeding the maximum possible for the periodic group.

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

SOLUTION

(a) $CsSO_4$. Sulfate ion has a 2− charge, so this formula would require a Cs^{2+} ion. Cesium, in Group 1A, forms only 1+ ions. The formula of cesium sulfate is Cs_2SO_4.

(b) $BaPO_4$. This formula implies a Ba^{3+} ion (because the phosphate anion is PO_4^{3-}). The cation charge does not equal the group number. The formula of barium phosphate is $Ba_3(PO_4)_2$.

(c) CO_3. Given that O has an oxidation number of −2, carbon would have to have an oxidation number of +6. Carbon is in Group 4A, however, and can have a maximum oxidation number of +4.

(d) PF_7. The formula implies P has an oxidation state of +7, whereas +5 is expected for the maximum possible P oxidation state.

Think about Your Answer There are a lot of facts to learn in chemistry. Fortunately, many can be organized in ways that make learning easier. Using the periodic table to predict the chemistry of each element, and recognizing similarities among elements in groups, are essential aspects.

Check Your Understanding

Explain why compounds with the following formulas would not be expected to exist: Na_2Cl, $CaCH_3CO_2$, Mg_2O.

21.3 Hydrogen

Goal for Section 21.3

- Know the basic properties of hydrogen and its preparation.

Chemical and Physical Properties of Hydrogen

Hydrogen has three isotopes, two of them stable (protium and deuterium) and one of them radioactive (tritium).

Isotopes of Hydrogen		
Isotope Mass (u)	Symbol	Name
1.0078	^{1}H (H)	Hydrogen (protium)
2.0141	^{2}H (D)	Deuterium
3.0160	^{3}H (T)	Tritium

Of the three isotopes, only H and D are found in nature in significant quantities. Radioactive tritium (half-life, 12.26 years), which is produced by cosmic ray bombardment of nitrogen in the atmosphere, occurs to the extent of only about 1 atom per 10^{18} atoms of ordinary hydrogen.

Under standard conditions, hydrogen is a colorless gas. Its very low boiling point, 20.7 K, reflects its nonpolar character and low molar mass. As the least dense gas known, it is ideal for filling lighter-than-air craft.

Deuterium compounds are widely used in research. One important observation is that, because D has twice the mass of H, reactions involving D atom transfer are slightly slower than those involving H atoms. This knowledge led to a way to obtain D_2O, which is sometimes called "heavy water." Hydrogen can be produced, albeit expensively, by electrolysis of water (Figure 21.4).

$$2\ H_2O(\ell) + \text{electrical energy} \longrightarrow 2\ H_2(g) + O_2(g)$$

© Cengage Learning/Charles D. Winters

Figure 21.4 Electrolysis of water. Electrolysis of water (containing dilute H_2SO_4 as an electrolyte) gives O_2 *(left)* and H_2 *(right)*.

John C. Kotz

Heavy water. This exhibit in the Nobel Museum in Stockholm, Sweden shows that the sample of D_2O (d = 1.107 g/mL) on the left is heavier than a sample of H_2O with the same volume on the right.

A CLOSER LOOK

Hydrogen, Helium, and Balloons

In 1783, Jacques Charles first used hydrogen to fill a balloon large enough to float above the French countryside (see page 459). In World War I, hydrogen-filled observation balloons were used. The Graf Zeppelin, a passenger-carrying dirigible built in Germany in 1928, was also filled with hydrogen. It carried more than 13,000 people between Germany and the United States until 1937, when it was replaced by the Hindenburg. The Hindenburg was designed to be filled with nonflammable helium. At that time, World War II was approaching, and the United States, which has much of the world's supply of helium, would not sell the gas to Germany. As a consequence, the Hindenburg had to use hydrogen. Unfortunately, the Hindenburg exploded and burned when landing in Lakehurst, New Jersey, in May 1937. Of the 62 people on board, only about half escaped uninjured. As a result of this disaster, hydrogen has acquired a reputation as being a very dangerous substance. Actually, it is as safe to handle as many other fuels.

Everett Historical/Shutterstock.com

The Hindenburg. This hydrogen-filled dirigible crashed in Lakehurst, New Jersey, in May 1937. Some have speculated that the reflective aluminum paint coating the skin of the dirigible was involved in sparking the fire.

Any sample of natural water always contains a tiny concentration of D_2O. When electrolyzed, H_2O is electrolyzed more rapidly than D_2O. Thus, as the electrolysis proceeds, the liquid remaining is enriched in D_2O, and repeating the process many times will eventually give pure D_2O. Large amounts of D_2O are now produced because this compound is used as a moderator in some nuclear reactors.

Hydrogen combines chemically with virtually every other element, except the noble gases. There are three different types of binary hydrogen-containing compounds.

Ionic metal hydrides are formed in the reaction of H_2 with a Group 1A or 2A metal.

$$2\ Na(s) + H_2(g) \rightarrow 2\ NaH(s)$$

$$Ca(s) + H_2(g) \rightarrow CaH_2(s)$$

© Cengage Learning/Charles D. Winters

Figure 21.5 The reaction of H_2 and Br_2. Hydrogen gas burns in an atmosphere of bromine vapor to give hydrogen bromide, HBr.

These compounds contain the hydride ion, H^-, in which hydrogen has a -1 oxidation number.

Molecular compounds (such as H_2O, HF, and NH_3) are generally formed by direct combination of hydrogen with nonmetallic elements (Figure 21.5). The oxidation number of the hydrogen atom in these compounds is $+1$, and the non-metal and hydrogen are linked by covalent bonds.

$$N_2(g) + 3\ H_2(g) \rightarrow 2\ NH_3(g)$$

$$F_2(g) + H_2(g) \rightarrow 2\ HF(g)$$

Hydrogen is absorbed by many metals to form *interstitial hydrides*, the third general class of hydrogen compounds. This name refers to the structures of these species, in which the hydrogen atoms reside in the spaces between the metal atoms (called *interstices*) in the crystal lattice (Figure 12.22b). Palladium metal, for example, can soak up 1000 times its volume of hydrogen (at STP). Most interstitial hydrides are non-stoichiometric; that is, the ratio of metal and hydrogen is not a whole number. When interstitial metal hydrides are heated, H_2 is driven out. This behavior means these materials can be used to store H_2, just as a sponge can store water, and they have been suggested as one way to store hydrogen for use in automobiles.

Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

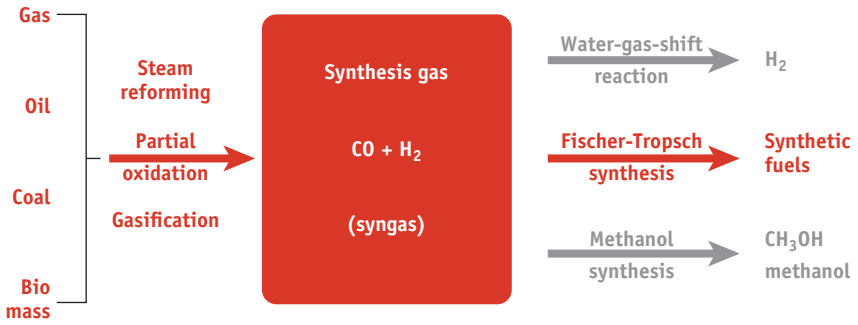

Figure 21.6 Production of water gas. Water gas, also called *synthesis gas*, is a mixture of CO and H_2. It is produced by treating coal, coke, or a hydrocarbon like methane with steam at high temperatures. Methane has the advantage that it gives more total H_2 per gram than other hydrocarbons, and the ratio of the by-product CO_2 to H_2 is lower. The syngas mixture (CO and H_2) is used to make synthetic fuels or methanol. Or, the mixture is treated further to isolate H_2, which is then used to make NH_3.

Preparation of Hydrogen

About 300 billion liters (STP) of hydrogen gas are produced annually worldwide, and virtually all is used immediately in the manufacture of ammonia (Section 21.8), methanol (CH_3OH), or other chemicals.

Some hydrogen is made from coal and steam, a reaction that has been used for more than 100 years.

$$C(s) + H_2O(g) \longrightarrow \underbrace{H_2(g) + CO(g)}_{\text{water gas or synthesis gas}} \qquad \Delta_r H° = +131 \text{ kJ/mol-rxn}$$

The reaction is carried out by injecting water into a bed of red-hot coke. The mixture of gases produced, called *water gas* or *synthesis gas*, was used until about 1950 as a fuel for cooking, heating, and lighting. However, it has serious drawbacks. It produces only about half as much heat as an equal amount of methane, and the flame is nearly invisible. Moreover, because it contains carbon monoxide, water gas is toxic.

The largest quantity of hydrogen is now produced by the *catalytic steam reformation* of methane in natural gas (Figure 21.6). Methane reacts with steam at high temperature to give H_2 and CO.

$$CH_4(g) + H_2O(g) \rightarrow 3\ H_2(g) + CO(g) \qquad \Delta_r H° = +206 \text{ kJ/mol-rxn}$$

The reaction is rapid at 900–1000 °C and goes nearly to completion. More hydrogen can be obtained in a second step in which the CO formed in the first step reacts with more water. This so-called *water gas shift reaction* is run at 400–500 °C and is slightly exothermic.

$$H_2O(g) + CO(g) \rightarrow H_2(g) + CO_2(g) \qquad \Delta_r H° = -41 \text{ kJ/mol-rxn}$$

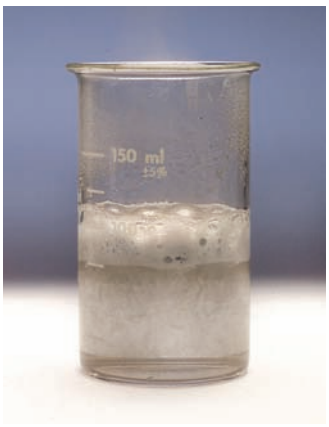
The CO_2 formed in the process is removed by reaction with CaO (to give solid $CaCO_3$), leaving fairly pure hydrogen.

Perhaps the cleanest way to make hydrogen on a relatively large scale is the electrolysis of water (Figure 21.4). This approach provides not only hydrogen gas but also high-purity O_2. However, because electricity is quite expensive, this method is not generally used commercially.

Table 21.4 and Figure 21.7 give examples of reactions used to produce H_2 gas in the laboratory. The most often used method is the reaction of a metal with an acid.

Hydrogen from Sunlight A problem chemists have worked on for some years is to split water into H_2 and O_2 using sunlight. The goal has been reached on a small, laboratory scale, but there are enormous problems to overcome to make the process commercially viable. The semiconductors (such as InGaP and GaAs) that absorb light energy are expensive, and scaling up the processes will be difficult. See *Chemical and Engineering News*, November 21, 2016, pages 33–38.

TABLE 21.4 Methods for Preparing H_2 in the Laboratory



1. Metal + Acid → metal salt + H_2 $Mg(s) + 2\ HCl(aq) \rightarrow MgCl_2(aq) + H_2(g)$
2. Metal + H_2O → metal hydroxide or oxide + H_2 $2\ Na(s) + 2\ H_2O(\ell) \rightarrow 2\ NaOH(aq) + H_2(g)$ $2\ Fe(s) + 3\ H_2O(\ell) \rightarrow Fe_2O_3(s) + 3\ H_2(g)$
3. Metal hydride + H_2O → metal hydroxide + H_2 $CaH_2(s) + 2\ H_2O(\ell) \rightarrow Ca(OH)_2(s) + 2\ H_2(g)$

(a) The reaction of magnesium and acid. The products are hydrogen gas and a magnesium salt.

(b) The reaction of aluminum and aqueous NaOH. The products of this reaction are hydrogen gas and a solution of $Na[Al(OH)_4]$.

(c) The reaction of CaH_2 and water. The products are hydrogen gas and $Ca(OH)_2$.

© Cengage Learning/Charles D. Winters

Figure 21.7 Producing hydrogen gas.

Alternatively, the reaction of aluminum with aqueous NaOH (Figure 21.7b) can be used.

$$2\ Al(s) + 2\ KOH(aq) + 6\ H_2O(\ell) \longrightarrow 2\ K[Al(OH)_4](aq) + 3\ H_2(g)$$

During World War II, this reaction was used to obtain hydrogen to inflate small balloons for weather observation and to raise radio antennas. Metallic aluminum was plentiful at the time because it came from damaged aircraft.

The combination of a metal hydride and water (Figure 21.7c) is an efficient but expensive way to synthesize H_2 in the laboratory. The reaction is commonly used in laboratories to dry organic solvents because the metal hydride reacts with traces of water present in the solvent.

21.4 The Alkali Metals, Group 1A

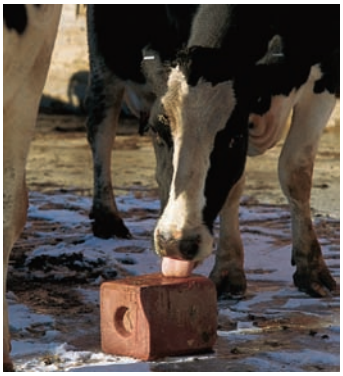
Goal for Section 21.4

- Know the general chemical properties of the alkali metals.

Sodium and potassium are, respectively, the sixth and eighth most abundant elements in the Earth's crust. In contrast, lithium is relatively rare, as are rubidium and cesium. Only traces of radioactive francium occur in nature. Its longest-lived isotope (^{223}Fr) has a half-life of only 22 minutes.

The Group 1A elements are metals, and all are highly reactive with oxygen, water, and other oxidizing agents (described on page 972). In all cases, these reactions yield compounds containing the Group 1A metals as a 1+ ion. Because the elements are so reactive, the free metal is never found in nature.

Most sodium and potassium compounds are water-soluble (solubility guidelines are given in Figure 3.10), so it is not surprising that sodium and potassium compounds are found either in the oceans or in underground deposits that are the residue of ancient seas. To a much smaller extent, these elements are also found in minerals, such as Chile saltpeter ($NaNO_3$).



Despite the fact that sodium is only slightly more abundant than potassium on the Earth, seawater contains significantly more sodium than potassium (2.8% NaCl versus 0.8% KCl). Why the great difference? Most compounds of both elements are

water-soluble, so why doesn't rain dissolve Na- and K-containing minerals over the centuries and carry them down to the sea, so that they appear in the same proportions in the oceans as on land? The answer is that potassium is an important factor in plant growth. Most plants contain four to six times as much combined potassium as sodium. Thus, most of the potassium ions in groundwater from dissolved minerals are taken up preferentially by plants, whereas sodium ions continue on to the oceans.

Some NaCl is essential in the diet of humans and other animals because many biological functions are controlled by the concentrations of Na^+ and Cl^- ions (Figure 21.8). The fact that salt has long been recognized as important is evident in surprising ways. For example, we are paid a "salary" for work done. This word is derived from the Latin *salarium*, which meant "salt money" because Roman soldiers were paid in salt.

© Cengage Learning/Charles D. Winters

Figure 21.8 The importance of salt. All animals, including humans, need a certain amount of salt in their diet. Sodium ions are important in maintaining electrolyte balance and in regulating osmotic pressure. For an interesting account of the importance of salt in society, culture, history, and economy, see *Salt, A World History*, by M. Kurlansky, New York, Penguin Books, 2003.

Preparation of Sodium and Potassium

Sodium is produced by reducing sodium ions in sodium salts. This is usually done by electrolysis, because few chemical reducing agents are powerful enough to convert sodium ions to sodium metal.

The English chemist Sir Humphry Davy first isolated sodium in 1807 by the electrolysis of molten sodium carbonate. However, the element remained a laboratory curiosity until 1824 when chemists found sodium could be used to reduce aluminum chloride to aluminum metal. At that time, metallic aluminum was rare and very valuable, so this discovery inspired considerable interest in manufacturing sodium. By 1886, a practical method of sodium production had been devised (the reduction of NaOH with carbon). Unfortunately for sodium producers, in this same year Charles Hall and Paul Heroult invented a better way to produce aluminum (by electrolysis, page 979), thereby eliminating this market for sodium.

Sodium is currently produced by the electrolysis of molten NaCl (Section 19.7). The Downs cell for the electrolysis of molten NaCl operates at 7 to 8 V with currents of 25,000 to 40,000 amps (Figure 21.9). The cell is filled with a mixture of dry NaCl, $CaCl_2$, and $BaCl_2$. [Adding other salts to NaCl lowers the melting point from that of pure NaCl (800.7 °C) to about 600 °C. Recall that solutions have lower melting points than pure solvents (Chapter 13).] Sodium is produced at a copper or iron cathode that surrounds a circular graphite anode. Directly over the cathode is an inverted trough in which the low-density, molten sodium (melting point, 97.8 °C) collects. Chlorine, a valuable by-product, collects at the anode.

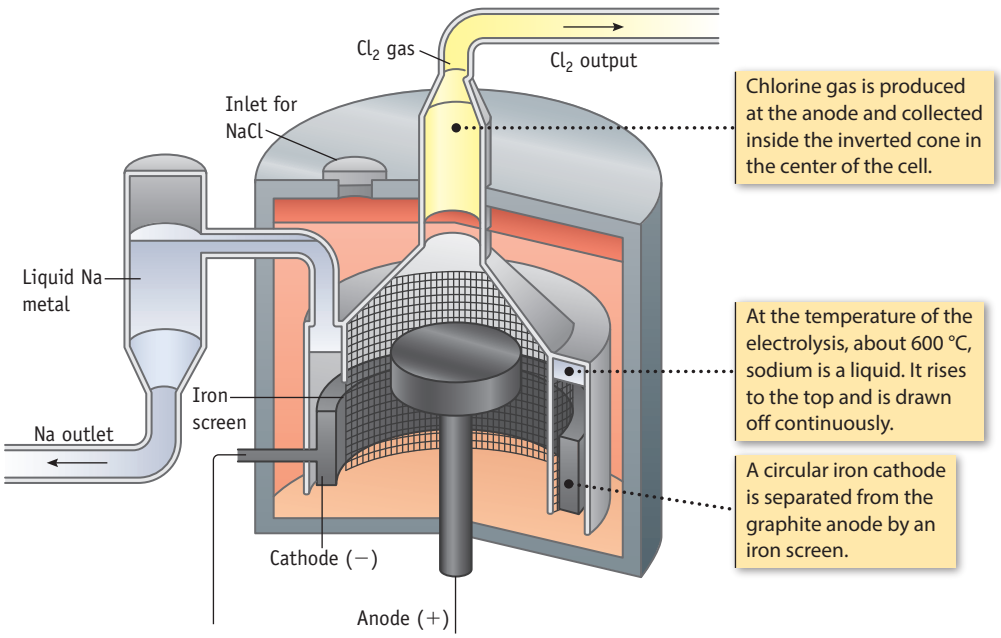

Figure 21.9 A Downs cell for preparing sodium.

Potassium can also be made by electrolysis, but separation of the metal is difficult because molten potassium is soluble in molten KCl. The preferred method for potassium preparation is the reaction of sodium vapor with molten KCl, with potassium being continually removed from the equilibrium mixture.

$$Na(g) + KCl(\ell) \rightleftharpoons K(g) + NaCl(\ell)$$

Properties of Sodium and Potassium

Sodium and potassium are silvery metals that are soft and easily cut with a knife (Figure 2.5). They are just a bit less dense than water. Their melting points, 97.8 °C for sodium and 63.7 °C for potassium, are quite low.

When exposed to moist air, the surface of an alkali metal quickly becomes coated with a film of oxide or hydroxide. Consequently, the metals must be stored in a way that avoids contact with air, typically by placing them in kerosene or mineral oil.

The great reactivity of Group 1A metals is exemplified by their reaction with water, which generates an aqueous solution of the metal hydroxide and hydrogen gas (see page 972 and *A Closer Look: The Reactivity of the Alkali Metals*),

$$2\ Na(s) + 2\ H_2O(\ell) \rightarrow 2\ Na^+(aq) + 2\ OH^-(aq) + H_2(g)$$

and their reaction with any of the halogens to yield a metal halide (Figure 1.2),

$$2\ Na(s) + Cl_2(g) \rightarrow 2\ NaCl(s)$$

$$2\ K(s) + Br_2(\ell) \rightarrow 2\ KBr(s)$$

Courtesy Neutronics, Inc.

Figure 21.10 A closed-circuit breathing apparatus. Both carbon dioxide and moisture are exhaled by the wearer into a breathing tube. All of the exhaled CO_2 is consumed in the reaction with KO_2. Three moles of oxygen are produced from 2 mol of CO_2, replacing the oxygen consumed in respiration.

Chemistry often produces surprises. Group 1A metal oxides, M_2O, are known, but they are not the principal products of the reaction of Group 1A elements and oxygen. Instead, the primary product of the reaction of sodium and oxygen is sodium *peroxide*, Na_2O_2, whereas the principal product from the reaction of potassium and oxygen is KO_2, potassium *superoxide*.

$$2\ Na(s) + O_2(g) \rightarrow Na_2O_2(s)$$

$$K(s) + O_2(g) \rightarrow KO_2(s)$$

Both Na_2O_2 and KO_2 are ionic compounds where the Group 1A cation is paired with either the peroxide ion (O_2^{2-}) or the superoxide ion (O_2^-).

The peroxide and superoxide are not merely laboratory curiosities. Potassium superoxide in particular is used in oxygen-generation devices in places where people are confined, such as submarines, aircraft, and spacecraft, or when an emergency supply is needed. The KO_2 closed-circuit breathing equipment in Figure 21.10 is self-contained, that is, it is able to both consume exhaled CO_2 and provide a continuous supply of oxygen. On average, a person exhales 0.82 L of CO_2 and some water vapor for every 1.0 L of O_2 inhaled. The reaction of KO_2 and exhaled water vapor produces O_2 and KOH, and the latter absorbs exhaled CO_2.

$$4\ KO_2(s) + 2\ H_2O(g) \rightarrow 4\ KOH(aq) + 3\ O_2(g)$$

$$4\ KOH(aq) + 2\ CO_2(g) \rightarrow 2\ K_2CO_3(s) + 2\ H_2O(g)$$

Notice that, for every 4 mol of KO_2, 3 mol O_2 is produced and 2 mol CO_2 is absorbed.

Important Lithium, Sodium, and Potassium Compounds

Electrolysis of aqueous sodium chloride (*brine*) is the basis of one of the largest chemical industries in the United States.

$$2\ NaCl(aq) + 2\ H_2O(\ell) \rightarrow Cl_2(g) + 2\ NaOH(aq) + H_2(g)$$

Two of the products from this process—chlorine and sodium hydroxide—give the industry its name: the *chlor-alkali industry*. More than 10 billion kilograms of Cl_2 is

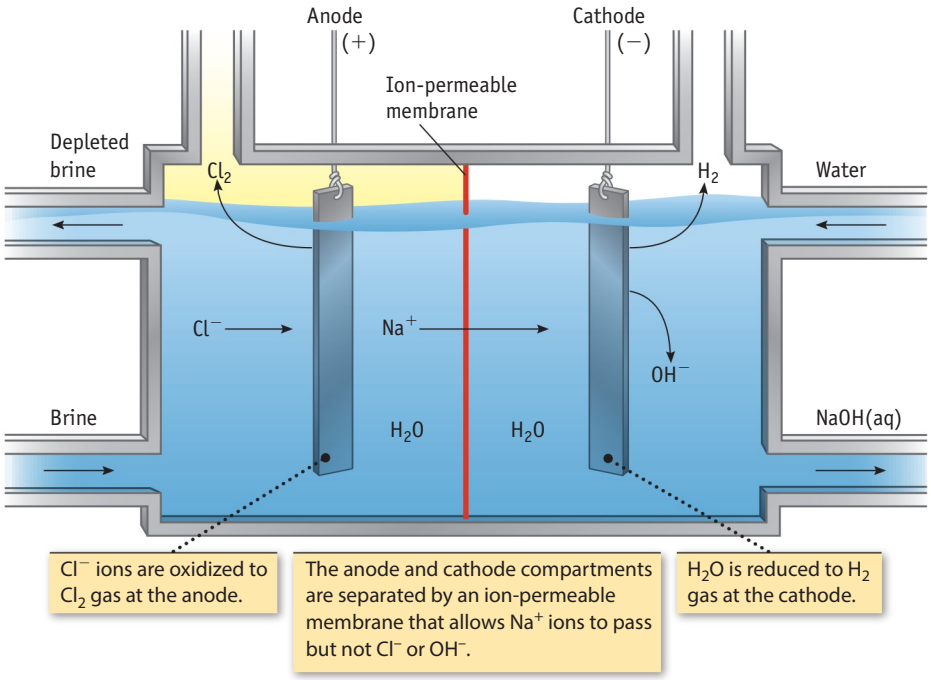

Figure 21.11 Producing chlorine and sodium hydroxide in a membrane cell. This is the basis of the chlor-alkali industry. Brine (a concentrated aqueous solution of NaCl) is fed into the anode compartment and dilute sodium hydroxide or water into the cathode compartment. Pipes carry the evolved gases and NaOH away from the chambers of the electrolysis cell.

produced annually in the United States (as well as NaOH). Oxidation of chloride ion to Cl_2 gas in the electrolysis process occurs at the anode and reduction of water to hydroxide ion and H_2 occurs at the cathode (Figure 21.11).

Anode reaction (oxidation): $2\ Cl^-(aq) \longrightarrow Cl_2(g) + 2\ e^-$

Cathode reaction (reduction): $2\ H_2O(\ell) + 2\ e^- \longrightarrow H_2(g) + 2\ OH^-(aq)$

Activated titanium is used for the anode, and stainless steel or nickel is preferred for the cathode. The anode and cathode compartments are separated by a membrane that allows Na^+ ions to pass to maintain the charge balance. Thus, the membrane functions as a "salt" bridge between the anode and cathode compartments. The energy consumption of these cells is in the range of 2000–2500 kWh per ton of NaOH produced.

Sodium carbonate, Na_2CO_3, another commercially important compound of sodium, is known by two common names, *soda ash* and *washing soda*. In the past, it was largely manufactured by combining NaCl, ammonia, and CO_2 in the *Solvay process* (which remains the method of choice in many countries). In the United States, however, sodium carbonate is obtained from naturally occurring deposits of the mineral *trona*, $Na_2CO_3 \cdot NaHCO_3 \cdot 2\ H_2O$ (Figure 21.12).

Sodium bicarbonate, $NaHCO_3$, also known as *baking soda*, is another common sodium compound. Not only is $NaHCO_3$ used in cooking, but it is also added in small amounts to table salt. NaCl is often contaminated with small amounts of $MgCl_2$. The magnesium salt is *hygroscopic*; that is, it picks water up from the air and, in doing so, causes the NaCl to clump. Adding $NaHCO_3$ converts $MgCl_2$ to magnesium carbonate, a nonhygroscopic salt.

$$MgCl_2(s) + 2\ NaHCO_3(s) \longrightarrow MgCO_3(s) + 2\ NaCl(s) + H_2O(\ell) + CO_2(g)$$

Sodium nitrate, $NaNO_3$, is another common sodium compound, and large deposits are found in Chile, which explains its common name of "Chile saltpeter." These deposits are thought to have formed eons ago by bacterial action on organisms in shallow seas. The initial product was ammonia, which was subsequently oxidized to nitrate ion; combination with sea salt led to sodium nitrate. Because nitrates in general, and alkali metal nitrates in particular, are highly water-soluble, deposits of $NaNO_3$ are found only in areas with very little rainfall.

Figure 21.12 Soda ash. Trona mined in Wyoming and California is processed into soda ash (Na_2CO_3) and other sodium-based chemicals. Soda ash is the ninth most widely used chemical in the United States. Domestically, about half of all soda ash produced is used in making glass. Most of the remainder goes to make chemicals such as sodium silicate, sodium phosphate, and sodium cyanide. Some is also used to make detergents, in the pulp and paper industry, and in water treatment.

Mark Harvey/Alamy Stock Photo

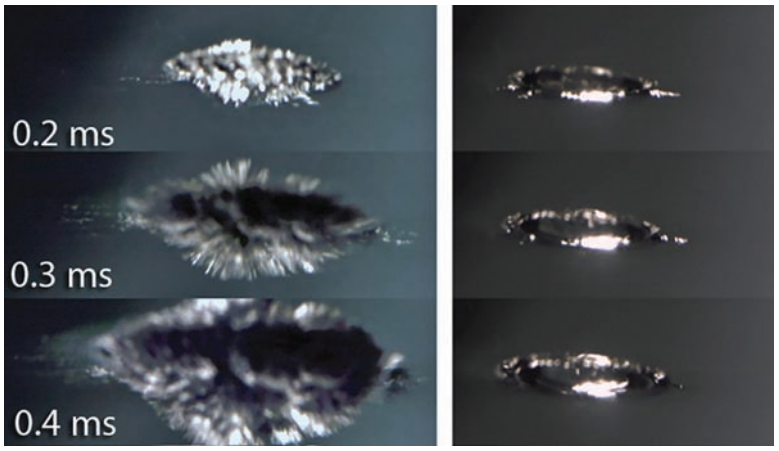
Sodium nitrate can be converted to potassium nitrate by an exchange reaction.

$$NaNO_3(aq) + KCl(aq) \rightleftharpoons KNO_3(aq) + NaCl(s)$$

Equilibrium favors the products here because, of the four salts involved in this reaction, NaCl is least soluble in hot water. Sodium chloride precipitates, and the KNO_3 that remains in solution can be recovered by evaporating the water.

A CLOSER LOOK

The Reactivity of the Alkali Metals



A favorite demonstration in chemistry classes is to put a small piece of one of the alkali metals in water. Lithium reacts sluggishly, but as you can see on page 310 sodium reacts much more vigorously. Potassium, rubidium, and cesium are even more reactive, exploding on contact with water.

One question is why the reaction is so rapid, and this was answered recently by clever experiments and high speed filming when liquid Na/K alloy was dropped into water (Figure 2, left). Within a fraction of a millisecond of a tiny drop of the metal contacting water, "spikes" appeared from the drop. The researchers showed that there was nearly instantaneous transfer of electrons from the metal through these "spikes" to the water, thus creating metal ions. The ions strongly repelled each other and created what is called a "Coulomb explosion," blowing the metal drop apart and creating more, even tinier drops, which react further.

Potassium nitrate has been used for centuries as the oxidizing agent in gunpowder. A mixture of KNO_3, charcoal, and sulfur will react when ignited.

$$2\ KNO_3(s) + 4\ C(s) \rightarrow K_2CO_3(s) + 3\ CO(g) + N_2(g)$$

$$2\ KNO_3(s) + 2\ S(s) \rightarrow K_2SO_4(s) + SO_2(g) + N_2(g)$$

Notice that both reactions (which are doubtless more complex than described in these equations) produce gases. These gases propel the bullet from a gun or cause a firecracker to explode.

In the past several years lithium has become a significant commodity because of its use in lithium ion batteries (described in *Applying Chemical Principles: 12.1—Lithium and "Green Cars"* page 553). In fact, there is some concern that shortages of lithium will arise if the use of lithium ion batteries in cars becomes widespread. Currently, most lithium is obtained from concentrated brines in Chile and Bolivia, from which Li_2CO_3 is extracted. There are also ores from which lithium can be obtained. Like sodium (Figure 21.9), lithium metal is obtained from its compounds by molten salt electrolysis.

© Cengage Learning/Charles D. Winters

Gunpowder. Gunpowder was developed well over 1000 years ago by the Chinese. One of the three ingredients is KNO_3, commonly called *saltpeter*. Although there are places in the world where it is prevalent and can be mined, for centuries it was obtained by mixing manure or human waste with wood ashes. Animal and human waste contain ammonia, which is converted by bacterial oxidation to nitrates. Wood ashes contain potash, potassium carbonate, the source of potassium in KNO_3. See *Gunpowder* by J. Kelly, Basic Books, 2004.

21.5 The Alkaline Earth Elements, Group 2A

Goals for Section 21.5

- Know some of the common, commercially important compounds of the Group 2A elements.
- Know the general chemical properties of the alkaline earth elements.

The "earth" part of the name *alkaline earth* dates back to the days of medieval alchemy. To alchemists, any solid that did not melt and was not changed by fire into another substance was called an "earth." The word "alkaline" applies because compounds of Group 2A elements, such as CaO, are alkaline according to experimental tests conducted by the alchemists: The compounds had a bitter taste and neutralized acids. Finally, with very high melting points, these compounds were unaffected by fire.

Calcium and magnesium rank fifth and seventh, respectively, in abundance on Earth. Both elements form many commercially important compounds, and we shall focus on those.

Like the Group 1A elements, Group 2A elements are very reactive, and the free elements are not found in nature. Unlike most of the compounds of the Group 1A metals, however, many compounds of the Group 2A elements are poorly soluble in water, which explains their occurrence in various minerals (Figure 21.13). Calcium minerals include limestone ($CaCO_3$), gypsum ($CaSO_4 \cdot 2\ H_2O$), and fluorite (CaF_2). Magnesite ($MgCO_3$), talc or soapstone ($3\ MgO \cdot 4\ SiO_2 \cdot H_2O$), and asbestos ($3\ MgO \cdot 4\ SiO_2 \cdot 2\ H_2O$) are common magnesium-containing minerals. The mineral dolomite, $MgCa(CO_3)_2$, contains both magnesium and calcium.

Limestone, a sedimentary rock, is found widely on the Earth's surface. Many of these deposits contain the fossilized remains of marine life. Other forms of calcium carbonate include marble, aragonite (page 958), and Iceland spar (a form of calcite), the latter occurring as large, clear crystals with the interesting optical property of *birefringence* (Figure 21.13).

Figure 21.14 The reaction of calcium and warm water. Hydrogen gas bubbles are seen rising from the metal surface. The other reaction product is $Ca(OH)_2$. The inset is a model of hexagonal close-packed calcium metal (Section 12.1).

Properties of Calcium and Magnesium

Calcium and magnesium are fairly high-melting, silvery metals, and share chemical properties with other elements of Group 2A. They are oxidized by a wide range of oxidizing agents to form ionic compounds that contain the M^{2+} ion. For example, these elements combine with halogens to form MX_2, with oxygen or sulfur to form MO or MS, and with water to form hydrogen and the metal hydroxide, $M(OH)_2$ (Figure 21.14). With acids, hydrogen is evolved (Figure 21.7), and a salt of the metal cation and the anion of the acid results.

Several hundred thousand tons of magnesium are produced annually, largely for use in lightweight alloys. (Magnesium has a very low density, 1.74 g/cm^3.) Most aluminum used today contains about 5% magnesium to improve its mechanical properties and to make it more resistant to corrosion. Other alloys having more magnesium than aluminum are used when a high strength-to-weight ratio is needed and when corrosion resistance is important, such as in aircraft and automotive parts and in lightweight tools.

Interestingly, magnesium-containing minerals are not the commercial source of this element. Most magnesium is obtained from seawater, in which Mg^{2+} ion has a concentration of about 0.05 M. To obtain the metal, magnesium ions in seawater are first precipitated (Figure 21.15) as the relatively insoluble hydroxide [K_{sp} for $Mg(OH)_2 = 5.6 \times 10^{-12}$]. Calcium hydroxide, the source of OH^- in this reaction, is prepared in a sequence of reactions beginning with $CaCO_3$, which may be in the form of seashells. Heating $CaCO_3$ gives CO_2 and CaO, and addition of water to CaO gives calcium hydroxide. When $Ca(OH)_2$ is added to seawater, $Mg(OH)_2$ precipitates:

$$Mg^{2+}(aq) + Ca(OH)_2(s) \rightleftharpoons Mg(OH)_2(s) + Ca^{2+}(aq)$$

Magnesium hydroxide is isolated by filtration and then converted to magnesium chloride by reaction with hydrochloric acid.

$$Mg(OH)_2(s) + 2\ HCl(aq) \rightarrow MgCl_2(aq) + 2\ H_2O(\ell)$$

After evaporating the water, anhydrous magnesium chloride remains. Solid $MgCl_2$ melts at 714 °C, and the molten salt is electrolyzed to give the metal and chlorine.

$$MgCl_2(\ell) \rightarrow Mg(s) + Cl_2(g)$$

"Hard" Water Calcium and magnesium are found in common minerals, and their ions are often in natural waters. There they can interact with atmospheric CO_2 to form insoluble carbonates, and these can deposit in unwanted places, like the water pipes in your home. For more on this problem, see *Applying Chemical Principles: 20.2—Hard Water*, page 950.

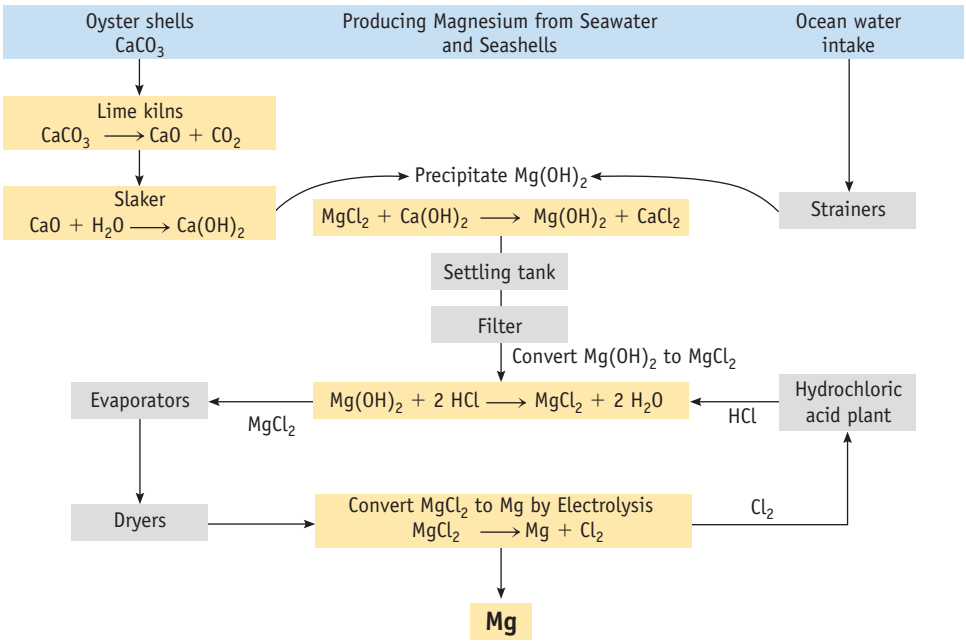

Figure 21.15 The process used to produce magnesium metal from the magnesium in seawater. This process illustrates the kind of chemistry you have seen in previous chapters.

Calcium Minerals and Their Applications

The most common calcium-based minerals are its fluoride, phosphate, and carbonate salts. Fluorite, CaF_2, and fluoroapatite, $Ca_5F(PO_4)_3$, are important as commercial sources of fluorine. Almost half of the CaF_2 mined is used in the steel industry, where it is added to the mixture of materials that is melted to make crude iron. The CaF_2 acts to remove some impurities and improves the separation of molten iron from silicates and other by-products resulting from the reduction of iron ore to the metal (Chapter 22). A second major use of fluorite is in the manufacture of hydrofluoric acid by a reaction of the mineral with concentrated sulfuric acid.

$$CaF_2(s) + H_2SO_4(\ell) \longrightarrow 2\ HF(g) + CaSO_4(s)$$

Hydrofluoric acid is used to make cryolite, Na_3AlF_6, a material needed in aluminum production (Section 21.6) and in the manufacture of fluorocarbons such as tetrafluoroethylene ($F_2C{=}CF_2$), the precursor to Teflon (Table 23.12).

Apatites have the general formula $Ca_5X(PO_4)_3$ (X = F, Cl, OH). More than 100 million tons of apatite is mined annually, with Florida alone accounting for about one third of the world's output. Most of this material is converted to phosphoric acid by reaction with sulfuric acid. Phosphoric acid is needed in the manufacture of a multitude of products, including fertilizers and detergents, baking powder, and various food products (Section 21.8).

Limestone, which consists mostly of calcium carbonate, has been used in agriculture for centuries. It is spread on fields to neutralize acidic compounds in the soil and to supply Ca^{2+}, an essential nutrient. Because magnesium carbonate is often present in limestone, "liming" a field also supplies Mg^{2+}, another important nutrient for plants.

Calcium carbonate and calcium oxide (*lime*) are of special interest. The thermal decomposition of $CaCO_3$ to give lime (and CO_2) is one of the oldest chemical reactions known. Lime is one of the top 10 industrial chemicals produced today, with about 20 billion kilograms produced annually.

For several thousand years, lime has been used in *mortar* (a lime, sand, and water paste) to secure stones to one another in building houses, walls, and roads. The Chinese used it to set stones in the Great Wall. The Romans perfected its use, and the fact that many of their constructions still stand today is testament both to their skill and to the usefulness of lime. The famous Roman road, the Appian Way, used lime mortar between several layers of its stones.

A CLOSER LOOK

Alkaline Earth Metals and Biology

Plants and animals derive energy from the oxidation of a sugar, glucose, with oxygen. Plants are unique, however, in being able to synthesize glucose from CO_2 and H_2O using sunlight as an energy source. This process is initiated by *chlorophyll*, a very large, magnesium-based molecule.

A molecule of chlorophyll. Magnesium is its central element.

In your body, the alkaline earth metal ions Mg^{2+} and Ca^{2+} serve regulatory functions. Although these two metal ions are required by living systems, the other Group 2A elements are toxic. Beryllium compounds are carcinogenic, and soluble barium salts are poisons. You may be concerned if your physician asks you to drink a "barium cocktail" to check the condition of your digestive tract. Don't be afraid, because the "cocktail" contains very insoluble $BaSO_4$ ($K_{sp} = 1.1 \times 10^{-10}$), so it passes through your digestive tract without a significant amount being absorbed. Barium sulfate is opaque to x-rays, so its path through your organs appears on the developed x-ray image.

The calcium-containing compound *hydroxyapatite* is the main component of tooth enamel. Cavities in your teeth form when acids (such as those in soft drinks) decompose the weakly basic hydroxy apatite coating.

$$Ca_5(OH)(PO_4)_3(s) + 4\ H_3O^+(aq) \rightarrow 5\ Ca^{2+}(aq) + 3\ HPO_4^{2-}(aq) + 5\ H_2O(\ell)$$

This reaction can be prevented by converting hydroxyapatite to the much more acid-resistant coating of fluoroapatite.

$$Ca_5(OH)(PO_4)_3(s) + F^-(aq) \rightarrow Ca_5F(PO_4)_3(s) + OH^-(aq)$$

CNRI/Science Source

X-ray of a gastrointestinal tract using $BaSO_4$ to make the organs visible.

The source of the fluoride ion can be sodium fluoride or sodium monofluorophosphate (Na_2FPO_3, commonly known as MFP) in your toothpaste.

The utility of mortar depends on some simple chemistry. Mortar consists of one part lime to three parts sand, with water added to make a thick paste. The first reaction, referred to as *slaking*, occurs after the solids are mixed with water. This produces a slurry containing calcium hydroxide, which is known as *slaked lime*.

$$CaO(s) + H_2O(\ell) \rightleftharpoons Ca(OH)_2(s)$$

When the wet mortar mix is placed between bricks or stone blocks, it slowly reacts with CO_2 from the air, and the slaked lime is converted to calcium carbonate.

$$Ca(OH)_2(s) + CO_2(g) \rightleftharpoons CaCO_3(s) + H_2O(\ell)$$

The sand grains are bound together by the particles of calcium carbonate.

21.6 Boron, Aluminum, and the Group 3A Elements

Goal for Section 21.6

- Know the general chemical properties of the Group 3A elements.

With Group 3A, we see the first evidence of a change from metallic behavior of the elements at the left side of the periodic table to nonmetal behavior on the right side

A CLOSER LOOK

Cement—The Second Most Used Substance

Cement is such a commonplace material that we tend to take it for granted. The preparation of cement has origins more than 2000 years ago and was used in Roman roads that still exist today. The current "recipe" for cement was patented in 1824 by a British bricklayer, Joseph Aspdin, and has seen little change since that time. Aspdin called his product *Portland cement* because it was similar in appearance to Portland stone, from the Isle of Portland in Dorset, England. In 2016, the world production of Portland cement was 4.3 billion tons; this amount is second only to water among substances people use.

The preparation of Portland cement involves heating a mixture of $CaCO_3$, SiO_2, and alumina silicate (clay) at 1450 °C. This produces a solid mass called a *clinker*. Grinding the material with a little $CaSO_4$ gives cement as a fine gray powder; its main components are CaO (60–67%), SiO_2 (17–25%), Al_2O_3 (3–8%), and Fe_2O_3 (0–6%). Mixing cement with sand and gravel produces concrete. The usefulness of cement in these products comes from the fact that when it is mixed with water a series of not-well-understood reactions ensue to produce a hard, strong, solid product that is ideal for use in construction.

The high temperature required to prepare the clinker makes this process energy intensive. Furthermore, it releases about 900 kg of CO_2 for each 1000 kg of cement, which is estimated to be about 5% of the anthropogenic emissions of CO_2. (About half of the CO_2 comes from decomposition of $CaCO_3$ to form CO_2; the other half is from fuel combustion.) Improving these figures would help address two current environmental concerns, energy consumption and greenhouse gas evolution.

of the table. Boron is a metalloid, whereas all the other elements of Group 3A are metals.

The elements of Group 3A vary widely in their relative abundances on Earth. Aluminum is the third most abundant element in Earth's crust (82,000 ppm), whereas the other elements of the group are relatively rare, and, except for boron, their compounds have limited commercial uses.

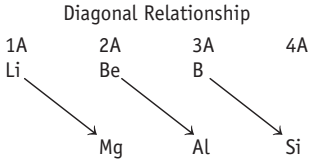
10 ppm	82,000 ppm	18 ppm	0.05 ppm	0.6 ppm



Element abundances are in **parts per million** *in the Earth's crust.*

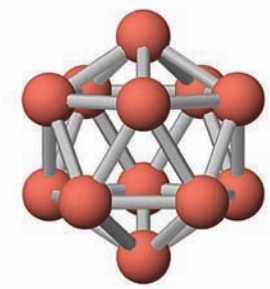
Chemistry of the Group 3A Elements

One way to remember the chemistry of the elements is to recognize that there are chemical similarities between some elements diagonally situated in the periodic table. This *diagonal relationship* means that lithium and magnesium share some chemical properties, as do Be and Al, and B and Si. For example:

- Boric oxide, B_2O_3, and boric acid, $B(OH)_3$, are weakly acidic, as are SiO_2 and its acid, orthosilicic acid (H_4SiO_4). Boron–oxygen compounds, borates, are often chemically similar to silicon–oxygen compounds, silicates.
- Both $Be(OH)_2$ and $Al(OH)_3$ are amphoteric, dissolving in a strong base such as aqueous NaOH (Figure 16.11).
- Chlorides, bromides, and iodides of boron and silicon (such as BCl_3 and $SiCl_4$) react vigorously with water.
- The hydrides of boron and silicon are simple, molecular species; are volatile and flammable; and react readily with water.
- Beryllium hydride and aluminum hydride are colorless, nonvolatile solids that are extensively polymerized through Be—H—Be and Al—H—Al three-center, two-electron bonds (page 437).

Finally, the Group 3A elements are characterized by electron configurations of the type ns^2np^1. This means that each atom may lose three electrons to form compounds in which the element has a +3 oxidation number, although the heavier elements, especially thallium, also form compounds with an oxidation number of +1.

Diagonal Relationship The chemistries of elements diagonally situated in the periodic table are often quite similar.



Boron Minerals and Production of the Element

Although boron has a low abundance on Earth, its minerals are found in concentrated deposits. For example, large deposits of borax, $Na_2B_4O_7 \cdot 10\ H_2O$, are currently mined in the Mojave Desert near the town of Boron, California.

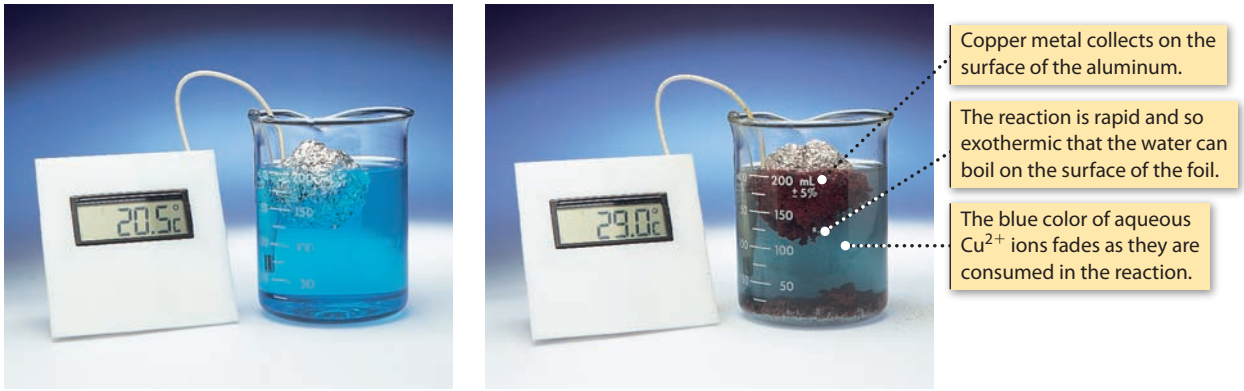
Isolation of pure, elemental boron from boron-containing minerals is difficult and is done only in small quantities. Like most metals and metalloids, boron can be obtained by chemically or electrolytically reducing an oxide or halide. Magnesium has often been used for chemical reductions, but the product of this reaction is noncrystalline boron of low purity.

$$B_2O_3(s) + 3\ Mg(s) \rightarrow 2\ B(s) + 3\ MgO(s)$$

Boron has several allotropes, some characterized by having an icosahedron of boron atoms as a structural element. Elemental boron is a very hard and refractory (resistant to heat) semiconductor. In this regard, it differs from the other Group 3A elements; Al, Ga, In, and Tl are all relatively low-melting, rather soft metals with high electrical conductivity.

Boron Icosahedron. Several allotropes of elemental boron have an icosahedron (a 20-sided polyhedron) of 12 covalently linked boron atoms as a structural element.

Metallic Aluminum and Its Production



The low cost of aluminum and the excellent characteristics of its alloys with other metals (low density, strength, ease of handling in fabrication, and inertness toward corrosion, among others) have led to its widespread use. You know it best in the form of aluminum foil, aluminum cans, and parts of aircraft.

Pure aluminum is soft and weak; moreover, it loses strength rapidly at temperatures higher than 300 °C. What you might refer to as "aluminum" is actually aluminum alloyed with small amounts of other elements to strengthen the metal and improve its properties. A typical alloy may contain about 4% copper with smaller amounts of silicon, magnesium, and manganese. Softer, more corrosion-resistant alloys for window frames, furniture, highway signs, and cooking utensils may include only manganese.

The standard reduction potential of aluminum [$Al^{3+}(aq) + 3\ e^- \rightarrow Al(s)$; $E° = -1.66$ V] tells you that aluminum is easily oxidized and so might be expected

(a) A ball of aluminum foil is added to a solution of copper(II) nitrate and sodium chloride. Normally, the coating of chemically inert Al_2O_3 on the surface of aluminum protects the metal from further oxidation.

(b) In the presence of the Cl^- ion, the coating of Al_2O_3 is breached, and aluminum reduces copper(II) ions to copper metal in an exothermic reaction.

Figure 21.16 Corrosion of aluminum.

to be highly susceptible to corrosion. In fact, it is quite resistant to corrosion due to the formation of a thin, tough, and transparent skin of Al_2O_3 that adheres to the metal surface. However, if you penetrate the surface coating by scratching it or using a chemical agent, aluminum on the exposed surface can react immediately with oxygen or other oxidizing agent. In Figure 21.16, the surface is breached by chloride ions, and the exposed aluminum reacts rapidly with aqueous copper(II) ions.

Aluminum was first prepared by reducing $AlCl_3$ with sodium or potassium. This was a costly process, so aluminum was considered a precious metal in the 19th century. At the 1855 Paris Exposition a sample of aluminum was exhibited along with the crown jewels of France. In 1886, in an interesting coincidence, Frenchman Paul Heroult (1863–1914) and American Charles Martin Hall (1863–1914) simultaneously and independently conceived of the less expensive electrochemical method used today. The Hall–Heroult electrolysis method bears the names of the two discoverers.

Aluminum is found in nature as aluminosilicates, minerals such as clay that are based on aluminum, silicon, and oxygen. As these minerals weather, they break down to various forms of hydrated aluminum oxide, $Al_2O_3 \cdot n\ H_2O$, called *bauxite*. Mined in huge quantities, bauxite is the raw material from which aluminum is obtained. The first step is to purify the ore, separating Al_2O_3 from iron and silicon oxides. This is done by the *Bayer process*, which relies on the amphoteric, basic, or acidic nature of the various oxides. (Silica, SiO_2, is an acidic oxide, whereas Al_2O_3 is amphoteric, and Fe_2O_3 is a basic oxide.) Silica and Al_2O_3 dissolve in a hot concentrated solution of caustic soda (NaOH), leaving insoluble Fe_2O_3 to be filtered out.

$$Al_2O_3(s) + 2\ NaOH(aq) + 3\ H_2O(\ell) \longrightarrow 2\ Na[Al(OH)_4](aq)$$

$$SiO_2(s) + 2\ NaOH(aq) + 2\ H_2O(\ell) \longrightarrow Na_2[Si(OH)_6](aq)$$

If a solution containing aluminate and silicate anions is treated with CO_2, Al_2O_3 precipitates, and the silicate ion remains in solution. Recall that CO_2 is an acidic oxide that forms the weak acid H_2CO_3 in water, so the Al_2O_3 precipitation in this step is an acid–base reaction.

$$H_2CO_3(aq) + 2\ Na[Al(OH)_4](aq) \longrightarrow Na_2CO_3(aq) + Al_2O_3(s) + 5\ H_2O(\ell)$$

Metallic aluminum is obtained from purified bauxite by electrolysis (Figure 21.17). Bauxite is first mixed with cryolite, Na_3AlF_6, to give a lower-melting mixture (melting temperature = 980 °C) that is electrolyzed in a cell with graphite electrodes. The cell operates at a relatively low voltage (4.0–5.5 V) but with an

Oesper Collection in The History of Chemistry/University of Cincinnati

Charles Martin Hall (1863–1914) Hall was only 22 years old when, in a woodshed behind the family home in Oberlin, Ohio, he worked out the electrolytic process for extracting aluminum from Al_2O_3. He went on to found a company that eventually became ALCOA, the Aluminum Corporation of America.

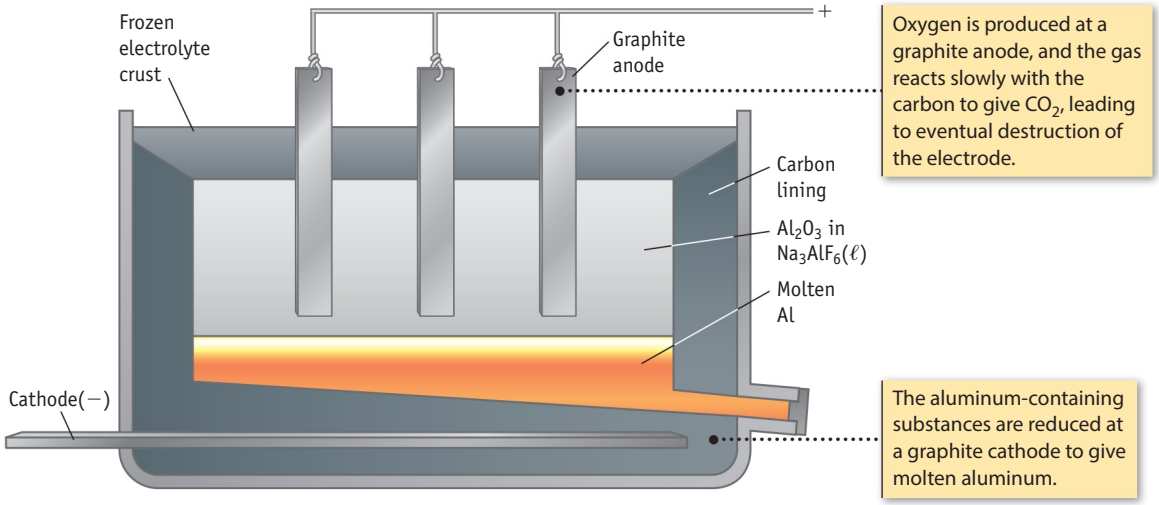

Figure 21.17 Industrial production of aluminum. Purified aluminum-containing ore (bauxite) is essentially Al_2O_3. In the Hall–Heroult process this is mixed with cryolite (Na_3AlF_6) and other fluorides such as AlF_3. (The additives serve to lower the melting point of the mixture and increase the conductivity.)

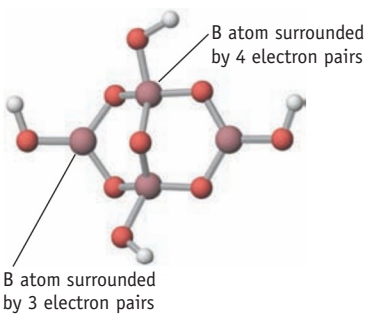
extremely high current (50,000–150,000 A). Aluminum is produced at the cathode and oxygen at the anode. To produce 1 kg of aluminum requires 13 to 16 kilowatt-hours of energy plus the energy required to maintain the high temperature.

Boron Compounds



Borax, $Na_2B_4O_7 \cdot 10\ H_2O$, is the most important boron–oxygen compound and is the form of the element most often found in nature (Figure 21.18). It has been used for centuries in metallurgy because of the ability of molten borax to dissolve other metal oxides. Because of this, borax is used as a *flux* that cleans the surfaces of metals to be joined and permits a good metal-to-metal contact.

The formula for borax gives little information about its structure. The anion is better described by the formula $[B_4O_5(OH)_4]^{2-}$, the structure of which illustrates two commonly observed structural features in inorganic chemistry. First, many minerals consist of MO_n groups that share O atoms. Second, the sharing of O atoms between two metals or metalloids often leads to MO rings.

Borax can be treated with sulfuric acid to produce boric acid, $B(OH)_3$,

$$Na_2B_4O_7 \cdot 10\ H_2O(s) + H_2SO_4(aq) \rightarrow 4\ B(OH)_3(aq) + Na_2SO_4(aq) + 5\ H_2O(\ell)$$

an acid that exhibits both Lewis and Brønsted acid behavior. Hydronium ions are produced by a Lewis acid–base interaction between boric acid and water.

$$K_a = 7.3 \times 10^{-10}$$

Because of its weak acid properties and slight biological activity, boric acid has been used for many years as an antiseptic. Furthermore, because boric acid is a weak acid, salts of borate ions, such as the $[B_4O_5(OH)_4]^{2-}$ ion in borax, are weak bases.

Boric acid is dehydrated to boric oxide when strongly heated.

$$2\ B(OH)_3(s) \rightarrow B_2O_3(s) + 3\ H_2O(\ell)$$

By far the largest use for the oxide is in the manufacture of borosilicate glass (the type of glass used in most laboratory glassware). This type of glass is composed of 76% SiO_2, 13% B_2O_3, and much smaller amounts of Al_2O_3 and Na_2O. The presence of boric oxide gives the glass a higher softening temperature, imparts a better resistance to attack by acids, and limits the expansion of the glass on heating. This last property makes borosilicate glass less prone to breakage when heated or cooled.

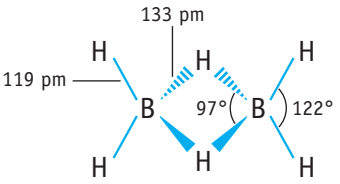
Like its metalloid neighbor silicon, boron forms a series of molecular compounds with hydrogen. Because boron is slightly less electronegative than hydrogen, these compounds are described as hydrides, in which the H atoms bear a partial negative charge. More than 20 neutral boron hydrides, or boranes, with the general formula B_xH_y are known. The simplest of these is diborane, B_2H_6, a colorless, gaseous compound with a boiling point of −92.6 °C. This molecule is described as *electron deficient* because there are not enough electrons to attach all of the atoms using two-electron bonds. Instead, the description of bonding uses three-center two-electron bonds in the B—H—B bridges (page 437).

Diborane has an endothermic enthalpy of formation ($\Delta_f H° = +41.0$ kJ/mol), so its combustion in air (to give boric oxide and water vapor) is extremely exothermic.

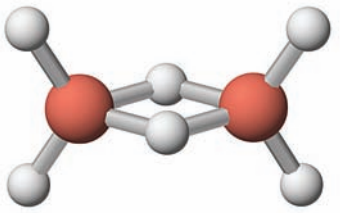
$$B_2H_6(g) + 3\ O_2(g) \rightarrow B_2O_3(s) + 3\ H_2O(g) \qquad \Delta_r H° = -2038\ \text{kJ/mol-rxn}$$

Because of this, diborane and other boron hydrides were once considered as possible rocket fuels. However, this was not realized because they are difficult to handle. Furthermore, one combustion product is solid B_2O_3, which means a rocket engine could spew massive amounts of white, powdered B_2O_3 into the environment.

Diborane can be synthesized from sodium borohydride, $NaBH_4$, the only B—H compound produced in ton quantities.



$$2\ NaBH_4(s) + I_2(s) \rightarrow B_2H_6(g) + 2\ NaI(s) + H_2(g)$$



Sodium borohydride, $NaBH_4$, a white, crystalline, water-soluble solid, is made from NaH and borate esters such as $B(OCH_3)_3$.

$$4\ NaH(s) + B(OCH_3)_3(g) \rightarrow NaBH_4(s) + 3\ NaOCH_3(s)$$

The main use of $NaBH_4$ is as a reducing agent in organic synthesis (Chapter 23).

Boron in Fireworks Barium salts and chlorinated organic compounds are used in fireworks to produce a green color. The problem is, however, that these ingredients are toxic. Fortunately, a solution was recently found: boron carbide, B_4C, gives off an intense green color when combined with an oxidizing agent such as KNO_3 at high temperatures.

Diborane, B_2H_6, the simplest member of a large family of boron hydrides.

Aluminum Compounds

Aluminum is an excellent reducing agent, so it reacts readily with hydrochloric acid (forming Al^{3+} ions and H_2). In contrast, it does not react with nitric acid because the acid oxidizes the surface of aluminum and produces a film of Al_2O_3 that protects the metal from further attack. In fact, this means nitric acid can be shipped in aluminum tanks.

Various salts of aluminum dissolve in water, giving the hydrated $Al^{3+}(aq)$ ion, which is a weak Brønsted acid (Table 16.2).

$$[Al(H_2O)_6]^{3+}(aq) + H_2O(\ell) \rightleftharpoons [Al(H_2O)_5(OH)]^{2+}(aq) + H_3O^+(aq)$$

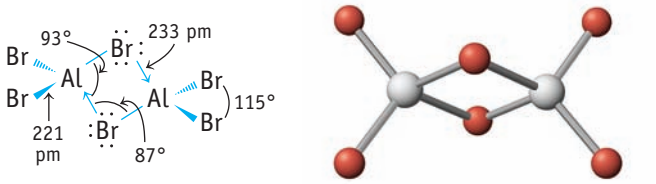
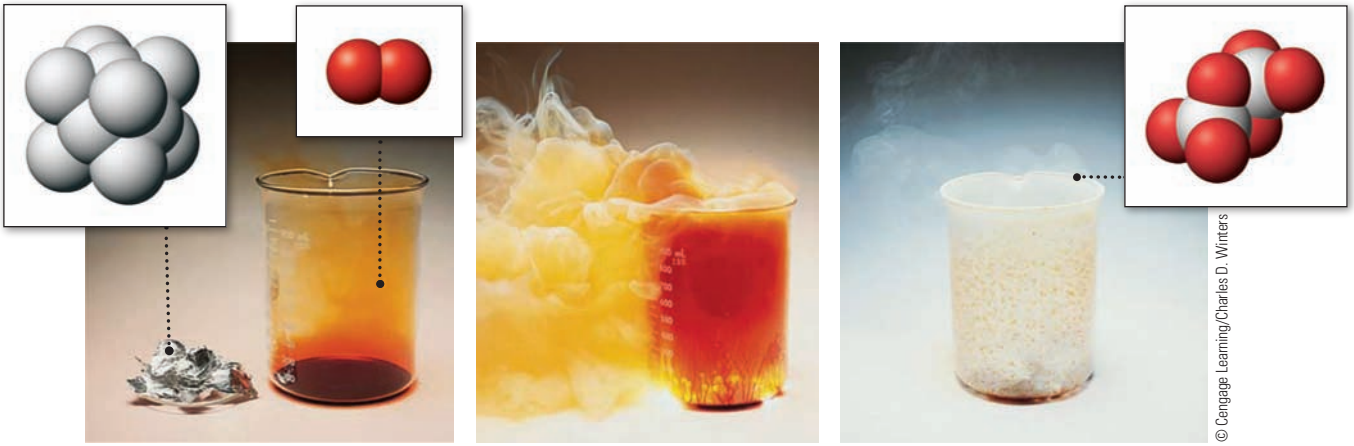
Figure 21.19 Corundum, Al_2O_3. Corundum is a crystalline form of aluminum oxide. Both rubies and sapphires are a form of corundum in which a few Al^{3+} ions have been replaced by ions such as Cr^{3+}, Fe^{2+}, or Ti^{4+}.

Adding acid shifts the equilibrium to the left, whereas adding base causes the equilibrium to shift to the right. Addition of sufficient hydroxide ion results ultimately in precipitation of the hydrated oxide $Al_2O_3 \cdot 3\ H_2O$.



Aluminum oxide, Al_2O_3, formed by dehydrating the hydrated oxide, is quite insoluble in water and generally resistant to chemical attack. In the crystalline form, aluminum oxide is known as *corundum* (Figure 21.19). This material is extraordinarily hard, a property that leads to its use as an abrasive in grinding wheels, "sandpaper," and toothpaste.

Some gems are impure aluminum oxide. Rubies, beautiful red crystals prized for jewelry and used in some lasers, are composed of Al_2O_3 contaminated with a small amount of Cr^{3+}. The Cr^{3+} ions replacing some of the Al^{3+} ions in the crystal lattice are the source of the red color. Synthetic rubies were first made in 1902, and the worldwide capacity is now about 200,000 kg/year; much of this production is used for jewel bearings in watches and instruments. Blue sapphires consist of Al_2O_3 with Fe^{2+} and Ti^{4+} impurities in place of Al^{3+} ions.



Boron forms halides such as gaseous BF_3 and BCl_3 that have the expected trigonal planar molecular geometry of halogen atoms surrounding an sp^2 hybridized boron atom. In contrast, the aluminum halides are all solids and have different structures. Aluminum bromide, which is made by the very exothermic reaction of aluminum metal and bromine (Figure 21.20),

$$2\ Al(s) + 3\ Br_2(\ell) \rightarrow Al_2Br_6(s)$$

has the formula Al_2Br_6. The structure resembles that of diborane in that bridging atoms appear between the two Al atoms. However, unlike B_2H_6, Al_2Br_6 is not electron deficient; the bridge is formed when a Br atom on one $AlBr_3$ uses a lone pair to form a coordinate covalent bond to a neighboring tetrahedral, sp^3-hybridized aluminum atom.

The structure of Al_2Br_6. The bonding in Al_2Br_6 is not unique to the aluminum halides. Metal–halogen–metal bridges are found in many other metal–halogen compounds.

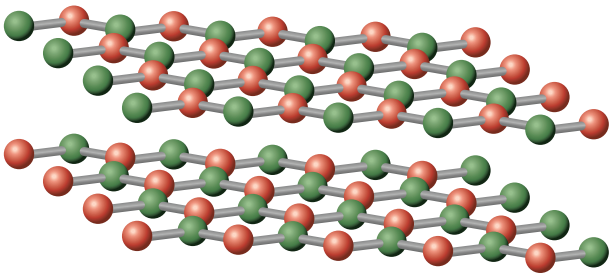
A CLOSER LOOK



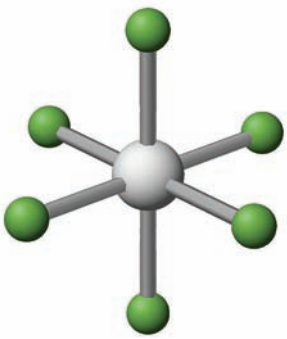
Complexity in Boron Chemistry

In addition to commercially important boron compounds like boric acid and borax, chemists who study boron compounds have synthesized a wide range of materials. A recent issue of *Science* magazine said "no other p-block elements shows a similar complexity of chemical bonding, which is well displayed within the cluster chemistry of boron hydrides and carboranes."

Reaction of boric acid and ammonia in a nitrogen atmosphere at high temperature gives h-BN, hexagonal boron nitride, with a structure very similar to that of graphite. The material, which is stable up to 900 °C, even in air, is a lubricant like graphite, but it is even more useful. Graphite requires water or gas molecules trapped between the layers to be an effective lubricant, but h-BN does not. It can be used, therefore, in space applications.

Boron nitride also has commercial uses: h-BN is found in nearly all cosmetics (foundations, eye shadows, lipsticks, and so on).

Recently the range of boron materials has been extended even further when an atomically thin boron film—called boraphene—was discovered. This consists of planar 6-member B rings (like the C_6 rings in graphene or the six-member BN rings in BN). But, there is a 7th B atom centered above each ring, giving effectively a B_7 cluster. Early results indicate boraphene has the characteristics of a 2D metal. The paper in *Science* magazine said " . . . boraphene layers have the potential to play a key role in future 2D materials research and within the growing field of boron-based nanomaterials."



Hexagonal boron nitride, h-BN. There are layers of interlaced BN rings. In h-BN the B atom of one layer lies above the N of a lower layer. In contrast, in graphite, the C atom of one layer is over the middle of the C_6 ring in the lower layer (Figure 12.19).

REFERENCE

- H. Sachdev, *Science*, Vol. 350, page 1468, December 2015.

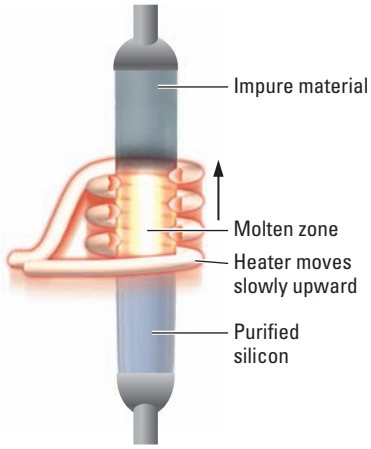
Both aluminum bromide and aluminum iodide have this structure. Aluminum chloride has a different solid state structure, but it exists as dimeric molecules in the vapor state. Aluminum fluoride has an ionic lattice structure, built from Al^{3+} and F^- ions.

Aluminum chloride can react with a chloride ion to form the tetrahedral anion $[AlCl_4]^-$. Aluminum fluoride, in contrast, can accommodate three additional F^- ions to form an octahedral $[AlF_6]^{3-}$ ion. This is the anion found in cryolite, Na_3AlF_6, the compound added to aluminum oxide in the electrolytic production of aluminum metal. Apparently, the Al^{3+} ion can bind to six of the smaller F^- ions, whereas only four of the larger Cl^-, Br^-, or I^- ions can surround an Al^{3+} ion.

The octahedral $[AlF_6]^{3-}$ anion. This is the anion in the mineral cryolite.

21.7 Silicon and the Group 4A Elements

Goals for Section 21.7



- Know how elemental silicon is produced.
- Know the general chemical properties of the Group 4A elements.

The elements of Group 4A have a broad range of chemical behavior: carbon is a nonmetal; silicon and germanium are classified as metalloids; and tin and lead are metals.

The Group 4A elements are characterized by half-filled valence shells with two electrons in the *ns* orbital and two electrons in *np* orbitals. The bonding in carbon and silicon compounds is largely covalent and involves sharing four electron pairs with neighboring atoms. In germanium compounds, the +4 oxidation state is common (GeO_2 and $GeCl_4$), but some +2 oxidation state compounds exist (GeI_2). Oxidation numbers of both +2 and +4 are common in compounds of tin and lead (such as $SnCl_2$, $SnCl_4$, PbO, and PbO_2). Oxidation numbers two units less than the group number are often encountered for heavier elements in Groups 3A–7A.

(a) To purify silicon, a rod of impure material is heated in an inert atmosphere by a circular heater that travels slowly along the rod. The molten zone is a solution of silicon and impurities. The melt has a lower melting point than the pure element, so the pure element crystallizes out of the melt. The impurities stay in the molten zone and so travel along the rod with the heater.

(b) This is a rod of silicon after purification. After cutting off the ends where impurities have accumlated, thin wafers of silicon are cut from the bars and are the basis for the semiconducting chips in computers and other devices.

Element abundances are in **parts per million** *in the Earth's crust.*

Silicon

Silicon is second after oxygen in abundance in the Earth's crust, so it is not surprising we are surrounded by silicon-containing materials: bricks, pottery, porcelain, lubricants, sealants, computer chips, and solar cells. The computer revolution is based on the semiconducting properties of silicon (Section 12.4).

Reasonably pure silicon can be made in large quantities by heating pure silica sand with purified coke to approximately 3000 °C in an electric furnace.

$$SiO_2(s) + 2\ C(s) \rightarrow Si(\ell) + 2\ CO(g)$$

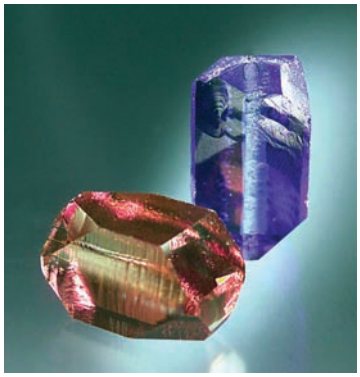
The molten silicon is drawn off the bottom of the furnace and allowed to cool to a shiny blue-gray solid. Because extremely high-purity silicon is needed for the electronics industry, purifying raw silicon requires several steps. First, the silicon in the impure sample is treated with chlorine to convert the silicon to liquid silicon tetrachloride.

$$Si(s) + 2\ Cl_2(g) \rightarrow SiCl_4(\ell)$$

Silicon tetrachloride (boiling point of 57.6 °C) is carefully purified by distillation and then reduced to silicon with magnesium.

$$SiCl_4(g) + 2\ Mg(s) \rightarrow 2\ MgCl_2(s) + Si(s)$$

The by-product, magnesium chloride, is washed out with water, and the silicon is remelted and cast into bars. A final purification is carried out by *zone refining*, a process in which a special heating device is used to melt a narrow segment of the silicon rod. As the heater is moved slowly along the rod, impurities contained in the silicon tend to remain in the liquid phase. The silicon that crystallizes from the heated zone is therefore of a higher purity (Figure 21.21).



Silicon Dioxide

The simplest oxide of silicon is SiO_2, commonly called *silica*, a constituent of many rocks such as granite and sandstone. Quartz is a pure crystalline form of silica, but impurities in quartz produce gemstones such as amethyst (Figure 21.22).

Silica and CO_2 are oxides of two elements in the same chemical group, so similarities between them might be expected. In fact, SiO_2 is a high-melting solid (quartz melts at 1610 °C), whereas CO_2 is a gas at room temperature and 1 atm. This great disparity arises from the different structures of the two oxides. Carbon dioxide is a

Synthetic quartz. These crystals were grown from silica in sodium hydroxide. The colors come from added Co^{2+} ions (blue) or Fe^{2+} ions (brown).

Natural quartz. Pure quartz is colorless, but impurities add color to produce purple amethyst and brown citrine.

Quartz, a network solid. Each Si atom is bound tetrahedrally to four O atoms, each linked to another Si atom.

Figure 21.22 Various forms of quartz.

molecular compound, with the carbon atom linked to each oxygen atom by a double bond. In contrast, SiO_2 is a network solid, which is the preferred structure because the bond energy of two Si═O double bonds is much less than the bond energy of four Si—O single bonds. The contrast between SiO_2 and CO_2 is an example of a more general phenomenon. *Multiple bonds, often encountered between second period elements, are rare among elements in the third period and beyond.* There are many compounds with multiple bonds to carbon but very few compounds featuring multiple bonds to silicon.

Quartz crystals are used to control the frequency of radio and television transmissions. Because these and related applications use so much quartz, there is not enough natural quartz to fulfill demand, and quartz must be synthesized. Noncrystalline, or vitreous, quartz, made by melting pure silica sand, is placed in a steel "bomb," and dilute aqueous NaOH is added. A "seed" crystal is placed in the mixture, just as you might use a seed crystal in a hot sugar solution to grow rock candy. When the mixture is heated above the critical temperature of water (above 400 °C and 1700 atm) over a period of days, pure quartz crystallizes.

Silicon dioxide also dissolves slowly in hot, *molten* NaOH or Na_2CO_3 to give Na_4SiO_4, sodium silicate.

$$SiO_2(s) + 2\ Na_2CO_3(\ell) \rightarrow Na_4SiO_4(s) + 2\ CO_2(g)$$

After the molten mixture has cooled, hot water is added under pressure. This partially dissolves the material to give a solution of sodium silicate. After filtering off insoluble sand or glass, the solvent is evaporated to leave sodium silicate, called *water glass*. The biggest single use of this material is in household and industrial detergents because a sodium silicate solution can maintain pH by its buffering ability. Additionally, sodium silicate is used in various adhesives and binders, especially for gluing corrugated cardboard boxes.

If sodium silicate is treated with acid, a gelatinous precipitate of SiO_2 called *silica gel* is obtained. Washed and dried, silica gel is a highly porous material with many uses. It is a drying agent, readily absorbing up to 40% of its own weight of water. Small packets of silica gel are often placed in packing boxes of merchandise. The material is frequently stained with $(NH_4)_2CoCl_4$, a humidity detector that is pink when hydrated and blue when dry.

Silicate Minerals with Chain and Ribbon Structures

The structure and chemistry of silicate minerals is an enormous topic in geology and chemistry. Although all silicates are built from tetrahedral SiO_4 units, they have

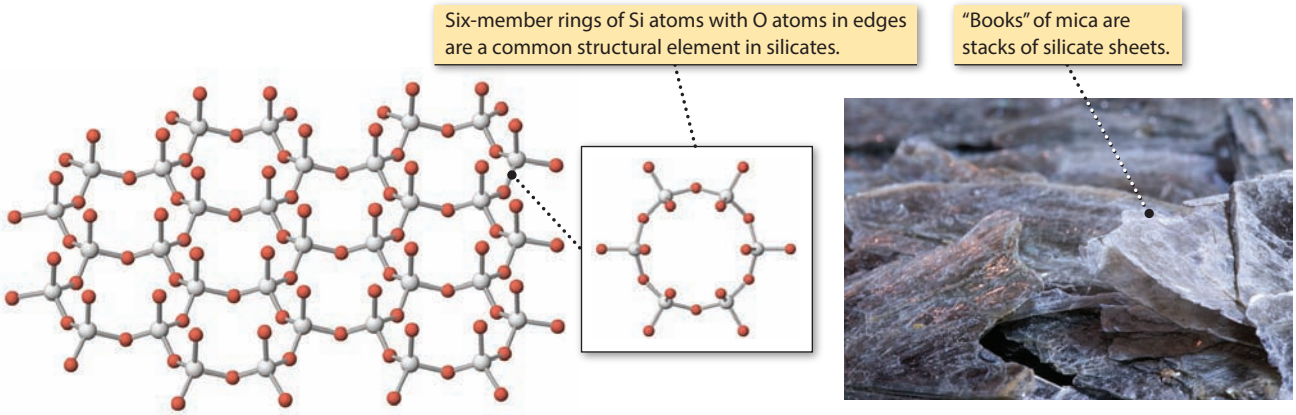
Asbestos. The asbestos minerals are fibrous silicates. The family includes the minerals actinolite, amosite, anthophyllite, chrysotile (photo above), crocidolite, and tremolite. About 90% of the asbestos used in the U.S. is chrysotile. More than 50 countries have banned the use of asbestos because of its link to mesothelioma, a lung cancer. Now there is a significant effort in the U. S. to clean up places where it has been used in insulation materials, floor tiles, brake linings, and cement sheeting. [*Chemical & Engineering News* (CEN.ACS.org), November 28, 2016.]

different properties and an enormous variety of structures because of the way these tetrahedral SiO_4 units link together.

The simplest silicates, *orthosilicates*, contain SiO_4^{4-} anions. The 4− charge of the anion is balanced by four M^+ ions, two M^{2+} ions, or a combination of ions. Olivine, an important mineral in the Earth's mantle, contains Mg^{2+} and Fe^{2+}, with the Fe^{2+} ion giving the mineral its characteristic olive color, and gem-like zircons are $ZrSiO_4$. Calcium orthosilicate, Ca_2SiO_4, is a component of Portland cement (*A Closer Look: Cement—The Second Most Used Substance*, page 977).

Pyroxenes are minerals with the empirical formula $(MSiO_3)_x$, where M is a divalent metal cation such as Mg^{2+}. They are characterized by having a chain of SiO_4 tetrahedra as the basic structural unit.



A chain of linked SiO_4 tetrahedra.

If two such chains are linked together by sharing oxygen atoms, the result is an *amphibole*, of which the asbestos minerals are one example. The molecular chain results in asbestos being a fibrous material.

Silicates with Sheet Structures and Aluminosilicates

Linking many silicate chains together produces a sheet of SiO_4 tetrahedra (Figure 21.23). This sheet is the basic structural feature of some of Earth's most important minerals, particularly the clay minerals (such as china clay), mica, talc, and the chrysotile form of asbestos. However, these minerals do not contain just silicon and oxygen. Rather, they are often referred to as *aluminosilicates* because they frequently have Al^{3+} ions in place of some Si^{4+} ions (which means that other positive ions such as Na^+, K^+, and Mg^{2+} must also be present in the lattice to balance the net negative and positive charges). In kaolinite clay, for example, the sheet of SiO_4 tetrahedra is bonded to a sheet of AlO_6 octahedra (Figure 21.24). Another example is muscovite, a form of mica. Aluminum ions have replaced some Si^{4+} ions, and there are charge-balancing K^+ ions, so it is best represented by the formula $KAl_2(OH)_2(Si_3AlO_{10})$.

John C. Kotz

Figure 21.23 Mica, a sheet silicate. The sheet-like molecular structure of mica explains its physical appearance. As in the pyroxenes, each silicon is bonded to four oxygen atoms, but the Si and O atoms form a sheet of six-member rings of Si atoms with O atoms in each edge. The ratio of Si to O in this structure is 1 to 2.5. A formula of $SiO_{2.5}$ requires a positive ion, such as Na^+, to counterbalance the charge. Thus, mica and other sheet silicates, and aluminosilicates such as talc and many clays, have positive ions between the sheets.

Remedy for stomach upset. One of the ingredients in Kaopectate is kaolin, one form of clay. The off-white objects are pieces of clay purchased in a market in Ghana, West Africa. It is eaten for an upset stomach, a practice widespread round the world.

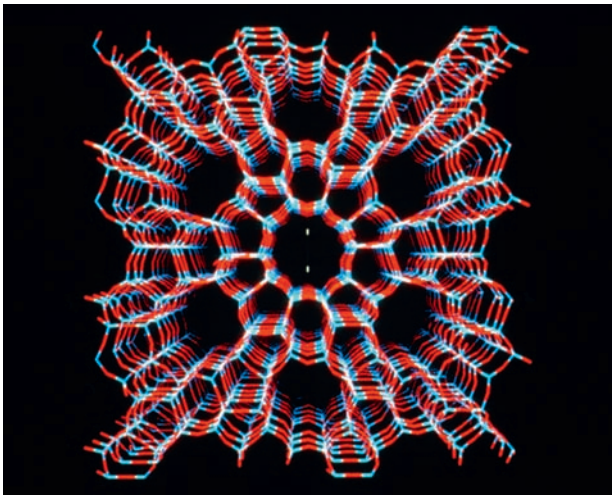
Figure 21.24 **Clay, an aluminosilicate.**

© Cengage Learning/Charles D. Winters

Kaolinite clay. The basic structural feature of many clays, and kaolinite in particular, is a sheet of SiO_4 tetrahedra (black and red spheres) bonded to a sheet of AlO_6 octahedra (gray and green spheres).

There are some interesting uses of clays, one being in medicine (Figure 21.24). In certain cultures, clay is eaten for medicinal purposes. Several remedies for the relief of upset stomach contain highly purified clays that absorb excess stomach acid as well as potentially harmful bacteria and their toxins by exchanging the intersheet cations in the clays for the toxins, which are often organic cations.

Other aluminosilicates include the feldspars, common minerals that make up about 60% of the Earth's crust, and zeolites (Figure 21.25). Both materials are composed of SiO_4 tetrahedra in which some of the Si atoms have been replaced by Al atoms, along with alkali and alkaline earth metal ions for charge balance. The main feature of zeolite structures is their regularly shaped tunnels and cavities. Hole diameters are between 300 and 1000 pm, and small molecules such as water can fit into the cavities of the zeolite structure. As a result, zeolites can be used as drying agents to selectively absorb water from air or a solvent. Small amounts of zeolites are often sealed into multipane windows to keep the air dry between the panes.



Zeolites are also used as catalysts. For example, ExxonMobil has patented a process in which methanol, CH_3OH, is converted to gasoline in the presence of specially tailored zeolites. In addition, zeolites are added to detergents, where they function as water-softening agents because the sodium ions of the zeolite can be exchanged for Ca^{2+} ions in hard water, effectively removing Ca^{2+} ions from the water. Finally, you will find them in consumer products that remove odor-causing molecules from air.

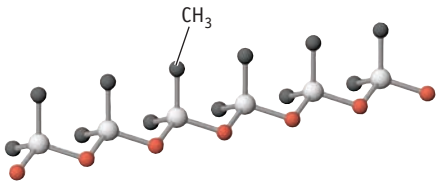

Figure 21.26. A silicone polymer. This silicone polymer has the formula $(R_2SiO)_x$, where R represents an organic group such as CH_3. In this structure, the silicon atoms have tetrahedral geometry, bonding to two O atoms and two organic groups. Groups other than CH_3 can be used, and chains can be cross-linked.

Silicone Polymers

Silicon and chloromethane (CH_3Cl) react at 300 °C in the presence of a catalyst, Cu powder. The primary product of this reaction is $(CH_3)_2SiCl_2$.

$$Si(s) + 2\ CH_3Cl(g) \rightarrow (CH_3)_2SiCl_2(\ell)$$

Halides of Group 4A elements other than carbon hydrolyze readily, so the reaction of $(CH_3)_2SiCl_2$ with water initially produces $(CH_3)_2Si(OH)_2$. On standing, these molecules combine to form a polymer by eliminating water. The polymer is called polydimethylsiloxane, a member of the *silicone* family of polymers (Figure 21.26).

$$(CH_3)_2SiCl_2 + 2\ H_2O \rightarrow (CH_3)_2Si(OH)_2 + 2\ HCl$$

$$n\ (CH_3)_2Si(OH)_2 \rightarrow [—(CH_3)_2SiO—]_n + n\ H_2O$$

Silicone polymers are nontoxic and have good stability to heat, light, and oxygen; they are chemically inert and have valuable antistick and antifoam properties. They can take the form of oils, greases, and resins. Some have rubber-like properties ("Silly Putty," for example, is a silicone polymer). More than 1 million tons of silicone polymers are made worldwide annually. These materials are used in a wide variety of products: lubricants, peel-off labels, lipstick, suntan lotion, car polish, and building caulk.

The Heavier Elements of Group 4A: Ge, Sn, and Pb

Just as silicon chemistry is dominated by oxides, so too is the chemistry of the heavier elements in Group 4A. For example, the source of tin is an oxide, the mineral cassiterite, SnO_2. Thousands of tons are used in the ceramics industry in glazes, enamels, and pigments. A yellow glaze is a mixture of oxides, SnO_2 and V_2O_5.

Lead(II) oxide, PbO, is a red solid at room temperature. The red form is commonly called *litharge*, but above 488 °C a yellow form (called *massicot*) with a different unit cell is stable. PbO is the most important lead compound, one large use being in the manufacture of lead glass, a glass with a high index of refraction that gives it a special brilliance.

The other major use for PbO is in lead storage batteries (Figure 19.11). The oxide is applied as a paste in sulfuric acid to lead battery plates. The positive plate (cathode) is prepared by oxidizing PbO to lead(IV) oxide, PbO_2. The negative plate (anode) is elemental lead.

If lead(II) oxide is heated in air, it forms "red lead," Pb_3O_4, which is best formulated as a mixture of Pb(II) and Pb(IV) oxides. It was once widely used in rust-inhibiting paint and primers for iron and steel.

Other lead compounds that were used in paints include brilliant yellow $PbCrO_4$, which was used to paint the yellow lines on roadways. Finally, a mixed carbonate, $2\ PbCO_3 \cdot Pb(OH)_2$, is a white pigment.

Paints with lead-containing pigments were useful because they dried faster, resisted moisture, and were durable. But lead is known to be toxic, and lead-based paints were banned in 1978. Nonetheless, they are used in other countries and remain in our environment (*Applying Chemical Principles: 21.1—Lead in the Environment*).

21.8 Nitrogen, Phosphorus, and the Group 5A Elements

Goal for Section 21.8

- Know common compounds of nitrogen and phosphorus, particularly the oxides.

Group 5A elements are characterized by the ns^2np^3 configuration with its half-filled *np* subshell. Although nitrogen in its compounds displays a range of oxidation numbers from −3 to +5, the primary oxidation numbers for the heavier Group 5A elements are +3 and +5. Once again, as in Groups 3A and 4A, the lower oxidation state is more common in the heavier elements than in the lighter ones. In many arsenic, antimony, and bismuth compounds, the element has an oxidation number of +3. Compounds of these elements with oxidation numbers of +5 are powerful oxidizing agents.

This part of our tour of the main group elements will concentrate on the chemistries of nitrogen and phosphorus. Nitrogen is found primarily as N_2 in the atmosphere, where it constitutes 78.1% by volume (75.5% by weight). In contrast, phosphorus occurs in Earth's crust in solids. More than 200 different phosphorus-containing minerals are known, and all contain the tetrahedral phosphate ion, PO_4^{3-}, or a derivative of this ion. By far, the most abundant phosphorus-containing minerals are apatites such as $Ca_5X(PO_4)_3$ (where X can be OH^-, F^-, Cl^-, or some other anion).

Nitrogen and its compounds play a key role in our economy, with ammonia being particularly important. Phosphoric acid is an important commodity chemical, and it finds its greatest use in producing fertilizers.

Both phosphorus and nitrogen are part of every living organism. Phosphorus is contained in nucleic acids and phospholipids, and nitrogen occurs in proteins and nucleic acids (Chapter 24: *Biochemistry*).

Group **5A**

Nitrogen	Phosphorus	Arsenic	Antimony	Bismuth
7	15	33	51	83
N	**P**	**As**	**Sb**	**Bi**
25 ppm	1000 ppm	1.5 ppm	0.2 ppm	0.048 ppm

Element abundances are in **parts per million** *in the Earth's crust.*

Properties of Elemental Nitrogen and Phosphorus

Nitrogen (N_2) is a colorless gas that liquefies at 77 K (−196 °C) (Figure 11.1). Its most notable feature is its reluctance to react with other elements or compounds because the N≡N triple bond has a large bond dissociation enthalpy (945 kJ/mol) and because the molecule is nonpolar. Nitrogen does, however, react with hydrogen to give ammonia in the presence of a catalyst (*Applying Chemical Principles: 15.1—Applying Equilibrium Concepts—The Haber-Bosch Ammonia Process,* page 695) and with a few metals (notably lithium and magnesium) to give metal nitrides, compounds containing the N^{3-} ion.

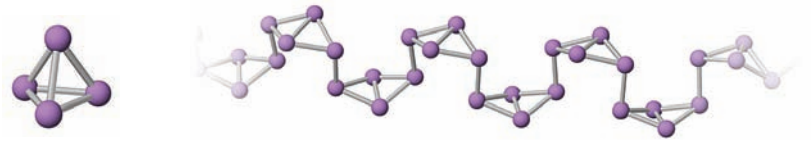
$$3\ Mg(s) + N_2(g) \longrightarrow \underset{\text{magnesium nitride}}{Mg_3N_2(s)}$$

Elemental nitrogen is very useful. Because of its lack of reactivity, it can provide a nonoxidizing atmosphere for packaged foods and wine and is used to pressurize electric cables and telephone wires. Liquid nitrogen (b.p. −196 °C) is valuable as a coolant in freezing biological samples such as blood and semen, in freeze-drying food, and for other applications that require extremely low temperatures.

Elemental phosphorus was first derived from human waste (*A Closer Look: Making Phosphorus*), but it is now produced by the reduction of phosphate minerals in an electric furnace.

$$2\ Ca_3(PO_4)_2(s) + 10\ C(s) + 6\ SiO_2(s) \rightarrow P_4(g) + 6\ CaSiO_3(s) + 10\ CO(g)$$

The phosphorus vapor is cooled under water to prevent its spontaneous combustion and eventually yields the solid white waxy allotrope. Although white phosphorus is defined as the standard state of the element, it is the least stable form thermodynamically.



© Cengage Learning/Charles D. Winters

The red and white allotropes of phosphorus. White phosphorus is stored under water; this form of phosphorus burns when exposed to air. In contrast, red phosphorus is stable in air.

Rather than occurring as a diatomic molecule with a triple bond, like its second-period relative nitrogen (N_2), white phosphorus is composed of tetrahedral P_4 molecules in which each P atom is joined to three others via single bonds.

white phosphorus, P_4 — polymeric red phosphorus

The red allotrope of phosphorus, a polymer of P_4 units, is made by heating the white form out of contact with air. It is much less reactive than the white form and is easier to handle. If this allotrope is heated under pressure, it eventually produces the thermodynamically most stable allotrope, black phophorus, which is a complex polymer of phosphorus atoms.

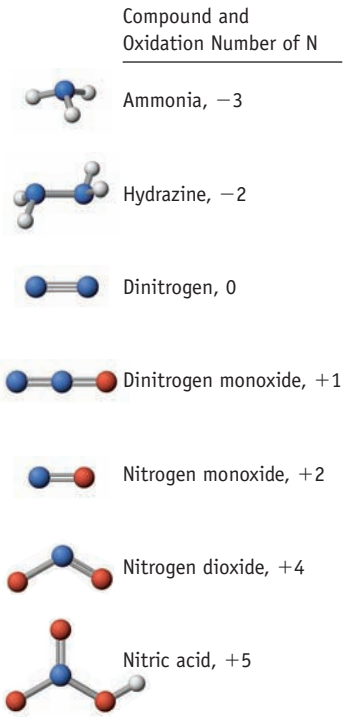

Figure 21.27 Compounds and oxidation numbers for nitrogen. In its compounds, the N atom can have oxidation states ranging from −3 to +5.

Nitrogen Compounds

A notable feature of the chemistry of nitrogen is the wide diversity of its compounds. Compounds are known with nitrogen in all oxidation numbers between −3 and +5 (Figure 21.27).

Hydrogen Compounds of Nitrogen: Ammonia and Hydrazine

Ammonia is a gas at room temperature and pressure. It has a very penetrating odor and condenses to a liquid at −33 °C under 1 atm of pressure. Aqueous solutions of ammonia, often referred to as ammonium hydroxide, are basic due to the reaction of ammonia with water (Figure 3.13).

$$NH_3(aq) + H_2O(\ell) \rightleftharpoons NH_4^+(aq) + OH^-(aq) \qquad K_b = 1.8 \times 10^{-5} \text{ at } 25\ ^\circ C$$

Ammonia is a major industrial chemical and is prepared by the Haber-Bosch process (page 695), largely for use as a fertilizer.

A CLOSER LOOK

Making Phosphorus

He stoked his small furnace with more charcoal and pumped the bellows until his retort glowed red hot. Suddenly something strange began to happen. Glowing fumes filled the vessel and from the end of the retort dripped a shining liquid that burst into flames.

J. Emsley: *The 13th Element,* p. 5. New York, John Wiley, 2000.

John Emsley begins his story of phosphorus, its discovery, and its uses, by imagining what the German alchemist Hennig Brandt must have seen in his laboratory that day in 1669. He was in search of the philosopher's stone, the magic elixir that would turn the crudest substance into gold. (Some may recall that the first Harry Potter novel was titled *Harry Potter and the Philosopher's Stone* when it was published in Great Britain.)

Brandt was experimenting with urine, which had served as the source of useful chemicals since Roman times. It is not surprising that phosphorus could be extracted from this source. Humans consume much more phosphorus, in the form of phosphate, than they require, and the excess phosphorus (about 1.4 g per day) is excreted in the urine. It is nonetheless extraordinary that Brandt was able to isolate the element. According to an 18th-century chemistry book, about 30 g of phosphorus could be obtained from 60 gallons of urine. And the process was not simple. Another 18th century recipe states that "50 or 60 pails full" of urine was to be used. "Let it lie steeping . . . till it putrefy and breed worms." The chemist was then to reduce the whole to a paste and finally to heat the paste very strongly in a retort. After some days, phosphorus distilled from the mixture and was collected in water. (We know now that carbon from the organic compounds in the urine reduces the phosphate to phosphorus.) Phosphorus was made in this manner for more than 100 years.

Hydrazine, N_2H_4, is a colorless, fuming liquid with an ammonia-like odor (mp, 2.0 °C; bp, 113.5 °C). Almost 1 million kilograms of hydrazine are produced annually by the Raschig process—the oxidation of ammonia with alkaline sodium hypochlorite in the presence of gelatin (which is added to suppress metal-catalyzed side reactions that lower the yield of hydrazine).

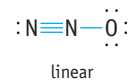
$$2\ NH_3(aq) + NaClO(aq) \rightleftharpoons N_2H_4(aq) + NaCl(aq) + H_2O(\ell)$$

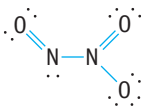
Hydrazine, like ammonia, is a base,

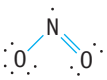
$$N_2H_4(aq) + H_2O(\ell) \rightleftharpoons N_2H_5^+(aq) + OH^-(aq) \qquad K_b = 8.5 \times 10^{-7}$$

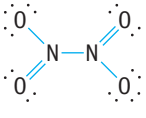
but it is also a strong reducing agent, as reflected in the reduction potential for the following half-reaction in basic solution:

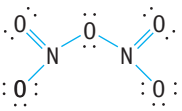
$$N_2(g) + 4\ H_2O(\ell) + 4\ e^- \rightarrow N_2H_4(aq) + 4\ OH^-(aq) \qquad E° = -1.15\ V$$











Hydrazine's reducing ability is exploited in its use in treating wastewater from chemical plants. It removes oxidizing ions such as CrO_4^{2-} by reducing them, thus preventing them from entering the environment. A related use is the treatment of water boilers in large electric-generating plants. Oxygen dissolved in the water presents a serious problem in these plants because the dissolved gas can corrode the metal of the boiler and pipes. Hydrazine reduces the amount of dissolved oxygen in water.

$$N_2H_4(aq) + O_2(g) \rightarrow N_2(g) + 2\ H_2O(\ell)$$

Oxides and Oxoacids of Nitrogen

Nitrogen is unique among all elements in the number of binary oxides it forms (Table 21.5). All are thermodynamically unstable with respect to decomposition to

TABLE 21.5 Some Oxides of Nitrogen

Formula	Name	Structure	Nitrogen Oxidation Number	Description
N_2O	Dinitrogen monoxide (nitrous oxide)	 linear	+1	Colorless gas (laughing gas)
NO	Nitrogen monoxide (nitric oxide)	*	+2	Colorless gas; odd-electron molecule (paramagnetic)
N_2O_3	Dinitrogen trioxide	 planar	+3	Blue solid (mp, −100.7 °C); reversibly dissociates to NO and NO_2 above its mp
NO_2	Nitrogen dioxide		+4	Brown, paramagnetic gas; odd-electron molecule
N_2O_4	Dinitrogen tetraoxide	 planar	+4	Colorless liquid/gas; dissociates to NO_2 (Figure 15.7)
N_2O_5	Dinitrogen pentaoxide		+5	Colorless solid

*It is not possible to draw a Lewis structure that accurately represents the electronic structure of NO (Chapter 8). Also note that only one resonance structure is shown for each structure.

Wellcome Images CC/Diomedia

Nitrous oxide, N_2O, laughing gas The famous English chemist Humphry Davy (1778-1829) was researching nitrous oxide, which he produced by heating NH_4NO_3. As chemists did in those days, he wanted to see what its effect might be on him, so he took a deep breath. He later recorded that "The objects around me became dazzling and my hearing more acute." In others it produced continual laughter. But it was soon apparent it dulled the senses, and it was used early on in dentistry, and is still used today, as a pain-deadening substance. (For a history of pain-killing chemicals see chemheritage.org/painless.)

N_2 and O_2; that is, all have positive $\Delta_f G°$ values. Most are slow to decompose, however, and so are described as kinetically stable.

Dinitrogen monoxide, N_2O, commonly called *nitrous oxide*, is a nontoxic, odorless, and tasteless gas in which nitrogen has the lowest oxidation number (+1) among the nitrogen oxides. It can be made by the careful decomposition of ammonium nitrate at 250 °C.

$$NH_4NO_3(s) \rightarrow N_2O(g) + 2\ H_2O(g)$$

It is used as an anesthetic in minor surgery and has been called "laughing gas" because of its euphoriant effects. Because it is soluble in vegetable fats, the largest commercial use of N_2O is as a propellant and aerating agent in cans of whipped cream.

Nitrogen monoxide, NO, is an odd-electron molecule. It has 11 valence electrons, giving it one unpaired electron and making it a free radical. The compound has recently been the subject of intense research because it has been found to be important in a number of biochemical processes.

Nitrogen dioxide, NO_2, is the brown gas you see when a bottle of nitric acid is allowed to stand in the sunlight,

$$2\ HNO_3(aq) \rightarrow 2\ NO_2(g) + H_2O(\ell) + \tfrac{1}{2}\ O_2(g)$$

and it is also a culprit in air pollution (Section 20.6). Nitrogen monoxide forms when atmospheric nitrogen and oxygen are heated in internal combustion engines. When released into the atmosphere, NO rapidly reacts with O_2 to form NO_2.

$$2\ NO(g) + O_2(g) \rightarrow 2\ NO_2(g)$$

Nitrogen dioxide has 17 valence electrons, so, like NO, it is an odd-electron molecule. Because the odd electron largely resides on the N atom, two NO_2 molecules can combine, forming an N—N bond and producing N_2O_4, *dinitrogen tetraoxide.*

$$\underset{\text{deep brown gas}}{2\ NO_2(g)} \longrightarrow \underset{\text{colorless (mp, } -11.2\ °C)}{N_2O_4(g)}$$

Solid N_2O_4 is colorless and consists entirely of N_2O_4 molecules. However, as the solid melts and the temperature increases to the boiling point, the color darkens as some N_2O_4 dissociates to form brown NO_2. At the normal boiling point (21.5 °C), the distinctly brown gas consists of 15.9% NO_2 and 84.1% N_2O_4 (Figure 15.7).

When NO_2 is bubbled into water, nitric acid and nitrous acid form.

$$2\ NO_2(g) + H_2O(\ell) \rightarrow \underset{\text{nitric acid}}{HNO_3(aq)} + \underset{\text{nitrous acid}}{HNO_2(aq)}$$

Nitric acid has been known for centuries and is an important compound in our modern economy. The oldest way to make the acid is to treat $NaNO_3$ with sulfuric acid (Figure 21.28).

$$2\ NaNO_3(s) + H_2SO_4(\ell) \rightarrow 2\ HNO_3(\ell) + Na_2SO_4(s)$$

However, enormous quantities of nitric acid are now produced industrially by the oxidation of ammonia in the multistep *Ostwald process*. The acid has many applications, but by far the greatest amount is turned into ammonium nitrate (for use as a fertilizer) by the reaction of nitric acid and ammonia.

Nitric acid is a powerful oxidizing agent, as the large, positive $E°$ values for the following half-reactions illustrate:

$$NO_3^-(aq) + 4\ H_3O^+(aq) + 3\ e^- \rightarrow NO(g) + 6\ H_2O(\ell) \qquad E° = +0.96\ V$$

$$NO_3^-(aq) + 2\ H_3O^+(aq) + e^- \rightarrow NO_2(g) + 3\ H_2O(\ell) \qquad E° = +0.80\ V$$

Concentrated nitric acid attacks and oxidizes most metals. (Aluminum is an exception; Section 21.6.) In this process, the nitrate ion is reduced to one of the nitrogen oxides. Which oxide is formed depends on the metal and on reaction conditions. In

the case of copper, for example, either NO or NO_2 is produced, depending on the concentration of the acid (Figure 21.28b).

In dilute acid:

$$3\ Cu(s) + 8\ H_3O^+(aq) + 2\ NO_3^-(aq) \rightarrow 3\ Cu^{2+}(aq) + 12\ H_2O(\ell) + 2\ NO(g)$$

A CLOSER LOOK

Ammonium Nitrate—A Mixed Blessing

NH_4NO_3 is a widely used fertilizer as it is an excellent source of nitrogen. However, if mixed with organic material, it is also a powerful explosive, and many fatal accidents have happened over the past hundred years. Among the best known occurred on April 16, 1947 when almost 600 people died when a ship blew up in the harbor in Texas City, Texas. In April 2015 a plant making the material in West, Texas blew up, killing a number of people. And in 2015 the port of Tianjin, China experienced a massive explosion, again killing many.

Ammonium nitrate has also been used in weapons. On April 19, 1995 a bomb made from ammonium nitrate and fuel oil destroyed the Federal Building in Oklahoma City. In recent years it has been used in IEDs (Improvised Explosive Devices) in war zones.

There have been attempts to ban ammonium nitrate because of its weaponization, but this is detrimental to people dependent on fertilizer. A possible solution is to modify the chemical by adding a substance that prevents it from acting as a strong oxidant. One suggestion is to add a small amount of $FeSO_4$, which reacts with NH_4NO_3 to produce $Fe(NO_3)_2$ and $(NH_4)_2SO_4$, substances still useful in a fertilizer but that will not function in an explosive device.

In concentrated acid:

$$Cu(s) + 4\ H_3O^+(aq) + 2\ NO_3^-(aq) \rightarrow Cu^{2+}(aq) + 6\ H_2O(\ell) + 2\ NO_2(g)$$

Four metals (Au, Pt, Rh, and Ir) that are *not* attacked by nitric acid are often described as the "noble metals." The alchemists of the 14th century, however, knew that if they mixed HNO_3 with HCl in a ratio of about 1:3, this *aqua regia*, or "kingly water," would attack even gold, the noblest of metals.

$$Au(s) + NO_3^-(aq) + 4\ Cl^-(aq) + 4\ H_3O^+(aq) \rightarrow [AuCl_4]^-(aq) + NO(g) + 6\ H_2O(\ell)$$

Hydrogen Compounds of Phosphorus and Other Group 5A Elements

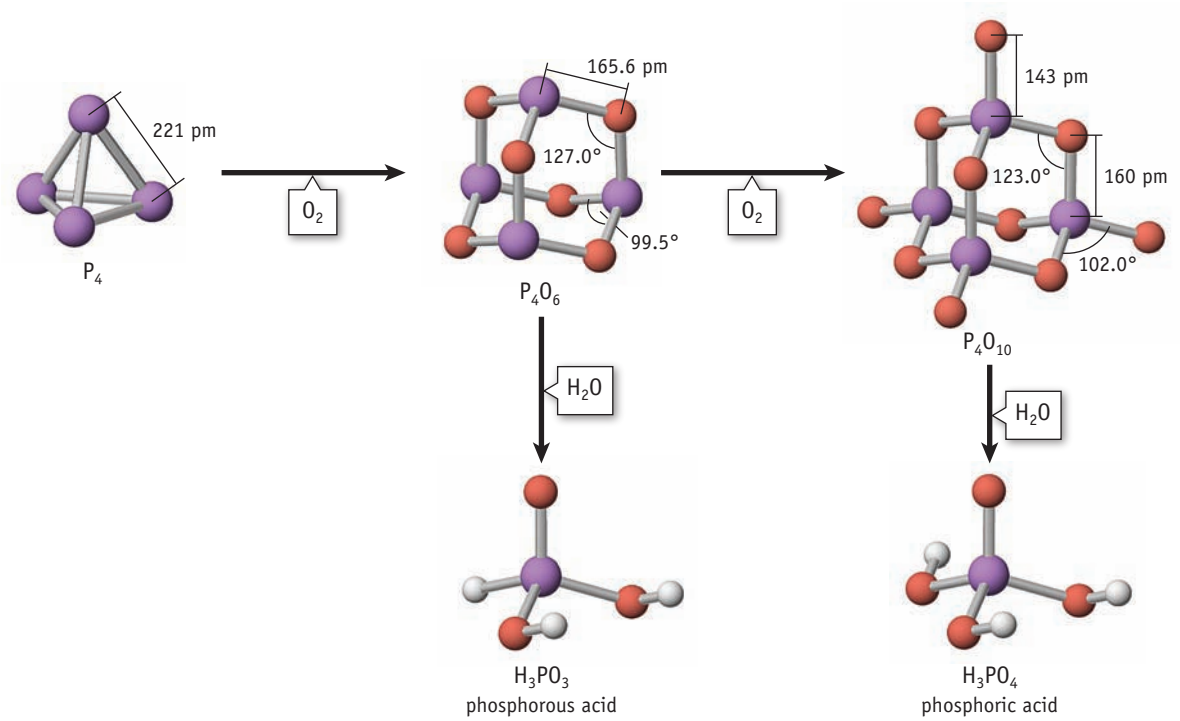
The phosphorus analog of ammonia, phosphine (PH_3), is a poisonous, highly reactive gas with a faint garlic-like odor. Industrially, it is made by the reaction of white phosphorus and aqueous KOH.

$$P_4(s) + 3\ KOH(aq) + 3\ H_2O(\ell) \rightarrow PH_3(g) + 3\ KH_2PO_2(aq)$$

The hydrides of the heavier Group 5A elements are also toxic and become more unstable as the atomic number of the element increases. Nonetheless, arsine (AsH_3) is important in the semiconductor industry as a starting material in the preparation of gallium arsenide (GaAs) semiconductors.

Phosphorus Oxides and Sulfides

The most important compounds of phosphorus are those with oxygen, and there are at least six simple binary compounds containing just phosphorus and oxygen. All of them can be thought of as being derived structurally from the P_4 tetrahedron of white phosphorus. For example, if P_4 is carefully oxidized, P_4O_6 is formed; an O atom has been placed into each P—P bond in the tetrahedron (Figure 21.29).



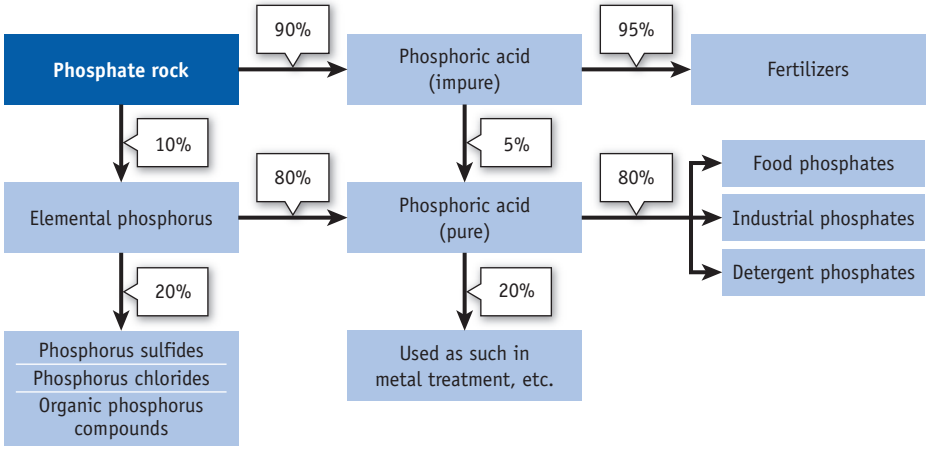


Figure 21.29 Phosphorus oxides. Other binary P—O compounds have formulas between P_4O_6 and P_4O_{10}. They are formed by starting with P_4O_6 and adding O atoms successively to the P atom vertices.

Uses of phosphorus and phosphoric acid.

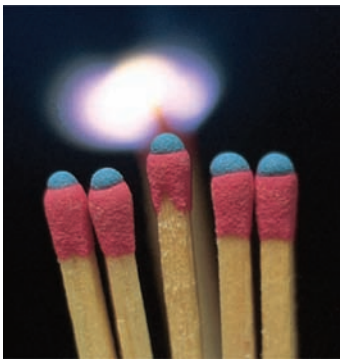

Figure 21.30 **Uses of phosphate rock, phosphorus, and phosphoric acid.**

The most common and important phosphorus oxide is tetraphosphorus decaoxide (P_4O_{10}). In P_4O_{10}, each phosphorus atom is surrounded tetrahedrally by O atoms.

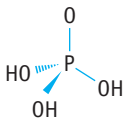
Phosphorus also forms a similar series of compounds with sulfur. Of these, the most important is P_4S_3. In this compound, S atoms are inserted in only three of the P—P bonds. The principal use of P_4S_3 is in "strike anywhere" matches, the kind that light when you rub the head against a rough object. The active ingredients are P_4S_3 and the powerful oxidizing agent potassium chlorate, $KClO_3$. The "safety match" is now more common than the "strike anywhere" match. In safety matches, the head is predominantly $KClO_3$, and the material on the match book is red phosphorus (about 50%), Sb_2S_3, Fe_2O_3, and glue.

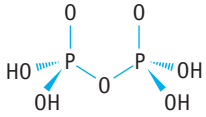
Enormous quantities of phosphorus compounds are used around the world, and most of this begins with phosphate rock, which is largely $Ca_3(PO_4)_2$ or apatite. As outlined in Figure 21.30, phosphate rock is converted to impure phosphoric acid and then to other products, or to elemental phosphorus, from which pure phosphoric acid and other products are made.

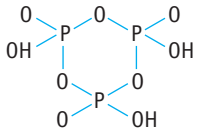
© Cengage Learning/Charles D. Winters

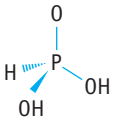
Matches. The head of a "strike anywhere" match contains P_4S_3 and the oxidizing agent $KClO_3$. (Other components are ground glass, Fe_2O_3, ZnO, and glue.) Safety matches have sulfur (3–5%) and $KClO_3$ (45–55%) in the match head and red phosphorus in the striking strip.

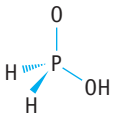
Phosphorus Oxoacids and Their Salts











A few of the many known phosphorus oxoacids are illustrated in Table 21.6. Indeed, there are so many acids and their salts in this category that structural principles have been developed to organize and understand them.

- All P atoms in the oxoacids and their anions (conjugate bases) are four-coordinate and tetrahedral.
- All the P atoms in the acids have at least one P—OH group. (This is the acidic hydrogen atom in these compounds.)
- Some oxoacids have one or more P—H bonds. These H atoms are not ionizable as H^+.

TABLE 21.6 Phosphorus Oxoacids

Formula	Name	Structure	pK_a
H_3PO_4	Orthophosphoric acid		2.21, 7.21, 12.67
$H_4P_2O_7$	Pyrophosphoric acid (diphosphoric acid)		0.85, 1.49, 5.77, 8.22
$(HPO_3)_3$	Metaphosphoric acid		
H_3PO_3	Phosphorous acid (phosphonic acid)		2.00, 6.59
H_3PO_2	Hypophosphorous acid (phosphinic acid)		1.24

- Polymerization can occur by P—O—P bond formation to give both linear and cyclic species. Two P atoms are never joined by more than one P—O—P bridge.
- When a P atom is surrounded only by O atoms (as in H_3PO_4), its oxidation number is +5. For each P—OH that is replaced by P—H, the oxidation number drops by 2. For example, the oxidation number of P in H_3PO_2 is +1.

Orthophosphoric acid, H_3PO_4, and its salts are far more important commercially than other P—O acids. Millions of tons of phosphoric acid are made annually, some using white phosphorus as the starting material. The element is burned in oxygen to give P_4O_{10}, and the oxide reacts with water to produce the acid (Figure 21.31).

$$P_4O_{10}(s) + 6\ H_2O(\ell) \rightarrow 4\ H_3PO_4(aq)$$

© Cengage Learning/Charles D. Winters

Figure 21.31 Reaction of P_4O_{10} and water. The white solid oxide reacts vigorously with water to give orthophosphoric acid, H_3PO_4. (The heat generated vaporizes the water, so steam is visible.)

This approach gives a pure product, so it is used to make the acid found in food products in particular. The acid is nontoxic, and it gives the tart or sour taste to carbonated "soft drinks," such as various colas (about 0.05% H_3PO_4) or root beer (about 0.01% H_3PO_4).

A major use for phosphoric acid is to impart corrosion resistance to metal objects such as nuts and bolts, tools, and car-engine parts by plunging the object into a hot acid bath. Car bodies are similarly treated with metal phosphates (such as $Zn_3(PO_4)_2$, page 901) and aluminum trim is "polished" by treating it with phosphoric acid.

The reaction of H_3PO_4 with strong bases produces salts such as NaH_2PO_4, Na_2HPO_4, and Na_3PO_4. In industry, the monosodium and disodium salts are produced using Na_2CO_3 as the base, but an excess of the stronger (and more expensive) base NaOH is required to remove the third proton to give Na_3PO_4.

Sodium phosphate (Na_3PO_4) is used in scouring powders and paint strippers because the anion PO_4^{3-} is a relatively strong base in water ($K_b = 0.028$). Sodium monohydrogen phosphate, Na_2HPO_4, which has a less basic anion than PO_4^{3-}, is widely used in food products. Kraft has patented a process using this compound in the manufacture of pasteurized cheese, for example. Thousands of tons of Na_2HPO_4

are still used for this purpose, even though the function of the salt in this process is not completely understood. In addition, a small amount of Na_2HPO_4 in pudding mixes enables the mix to gel in cold water, and the basic anion raises the pH of cereals to provide "quick-cooking" breakfast cereal. (The OH^- ion from HPO_4^{2-} hydrolysis accelerates the breakdown of the cellulose material in the cereal.)

Calcium phosphates are used in a broad spectrum of products. For example, the weak acid $Ca(H_2PO_4)_2 \cdot H_2O$ is used as the acid leavening agent in baking powder. A typical baking powder contains (along with inert ingredients) 28% $NaHCO_3$, 10.7% $Ca(H_2PO_4)_2 \cdot H_2O$, and 21.4% $NaAl(SO_4)_2$ (also a weak acid). The weak acids react with sodium bicarbonate to produce CO_2 gas. For example,

$$Ca(H_2PO_4)_2 \cdot H_2O(s) + 2\ NaHCO_3(aq) \rightarrow 2\ CO_2(g) + 3\ H_2O(\ell) + Na_2HPO_4(aq) + CaHPO_4(aq)$$

Finally, calcium monohydrogen phosphate, $CaHPO_4$, is used as an abrasive and polishing agent in toothpaste.

Phosphates in Water Treatment Phosphates figured prominently in the environmental lead problem in Flint, Michigan in 2016 ("*A Closer Look: The Flint, Michigan Water Treatment Problem*", page 929. Section 20.2.)

21.9 Oxygen, Sulfur, and the Group 6A Elements

Goal for Section 21.9

- Know common compounds of oxygen and sulfur, particularly the oxides of sulfur.

Oxygen is by far the most abundant element in Earth's crust, representing slightly less than 50% of it by weight. It is present as elemental oxygen in the atmosphere and is combined with other elements in water and in many minerals. Scientists believe that elemental oxygen did not appear on this planet until about 3.5 billion years ago, when it was formed by plants through the process of photosynthesis.

Sulfur, seventeenth in abundance in the Earth's crust, is also found in its elemental form in nature, but only in certain concentrated deposits. Sulfur-containing compounds occur in natural gas, coal, and oil. In minerals, sulfur occurs as the sulfide ion (Figure 21.32) and as sulfate ion (e.g., in gypsum, $CaSO_4 \cdot 2\ H_2O$). Sulfur oxides (SO_2 and SO_3) also occur in nature, primarily as products of volcanic activity.

In the United States, several million tons per year of sulfur are obtained from deposits of the element found along the Gulf of Mexico. These deposits occur typically at a depth of 150 to 750 m below the surface in layers about 30 m thick. They are thought to have been formed by anaerobic ("without elemental oxygen") bacteria acting on sedimentary sulfate deposits such as gypsum.

Preparation and Properties of the Elements

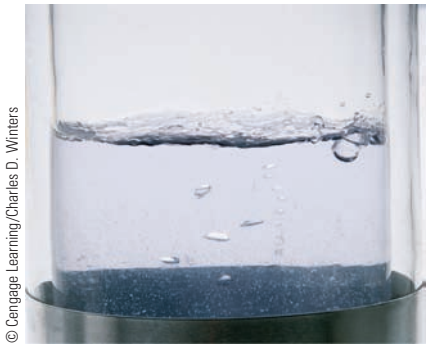
Pure oxygen is obtained by the fractional distillation of air and is among the top five industrial chemicals produced in the United States. Oxygen can be made in the laboratory by electrolysis of water (Figure 21.4) and by the catalyzed decomposition of metal chlorates such as $KClO_3$.

$$2\ KClO_3(s) \xrightarrow{\text{catalyst}} 2\ KCl(s) + 3\ O_2(g)$$

At room temperature and pressure, oxygen is a colorless gas, but it is pale blue when condensed to a liquid at −183 °C (Figure 21.33a). As described in Section 9.2, diatomic oxygen is paramagnetic because it has two unpaired electrons.

An allotrope of oxygen, ozone (O_3), is a blue, diamagnetic gas with an odor so strong that it can be detected in concentrations as low as 0.05 ppm. Ozone is synthesized by passing O_2 through an electric discharge or by irradiating O_2 with ultraviolet light. It is often in the news because of the realization that the Earth's protective layer of ozone in the stratosphere is disrupted by chlorofluorocarbons and other chemicals (Section 20.1).

Sulfur has numerous allotropes. The most common and most stable allotrope is the yellow, orthorhombic form, which consists of S_8 molecules with the sulfur atoms arranged in a crown-shaped ring (Figure 21.33b). Less stable allotropes are known that have rings of 6 to 20 sulfur atoms. Another form of sulfur, called plastic sulfur, has a molecular structure with chains of sulfur atoms (Figure 21.33c).



Selenium and tellurium are comparatively rare on Earth, having abundances about the same as those of silver and gold, respectively. Because their chemistry is similar to that of sulfur, they are often found in minerals associated with the sulfides of copper, silver, iron, and arsenic, and they are recovered as by-products of the industries devoted to those elements.

Selenium has a range of uses, including glass making. A cadmium sulfide/selenide mixture is added to glass to give it a brilliant red color. The most familiar use of selenium is in xerography, a word meaning "dry printing" and a process at the heart of the modern copy machine. Most photocopy machines use an aluminum plate or roller coated with selenium. Light coming from the imaging lens selectively discharges a static electric charge on the selenium surface, and the black toner sticks only on the areas that remain charged. A copy is made when the toner is transferred to a sheet of plain paper.

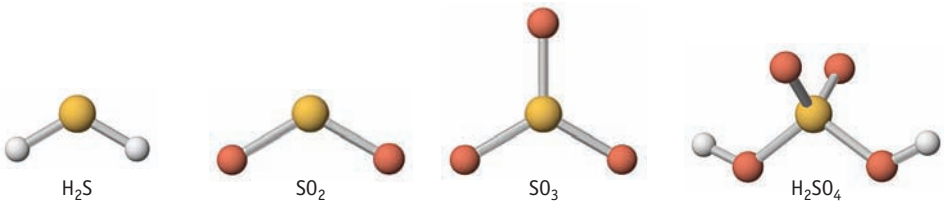
The heaviest element of Group 6A, polonium, is radioactive and found only in trace amounts on Earth. It was discovered in Paris, France, in 1898 by Marie Sklodowska Curie (1867–1934), a native of Poland, and her husband Pierre Curie (1859–1906). The Curies painstakingly separated this element from a large quantity of pitchblende, a uranium-containing ore.

Sulfur Compounds

Hydrogen sulfide, H_2S, has a bent molecular geometry, like water. Unlike water, however, H_2S is a gas under standard conditions (mp, −85.6 °C; bp, −60.3 °C) because its intermolecular forces are weak compared with the strong hydrogen bonding in water (Figure 11.4). Hydrogen sulfide is poisonous, comparable in toxicity to hydrogen cyanide, but fortunately it has a strong odor and is detectable in concentrations as low as 0.02 ppm. You must be careful with H_2S, though. Because it has an anesthetic effect, your nose rapidly loses its ability to detect it. Death occurs at H_2S concentrations of 100 ppm.

Bad Breath Halitosis or "bad breath" is due to three sulfur-containing compounds: H_2S, CH_3SH (methyl mercaptan), and $(CH_3)_2S$ (dimethyl sulfide). All three can be detected in very tiny concentrations. For example, your nose knows if as little as 0.2 microgram of CH_3SH is present per liter of air. The compounds result from bacteria's attack on the sulfur-containing amino acids cysteine and methionine in food particles in the mouth.

Sulfur is often found as the sulfide ion in conjunction with metals and most metal sulfides (except those based on Group 1A metals) are not water soluble. The recovery of metals from their sulfide ores usually begins by heating the ore in air.



$$2\ PbS(s) + 3\ O_2(g) \rightarrow 2\ PbO(s) + 2\ SO_2(g)$$

Here, lead(II) sulfide (the mineral galena) is converted to lead(II) oxide, and this is then reduced to lead using carbon or carbon monoxide in a blast furnace.

$$PbO(s) + CO(g) \rightarrow Pb(\ell) + CO_2(g)$$

Alternatively, the oxide can be reduced to elemental lead by combining it with fresh lead sulfide.

$$2\ PbO(s) + PbS(s) \rightarrow 3\ Pb(s) + SO_2(g)$$

Models of some common sulfur-containing molecules.

Sulfur dioxide (SO_2), a colorless, toxic gas with a sharp odor, is produced on an enormous scale by the combustion of sulfur and by roasting sulfide ores in air. The combustion of sulfur in sulfur-containing coal and fuel oil creates particularly large environmental problems. It has been estimated that about 2.0×10^8 tons of sulfur oxides (primarily SO_2) are released into the atmosphere each year by human activities; this is more than half of the total emitted by all other natural sources of sulfur in the environment.

The most important reaction of sulfur dioxide is its oxidation to SO_3.

$$SO_2(g) + \tfrac{1}{2}\ O_2(g) \rightarrow SO_3(g) \qquad \Delta_r H° = -98.9\ \text{kJ/mol-rxn}$$

Sulfur trioxide is almost never isolated but is converted directly to sulfuric acid, H_2SO_4, by reaction with water. This acid is the compound manufactured in largest quantity by the chemical industry (*A Closer Look: Sulfuric Acid*, page 145). Approximately 40×10^9 kg of sulfuric acid is produced annually in the United States.

In the United States, roughly 70% of the sulfuric acid is used to manufacture superphosphate fertilizer from phosphate rock. Plants need a soluble form of phosphorus for growth, but calcium phosphate and apatite [$Ca_5X(PO_4)_3$, X = F, OH, Cl]

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

are insoluble. Treating phosphate-containing minerals with sulfuric acid produces a mixture of soluble phosphates. The balanced equation for the reaction of excess sulfuric acid and calcium phosphate, for example, is

$$Ca_3(PO_4)_2(s) + 3\ H_2SO_4(\ell) \rightarrow 2\ H_3PO_4(\ell) + 3\ CaSO_4(s)$$

(Notice that the chemical principle behind this reaction is explained by Brønsted theory: sulfuric acid is a stronger acid than H_3PO_4 (Table 16.2), so the PO_4^{3-} ion is protonated by sulfuric acid.) This reaction, however, does not tell the whole story. Concentrated superphosphate fertilizer is actually mostly $CaHPO_4$ or $Ca(H_2PO_4)_2$ plus some H_3PO_4 and $CaSO_4$.

Smaller amounts of sulfuric acid are used in the conversion of ilmenite, a titanium-bearing ore, to TiO_2, which is then used as a white pigment in paint, plastics, and paper. The acid is also used to manufacture iron and steel as well as petroleum products, synthetic polymers, and paper.

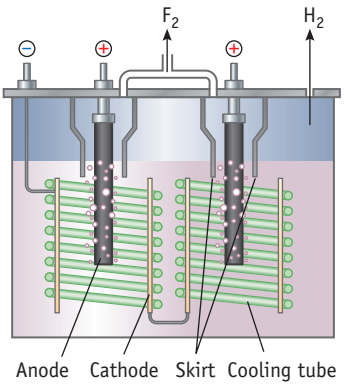

Figure 21.34 **Schematic of an electrolysis cell for producing fluorine.**

21.10 The Halogens, Group 7A

Goals for Section 21.10

- Know the methods for preparation of fluorine and chlorine.
- Know common compounds of chlorine.

Fluorine and chlorine are the most abundant halogens in Earth's crust, with fluorine somewhat more abundant than chlorine. If their abundance in seawater is measured, however, the situation is quite different. Chlorine has an abundance in seawater of 18,000 ppm, whereas the abundance of fluorine is only 1.3 ppm. This variation is a result of the differences in the solubility of their salts and plays a role in the methods used to obtain the elements themselves.

Preparation of the Elements

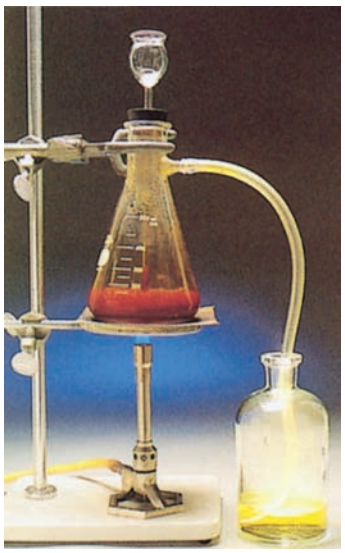
Fluorine

The water-insoluble mineral fluorspar or fluorite (calcium fluoride, CaF_2) is one of the many sources of fluorine. Because the mineral was originally used as a flux in metalworking, its name comes from the Latin word meaning "to flow." In the 17th century, it was discovered that solid fluorspar would emit light when heated, and the phenomenon was called *fluorescence*. In the early 1800s, when it was recognized that a new element was contained in fluorspar, A. M. Ampère (1775–1836) suggested that the element be called fluorine.

Although fluorine was recognized as an element by 1812, it was not until 1886 that it was isolated by the French chemist Henri Moisson (1852–1907) in elemental form as a very pale yellow gas by the electrolysis of KF dissolved in anhydrous HF.

Electrolysis is still the only practical way to obtain gaseous F_2 (Figure 21.34) because F_2 is such a powerful oxidizing agent that chemical oxidation of F^- to F_2 is not feasible. Further, because F_2 is so reactive, it corrodes the electrolysis equipment and reacts violently with traces of grease or other contaminants. In addition, the electrolysis products, F_2 and H_2, can recombine explosively, so they must not be allowed to come into contact with each other. (Compare with the reaction of another halogen, Br_2, with H_2 in Figure 21.5.) Current U.S. production of fluorine is approximately 5000 metric tons per year.

Chlorine



Chlorine is a strong oxidizing agent, and to prepare this element from chloride ion by a chemical reaction requires an even stronger oxidizing agent. Elemental chlorine was first made by the Swedish chemist Karl Wilhelm Scheele (1742–1786) in 1774,

by the reaction of sodium chloride with an oxidizing agent (MnO_2) in an acidic solution. Now, permanganate ions or dichromate ions in acid solution are used in laboratory preparations (Figure 21.35).

Industrially, chlorine is made by electrolysis of brine (concentrated aqueous NaCl), a process described on page 970 and in Figure 21.11.

© Cengage Learning/Charles D. Winters

Figure 21.35 Chlorine preparation. Chlorine is prepared by oxidation of chloride ion using a strong oxidizing agent. Here, oxidation of NaCl is accomplished using $K_2Cr_2O_7$ in H_2SO_4. (The Cl_2 gas is bubbled into water in a receiving flask.)

Bromine

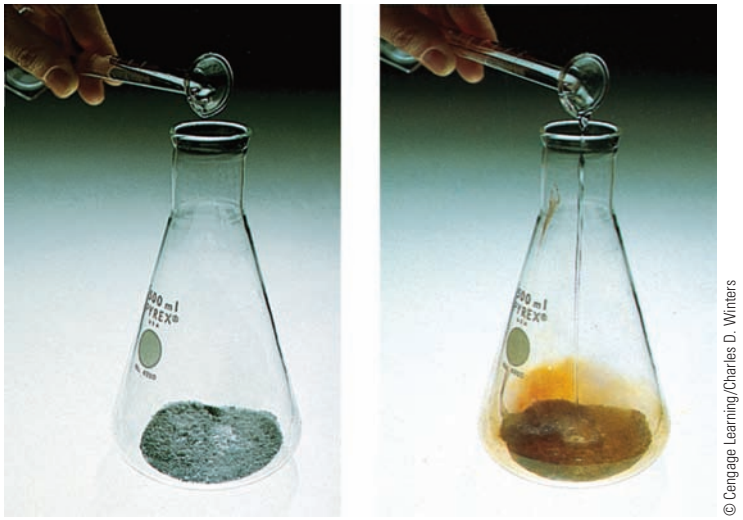
The standard reduction potentials of the halogens indicate that their strength as oxidizing agents decreases going from F_2 to I_2.

Half-Reaction	Reduction Potential ($E°$, V)
$F_2(g) + 2\ e^- \rightarrow 2\ F^-(aq)$	2.87
$Cl_2(g) + 2\ e^- \rightarrow 2\ Cl^-(aq)$	1.36
$Br_2(\ell) + 2\ e^- \rightarrow 2\ Br^-(aq)$	1.08
$I_2(s) + 2\ e^- \rightarrow 2\ I^-(aq)$	0.535

This means that Cl_2 will oxidize Br^- ions to Br_2 in aqueous solution, for example.

$$Cl_2(aq) + 2\ Br^-(aq) \rightarrow 2\ Cl^-(aq) + Br_2(aq)$$

$$E°_{net} = E°_{cathode} - E°_{anode} = 1.36\ V - 1.08\ V = +0.28\ V$$



In fact, this is the commercial method of preparing bromine from NaBr obtained from natural brine wells in Arkansas and Michigan.

Iodine

Iodine is a lustrous, purple-black solid, easily sublimed at room temperature and atmospheric pressure (Figure 12.26). The element was first isolated in 1811 from seaweed and kelp, extracts of which had long been used for treatment of goiter, the enlargement of the thyroid gland. It is now known that the thyroid gland produces a growth-regulating hormone (thyroxine) that contains iodine. Consequently, most table salt in the United States has 0.01% NaI added to provide the necessary iodine in the diet (*A Closer Look: Iodine and Your Thyroid Gland*).

A laboratory method for preparing I_2 is illustrated in Figure 21.36. The commercial preparation depends on the source of I^- and its concentration. One method is interesting because it involves some chemistry described earlier in this book. Iodide ions are first precipitated with silver ions to give insoluble AgI.

$$I^-(aq) + Ag^+(aq) \rightarrow AgI(s)$$

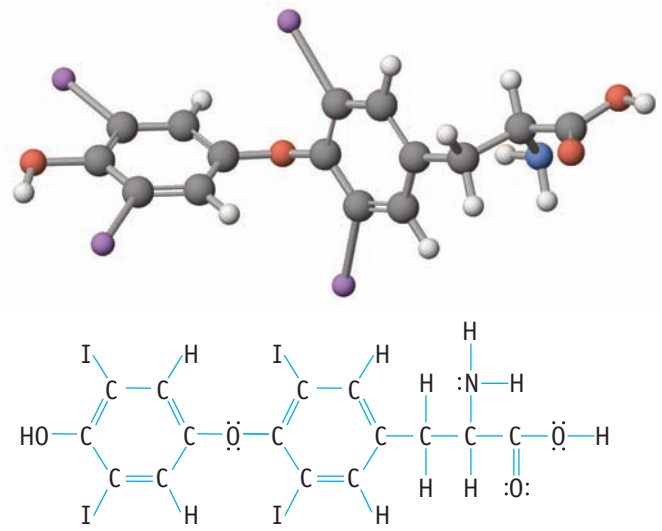
A CLOSER LOOK



Iodine and Your Thyroid Gland

The primary function of the thyroid gland, located in your neck, is the production of thyroxine (3,5,3′,5′-tetraiodothyronine) and 3,5,3′-triiodothyronine. These chemical compounds are hormones that help to regulate the rate of metabolism, a term that refers to all of the chemical reactions that take place in the body. In particular, the thyroid hormones play an important role in the processes that release energy from food.

Abnormally low levels of thyroxine result in a condition known as *hypothyroidism*. Its symptoms include lethargy and feeling cold much of the time. The remedy for this condition is medication, consisting of thyroxine pills. The opposite condition, *hyperthyroidism*, also occurs in some people. In this condition, the body produces too much of the hormone. Hyperthyroidism is diagnosed by symptoms such as nervousness, heat intolerance, increased appetite, and muscle weakness and fatigue when blood sugar is too rapidly depleted. The standard remedy for hyperthyroidism is to destroy part of the thyroid gland, and one way to do so is to use a compound containing radioactive iodine-123 or iodine-131.

To understand this procedure, you need to know something about iodine in the body. Iodine is an essential element. Some diets provide iodine naturally (seaweed, for example, is a good source of iodine), but in the Western world most iodine taken up by the body comes from iodized salt, NaCl containing about 0.01% of NaI. An adult man or woman of average size should take in about 150 μg (micrograms, 1 μg = 10^{-6} g) of iodine in the daily diet. In the body, iodide ion is transported to the thyroid, where it serves as one of the raw materials in making thyroxine.

The fact that iodine concentrates in the thyroid tissue is essential to the procedure for using radioiodine therapy as a treatment for hyperthyroidism. Typically, an aqueous NaI solution is used in which a small fraction of iodide is the radioactive isotope iodine-131 or iodine-123, and the rest is nonradioactive iodine-127. The radioactivity destroys thyroid tissue, resulting in a decrease in thyroid activity.

Thyroxine. The hormone 3,5,3′,5′-tetraiodothyronine (thyroxine) exerts a stimulating effect on metabolism.

This is reduced by clean scrap iron to give iron(II) iodide and metallic silver.

$$2\ AgI(s) + Fe(s) \rightarrow FeI_2(aq) + 2\ Ag(s)$$

The silver is recycled by oxidizing it with nitric acid (forming silver nitrate which is then reused). Finally, iodide ion from water-soluble FeI_2 is oxidized to iodine with chlorine [with iron(III) chloride as a by-product].

$$2\ FeI_2(aq) + 3\ Cl_2(aq) \rightarrow 2\ I_2(s) + 2\ FeCl_3(aq)$$

Bond Dissociation Enthalpies of Some Halogen Compounds (kJ/mol)

X	X—X	H—X	C—X (in CX_4)
F	155	565	485
Cl	242	432	339
Br	193	366	285
I	151	299	213

Fluorine Compounds

Fluorine is the most reactive of all of the elements, forming compounds with every element except He and Ne. In most cases, the elements combine directly, and some reactions can be so vigorous as to be explosive. This can be explained by at least two features of fluorine chemistry: the relatively weak F—F bond compared with chlorine and bromine, and, in particular, the relatively strong bonds formed by fluorine to other elements. This is illustrated by the table of bond dissociation enthalpies in the margin.

In addition to its oxidizing ability, another notable characteristic of fluorine is its small size. These properties lead to the formation of compounds where a number of F atoms can be bonded to a central element in a high oxidation state. Examples include PtF_6, UF_6, IF_7, and XeF_6.

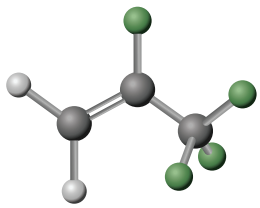
A CLOSER LOOK

The Many Uses of Fluorine-Containing Compounds

Chemical & Engineering News reported in 2012 that 3 out of 10 of the best selling drugs contain fluorine, and one fifth of newly approved drugs do so as well. In addition, three common anesthetic agents, sevoflurane, isoflurane, and desflurane, are all more than 50% F by mass.



Isoflurane, $CF_3CHClOCHF_2$ an anesthetic

But the incorporation of fluorine in pharmaceuticals is just the beginning. You likely have a non-stick pan coated with Teflon, a polymer with F atoms along the carbon chain.

You also probably live in a place that has air conditioning or drive a car with one. The working fluid in the unit is likely R-22 (also known as HCFC-22), CHF_2Cl. This is being phased out, however, as it harms Earth's ozone layer and is also a greenhouse gas (Section 20.6). It has been replaced to some extent by an HFC, a hydrofluorocarbon such as CH_2FCF_3. This is not as harmful to the ozone layer, but it is still a planet-warming gas. In an attempt to avert a planet-wide warming trend, an agreement was reached in October 2016 to freeze or decrease production of HFCs. The extent of decrease depends on the region of the planet. For example, the U.S. and European Union agreed to freeze production and consumption by 2018, and reduce HFCs to 15% of 2012 levels by 2036.

Now what? What can be used as a refrigerant? One substitute is HFO-1234y (CH_2CFCF_3) which should be installed in more than 18 million car air conditioners by 2017.

Among the many useful, fluorine-containing compounds is also a family of compounds based on perfluorooctanoic acid: $CF_3(CF_2)_6CO_2H$ (PFAs). This compound and its derivatives are widely used as fire retardants and as coatings on fast food containers, on stain-resistant carpets, and on non-stick cookware, among other things. Recently, environmental concern about these compounds has increased as well. One of the authors of this book has been involved with biologists studying alligators and crocodiles around the world, and trace amounts of PFAs are found in these creatures, even in remote locations.

HFO-1234y, CH_2CFCF_3, a refrigerant in air conditioners.

Hydrogen fluoride is an important industrial chemical. More than 1 million tons of hydrogen fluoride is produced annually worldwide, almost all by the action of concentrated sulfuric acid on fluorspar.

$$CaF_2(s) + H_2SO_4(\ell) \rightarrow CaSO_4(s) + 2\ HF(g)$$

The U.S. capacity for HF production is approximately 210,000 metric tons, but demand often exceeds supply. Anhydrous HF is used in a broad range of industries: in the production of refrigerants, herbicides, pharmaceuticals, high-octane gasoline, aluminum, plastics, electrical components, and "frosted" light bulbs.

The fluorspar used to produce HF must be very pure and free of SiO_2 because HF reacts readily with silicon dioxide.

$$SiO_2(s) + 4\ HF(aq) \rightarrow SiF_4(g) + 2\ H_2O(\ell)$$

$$SiF_4(g) + 2\ HF(aq) \rightarrow H_2SiF_6(aq)$$

This series of reactions also explains why HF can be used to etch or frost glass (such as the inside of light bulbs). And it explains why HF is not shipped in glass containers.

The aluminum industry consumes about 10–40 kg of cryolite, Na_3AlF_6, per metric ton of aluminum produced. The reason is that cryolite is added to aluminum oxide to produce a lower-melting mixture that can be electrolyzed. Cryolite is found in only small quantities in nature, so it is made in various ways, among them the following reaction:

$$6\ HF(aq) + Al(OH)_3(s) + 3\ NaOH(aq) \rightarrow Na_3AlF_6(s) + 6\ H_2O(\ell)$$

About 3% of the hydrofluoric acid produced is used in uranium fuel production. To separate uranium isotopes in a gas centrifuge (Section 25.6), the uranium must be in the form of a volatile compound. Naturally occurring uranium ore is processed to give UO_2. This oxide is treated with hydrogen fluoride to give UF_4, which is then reacted with F_2 to produce the volatile solid UF_6.

$$UO_2(s) + 4\ HF(aq) \rightarrow UF_4(s) + 2\ H_2O(\ell)$$

$$UF_4(s) + F_2(g) \rightarrow UF_6(s)$$

This last step consumes 70%–80% of the fluorine produced annually.

AP Images/Mike Egerton

Swimming Pool Chemistry. At the Summer Olympics in 2016 several swimming pools turned green from an algae bloom. It seemed a mystery at first, but it was soon discovered that a technician had mistakenly added H_2O_2. Hypochlorite, ClO^-, is added to pool water to kill microorganisms, but the H_2O_2 destroyed the hypochlorite and allowed algae to flourish.

$$ClO^-(aq) + H_2O_2(aq) \rightarrow Cl^-(aq) + H_2O + O_2(g)$$

Chlorine Compounds

Hydrogen Chloride

Hydrochloric acid, an aqueous solution of hydrogen chloride, is a valuable industrial chemical. Hydrogen chloride gas can be prepared by the reaction of hydrogen and chlorine, but the rapid, exothermic reaction is difficult to control. The classical method of making HCl in the laboratory uses the reaction of NaCl and sulfuric acid, a procedure that takes advantage of the facts that HCl is a gas and that H_2SO_4 will not oxidize the chloride ion.

$$2\ NaCl(s) + H_2SO_4(\ell) \rightarrow Na_2SO_4(s) + 2\ HCl(g)$$

Hydrogen chloride gas has a sharp, irritating odor. Both gaseous and aqueous HCl react with metals and metal oxides to give metal chlorides and, depending on the reactant, hydrogen or water.

$$Mg(s) + 2\ HCl(aq) \rightarrow MgCl_2(aq) + H_2(g)$$

$$ZnO(s) + 2\ HCl(aq) \rightarrow ZnCl_2(aq) + H_2O(\ell)$$

Oxoacids of Chlorine

Oxoacids of chlorine range from HClO, in which chlorine has an oxidation number of +1, to $HClO_4$, in which the oxidation number is equal to the group number, +7. All are strong oxidizing agents.

Oxoacids of Chlorine

Acid	Name	Anion	Name
HClO	Hypochlorous	ClO^-	Hypochlorite ion
$HClO_2$	Chlorous	ClO_2^-	Chlorite ion
$HClO_3$	Chloric	ClO_3^-	Chlorate ion
$HClO_4$	Perchloric	ClO_4^-	Perchlorate ion

Disproportionation A reaction in which an element or compound is simultaneously oxidized and reduced is called a disproportionation reaction. Here, Cl_2 is oxidized to ClO^- and reduced to Cl^-.

Hypochlorous acid, HClO, forms when chlorine dissolves in water. In this reaction, some of the chlorine is oxidized to hypochlorite ion and an equal amount is reduced to chloride ion in a **disproportionation reaction**.

$$Cl_2(g) + 2\ H_2O(\ell) \rightleftharpoons H_3O^+(aq) + HClO(aq) + Cl^-(aq)$$

If Cl_2 is dissolved in cold aqueous NaOH instead of in pure water the products are hypochlorite ion and chloride ion.

$$Cl_2(g) + 2\ OH^-(aq) \rightleftharpoons ClO^-(aq) + Cl^-(aq) + H_2O(\ell)$$

Under basic conditions, the equilibrium lies far to the right. The resulting alkaline solution is the "liquid bleach" used in home laundries. The bleaching action of this solution is a result of the oxidizing ability of ClO^-. Most dyes are colored organic compounds, and the hypochlorite ion oxidizes many dyes to colorless products.

Solid $Ca(ClO)_2$ is produced when calcium hydroxide is combined with Cl_2. This compound is easily handled and is the "chlorine" that is sold for swimming pool disinfection.

When a basic solution of hypochlorite ion is heated, another disproportionation occurs, forming chlorate ion and chloride ion:

$$3\ ClO^-(aq) \rightarrow ClO_3^-(aq) + 2\ Cl^-(aq)$$

Sodium and potassium chlorates are made in large quantities this way. The sodium salt can be reduced to ClO_2, a compound used for bleaching paper pulp. Some $NaClO_3$ is also converted to potassium chlorate, $KClO_3$, an oxidizing agent in fireworks and a component of safety matches.

Perchlorates, salts containing ClO_4^-, are powerful oxidants. Pure perchloric acid, $HClO_4$, is a colorless liquid that explodes if shocked. It explosively oxidizes organic materials and rapidly oxidizes silver and gold. Dilute aqueous solutions of the acid are safe to handle, however.

More than half of the sodium perchlorate currently manufactured is converted to the ammonium salt. The process for making this conversion is an exchange reaction that takes advantage of the fact that ammonium perchlorate is less soluble in water than sodium perchlorate:

$$NaClO_4(aq) + NH_4Cl(aq) \rightleftharpoons NaCl(aq) + NH_4ClO_4(s)$$

Perchlorate salts of most metals are usually relatively stable, albeit unpredictable. Great care should be used when handling any perchlorate salt. Ammonium perchlorate, for example, bursts into flame if heated above 200 °C.

$$2\ NH_4ClO_4(s) \rightarrow N_2(g) + Cl_2(g) + 2\ O_2(g) + 4\ H_2O(g)$$

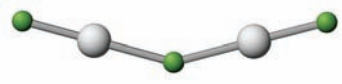
The strong oxidizing ability of the ammonium salt is the reason it has been used as the oxidizer in the solid booster rockets for the Space Shuttle and other space vehicles. The solid propellant in these rockets is largely NH_4ClO_4, the remainder being the reducing agent, powdered aluminum. Each launch requires about 750 tons of ammonium perchlorate.

John C. Katz

Fireworks and Oxoacids of Chlorine. Potassium chlorate, $KClO_3$, was commonly used as the oxidizer in fireworks. However, this was the source of numerous accidents because it formed friction-sensitive compounds in contact with sulfur and powdered metals. Now potassium perchlorate, $KClO_4$, is used, even though it is more difficult to ignite.

21.11 The Noble Gases, Group 8A

Goal for Section 21.11



- Apply the principles of structure and bonding to noble gas compounds.

We have already mentioned the noble or rare gases in various places in this text, and most notably their lack of chemical reactivity. At one time these elements were called the "inert gases" but that name was dismissed with the 1962 discovery of compounds of xenon. Since that time an elaborate chemistry of this element has been developed.

Helium was first detected spectroscopically in the Sun's spectrum in 1868, but it was not isolated until 1895. (The element's name is derived from the Greek word for Sun, *helios*.) It is now obtained mostly from natural gas wells where it may be present in amounts up to 7%.

Helium is arguably the most commercially important of these elements, with its main use as a coolant. Part of this use is in chemical instrumentation such as MRIs, which have superconducting magnets that require cooling to liquid helium temperatures (4.2 K) to function. Because of this widespread use, though, there are serious concerns about the supply of helium gas, and labs are encouraged to have helium recovery facilities in place.

Argon is the most abundant of the elements of this group, present in air to the extent of 0.93% by volume. The discovery of argon was an interesting experimental exercise (*Applying Chemical Principles, 2.3: Argon—An Amazing Discovery,* page 103),

The noble or rare gases. Neon and other gases are used in advertising signs, and xenon gas is found in automobile headlights. Radioactive radon gas occurs naturally in minerals in many parts of the United States. You can test your home for radon with a simple kit.

requiring highly accurate density measurements. Argon is mainly used to provide an inert atmosphere when required.

Soon after the discovery and characterization of argon in 1895, the other nonradioactive gases (neon, krypton, and xenon) were found as trace components of air. These gases are best known from their use in lamps: neon for the red color in neon lamps, krypton and xenon for the intense light in lasers, and in xenon headlights for cars. Radioactive radon is found in trace quantities as a product of the decay of uranium minerals (Chapter 25).

An unexpected property of xenon is that it is an inhalation anesthetic. It is more effective than nitrous oxide, but less so than commonly used compounds such as

A CLOSER LOOK

The Noble Gases—Not So Inert

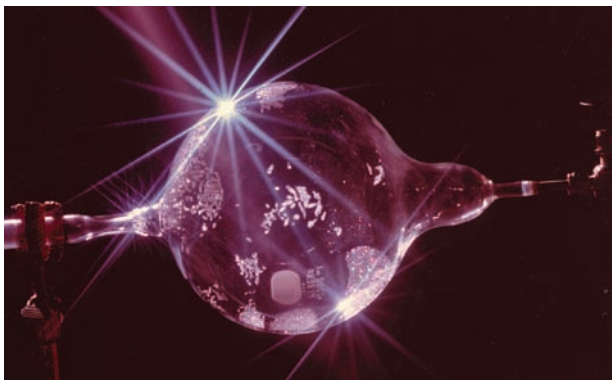
Before 1962, most chemists thought that compounds of noble gases could not exist. In fact, few chemists gave this issue much thought, but the data were there to predict that these compounds just might exist, had scientists looked for them.

An assessment of bond energy data is the clue to predicting that compounds of xenon should exist. Consider the formation of XeF_2 from Xe and F_2. The enthalpy of this reaction can be related to bond energies (Section 8.9).

$$Xe(g) + F_2(g) \rightarrow XeF_2(g)$$

$$\Delta_r H = \Delta H(\text{bonds broken}) - \Delta H(\text{bonds formed})$$

$$= \Delta H(\text{F—F}) - 2\,\Delta H(\text{Xe—F})$$



$$= 155 \text{ kJ/mol} - 2\,\Delta H(\text{Xe—F})$$

From these data, one can conclude that if the Xe—F bond energy is 78 kJ/mol or greater this reaction will be exothermic ($\Delta_r H$ will be negative).

How might you predict the bond energy of the Xe—F bond? The logical way is to look at trends within the periodic table. In this case, the trend in bond energies in the known compounds TeF_4 and IF_3 allows you to extrapolate a value for Xe—F. The bond dissociation enthalpies of the Te—F bond in TeF_4 (BDE = 335 kJ/mol) and the I—F bond in IF_3 (BDE = 272 kJ/mol) are known. Using these numbers, a chemist might predict a bond energy for Xe—F to be substantially more than 78 kJ/mol. This would, in turn, predict the reaction to be exothermic and likely product-favored.

The enthalpy of formation of $XeF_2(g)$ was found by experiment to be −108 kJ/mol. From this the Xe—F bond dissociation enthalpy is calculated to be 132 kJ/mol, significantly more than is required to make this an exothermic reaction.

A similar extrapolation predicted that XeF_4 should exist, and it is in fact now well known. On the other hand, compounds such as $XeCl_2$, KrF_2, and KrF_4 are all predicted to have positive enthalpies of formation, and they have not been found.

© Gary J. Schrobilgen

Preparing XeF_2. If a flask containing Xe and F_2 gas is placed in the sunlight for a few days, crystals of solid XeF_2 are found in the flask.

isoflurane ($CF_3CHClOCF_2H$). Xenon is nonpolluting, has analgesic properties and cardiovascular stability, and induces anesthesia rapidly. The problem is its cost (currently about \$1.20/g).

Xenon Compounds

The first evidence that xenon compounds could exist was reported in 1962. Neil Bartlett, then at the University of British Columbia, found that PtF_6, an exceedingly strong oxidizing agent, reacted with molecular oxygen to give $O_2^+PtF_6^-$. Noticing the similarity of the ionization energies of Xe and O_2, Bartlett next carried out a reaction between PtF_6 and Xe, and obtained a mixture of several compounds including $XeF^+PtF_6^-$ and $XeF^+Pt_2F_{11}^-$.

Bartlett's discovery was followed by rapid experimentation that resulted in the identification of a number of new xenon compounds. After chemists had for years predicted that the noble gases would not form compounds, it was particularly notable that XeF_2, XeF_4, and XeF_6 could be prepared readily by direct reaction of the elements. The chemistry of these compounds has been further extended, and a number of xenon oxides (such as $XeOF_4$, XeO_2F_2, and XeO_3) as well as ionic species (for example, $Xe_2F_3^+$ and XeF_5^+) are now known.

APPLYING CHEMICAL PRINCIPLES

21.1 Lead in the Environment

Lead anchors the bottom of Group 4A. One of a handful of elements known since ancient times, it has a variety of modern uses. It ranks fifth among metals in usage behind iron, copper, aluminum, and zinc. The major uses of the metal and its compounds are in storage batteries (Section 19.3), pigments, ammunition, solders, plumbing, and bearings.

Unfortunately, lead and its compounds are cumulative poisons, particularly in children. At a blood level as low as 50 ppb (parts per billion), blood pressure is elevated; intelligence is affected at 100 ppb; and blood levels higher than 800 ppb can lead to coma and possible death. The symptoms of lead poisoning include nausea, abdominal pain, irritability, headaches, and excess lethargy or hyperactivity.

Health experts believe more than 200,000 children become ill from lead poisoning annually, a problem caused chiefly by children eating paint containing lead-based pigments. Paint containing "white lead" [$2\ PbCO_3 \cdot Pb(OH)_2$] was used until about 40 years ago, when white lead was replaced by TiO_2. Lead salts have a sweet taste, which may contribute to the tendency of children to chew on painted objects.

Until 40 years ago one of the most important uses of lead was as a gasoline additive, tetraethyllead (TEL), $(C_2H_5)_4Pb$. It was introduced in the 1920s as an octane booster for gasoline. However, after it became clear that enormous amounts of lead were entering the environment from this source, TEL was phased out in the U.S. beginning in the 1970s. Other countries around the world have also banned TEL, but some did so only recently.

Fortunately, very recent research has found that the ban on leaded-gasoline has allowed the environmental lead level to return to levels comparable to those observed before the use of TEL.

But there was less good news from Flint, Michigan in 2015 when people discovered elevated lead levels in drinking water.

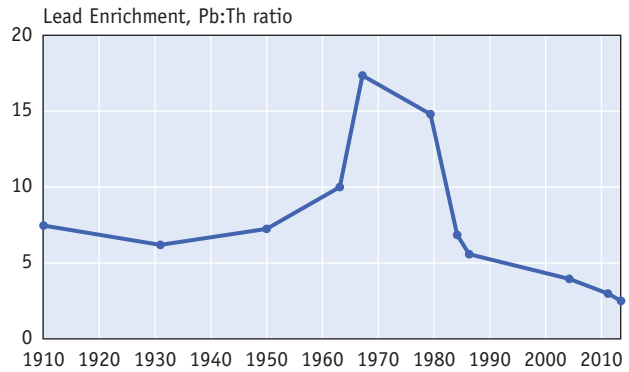

Figure A plot of the ratio of ^{210}Pb to Th for the last 100 years in the environment in northern Alberta, Canada. Lead in the environment was elevated from 1960 to 1990 when the ban on TEL fully took effect. (The amount of lead is compared with thorium, an indicator of general mineral abundance.)

The problem arose from incorrect treatment of the incoming water and from an old and poorly maintained water system. See page 929 for more on the Flint water problem.

Questions:

1. If blood contains 50. ppb lead, how many atoms of lead are there in 1.0 L of blood? (Assume d(blood) = 1.0 g/mL.)
2. Research has found that port wine stored for a year in lead-glass decanters contains 2000 ppm lead. If the decanter contains 750 mL of wine (d = 1.0 g/mL), what mass of lead has been extracted into the wine?
3. Suppose you consume a 0.15-g chip of paint with white lead pigment (12% by weight). What is the concentration of lead in your blood system if your body contains 4.7 L of blood?

21.2 Hydrogen Storage

The high energy content of hydrogen makes it an attractive energy source. However, there are some obstacles to overcome before wide use of hydrogen as a fuel is a reality. One obstacle is storage of hydrogen. Storage as a gas at one atmosphere requires a large volume, a problem that could be addressed by storing the gas under high pressure. However, then specialized containment is needed, and there are potential hazards involved.

There are several criteria necessary for a successful hydrogen storage device. Foremost is *hydrogen density*. A useful storage device would contain a large amount of hydrogen in a small volume. Also, the hydrogen must be released easily, and, once hydrogen has been removed from the device, it should be possible to refill it.

For a benchmark by which to consider this subject, consider the hydrogen density for gaseous H_2. At 1.0 atm and 20 °C, the hydrogen density is 0.084 g/L. The value improves under high pressure: at 20 °C and 700 bar (691 atm) the value is 40 g/L.

The very interesting compound ammonia borane, H_3NBH_3, is being studied as a possible answer to the storage problem. Ammonia borane is a colorless crystalline solid, stable in air and water. This molecular compound is isoelectronic and isostructural with ethane; however, its properties are in stark contrast to ethane. Most notably, ammonia borane is solid (melting point of 104 °C) whereas ethane is a gas. Its chemical properties are also significantly different. When mildly warmed, ammonia borane loses hydrogen, forming first an aggregate species $(H_2NBH_2)_x$ and then $B_3N_3H_6$ (borazine, a cyclic compound with a structure like benzene). Further heating at 500 °C results in the formation of boron nitride, $(BN)_x$. In contrast, ethane doesn't dissociate hydrogen when heated.

Recent studies on ammonia borane have used a variety of metal compounds as catalysts to speed up the decomposition to form gaseous hydrogen. An important question about ammonia borane is the proportion of hydrogen gas that can be released.

pbpgalleries/Alamy Stock Photo

Figure Hydrogen-powered Toyota Mirai.

Questions:

1. Draw the Lewis structure of ammonia borane. What are the formal charges on each of the atoms? (The strong intermolecular forces of attraction must be the result of the high polarity of the B—N bond.)
2. Calculate the mass of hydrogen in 1.00 kg of ammonia borane. The density of ammonia borane is 0.780 g/cm^3.
3. What is the hydrogen density (mass H_2 per liter) in ammonia borane?
4. The best catalysts used to accelerate the decomposition of ammonia borane result in release of 140 g H_2 per kg. What proportion of hydrogen is released?
5. Draw a Lewis structure for borazine. Note that the molecule is a six-member ring of alternating B and N atoms, each with an attached H atom. Is the compound isoelectronic with benzene?

CHAPTER GOALS REVISITED

The goals for this chapter are keyed to specific Study Questions to help you organize your review.

21.1 Abundance of the Elements

- Recognize patterns in element abundance. 14, 41.

21.2 The Periodic Table: A Guide to the Elements

- Know the general features of the chemistry of main group elements. 1, 3, 10, 12, 89, 91.

21.3 Hydrogen

- Know the basic properties of hydrogen and its preparation. 19, 21.

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

21.4 The Alkali Metals, Group 1A

- Know the general chemical properties of the alkali metals. **27, 28, 123.**

21.5 The Alkaline Earth Elements, Group 2A

- Know some of the common, commercially important compounds of the Group 2A elements. **33, 34, 37.**
- Know the general chemical properties of the alkaline earth elements. **33, 35, 94, 118.**

21.6 Boron, Aluminum, and the Group 3A Elements

- Know the general chemical properties of the Group 3A elements. **41–43, 47, 107, 127.**

21.7 Silicon and the Group 4A Elements

- Know how elemental silicon is produced. **56.**
- Know the general chemical properties of the Group 4A elements. **53, 54, 57, 129.**

21.8 Nitrogen, Phosphorus, and the Group 5A Elements

- Know common compounds of nitrogen and phosphorus, particularly the oxides. **59–61, 67, 106.**

21.9 Oxygen, Sulfur, and the Group 6A Elements

- Know common compounds of oxygen and sulfur, particularly the oxides of sulfur. **69, 70, 73.**

21.10 The Halogens, Group 7A

- Know the methods for the preparation of fluorine and chlorine. **80, 81.**
- Know common compounds of chlorine. **75, 76.**

21.11 The Noble Gases, Group 8A

- Apply the principles of structure and bonding to noble gas compounds. **83, 84.**

STUDY QUESTIONS

▲ denotes challenging questions. **Blue-numbered questions** have answers in Appendix N and fully worked solutions in the *Student Solutions Manual.*

Practicing Skills

Properties of the Elements

(See Sections 21.1 and 21.2.)

1. Which of the following formulas is incorrect?
   (a) CaH_2 (c) CaS
   (b) CaI_2 (d) Ca_2O_3

2. The reaction of elemental phosphorus and excess oxygen produces P_4O_{10}. Name the compound.
   (a) phosphorus oxide
   (b) phosphoric acid
   (c) phosphorus decaoxide
   (d) tetraphosphorus decaoxide

3. Like sulfur, selenium forms compounds in several different oxidation states. Which of the following is NOT likely to be an oxidation state of selenium in its compounds?
(a) −2 (b) +3 (c) +6 (d) +4

4. What is the highest oxidation state that antimony can have in its compounds?
(a) 0 (b) +1 (c) +3 (d) +5

5. Give examples of two basic oxides. Write equations illustrating the formation of each oxide from its component elements. Write another chemical equation that illustrates the basic character of each oxide.

6. Give examples of two acidic oxides. Write equations illustrating the formation of each oxide from its component elements. Write another chemical equation that illustrates the acidic character of each oxide.

7. Give the name and symbol of each element having the valence configuration [noble gas] ns^2np^1.

8. Give symbols and names for four monatomic ions that have the same electron configuration as argon.

9. Select one of the alkali metals, and write a balanced chemical equation for its reaction with chlorine. Is the reaction likely to be exothermic or endothermic? Is the product ionic or molecular?

10. Select one of the alkaline earth metals and write a balanced chemical equation for its reaction with oxygen. Is the reaction likely to be exothermic or endothermic? Is the product ionic or molecular?

11. For the product of the reaction you selected in Study Question 9, predict the following physical properties: color, state of matter (s, ℓ, or g), solubility in water.

12. For the product of the reaction you selected in Study Question 10, predict the following physical properties: color, state of matter (s, ℓ, or g), solubility in water.

13. Would you expect to find calcium occurring naturally in the Earth's crust as a free element? Why or why not?

14. Which of the first 10 elements in the periodic table are found as free elements in the Earth's crust? Which elements in this group occur in the Earth's crust only as part of a chemical compound?

15. Place the following oxides in order of increasing basicity: CO_2, SiO_2, SnO_2.

16. Place the following oxides in order of increasing basicity: Na_2O, Al_2O_3, SiO_2, SO_3.

17. Complete and balance the equations for the following reactions. [Assume an excess of oxygen for (d).]
(a) $Na(s) + Br_2(\ell) \rightarrow$ (c) $Al(s) + F_2(g) \rightarrow$
(b) $Mg(s) + O_2(g) \rightarrow$ (d) $C(s) + O_2(g) \rightarrow$

18. Complete and balance the equations for the following reactions:
(a) $K(s) + I_2(g) \rightarrow$ (c) $Al(s) + S_8(s) \rightarrow$
(b) $Ba(s) + O_2(g) \rightarrow$ (d) $Si(s) + Cl_2(g) \rightarrow$

Hydrogen

(See Section 21.3.)

19. Which of the following elements does not react with hydrogen?
(a) neon (c) potassium
(b) nitrogen (d) fluorine

20. Which of the methods below is the most suitable for the preparation of large quantities of hydrogen (such as the amounts needed as a reagent for the synthesis of compounds such as ammonia)?
(a) Electrolysis of water
(b) The reaction of metal hydrides with water
(c) The high-temperature reaction of methane and water
(d) The reaction of zinc and hydrochloric acid

21. Write balanced chemical equations for the reaction of hydrogen gas with oxygen, chlorine, and nitrogen.

22. Write an equation for the reaction of potassium and hydrogen. Name the product. Is it ionic or covalent? Predict one physical property and one chemical property of this compound.

23. Write a balanced chemical equation for the preparation of H_2 (and CO) by the reaction of CH_4 and water. Using data in Appendix L, calculate $\Delta_r H°$, $\Delta_r G°$, and $\Delta_r S°$ for this reaction at 298 K.

24. Using data in Appendix L, calculate $\Delta_r H°$, $\Delta_r G°$, and $\Delta_r S°$ for the reaction of carbon and water to give CO and H_2 at 298 K.

25. A method recently suggested for the preparation of hydrogen (and oxygen) from water proceeds as follows:
(a) Sulfuric acid and hydrogen iodide are formed from sulfur dioxide, water, and iodine.
(b) The sulfuric acid from the first step is decomposed by heat to water, sulfur dioxide, and oxygen.
(c) The hydrogen iodide from the first step is decomposed with heat to hydrogen and iodine.

Write a balanced equation for each of these steps, and show that their sum is the decomposition of water to form hydrogen and oxygen.

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

26. Compare the mass of H_2 expected from the reaction of steam (H_2O) per mole of methane, petroleum, and coal. (Assume complete reaction in each case. Use CH_2 and CH as representative formulas for petroleum and coal, respectively.)

Alkali Metals

(See Section 21.4.)

27. Which of the following is not a property of sodium?

(a) Reacts with Cl_2 to form NaCl
(b) Has a high melting point (>400 °C)
(c) Has a silvery color
(d) Conducts an electric current

28. The compound Na_2O_2 consists of

(a) two Na^+ ions and two O^{2-} ions
(b) molecules of Na_2O_2
(c) two Na^+ ions and one O_2^{2-} ion
(d) Na^{2+} and O^{2-} ions

29. Write equations for the reaction of sodium with each of the halogens. Predict at least two physical properties that are common to all of the alkali metal halides.

30. Write balanced equations for the reaction of lithium, sodium, and potassium with O_2. Specify which metal forms an oxide, which forms a peroxide, and which forms a superoxide.

31. The electrolysis of aqueous NaCl gives NaOH, Cl_2, and H_2.

(a) Write a balanced equation for the process.
(b) In the United States, 1.19×10^{10} kg of NaOH and 1.14×10^{10} kg of Cl_2 were produced in a recent year. Does the ratio of masses of NaOH and Cl_2 produced agree with the ratio of masses expected from the balanced equation? If not, what does this tell you about the way in which NaOH and Cl_2 are actually produced? Is the electrolysis of aqueous NaCl the only source of these chemicals?

32. (a) Write equations for the half-reactions that occur at the cathode and the anode when an aqueous solution of KCl is electrolyzed. Which chemical species is oxidized, and which chemical species is reduced in this reaction?
(b) Predict the products formed when an aqueous solution of CsI is electrolyzed.

Alkaline Earth Elements

(See Section 21.5.)

33. Which of the following insoluble calcium compounds does not dissolve in hydrochloric acid?

(a) limestone, $CaCO_3$
(b) slaked lime, $Ca(OH)_2$
(c) gypsum, $CaSO_4 \cdot 2\ H_2O$
(d) hydroxyapatite, $Ca_5(OH)(PO_4)_3$

34. Calcium minerals are the raw materials for a variety of large-scale industrial processes. Which of the following is not an industrial process?

(a) Converting limestone, $CaCO_3$, to lime
(b) Converting fluorite, CaF_2, to HF
(c) Converting slaked lime, $Ca(OH)_2$, to lime
(d) Converting apatite minerals to phosphate fertilizers

35. When magnesium burns in air, it forms both an oxide and a nitride. Write balanced equations for the formation of both compounds.

36. Calcium reacts with hydrogen gas at 300−400 °C to form a hydride. This compound reacts readily with water, so it is an excellent drying agent for organic solvents.

(a) Write a balanced equation showing the formation of calcium hydride from Ca and H_2.
(b) Write a balanced equation for the reaction of calcium hydride with water (Figure 21.7).

37. Name three uses of limestone. Write a balanced equation for the reaction of limestone with CO_2 in water.

38. Explain what is meant by "hard water." What causes hard water, and what problems are associated with it?

39. Calcium oxide, CaO, is used to remove SO_2 from power plant exhaust. These two compounds react to give solid $CaSO_3$. What mass of SO_2 can be removed using 1.2×10^3 kg of CaO?

40. $Ca(OH)_2$ has a K_{sp} of 5.5×10^{-5}, whereas K_{sp} for $Mg(OH)_2$ is 5.6×10^{-12}. Calculate the equilibrium constant for the reaction

$$Ca(OH)_2(s) + Mg^{2+}(aq) \rightleftharpoons Ca^{2+}(aq) + Mg(OH)_2(s)$$

Explain why this reaction can be used in the commercial isolation of magnesium from seawater.

Boron and Aluminum

(See Section 21.6.)

41. In terms of abundance of the elements in the Earth's crust, aluminum ranks

(a) first
(b) second
(c) third
(d) fourth

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

42. The element below aluminum in Group 3A is gallium, and there are numerous similarities in the chemistry of these two elements. For example, the hydroxides of both elements are amphoteric. A consequence of this is that both gallium hydroxide and aluminum hydroxide

(a) are insoluble in water

(b) dissolve only in acid

(c) dissolve only in base

(d) dissolve in acid and in base

43. Draw a possible structure for the cyclic anion in the salt $K_3B_3O_6$ and the anion in $Ca_2B_2O_5$.

44. The boron trihalides (except BF_3) hydrolyze completely to boric acid and the acid HX.

(a) Write a balanced equation for the reaction of BCl_3 with water.

(b) Calculate $\Delta_r H°$ for the hydrolysis of BCl_3 using data in Appendix L and the following information:

$$\Delta_f H°\ [BCl_3(g)] = -403\ \text{kJ/mol};\ \Delta_f H°\ [B(OH)_3(s)] = -1094\ \text{kJ/mol}.$$

45. When boron hydrides burn in air, the reactions are very exothermic.

(a) Write a balanced equation for the combustion of $B_5H_9(g)$ in air to give $B_2O_3(s)$ and $H_2O(g)$.

(b) Calculate the enthalpy of combustion for $B_5H_9(g)$ ($\Delta_f H° = 73.2$ kJ/mol), and compare it with the enthalpy of combustion of B_2H_6 (-2038 kJ/mol). (The enthalpy of formation of $B_2O_3(s)$ is -1271.9 kJ/mol.)

(c) Compare the enthalpy of combustion of $C_2H_6(g)$ with that of $B_2H_6(g)$. Which transfers more energy as heat per gram?

46. Diborane can be prepared by the reaction of $NaBH_4$ and I_2. Which substance is oxidized, and which is reduced?

47. Write balanced equations for the reactions of aluminum with HCl(aq), Cl_2, and O_2.

48. (a) Write a balanced equation for the reaction of Al and $H_2O(\ell)$ to produce H_2 and Al_2O_3.

(a) Using thermodynamic data in Appendix L, calculate $\Delta_r H°$, $\Delta_r S°$, and $\Delta_r G°$ for this reaction. Do these data indicate that the reaction should favor the products at equilibrium?

(b) Why is aluminum metal unaffected by water?

49. Aluminum dissolves readily in hot aqueous NaOH to give the aluminate ion, $[Al(OH)_4]^-$, and H_2. Write a balanced equation for this reaction. If you begin with 13.2 g of Al, what volume (in liters) of H_2 gas is produced when the gas is measured at 22.5 °C and a pressure of 735 mm Hg?

50. Alumina, Al_2O_3, is amphoteric. Among examples of its amphoteric character are the reactions that occur when Al_2O_3 is heated strongly or "fused" with acidic oxides and basic oxides.

(a) Write a balanced equation for the reaction of alumina with silica, an acidic oxide, to give aluminum metasilicate, $Al_2(SiO_3)_3$.

(b) Write a balanced equation for the reaction of alumina with the basic oxide CaO to give calcium aluminate, $Ca(AlO_2)_2$.

51. Aluminum sulfate is the most commercially important aluminum compound, after aluminum oxide and aluminum hydroxide. It is produced from the reaction of aluminum oxide and sulfuric acid. What masses (in kilograms) of aluminum oxide and sulfuric acid must be used to manufacture 1.00 kg of aluminum sulfate?

52. "Aerated" concrete bricks are widely used building materials. They are obtained by mixing gas-forming additives with a moist mixture of lime, cement, and possibly sand. Industrially, the following reaction is important:

$$2\ Al(s) + 3\ Ca(OH)_2(s) + 6\ H_2O(\ell) \rightarrow 3\ CaO \cdot Al_2O_3 \cdot 6\ H_2O(s) + 3\ H_2(g)$$

Assume the mixture of reactants contains 0.56 g of Al (as well as excess calcium hydroxide and water) for each brick. What volume of hydrogen gas do you expect at 26 °C and a pressure of 745 mm Hg?

Silicon

(See Section 21.7.)

53. Elemental silicon is oxidized by O_2 to give unknown A. Compound A is dissolved in molten Na_2CO_3 giving B. When B was treated with aqueous hydrochloric acid, C is produced. Identify compound C.

(a) SiH_4 (c) SiO_2

(b) H_4SiO_4 (d) $SiCl_4$

54. Silicon and oxygen form a six-membered ring in the silicate anion $[Si_3O_9]^{6-}$. What is the oxidation state of silicon in this anion? (The rare blue mineral benitoite, the California state gemstone, has the formula $BaTiSi_3O_9$.)

(a) 0 (c) +4

(b) +2 (d) −4

55. Describe the structure of pyroxenes (see page 986). What is the ratio of silicon to oxygen in this type of silicate?

56. Describe how ultrapure silicon can be produced from sand.

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

57. Silicate structures: Draw a structure, and give the charge for a cyclic silicate anion with the formula $[Si_6O_{18}]^{n-}$.

58. Silicates often have chain, ribbon, cyclic, or sheet structures. One of the simpler ribbon structures is $[Si_2O_5^{2-}]_n$. Draw a structure for this anionic material.

Nitrogen and Phosphorus

(See Section 21.8.)

59. Construct Lewis structures for the several resonance forms of N_2O. What is the predicted N—N bond order?

(a) 1 (c) between 2 and 3
(b) 2 (d) 3

60. Which statement about ammonia is *not correct*?

(a) Ammonia can be made by a direct reaction of the elements.
(b) Aqueous solutions of ammonia are acidic.
(c) Ammonia is a gas at room temperature and atmospheric pressure.
(d) Ammonia is used as a reactant in the synthesis of nitric acid.

61. Consult the data in Appendix L. Are any of the nitrogen oxides listed there stable with respect to decomposition to N_2 and O_2?

62. Use data in Appendix L to calculate the enthalpy and free energy change for the reaction

$$2\ NO_2(g) \rightarrow N_2O_4(g)$$

Is this reaction exothermic or endothermic? Is the reaction product- or reactant-favored at equilibrium?

63. Use data in Appendix L to calculate the enthalpy and free energy change for the reaction

$$2\ NO(g) + O_2(g) \rightarrow 2\ NO_2(g)$$

Is this reaction exothermic or endothermic? Is the reaction product- or reactant-favored at equilibrium?

64. The overall reaction involved in the industrial synthesis of nitric acid is

$$NH_3(g) + 2\ O_2(g) \rightarrow HNO_3(aq) + H_2O(\ell)$$

Calculate $\Delta_rG°$ for this reaction and its equilibrium constant at 25 °C.

65. A major use of hydrazine, N_2H_4, is in steam boilers in power plants.

(a) The reaction of hydrazine with O_2 dissolved in water gives N_2 and water. Write a balanced equation for this reaction.
(b) O_2 dissolves in water to the extent of 0.0044 g in 100. mL of water at 20 °C. What mass of N_2H_4 is needed to consume all of the dissolved O_2 in 3.00×10^4 L of water (enough to fill a small swimming pool)?

66. Before hydrazine came into use to remove dissolved oxygen in the water in steam boilers, Na_2SO_3 was commonly used for this purpose:

$$2\ Na_2SO_3(aq) + O_2(aq) \rightarrow 2\ Na_2SO_4(aq)$$

What mass of Na_2SO_3 is required to remove O_2 from 3.00×10^4 L of water as outlined in Study Question 65?

67. Review the structure of phosphorous acid in Table 21.6.

(a) What is the oxidation number of the phosphorus atom in this acid?
(b) Draw the structure of diphosphorous acid, $H_4P_2O_5$. What is the maximum number of ionizable protons in a molecule of this acid?

68. Unlike carbon, which can form extended chains of atoms, nitrogen can form chains of very limited length. Draw the Lewis electron dot structure of the azide ion, N_3^-. Is the ion linear or bent?

Oxygen and Sulfur

(See Section 21.9.)

69. Which of the following is not a common oxidation number for sulfur in its compounds?

(a) −2 (b) +6 (c) +3 (d) +4

70. Which statement about oxygen is *not* true?

(a) Liquid oxygen is attracted to a magnet.
(b) The allotropes of oxygen are O_2 and O_3.
(c) Oxygen is the most abundant element in the Earth's crust.
(d) All electrons in O_2 are paired.

71. In the "contact process" for making sulfuric acid, sulfur is first burned to SO_2. Environmental restrictions allow no more than 0.30% of this SO_2 to be vented to the atmosphere.

(a) If enough sulfur is burned in a plant to produce 1.80×10^6 kg of pure, anhydrous H_2SO_4 per day, what is the maximum amount of SO_2 that is allowed to be exhausted to the atmosphere?
(b) One way to prevent any SO_2 from reaching the atmosphere is to "scrub" the exhaust gases with slaked lime, $Ca(OH)_2$:

$$Ca(OH)_2(s) + SO_2(g) \rightarrow CaSO_3(s) + H_2O(\ell)$$

$$2\ CaSO_3(s) + O_2(g) \rightarrow 2\ CaSO_4(s)$$

What mass of $Ca(OH)_2$ (in kilograms) is needed to remove the SO_2 calculated in part (a)?

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

72. A sulfuric acid plant produces an enormous amount of heat. To keep costs as low as possible, much of this heat is used to make steam to generate electricity. Some of the electricity is used to run the plant, and the excess is sold to the local electrical utility. Three reactions are important in sulfuric acid production: (1) burning S to SO_2; (2) oxidation of SO_2 to SO_3; and (3) reaction of SO_3 with H_2O:

$$SO_3(g) + H_2O \text{ (in 98\% } H_2SO_4) \rightarrow H_2SO_4(\ell)$$

The enthalpy change of the third reaction is −130 kJ/mol. Estimate the enthalpy change when 1.00 mol of S is used to produce 1.00 mol of H_2SO_4. How much energy is produced per metric ton (1.00×10^3 kg) of H_2SO_4?

73. Sulfur forms anionic chains of S atoms called polysulfides. Draw a Lewis electron dot structure for the S_2^{2-} ion. The S_2^{2-} ion is the disulfide ion, an analogue of the peroxide ion. It occurs in iron pyrites, FeS_2.

74. Sulfur forms a range of compounds with fluorine. Draw Lewis electron dot structures for S_2F_2 (connectivity is FSSF), SF_2, SF_4, SF_6, and S_2F_{10}. What is the oxidation number of sulfur in each of these compounds?

The Halogens

(See Section 21.10.)

75. Which halogen has the highest bond dissociation enthalpy?

(a) F_2 (b) Cl_2 (c) Br_2 (d) I_2

76. Which of the following statements is *not* correct?

(a) The ease of oxidation of the halide ions is $F^- < Cl^- < Br^- < I^-$.

(b) Fluorine is the most abundant halogen in the Earth's crust.

(c) F_2 is prepared industrially by electrolysis of aqueous NaF.

(d) HF is used to etch glass.

77. The halogen oxides and oxoanions are good oxidizing agents. For example, the reduction of bromate ion has an $E°$ value of 1.44 V in acid solution:

$$2\ BrO_3^-(aq) + 12\ H^+(aq) + 10\ e^- \rightarrow Br_2(aq) + 6\ H_2O(\ell)$$

Is it possible to oxidize aqueous 1.0 M Mn^{2+} to aqueous MnO_4^- with 1.0 M bromate ion?

78. The hypohalite ions, XO^-, are the anions of weak acids. Calculate the pH of a 0.10 M solution of NaClO. What is the concentration of HClO in this solution?

79. Bromine is obtained from brine wells. The process involves treating water containing bromide ion with Cl_2 and extracting the Br_2 from the solution using an organic solvent. Write a balanced equation for the reaction of Cl_2 and Br^-. What are the oxidizing and reducing agents in this reaction? Using the table of standard reduction potentials (Appendix M), verify that this is a product-favored reaction at equilibrium.

80. To prepare chlorine from chloride ion a strong oxidizing agent is required. The dichromate ion, $Cr_2O_7^{2-}$, is one example (Figure 21.35). Consult the table of standard reduction potentials (Appendix M), and identify several other oxidizing agents that may be suitable. Write balanced equations for the reactions of these substances with chloride ion.

81. If an electrolytic cell for producing F_2 (Figure 21.34) operates at 5.00×10^3 A (at 10.0 V), what mass of F_2 can be produced per 24-hour day? Assume the conversion of F^- to F_2 is 100%.

82. Halogens combine with one another to produce *interhalogens* such as BrF_3. Sketch a possible molecular structure for this molecule, and decide if the F—Br—F bond angles will be less than or greater than ideal.

The Noble Gases

(See Section 21.11.)

83. In which of the following species is Xe in the + 4 oxidation state?

(a) $XeOF_4$ (c) XeF_3^+

(b) $Xe_2F_3^+$ (d) XeO_6^{4-}

84. Predict the electron pair geometry for the xenon atom in $XeOF_4$.

(a) linear

(b) trigonal bipyramid

(c) trigonal planar

(d) octahedral

(e) tetrahedral

85. The standard enthalpy of formation of XeF_4 is −218 kJ/mol. Use this value and the enthalpy of dissociation of the F—F bond to calculate the Xe—F bond dissociation enthalpy.

86. Draw the Lewis electron dot structure for XeO_3F_2. What is its electron-pair geometry and its molecular geometry?

87. Argon is present in dry air to the extent of 0.93% by volume. What quantity of argon is present in 1.00 L of air? If you wanted to isolate 1.00 mol of argon, what volume of air would you need at 1.00 atm pressure and 25 °C?

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

88. The reaction of XeF_6 with water gives a yellow solution from which solid xenon trioxide, XeO_3, can be isolated (using extreme caution).
    (a) Write a balanced equation for this reaction.
    (b) What is the molecular geometry of XeO_3?
    (c) Xenon trioxide is described as treacherous, exploding with little provocation. Even so, it has been possible to determine the enthalpy of formation, +402 kJ/mol, for this compound. Use this value, and the value of the O=O bond energy, to determine the bond energy of the Xe−O bond.

General Questions

The questions are not designated as to type or location in the chapter. They may combine several concepts.

89. For each of the third-period elements (Na through Ar), identify the following:
    (a) whether the element is a metal, nonmetal, or metalloid
    (b) the color and appearance of the element
    (c) the state of the element (s, ℓ, or g) under standard conditions

90. Consider the chemistries of C, Si, Ge, and Sn.
    (a) Write a balanced chemical equation to depict the reaction of each element with elemental chlorine.
    (b) Describe the bonding in each of the products of the reactions with chlorine as ionic or covalent.
    (c) Compare the reactions, if any, of some Group 4A chlorides —CCl_4, $SiCl_4$, and $SnCl_4$— with water.

91. Consider the chemistries of the elements potassium, calcium, gallium, germanium, and arsenic.
    (a) Write a balanced chemical equation depicting the reaction of each element with elemental chlorine.
    (b) Describe the bonding in each of the products of the reactions with chlorine as ionic or covalent.
    (c) Draw Lewis electron dot structures for the products of the reactions of gallium and arsenic with chlorine. What are their electron-pair and molecular geometries?

92. When BCl_3 gas is passed through an electric discharge, small amounts of the reactive molecule B_2Cl_4 are produced. (The molecule has a B—B covalent bond.)
    (a) Draw a Lewis electron dot structure for B_2Cl_4.
    (b) Describe the hybridization of the B atoms in the molecule and the geometry around each B atom.

93. Complete and balance the following equations.
    (a) $KClO_3$ + heat →
    (b) $H_2S(g) + O_2(g) \rightarrow$
    (c) $Na(s) + O_2(g) \rightarrow$
    (d) $P_4(s) + KOH(aq) + H_2O(\ell) \rightarrow$
    (e) $NH_4NO_3(s)$ + heat →
    (f) $In(s) + Br_2(\ell) \rightarrow$
    (g) $SnCl_4(\ell) + H_2O(\ell) \rightarrow$

94. (a) Heating barium oxide in pure oxygen gives barium peroxide. Write a balanced equation for this reaction.
    (b) Barium peroxide is an excellent oxidizing agent. Write a balanced equation for the reaction of iron with barium peroxide to give iron(III) oxide and barium oxide.

95. Worldwide production of silicon carbide, SiC, is several hundred thousand tons annually. If you want to produce 1.0×10^5 metric tons of SiC, what mass (metric tons) of silicon sand (SiO_2) will you use if 70% of the sand is converted to SiC? (A metric ton is exactly 1000 kg.)

96. To store 2.88 kg of gasoline with an energy equivalence of 1.43×10^8 J requires a volume of 4.1 L. In comparison, 1.0 kg of H_2 has the same energy equivalence. What volume is required if this quantity of H_2 is to be stored at 25 °C and 1.0 atm of pressure?

97. Using data in Appendix L, calculate $\Delta_r G°$ values for the decomposition of MCO_3 to MO and CO_2 where M = Mg, Ca, Ba. What is the relative tendency of these carbonates to decompose?

98. Ammonium perchlorate is used as the oxidizer in solid-fuel rockets. Assume that one launch requires 700. tons (6.35×10^5 kg) of the salt, and the salt decomposes according to the equation on page 1005.
    (a) What mass of water is produced? What mass of O_2 is produced?
    (b) If all the O_2 produced is assumed to react with the powdered aluminum present in the rocket engine, what mass of aluminum is required to use up all of the O_2?
    (c) What mass of Al_2O_3 is produced?

99. ▲ Metals react with hydrogen halides (such as HCl) to give the metal halide and hydrogen:

$$M(s) + n\ HX(g) \rightarrow MX_n(s) + \tfrac{1}{2}n\ H_2(g)$$

The free energy change for the reaction is $\Delta_r G° = \Delta_f G°(MX_n) - n\ \Delta_f G°[HX(g)]$.
    (a) $\Delta_f G°$ for HCl(g) is −95.1 kJ/mol. What must be the value for $\Delta_f G°$ for MX_n for the reaction to be product-favored at equilibrium?
    (b) Which of the following metals is (are) predicted to have product-favored reactions with HCl(g): Ba, Pb, Hg, Ti?

100. Halogens form polyhalide ions. Sketch Lewis electron dot structures and molecular structures for the following ions:

(a) I_3^-

(b) $BrCl_2^-$

(c) ClF_2^+

(d) An iodide ion and two iodine molecules form the I_5^- ion. Here, the ion has five I atoms in a row, but the ion is not linear. Draw the Lewis dot structure for the ion, and propose a structure for the ion.

101. The standard enthalpy of formation of OF_2 gas is +24.5 kJ/mol. Calculate the average O—F bond enthalpy.

102. Calcium fluoride can be used in the fluoridation of municipal water supplies. If you want to achieve a fluoride ion concentration of 2.0×10^{-5} M, what mass of CaF_2 must you use for 1.0×10^6 L of water? (K_{sp} for CaF_2 is 5.3×10^{-11}.)

103. The steering rockets in space vehicles use N_2O_4 and a derivative of hydrazine, 1,1-dimethylhydrazine (Study Question 5.86). This mixture is called a *hypergolic fuel* because it ignites when the reactants come into contact:

$$H_2NN(CH_3)_2(\ell) + 2\ N_2O_4(\ell) \rightarrow 3\ N_2(g) + 4\ H_2O(g) + 2\ CO_2(g)$$

(a) Identify the oxidizing agent and the reducing agent in this reaction.

(b) The same propulsion system was used by the Lunar Lander on moon missions in the 1970s. If the Lander used 4100 kg of $H_2NN(CH_3)_2$, what mass (in kilograms) of N_2O_4 was required to react with it? What mass (in kilograms) of each of the reaction products was generated?

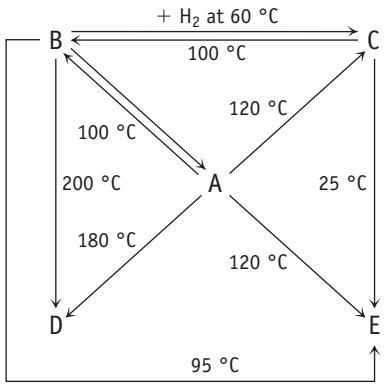
104. ▲ Liquid HCN is dangerously unstable with respect to trimer formation—that is, formation of $(HCN)_3$ with a cyclic structure.

(a) Propose a structure for this cyclic trimer.

(b) Estimate the energy of the trimerization reaction using bond dissociation enthalpies (Table 8.8).

105. Use $\Delta_f H°$ data in Appendix L to calculate the enthalpy change of the reaction

$$2\ N_2(g) + 5\ O_2(g) + 2\ H_2O(\ell) \rightarrow 4\ HNO_3(aq)$$



Speculate on whether such a reaction could be used to "fix" nitrogen. Would research to find ways to accomplish this reaction be a useful endeavor?

106. ▲ Phosphorus forms an extensive series of oxoanions.

(a) Draw a structure, and give the charge for an oxophosphate anion with the formula $[P_4O_{13}]^{n-}$. How many ionizable H atoms should the completely protonated acid have?

(b) Draw a structure, and give the charge for a cyclic oxophosphate anion with the formula $[P_4O_{12}]^{n-}$. How many ionizable H atoms should the completely protonated acid have?

107. ▲ Boron and hydrogen form an extensive family of compounds, and the diagram below shows how they are related by reaction.

The following table gives the weight percent of boron in each of the compounds. Derive the empirical and molecular formulas of compounds A–E.

Substance	State (at STP)	Mass Percent B	Molar Mass (g/mol)
A	Gas	78.3	27.7
B	Gas	81.2	53.3
C	Liquid	83.1	65.1
D	Liquid	85.7	63.1
E	Solid	88.5	122.2

108. ▲ In 1774, C. Scheele obtained a gas by reacting pyrolusite (MnO_2) with sulfuric acid. The gas, which had been obtained that same year by Joseph Priestley by a different method, was an element, A.

(a) What is the element isolated by Scheele and Priestley?

(b) Element **A** combines with almost all other elements. For example, with cesium it gives a compound in which the mass percent of **A** is 19.39%. The element combines with hydrogen to give a compound with a mass percent of element **A** of 94.12%. Determine the formulas of the cesium and hydrogen compounds.

(c) The compounds of cesium and hydrogen with element **A** react with one another. Write a balanced equation for the reaction.

109. When palladium metal is exposed to H_2 gas, the metal become brittle because H_2 molecules dissociate and H atoms fill some of the octahedral holes in the face-centered cubic lattice. To find the value of x in the formula PdH_x, you perform the following experiment: H_2 gas in a 2.25-L flask has a pressure of 113 mm at 23.0 °C. After exposing the gas to 0.192 g of Pd, the pressure is now 108 mm at 23 °C. What is the value of x in PdH_x?

110. The chemistry of gallium:

(a) Gallium hydroxide, like aluminum hydroxide, is amphoteric. Write a balanced equation to show how this hydroxide can dissolve in both HCl(aq) and NaOH(aq).

(b) Gallium ion in water, $Ga^{3+}(aq)$, has a K_a value of 1.2×10^{-3}. Is this ion a stronger or a weaker acid than $Al^{3+}(aq)$?

111. Silicon-oxygen rings are a common structural feature in silicate chemistry. Draw the structure for the anion $[Si_3O_9]^{6-}$, which is found in minerals such as benitoite. Is the ring expected to be planar?

112. Using enthalpy of formation data in Appendix L, determine whether the decomposition of $NH_4NO_3(s)$ to give $N_2O(g)$ and $H_2O(g)$ is endothermic or exothermic.

113. Metal sulfides roasted in air produce metal oxides.

$$2\ ZnS(s) + 3\ O_2(g) \rightarrow 2\ ZnO(s) + 2\ SO_2(g)$$

Use thermodynamics to decide if the reaction is product- or reactant-favored at equilibrium at 298 K. Will the reaction be more or less product-favored at a high temperature?

114. Metals generally react with hydrogen halides to give the metal halide and hydrogen. Determine whether this is true for silver by calculating $\Delta_r G°$ for the reaction with each of the hydrogen halides.

$$Ag(s) + HX(g) \rightarrow AgX(s) + {}^1/_2\ H_2(g)$$

The required free energies of formation are:

HX	$-\Delta_f G°$(kJ/mol)	AgX	$-\Delta_f G°$(kJ/mol)
HF	273.2	AgF	193.8
HCl	95.09	AgCl	109.76
HBr	53.45	AgBr	96.90
HI	1.56	AgI	66.19

In the Laboratory

115. One material needed to make silicones is dichlorodimethylsilane, $(CH_3)_2SiCl_2$. It is made by treating silicon powder at about 300 °C with CH_3Cl in the presence of a copper-containing catalyst.

(a) Write a balanced equation for the reaction.

(b) Assume you carry out the reaction on a small scale with 2.65 g of silicon. To measure the CH_3Cl gas, you fill a 5.60-L flask at 24.5 °C. What pressure of CH_3Cl gas must you have in the flask to have the stoichiometrically correct amount of the compound?

(c) What mass of $(CH_3)_2SiCl_2$ can be produced from 2.65 g of Si and excess CH_3Cl?

116. Sodium borohydride, $NaBH_4$, reduces many metal ions to the metal.

(a) Write a balanced equation for the reaction of $NaBH_4$ with $AgNO_3$ in water to give silver metal, H_2 gas, boric acid, and sodium nitrate. (The chemistry of $NaBH_4$ is described in Section 21.6.)

(b) What mass of silver can be produced from 575 mL of 0.011 M $AgNO_3$ and 13.0 g of $NaBH_4$?

117. A common analytical method for hydrazine involves its oxidation with iodate ion, IO_3^-, in acid solution. In the process, hydrazine acts as a four-electron reducing agent.

$$N_2(g) + 5\ H_3O^+(aq) + 4\ e^- \rightarrow N_2H_5^+(aq) + 5\ H_2O(\ell) \qquad E° = -0.23\ V$$

Write the balanced equation for the reaction of hydrazine in acid solution ($N_2H_5^+$) with $IO_3^-(aq)$ to give N_2 and I_2. Calculate $E°$ for this reaction.

118. When 1.00 g of a white solid **A** is strongly heated, you obtain another white solid, **B**, and a gas. An experiment is carried out on the gas, showing that it exerts a pressure of 209 mm Hg in a 450-mL flask at 25 °C. Bubbling the gas into a solution of $Ca(OH)_2$ gives another white solid, **C**. If the white solid **B** is added to water, the resulting solution turns red litmus paper blue. Addition of aqueous HCl to the solution of **B** and evaporation of the resulting solution to dryness yield 1.055 g of a white solid **D**. When **D** is placed in a Bunsen burner flame, it colors the flame green. Finally, if the aqueous solution of **B** is treated with sulfuric acid, a white precipitate, **E**, forms. Identify the lettered compounds in the reaction scheme.

© Cengage Learning/Charles D. Winters

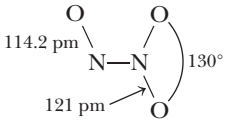
The salts of $CaCl_2$, $SrCl_2$, and $BaCl_2$ were suspended in methanol. When the methanol was set ablaze, the heat of combustion causes the salts to emit light of characteristic wavelengths: Calcium salts are yellow; strontium salts are red; and barium salts are green-yellow.

119. ▲ In 1937, R. Schwartz and M. Schmiesser prepared a yellow-orange bromine oxide (BrO_2) by treating Br_2 with ozone in a fluorocarbon solvent. Many years later, J. Pascal found that, on heating, this oxide decomposed to two other oxides, a less volatile golden yellow oxide (**A**) and a more volatile deep brown oxide (**B**). Oxide **B** was later identified as Br_2O. To determine the formula for oxide **A**, a sample was treated with sodium iodide. The reaction liberated iodine, which was titrated to an equivalence point with 17.7 mL of 0.065 M sodium thiosulfate.

$$I_2(aq) + 2\ S_2O_3^{2-}(aq) \rightarrow 2\ I^-(aq) + S_4O_6^{2-}(aq)$$

Compound **A** was also treated with $AgNO_3$, and 14.4 mL of 0.020 M $AgNO_3$ was required to completely precipitate the bromine from the sample.

(a) What is the formula of the unknown bromine oxide **A**?



(b) Draw Lewis structures for **A** and Br_2O. Speculate on their molecular geometry.

120. A mixture of PCl_5 (12.41 g) and excess NH_4Cl was heated at 145 °C for 6 hours. The two reacted in equimolar amounts and evolved 5.14 L of HCl (at STP). Three substances (**A**, **B**, and **C**) were isolated from the reaction mixture. The three substances had the same elemental composition but differed in their molar mass. Substance **A** had a molar mass of 347.7 g/mol and **B** had a molar mass of 463.5 g/mol. Give the empirical and molecular formulas for **A** and **B** and draw a reasonable Lewis structure for **A**.

Summary and Conceptual Questions

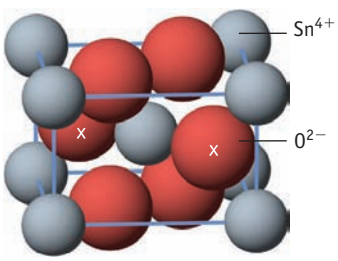
The following questions may use concepts from this and previous chapters.

121. Dinitrogen trioxide, N_2O_3, has the structure shown here.

The oxide is unstable, decomposing to NO and NO_2 in the gas phase at 25 °C.

$$N_2O_3(g) \rightarrow NO(g) + NO_2(g)$$

(a) Draw resonance structures for N_2O_3 and explain why one N—O bond distance is 114.2 pm, whereas the other two bonds are longer (121 pm) and nearly equal to each other.



(b) For the decomposition reaction, $\Delta_r H° = +40.5$ kJ/mol and $\Delta_r G° = -1.59$ kJ/mol. Calculate $\Delta S°$ and K for the reaction at 298 K.

(c) Calculate $\Delta_f H°$ for $N_2O_3(g)$.

122. ▲ The density of lead is 11.350 g/cm^3, and the metal crystallizes in a face-centered cubic unit cell. Estimate the radius of a lead atom.

123. How would you extinguish a sodium fire in the laboratory? What is the worst thing you could do?

124. Tin(IV) oxide, cassiterite, is the main ore of tin. It crystallizes in a rutile-like unit cell with tin(IV) ions taking the place of Ti^{4+} ions (Study Question 12.6). (The O^{2-} ions marked x are wholly within the unit cell.)

(a) How many tin(IV) ions and oxide ions are there per unit cell of this oxide?

(b) Is it thermodynamically feasible to transform solid SnO_2 into liquid $SnCl_4$ by reaction of the oxide with gaseous HCl? What is the equilibrium constant for this reaction at 25 °C?

125. You are given a stoppered flask that contains hydrogen, nitrogen, or oxygen. Suggest an experiment you could do to identify the gas.

126. The structure of nitric acid is illustrated on page 990.

(a) Why are the N—O bonds the same length, and why are both shorter than the N—OH bond length?

(b) Rationalize the bond angles in the molecule.

(c) What is the hybridization of the central N atom? Which orbitals overlap to form the N—O π bond?

127. The reduction potentials for the Group 3A metals, $E°$, are given below. What trend or trends do you observe in these data? What can you learn about the chemistry of the Group 3A elements from these data?

Half-Reaction	Reduction Potential ($E°$, V)
$Al^{3+}(aq) + 3\ e^- \longrightarrow Al(s)$	−1.66
$Ga^{3+}(aq) + 3\ e^- \longrightarrow Ga(s)$	−0.53
$In^{3+}(aq) + 3\ e^- \longrightarrow In(s)$	−0.338
$Tl^{3+}(aq) + 3\ e^- \longrightarrow Tl(s)$	+0.72

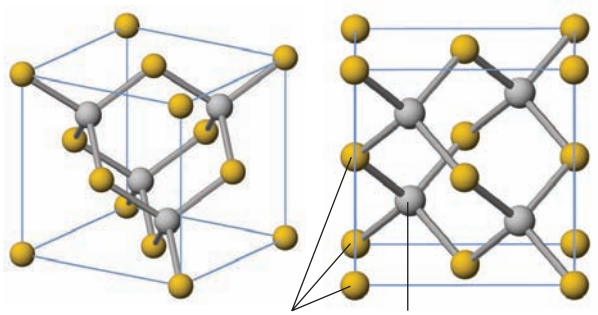
128. (a) Magnesium is obtained from seawater. If the concentration of Mg^{2+} in seawater is 0.050 M, what volume of seawater (in liters) must be treated to obtain 1.00 kg of magnesium metal? What mass of lime (CaO; in kilograms) must be used to precipitate the magnesium in this volume of seawater?

(b) When 1.2×10^3 kg of molten $MgCl_2$ is electrolyzed to produce magnesium, what mass (in kilograms) of metal is produced at the cathode? What is produced at the anode? What is the mass of this product? What is the total number of Faradays of electricity used in the process?

(c) One industrial process has an energy consumption of 18.5 kWh/kg of Mg. How many joules are required per mole (1 kWh = 1 kilowatt-hour = 3.6×10^6 J)? How does this energy compare with the energy of the following process?

$$MgCl_2(s) \rightarrow Mg(s) + Cl_2(g)$$

129. Comparing the chemistry of carbon and silicon.



(a) Write balanced chemical equations for the reactions of $H_2O(\ell)$ with CH_4 (forming CO_2 and H_2) and SiH_4 (forming SiO_2 and H_2).

(b) Using thermodynamic data, calculate the standard free energy change for the reactions in (a). Is either reaction product-favored at equilibrium?

(c) Look up the electronegativities of carbon, silicon, and hydrogen. What conclusion can you draw concerning the polarity of C—H and Si—H bonds?

(d) Carbon and silicon compounds with the formulas $(CH_3)_2CO$ (acetone) and $[(CH_3)_2SiO]_n$ (a silicone polymer) also have quite different structures. Draw Lewis structures for these species. This difference, along with the difference between structures of CO_2 and SiO_2, suggests a general observation about silicon compounds. Based on that observation, do you expect that a silicon compound with a structure similar to ethene (C_2H_4) exists?

130. ▲ Boron nitride, BN, has the same solid state structure as ZnS (Figure 12.10).

You can consider it a face-centered cube of nitrogen atoms with boron atoms in one half of the tetrahedral holes of the lattice. If the density of this form of BN is 3.45 g/cm^3, what is the B−N bond length?

131. ▲ Xenon trioxide, XeO_3, reacts with aqueous base to form the xenate anion, $HXeO_4^-$. This ion reacts further with OH^- to form the perxenate anion, XeO_6^{4-}, in the following reaction:

$$2\ HXeO_4^-(aq) + 2\ OH^-(aq) \rightarrow XeO_6^{4-}(aq) + Xe(g) + O_2(g) + 2\ H_2O(\ell)$$

Identify the elements that are oxidized and reduced in this reaction. You will note that the equation is balanced with respect to the number of atoms on either side. Verify that the redox part of this equation is also balanced, that is, that the extents of oxidation and reduction are also equal.

CHAPTER OUTLINE

22.1 Overview of the Transition Elements

22.2 Periodic Properties of the Transition Elements

22.3 Metallurgy

22.4 Coordination Compounds

22.5 Structures of Coordination Compounds

22.6 Bonding in Coordination Compounds

22.7 Colors of Coordination Compounds

22.1 Overview of the Transition Elements

Goals for Section 22.1

- Identify the general classes of transition metals based on their location in the periodic table.
- Recognize general features of transition metals and their compounds.

The transition elements are the large block of elements in the central portion of the periodic table, bridging the *s*-block elements at the left and the *p*-block elements on the right (Figure 22.1). The transition elements are divided into two groups, the ***d*-block elements**, whose occurrence in the periodic table coincides with the filling of the *d* orbitals and the ***f*-block elements**, characterized by filling of the *f* orbitals. Contained within this latter group of elements are two subgroups: the *lanthanides,* elements that occur between La and Hf, and the *actinides,* elements that occur between Ac and Rf.

The *d*-block metals include elements with a wide range of properties. They encompass the most common metal used in construction and manufacturing (iron), metals valued for their beauty (gold, silver, and platinum), and metals used in coins (nickel, copper, and zinc). There are metals used in modern technology (titanium) and metals known and used in early civilizations (copper, silver, gold, and iron). The *d*-block contains the densest elements (osmium, $d = 22.49$ g/cm^3, and iridium, $d = 22.41$ g/cm^3), the metals with the highest and lowest melting points (tungsten, mp = 3410 °C, and mercury, mp = −38.9 °C), and the only two elements with atomic numbers less than 83 that have only radioactive isotopes, technetium ($_{43}$Tc) and promethium ($_{61}$Pm).

With the exception of mercury, the transition elements are solids under ambient conditions. They have a metallic sheen and conduct electricity and heat. They react with various oxidizing agents to give ionic compounds, although there is considerable variation in such reactions among the elements. In contrast to most of these elements, gold and platinum resist oxidation; consequently, they are used for jewelry and decorative items.

Figure 22.1 The transition metals. The *d*-block elements and *f*-block elements (the transition elements) are highlighted in a darker shade of blue.

Certain *d*-block elements are important in living organisms. Cobalt is the crucial element in vitamin B_{12}, which is part of a catalyst essential for several biochemical reactions. Hemoglobin and myoglobin, oxygen-carrying and storage proteins, contain iron. Molybdenum and iron, together with sulfur, form the reactive portion of nitrogenase, a biological catalyst used by nitrogen-fixing organisms to convert atmospheric nitrogen into ammonia.

Many transition metal compounds are highly colored, which makes them useful as pigments in paints and dyes (Figure 22.2). Prussian blue, $Fe_4[Fe(CN)_6]_3 \cdot 14\ H_2O$, is a "bluing agent" used in engineering blueprints and in the laundry. A common pigment used by artists (cadmium yellow) contains cadmium sulfide, CdS, and the white pigment in most white paints is titanium(IV) oxide, TiO_2.

The presence of transition metal ions in crystalline silicates or alumina transforms these common materials into gemstones. Iron(II) ions produce the yellow color in citrine, and chromium(III) ions are responsible for the red color of a ruby. Transition metal compounds in small quantities add color to glass. Blue glass contains a small amount of a cobalt(III) oxide, and addition of chromium(III) oxide

(a) Paint pigments: yellow, CdS; green, Cr_2O_3; white, TiO_2 and ZnO; purple, $Mn_3(PO_4)_2$; blue, Co_2O_3; ochre, Fe_2O_3.

(b) Small amounts of transition metal compounds are used to color glass: blue, Co_2O_3; green, copper or chromium oxides; purple, nickel or cobalt oxides; red, copper oxide; iridescent green, uranium oxide.

© Cengage Learning/Charles D. Winters

(c) Traces of transition metal ions are responsible for the colors of green jade (iron), red corundum (chromium), blue azurite, blue-green turquoise (copper), and purple amethyst (iron).

Figure 22.2 Colorful chemistry. Transition metal compounds have a wide variety of colors.

gives glass a green color. Old window panes sometimes take on a purple color over time as a consequence of oxidation of traces of manganese(II) ion present in the glass to permanganate ion (MnO_4^-).

© Cengage Learning/Charles D. Winters

Prussian blue. The deep blue compound called Prussian blue has the formula $Fe_4[Fe(CN)_6]_3 \cdot 14\ H_2O$. The color arises from electron transfer between Fe(II) and Fe(III) ions in the compound.

22.2 Periodic Properties of the Transition Elements

Goal for Section 22.2

- Assess periodic trends of the transition metals based on electronic structure.

Electron Configurations

Because chemical behavior is related to electron structure, it is important to know the electron configurations of the *d*-block elements (Table 22.1) and their common ions (Sections 7.3 and 7.4). Recall that the configuration of these metals has the general form [noble gas core]$(n-1)d^b ns^a$; that is, valence electrons for the transition elements reside in the *ns* and $(n-1)d$ subshells.

Oxidation and Reduction

A characteristic chemical property of all metals is that they undergo oxidation by a wide range of oxidizing agents such as oxygen, the halogens, and aqueous acids. Standard reduction potentials for the elements of the first transition series can be used to predict which elements will be oxidized by a given oxidizing agent in aqueous solution. For example, all of these metals except vanadium and copper are oxidized by aqueous HCl (Table 22.2).

When a transition metal is oxidized, the outermost *s* electrons are transferred to the oxidizing agent, followed by one or more *d* electrons. With a few exceptions, transition metal ions have the electron configuration [noble gas core]$(n-1)d^x$. In contrast to ions formed by main group elements, transition metal cations often possess unpaired electrons, resulting in paramagnetism (Section 7.4). They are frequently colored as well, due to the absorption of light in the visible region of the

(b) Steel wool reacts with chlorine gas, Cl_2.

(c) Iron chips react with aqueous HCl.

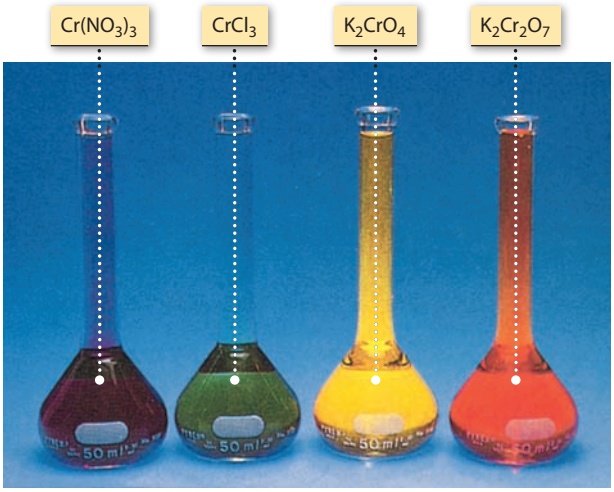

Figure 22.3 Typical reactions of transition metals. Iron reacts with oxygen, with halogens, and with acids under appropriate conditions.

electromagnetic spectrum. Color and magnetism figure prominently in a discussion of the properties and bonding of these elements, as you shall see shortly.

In the first transition series, the most commonly encountered compounds have metal ions with oxidation numbers of +2 and +3 (Table 22.2). With iron, for example, oxidation converts Fe([Ar]$3d^6 4s^2$) to either Fe^{2+}([Ar]$3d^6$) or Fe^{3+}([Ar]$3d^5$). Iron reacts with chlorine to give $FeCl_3$, and it reacts with aqueous acids to produce $Fe^{2+}(aq)$ and H_2 (Figure 22.3). Despite the preponderance of 2+ and 3+ ions in compounds of the first transition metal series, the range of possible oxidation states for these compounds is broad (Figure 22.4). Earlier in this text, we encountered chromium with a +6 oxidation number (CrO_4^{2-}, $Cr_2O_7^{2-}$), manganese with an oxidation number of +7 (MnO_4^-), silver and copper as 1+ ions, and vanadium oxidation numbers that can range from +5 to +1 (Figure 19.3).

(a) The most common oxidation states are indicated with *red squares;* less common oxidation states are indicated with *blue dots.*

(b) Aqueous solutions of chromium compounds with two different oxidation numbers: +3 in $Cr(NO_3)_3$ (violet) and $CrCl_3$ (green), and +6 in K_2CrO_4 (yellow) and $K_2Cr_2O_7$ (orange). The two Cr(III) species have different colors in solution because there are different complex ions based on Cr(III) in solution. The complex ion in the purple solution is $[Cr(H_2O)_6]^{3+}$; the complex ion in the green solution is $[Cr(H_2O)_4Cl_2]^+$.

Higher oxidation numbers are common in compounds of the elements in the second and third transition series. For example, the naturally occurring sources of molybdenum and tungsten are the ores molybdenite [MoS_2, Mo(IV)] and wolframite [WO_3, W(VI)]. This general trend to form compounds in high oxidation states is carried over in the *f*-block. Most lanthanide compounds have the metal ion in the +3 oxidation state. In contrast, actinide elements usually have higher oxidation numbers in their compounds; +4 and even +6 are typical. For example, UO_3 [(U(VI)]is a common oxide of uranium, and UF_6 [(U(VI)] is a compound important in processing uranium fuel for nuclear reactors (Section 25.6).

The Highest Oxidation Number The heavy transition elements such as Ru, Os, and Ir have interesting chemistries. Iridium, for example, is found in compounds where the element has an oxidation number ranging from –3 to +8. Recently the cation IrO_4^+ was characterized, the first time an oxidation number of +9 has been observed for any element.

Periodic Trends in the *d* Block: Size, Density, Melting Point

Let us look at three important physical properties of the transition elements that vary periodically: atomic radii, density, and melting point.

Metal Atom Radii

The radii of the transition elements vary over a fairly narrow range, with a small decrease to a minimum being observed around the middle of this group of elements (Figure 7.8). Atom size is determined by the electrons in the outermost orbital, which for these elements is the *ns* orbital ($n = 4$, 5, or 6). Progressing from left to right in the periodic table, the size decline expected from increasing the number of protons in the nucleus is mostly canceled out by an opposing effect, repulsion from additional electrons in the $(n - 1)d$ orbitals.

The radii of the *d*-block elements in the fifth and sixth periods in each group are almost identical. The reason is that the lanthanide elements immediately precede the third series of *d*-block elements. The filling of 4*f* orbitals is accompanied by a steady contraction in size, consistent with the general trend of decreasing size from left to right in the periodic table. At the point where the 5*d* orbitals begin to fill again, the radii have decreased to a size similar to that of elements in the previous period. The decrease in size that results from the filling of the 4*f* orbitals is called the **lanthanide contraction**.

The similar sizes of the second and third series *d*-block elements have significant consequences for their chemistry. For example, the "platinum group metals" (Ru, Os, Rh, Ir, Pd, and Pt) form similar compounds. Thus, it is not surprising that minerals containing these metals are found in the same geological zones on Earth. Nor is it surprising that it is difficult to separate these elements from one another.

Density

The variation in metal radii causes the densities of the transition elements to first increase and then decrease across a period (Figure 22.5, *left*). Although the overall change in radii among these elements is small, the effect is magnified because the volume is actually changing with the cube of the radius [$V = (4/3)\pi r^3$].

The lanthanide contraction explains why elements in the sixth period have the highest densities. The relatively small radii of sixth-period transition metals, combined with the fact that their atomic masses are considerably larger than their counterparts in the fifth period, causes sixth-period metal densities to be larger.

Melting Point

Melting points reflect the forces of attraction between the atoms, molecules, or ions that compose the solid. With transition elements, the melting points rise to a maximum around the middle of the series (Figure 22.5, *right*), then descend, indicating that the strongest metallic bonds occur when the *d* subshell is about half filled. This is also the point at which the largest number of electrons occupy the bonding molecular orbitals in the metal. (See the discussion of bonding in metals in Section 12.4.)

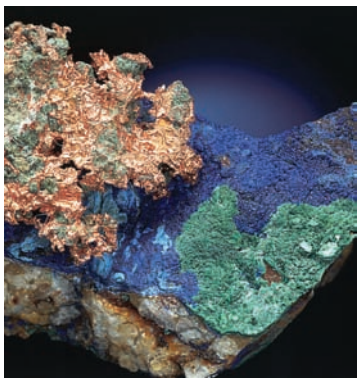
22.3 Metallurgy



Goal for Section 22.3

- Describe the metallurgy of iron and copper.

Most metals are found in nature as oxides, sulfides, halides, carbonates, or other ionic compounds (Figure 22.6), but metals such as copper, silver, and gold can occur uncombined. Some metal-containing mineral deposits have little economic value, either because the concentration of the metal is too low or because the metal is difficult to separate from impurities. The relatively few minerals from which elements can be obtained profitably are called *ores*. **Metallurgy** is the general name given to the process of obtaining metals from their ores.

Very few ores are chemically pure substances. Instead, the desired mineral is usually mixed with large quantities of impurities such as sand and clay, called **gangue** (pronounced "gang"). Generally, the first step in a metallurgical process is to separate the mineral from the gangue. Then the ore is converted to the metal, a reduction process.

Pyrometallurgy and hydrometallurgy are two methods of recovering metals from their ores. As the names imply, **pyrometallurgy** involves high temperatures

© Cengage Learning/Charles D. Winters

Copper occurs in nature as the metal (native copper) and as minerals such as blue azurite [2 $CuCO_3 \cdot Cu(OH)_2$] and green malachite [$CuCO_3 \cdot Cu(OH)_2$].

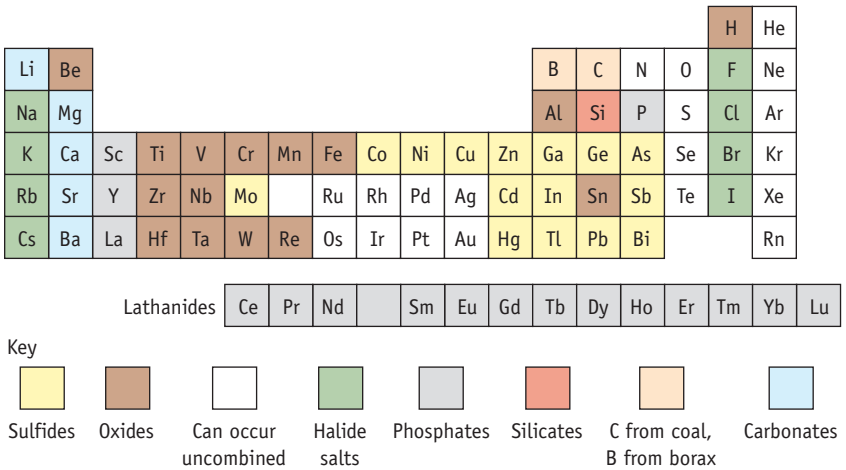


Figure 22.6 Sources of the elements. A few transition metals, such as copper and gold, occur in nature as the metal. Most other elements are found naturally as oxides, sulfides, or other salts.

and **hydrometallurgy** uses aqueous solutions (and thus is limited to the relatively low temperatures at which water is a liquid). Iron and copper metallurgy illustrate these two methods of metal production.

Pyrometallurgy: Iron Production

The production of iron from its ores is carried out in a blast furnace (Figure 22.7). The furnace is charged with a mixture of ore (usually hematite, Fe_2O_3), coke (which is primarily carbon), and limestone ($CaCO_3$). A blast of hot air forced in at the bottom of the furnace causes the coke to burn with such an intense heat that the temperature at the bottom is almost 1500 °C. The quantity of air forced into the furnace is controlled so that carbon monoxide is the primary product. Both carbon and carbon monoxide participate in the reduction of iron(III) oxide to give impure metal.

Coke: A Reducing Agent Coke is made by heating coal in a tall, narrow oven that is sealed to keep out oxygen. Heating drives off volatile chemicals, including benzene and ammonia. What remains is nearly pure carbon.

$$Fe_2O_3(s) + 3\ C(s) \longrightarrow 2\ Fe(\ell) + 3\ CO(g)$$

$$Fe_2O_3(s) + 3\ CO(g) \longrightarrow 2\ Fe(\ell) + 3\ CO_2(g)$$

Much of the carbon dioxide formed in the reduction process (and from heating limestone) is reduced on contact with unburned coke and produces carbon monoxide, which can then function as a reducing agent.

$$CO_2(g) + C(s) \longrightarrow 2\ CO(g)$$

The molten iron flows down through the furnace and collects at the bottom, where it is tapped off through an opening in the side. This impure iron is called *cast iron* or *pig iron*. Usually, the impure metal is either brittle or soft (undesirable properties for most uses) due to the presence of impurities such as elemental carbon, phosphorus, and sulfur.

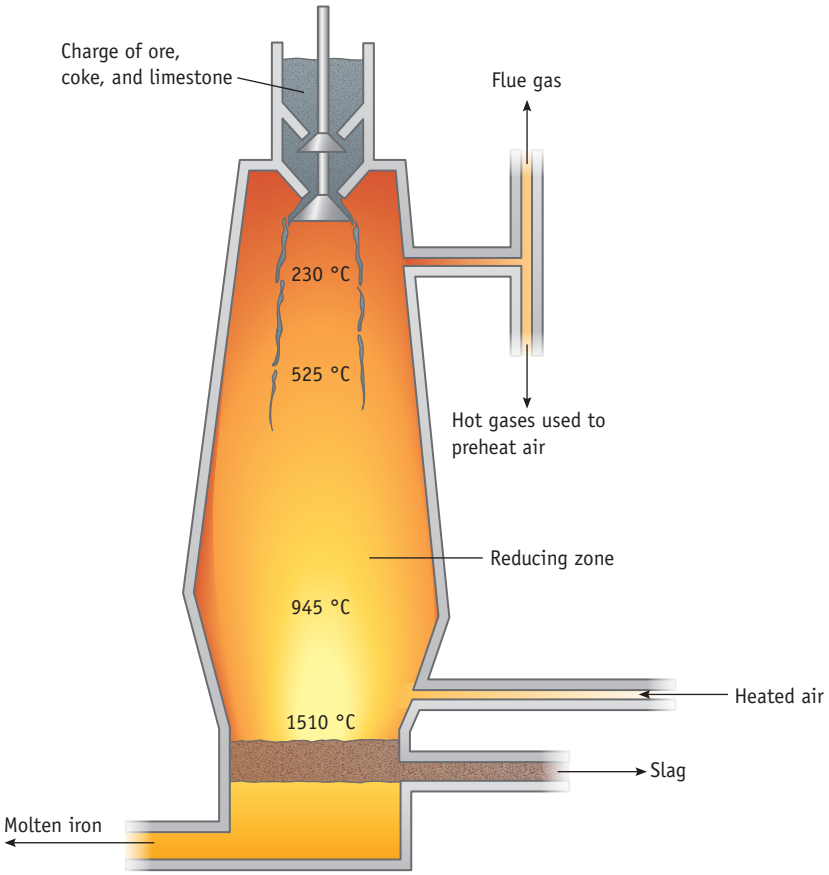

Figure 22.7 A blast furnace. The largest modern furnaces have hearths 14 meters in diameter. They can produce as much as 10,000 tons of iron per day.

Figure 22.8 Molten iron being poured from a basic oxygen furnace.

Iron ores generally contain silicate minerals and silicon dioxide. Lime (CaO), formed when limestone is heated, reacts with these materials to give calcium silicate.

$$SiO_2(s) + CaO(s) \longrightarrow CaSiO_3(\ell)$$

(This is an acid–base reaction because CaO is a basic oxide and SiO_2 is an acidic oxide.) The calcium silicate, molten at the temperature of the blast furnace and less dense than molten iron, floats on the iron. Other nonmetal oxides dissolve in this layer and the mixture, called *slag*, is easily removed.

Pig iron from the blast furnace may contain as much as 4.5% carbon, 0.3% phosphorus, 0.04% sulfur, 1.5% silicon, and some other elements as well. The impure iron must be purified to remove these nonmetal components. Several purification processes are available, but the most important uses the *basic oxygen furnace* (Figure 22.8). Pure oxygen is blown into the molten pig iron and oxidizes phosphorus to P_4O_{10}, sulfur to SO_2, and carbon to CO_2. These nonmetal oxides either escape as gases or react with basic oxides such as CaO that are added or are used to line the furnace. For example,

$$P_4O_{10}(g) + 6\ CaO(s) \longrightarrow 2\ Ca_3(PO_4)_2(\ell)$$

The result is ordinary *carbon steel*. Almost any degree of flexibility, hardness, strength, and malleability can be achieved in carbon steel by reheating and cooling in a process called *tempering*. The resulting material can then be used in a wide variety of applications. The major disadvantages of carbon steel are that it corrodes easily and that it loses its properties when heated strongly.

Other transition metals, such as chromium, manganese, and nickel, can be added during the steel-making process, giving *alloys* (solids made up of two or more metals, page 547) that have specific physical, chemical, and mechanical properties. One well-known alloy is stainless steel, which contains 18% to 20% Cr and 8% to 12% Ni. Stainless steel is much more resistant to corrosion than carbon steel. Another alloy of iron is Alnico V. Used in loudspeaker magnets because of its permanent magnetism, it contains five elements: Al (8%), Ni (14%), Co (24%), Cu (3%), and Fe (51%).

Hydrometallurgy: Copper Production

In contrast to iron ores, which are usually oxides, most copper minerals are sulfides. Copper-bearing minerals include chalcopyrite ($CuFeS_2$), chalcocite (Cu_2S), and covellite (CuS). Because ores containing these minerals generally have a very low percentage of copper, enrichment is necessary. This step is carried out by a process known as *flotation*. First, the ore is finely powdered. Next, oil is added and the mixture is agitated with soapy water in a large tank (Figure 22.9a). At the same time, compressed air is forced through the mixture, so that the lightweight, oil-covered copper sulfide particles are carried to the top as a frothy mixture. The heavier gangue settles to the bottom of the tank, and the copper-laden froth is skimmed off.

Hydrometallurgy can be used to obtain copper from an enriched ore. In one method, enriched chalcopyrite ore ($CuFeS_2$) is treated with a solution of copper(II) chloride. These react to leave copper in the form of solid, insoluble copper(I) chloride, CuCl, which is easily separated from the iron that remains in solution as aqueous $FeCl_2$.

$$CuFeS_2(s) + 3\ CuCl_2(aq) \longrightarrow 4\ CuCl(s) + FeCl_2(aq) + 2\ S(s)$$

Aqueous NaCl is then added, and CuCl dissolves upon formation of the soluble complex ion $[CuCl_2]^-$.

$$CuCl(s) + Cl^-(aq) \longrightarrow [CuCl_2]^-(aq)$$

Copper(I) compounds in solution are unstable with respect to Cu(0) and Cu(II). Thus, $[CuCl_2]^-$ disproportionates to the metal and copper(II) chloride, $CuCl_2$, and the latter is used to treat further ore.

$$2\ [CuCl_2]^-(aq) \longrightarrow Cu(s) + Cu^{2+}(aq) + 4\ Cl^-(aq)$$

(a) Flotation. The less dense particles of Cu_2S are trapped in the soap bubbles and float. The denser gangue settles to the bottom.

(b) Electrolysis

imon Fraser/Northumbria Circuits/ Science Photo Library/Science Source

(c) Producing pure copper by electrolysis

Figure 22.9 Copper metallurgy.

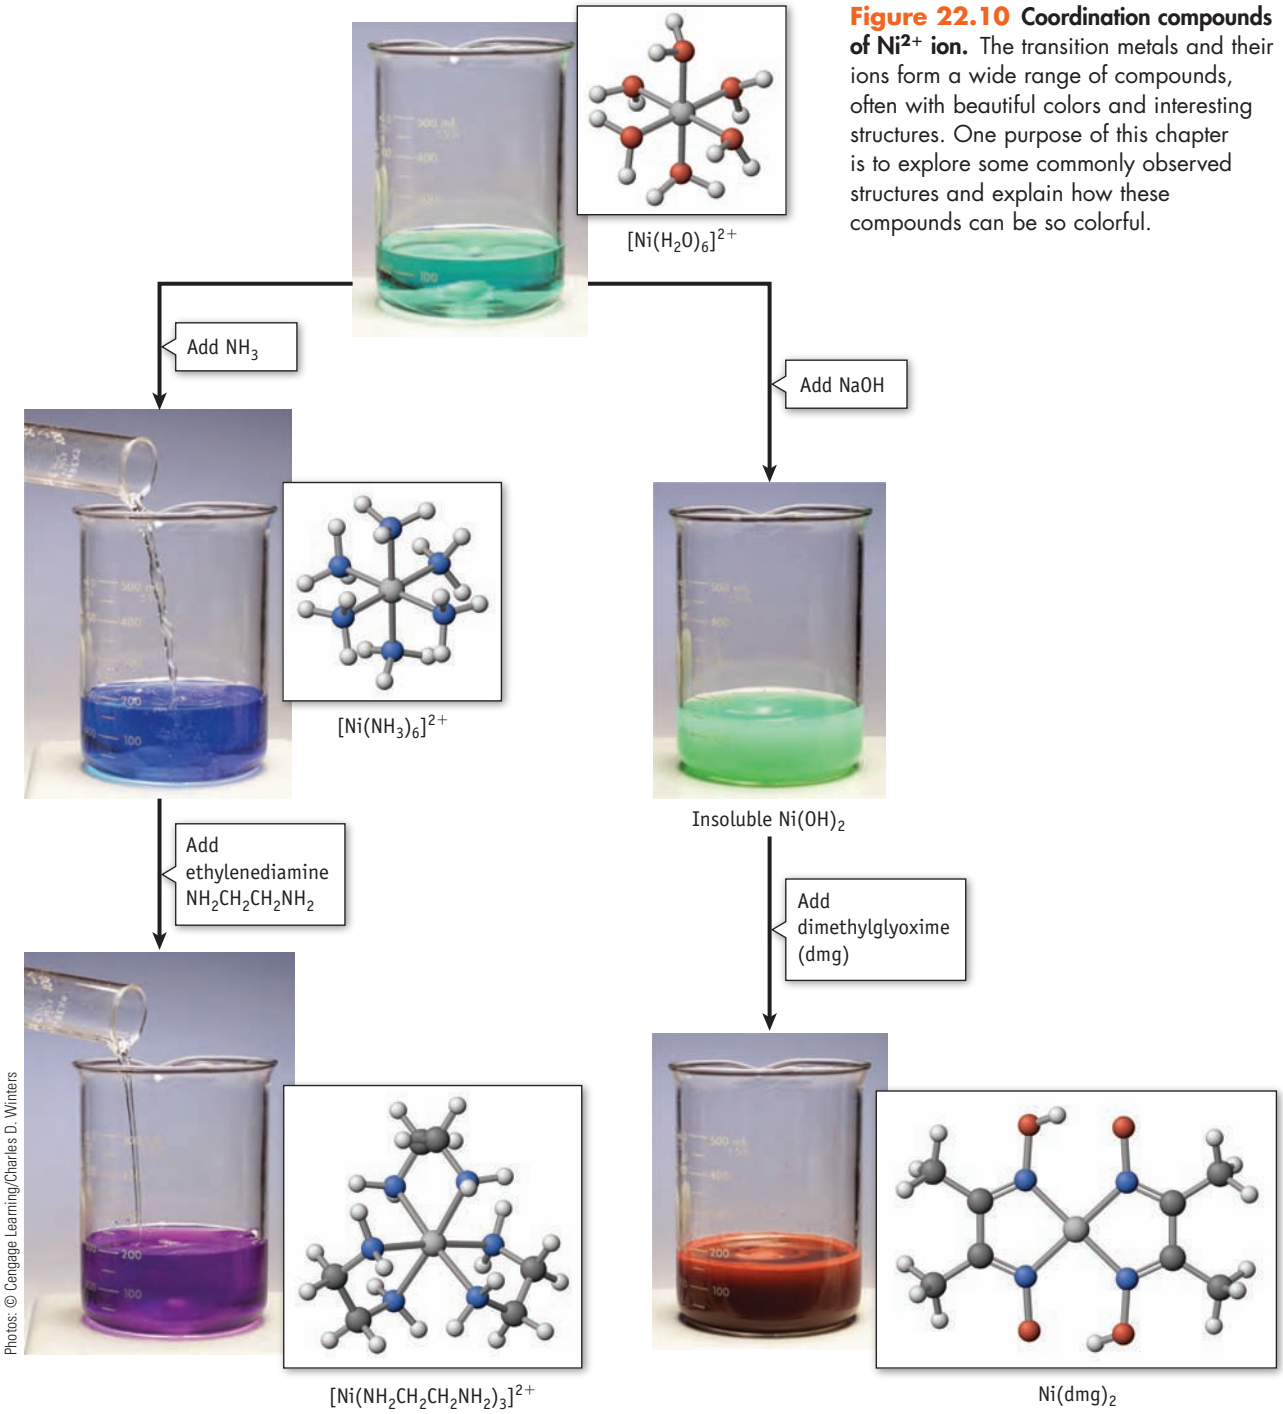
Approximately 10% of the copper produced in the United States is obtained with the aid of bacteria. Acidified water is sprayed onto copper-mining wastes that contain low levels of copper. As the water trickles down through the crushed rock, the bacterium *Thiobacillus ferrooxidans* breaks down the iron sulfides in the rock and converts iron(II) to iron(III). Iron(III) ions oxidize the sulfide ion of copper sulfide to sulfate ions, leaving copper(II) ions in solution. Then the copper(II) ion is reduced to metallic copper by reaction with iron.

$$Cu^{2+}(aq) + Fe(s) \longrightarrow Cu(s) + Fe^{2+}(aq)$$

The purity of the copper obtained by these metallurgical processes is about 99%, but this is not acceptable because even traces of impurities greatly diminish the electrical conductivity of the metal. Consequently, a further purification step involving electrolysis is needed (Figures 22.9b and 22.9c). Thin sheets of pure copper metal and slabs of impure copper are immersed in a solution containing $CuSO_4$ and H_2SO_4. The pure copper sheets serve as the cathode of an electrolysis cell, and the impure slabs are the anode. Copper in the impure sample is oxidized to copper(II) ions at the anode, and copper(II) ions in solution are reduced to pure copper at the cathode.

22.4 Coordination Compounds

Goals for Section 22.4



- Know the names and formulas of common monodentate and bidentate ligands.
- Given the formula for a coordination complex, identify the metal and its oxidation state, the ligands, the coordination number and coordination geometry, and the overall charge on the complex.
- Given a formula, name a complex; given a name of a complex, write its formula.

Complexes and Ligands

A green solution formed by dissolving nickel(II) chloride in water contains $Ni^{2+}(aq)$ and $Cl^-(aq)$ ions (Figure 22.10). If the solvent is removed, a green crystalline solid is obtained. The formula of this solid is often written as $NiCl_2 \cdot 6\ H_2O$, and the classical name for this compound is nickel(II) chloride hexahydrate. Addition of ammonia to the aqueous nickel(II) chloride solution gives a lilac-colored solution from which another compound, $NiCl_2 \cdot 6\ NH_3$, can be isolated. This formula looks very similar to the formula for the hydrate, with ammonia substituted for water.

Figure 22.10 Coordination compounds of Ni^{2+} ion. The transition metals and their ions form a wide range of compounds, often with beautiful colors and interesting structures. One purpose of this chapter is to explore some commonly observed structures and explain how these compounds can be so colorful.

What are these two nickel species? The formulas identify the compositions of the compounds but give no information about their structures. Because properties of compounds derive from their structures, we need to evaluate the structures in more detail. Typically, metal compounds are ionic, and solid ionic compounds have structures with cations and anions arranged in a regular array. The structure of hydrated nickel(II) chloride contains cations with the formula $[Ni(H_2O)_6]^{2+}$ and chloride anions. The structure of the ammonia-containing compound is similar to the hydrate; it is made up of $[Ni(NH_3)_6]^{2+}$ cations and chloride anions.

Ions such as $[Ni(H_2O)_6]^{2+}$ and $[Ni(NH_3)_6]^{2+}$, in which a metal ion and either water or ammonia molecules compose a single structural unit, are examples of **coordination complexes**, also known as **complex ions** (Figure 22.11). Compounds containing a coordination complex as part of the structure are called **coordination compounds**, and their chemistry is known as **coordination chemistry**. Although the older "hydrate" formulas are still used, the preferred method of writing the formula for coordination compounds places the metal atom or ion and the molecules or anions directly bonded to it within brackets to show that it is a single structural entity. Thus, the formula for the nickel(II)–ammonia compound is better written as $[Ni(NH_3)_6]Cl_2$.

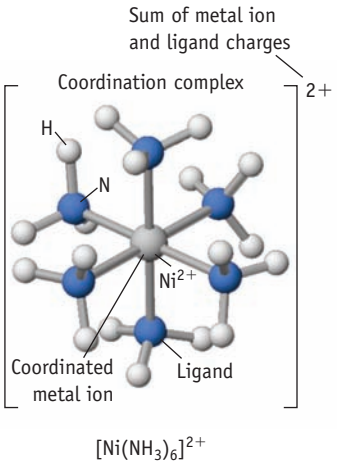
All coordination complexes contain a metal atom or ion as the central part of the structure. Bonded to the metal are molecules or ions called **ligands** (from the Latin verb *ligare*, meaning "to bind"). In the preceding examples, water and ammonia are the ligands. The number of ligand atoms attached to the metal defines the **coordination number** of the metal. The geometry around the metal described by the attached ligands is called the **coordination geometry**. In $[Ni(NH_3)_6]^{2+}$ (Figure 22.11), nickel has a coordination number of six and the six ligands are arranged in a regular octahedral geometry around the central metal ion.

Ligands can be either neutral molecules or anions (or, in rare instances, cations). The characteristic feature of a ligand is that it contains a lone pair of electrons. In the classic description of bonding in a coordination complex, the lone pair of electrons on a ligand is shared with the metal ion. The attachment is a coordinate covalent bond (Section 8.5), because the electron pair being shared was originally on the ligand. The name "coordination complex" derives from the name given to this kind of bonding.

The net charge on a coordination complex is the sum of the charges on the metal and its attached groups. Complexes can be cations (as in the two nickel complexes used as examples here), anions, or neutral species; that is, they could have no net charge.

Ligands such as H_2O and NH_3, which coordinate to the metal via a single Lewis base atom, are termed **monodentate**. The word "dentate" comes from the Latin word *dentis*, meaning "tooth," so NH_3 is a "one-toothed" ligand. Some ligands—called **polydentate** ligands—attach to the metal with more than one donor atom. Ethylenediamine (1,2-diaminoethane), $H_2NCH_2CH_2NH_2$, often abbreviated as en; oxalate ion, $C_2O_4^{2-}$ (ox^{2-}); and phenanthroline, $C_{12}H_8N_2$ (phen) are examples of **bidentate** ligands (Figure 22.12). Structures and examples of some complex ions with bidentate ligands are shown in Figure 22.13.

Polydentate ligands are also called **chelating ligands**, or just *chelates* (pronounced "key-lates"). The name derives from the Greek *chele*, meaning "claw." Because two or more bonds need to be broken to separate the ligand from the metal,



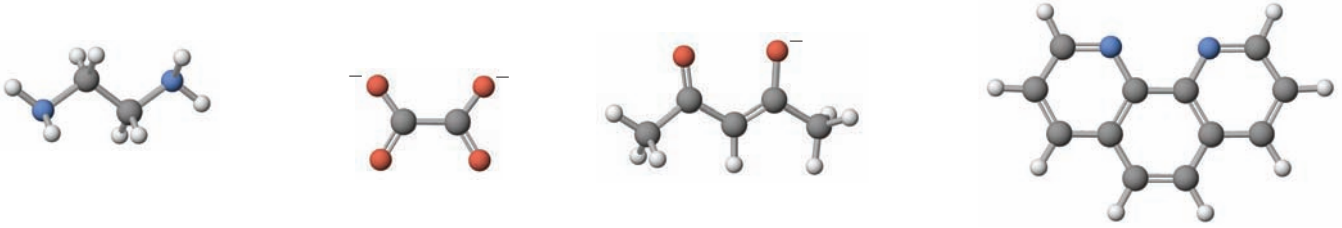


Figure 22.11 A coordination complex. In the $[Ni(NH_3)_6]^{2+}$ ion, the ligands are NH_3 molecules. Because the metal has a 2+ charge and the ligands have no charge, the charge on the complex ion is 2+.

Ligands Are Lewis Bases Ligands are Lewis bases because they furnish the electron pair; the metal ion is a Lewis acid because it accepts electron pairs (Section 16.10). Thus, the coordinate covalent bond between ligand and metal can be viewed as a Lewis acid–Lewis base interaction.

Bidentate Ligands All common bidentate ligands bind to *adjacent* sites on the metal.

$[Fe(C_2O_4)_3]^{3-}$ $[Co(en)_3]^{3+}$ $Cr(acac)_3$

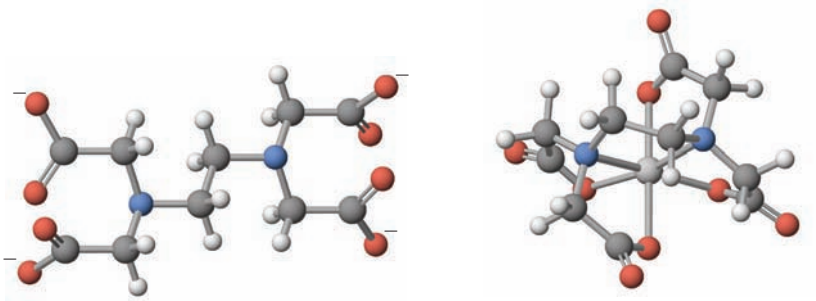

Figure 22.13 Complex ions with bidentate ligands. The three ligands shown are the oxalate anion ($C_2O_4^{2-}$), ethylenediamine (en), and the acetylacetonate anion (acac) (Figure 22.12).

complexes with chelated ligands often have greater stability than those with monodentate ligands. Complexes with chelating ligands are important in everyday life. For example, one way to clean the rust out of water-cooled automobile engines and steam boilers is to add a solution of oxalic acid. Iron(III) oxide reacts with oxalic acid to give a water-soluble iron oxalate complex ion:

$$3\ H_2O(\ell) + Fe_2O_3(s) + 6\ H_2C_2O_4(aq) \longrightarrow 2\ [Fe(C_2O_4)_3]^{3-}(aq) + 6\ H_3O^+(aq)$$

Ethylenediaminetetraacetate ion ($EDTA^{4-}$), a hexadentate ligand (Figure 22.14), is an excellent chelating ligand because it can wrap around a metal ion, encapsulating it. Salts of this anion are often added to commercial salad dressings to remove traces of free metal ions from solution; otherwise, these metal ions could act as catalysts for the oxidation of the oils in the dressing. Without $EDTA^{4-}$, the dressing would quickly become rancid. Another use is in bathroom cleansers. The $EDTA^{4-}$ ion removes deposits of $CaCO_3$ and $MgCO_3$ left by hard water by coordinating to Ca^{2+} or Mg^{2+} ions to create soluble complex ions.

Complexes with polydentate ligands play particularly important roles in biochemistry, one example of which is described in *A Closer Look: Hemoglobin: A Molecule with a Tetradentate Ligand.*

A CLOSER LOOK

Hemoglobin: A Molecule with a Tetradentate Ligand

Metal-containing coordination compounds figure prominently in many biochemical reactions. Perhaps the best-known example is hemoglobin, the molecule responsible for O_2 transport in the blood. It is also one of the most thoroughly studied bioinorganic compounds.

Hemoglobin (Hb) is a large iron-containing protein (Figure 24.4). It includes four polypeptide segments, each containing an iron(II) ion locked inside a porphyrin ring system and coordinated to a nitrogen atom from another part of the protein. A sixth site is available to attach to oxygen.

Hemoglobin functions by reversibly adding oxygen to the sixth coordination position of each iron, giving a complex called *oxyhemoglobin*.

Because hemoglobin features four iron centers, a maximum of four molecules of oxygen can bind to the molecule. The binding to oxygen is cooperative; that is, binding one O_2 molecule enhances the tendency to bind the second, third, and fourth O_2 molecules. Formation of the oxygenated complex is favored, but not too highly, because oxygen must also be released by the molecule to body tissues. Interestingly, an increase in acidity leads to a decrease in the stability of the oxygenated complex. This phenomenon is known as the *Bohr effect*, named for Christian Bohr, the father of Niels Bohr (Section 6.3). Release of oxygen in tissues is facilitated by an increase in acidity that results from the presence of CO_2 formed by metabolism.

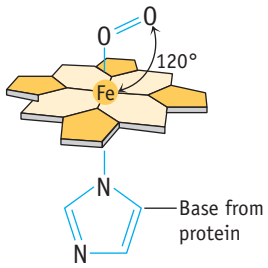

Figure Oxygen binding. Oxygen binds to the iron of the heme group in oxyhemoglobin (and in myoglobin). Interestingly, the Fe—O—O angle is bent.

Among the properties of hemoglobin is its ability to form a complex with carbon monoxide. This complex is very stable, with the equilibrium constant for the following reaction being about 200 (where Hb is hemoglobin):

$$HbO_2(aq) + CO(g) \rightleftharpoons HbCO(aq) + O_2(g)$$

When CO complexes with iron, the oxygen-carrying capacity of hemoglobin is lost. Consequently, CO is highly toxic to humans. Exposure to even small amounts greatly reduces the capacity of the blood to transport oxygen.

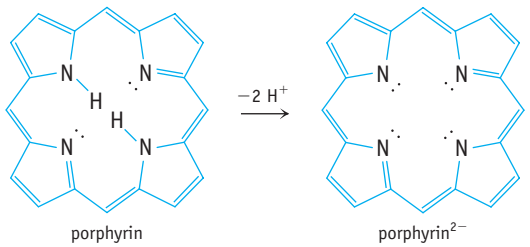

Figure Porphyrin ring of the heme group. The tetradentate ligand surrounding the iron(II) ion in hemoglobin is a dianion of a molecule called a *porphyrin*. Because of the double bonds in this structure, all of the carbon and nitrogen atoms in the dianion of the porphyrin lie in a plane. In addition, the nitrogen lone pairs are directed toward the center of the ion, and the molecular dimensions are such that a metal ion may fit nicely into the cavity.

Formulas of Coordination Compounds

It is useful to be able to predict the formula of a coordination complex, given the metal ion and ligands, and to derive the oxidation number of the coordinated metal ion, given the formula of a coordination compound. The following examples explore these issues.

EXAMPLE 22.1

Formulas of Coordination Complexes

Problem Give the formula for each of the following coordination complexes:

(a) A Ni^{2+} ion is bound to two water molecules and two bidentate oxalate ions.

(b) A Co^{3+} ion is bound to one Cl^- ion, one ammonia molecule, and two bidentate ethylenediamine (en) molecules.

What Do You Know? The composition of each coordination complex is given.

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Strategy The problem requires determining the net charge, which equals the sum of the charges of the various parts of the complex ion. With that information, the metal and ligands can be assembled in the formula, which is placed in brackets, and the net charge indicated.

SOLUTION

(a) This complex ion is constructed from two neutral H_2O molecules, two $C_2O_4^{2-}$ ions, and one Ni^{2+} ion, so the net charge on the complex is 2−. The formula for the complex ion is

$$[Ni(C_2O_4)_2(H_2O)_2]^{2-}$$

(b) This cobalt(III) complex ion combines two ethylenediamine molecules and one NH_3 molecule, none having a charge, as well as one Cl^- ion and a Co^{3+} ion. Thus, the net charge is 2+. The formula for this complex (writing out the formula for ethylenediamine) is

$$[Co(H_2NCH_2CH_2NH_2)_2(NH_3)Cl]^{2+}$$

Think about Your Answer Enclosing the formula of a complex in brackets is done to designate that this is a single unit. Species outside the brackets are counterions (when shown).

Check Your Understanding

(a) What is the formula of a complex ion composed of one Co^{3+} ion, three ammonia molecules, and three Cl^- ions?

(b) What is the formula for the coordination complex of an Fe^{2+} ion having two ethylenediamine ligands and two bromide ion ligands?

EXAMPLE 22.2

Coordination Compounds

Problem In each of the following coordination complexes, determine the metal's oxidation number and coordination number.

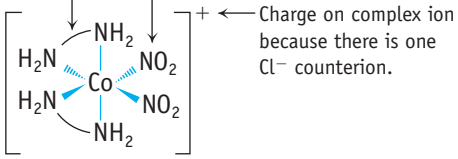
(a) $[Co(en)_2(NO_2)_2]Cl$

(b) $Pt(NH_3)_2(C_2O_4)$

(c) $Pt(NH_3)_2Cl_4$

(d) $[Co(NH_3)_5Cl]SO_4$

What Do You Know? The oxidation number is the charge that must be present on the metal ion. The coordination number is the number of ligand attachments to the metal. Remember that bidentate ligands coordinate to two adjacent positions.



Strategy Each formula consists of a complex ion or molecule made up of the metal ion, neutral, and anionic ligands. Counterions (shown outside the square brackets) may also be present. The oxidation number of the metal is the charge necessary to balance the sum of the negative charges associated with any anionic ligands and counterions. The coordination number is the number of donor atoms in the ligands that are bonded to the metal. Remember that bidentate ligands in these examples (en, oxalate ion) attach to the metal at two sites and any counterions present are not part of the complex ion—that is, they are not ligands.

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

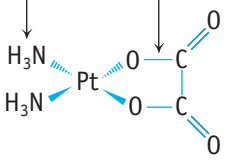
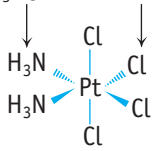
SOLUTION



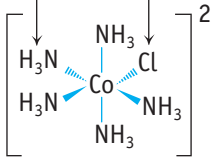
(a) Two neutral en ligands; Two NO_2^- ligands

← Charge on complex ion because there is one Cl^- counterion.



The central cobalt ion has a 3+ charge and the coordination number is 6.

(b) Two neutral NH_3 ligands; One $C_2O_4^{2-}$ ligand



The central platinum ion has a 2+ charge and the coordination number is 4.

(c) Two neutral NH_3 ligands; Four Cl^- ligands

The central platinum ion has a 4+ charge and the coordination number is 6.

(d) Five neutral NH_3 ligands; One Cl^- ligand

← Charge on complex ion because there is one SO_4^{2-} counterion.

The central cobalt ion has a 3+ charge and the coordination number is 6.

Think about Your Answer Knowing the oxidation state of the metal in a coordination compound is important. From this, you can determine the electron configuration of the metal. As you will see in Sections 22.6 and 22.7, this information is needed to determine important properties of a complex such as magnetism and color.

Check Your Understanding

(a) Determine the metal's oxidation number and coordination number in (i) $K_3[Co(NO_2)_6]$ and in (ii) $Mn(NH_3)_4Cl_2$.

(b) Determine the oxidation number and coordination number of cobalt in the complex $NH_4[Co(EDTA)]$.

Naming Coordination Compounds

Coordination compounds are named according to an established system. The three compounds below are named according to the rules that follow.

Compound	Systematic Name
$[Ni(H_2O)_6]SO_4$	Hexaaquanickel(II) sulfate
$[Cr(en)_2(CN)_2]Cl$	Dicyanobis(ethylenediamine)chromium(III) chloride
$K[Pt(NH_3)Cl_3]$	Potassium amminetrichloroplatinate(II)

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

1. Name the cation first and then the anion. (This is how all salts are commonly named.)
2. When giving the name of the complex ion or molecule, name the ligands first, in alphabetical order, followed by the name of the metal. (When determining the alphabetical order of the ligands, ignore any prefix.)
3. Ligands and their names:
   (a) If a ligand is an anion whose name ends in *-ite* or *-ate*, the final *e* is changed to *o* (sulfate ⟶ sulfato or nitrite ⟶ nitrito).
   (b) If the ligand is an anion whose name ends in *-ide*, the ending is changed to *o* (chloride ⟶ chloro, cyanide ⟶ cyano).
   (c) If the ligand is a neutral molecule, its common name is usually used with several important exceptions: Water as a ligand is referred to as *aqua;* ammonia is called *ammine;* and CO is called *carbonyl.*
   (d) When there is more than one of a particular monodentate ligand with a simple name, the number of ligands is designated by the appropriate prefix: *di*, *tri*, *tetra*, *penta*, or *hexa*. If the ligand name is complicated (such as ethylenediamine), the prefix changes to *bis*, *tris*, *tetrakis*, *pentakis*, or *hexakis*, followed by the ligand name in parentheses.
4. If the coordination complex is an anion, the suffix *-ate* is added to the metal name.
5. Following the name of the metal, the oxidation number of the metal is given in Roman numerals.

Common Monodentate Ligands and Their Names

Ligand	Name
F^-	fluoro
Cl^-	chloro
Br^-	bromo
I^-	iodo
H_2O	aqua
NH_3	ammine
CO	carbonyl
CN^-	cyano
OH^-	hydroxo
$—NO_2^-$	nitro

EXAMPLE 22.3

Naming Coordination Compounds

Problem Name the following compounds:

(a) $[Cu(NH_3)_4]SO_4$ (c) $Co(phen)_2Cl_2$

(b) $K_2[CoCl_4]$ (d) $[Co(en)_2(H_2O)Cl]Cl_2$

What Do You Know? The formula of each compound is given.

Strategy Apply the rules for nomenclature given above.

SOLUTION

(a) The complex ion (in square brackets) is composed of four NH_3 molecules (named *ammine* in a complex) and the copper ion. To balance the 2− charge on the sulfate counterion and account for four NH_3 ligands with no charge, copper must have a 2+ charge. The compound's name is

tetraamminecopper(II) sulfate

(b) The complex ion $[CoCl_4]^{2-}$ has a 2− charge to balance two K^+ counterions. With four Cl^- ligands, the cobalt ion must have a 2+ charge, so the sum of charges is 2−. The name of the compound is

potassium tetrachlorocobaltate(II)

(c) This is a neutral coordination compound. The ligands include two Cl^- ions and two neutral bidentate *phen* (phenanthroline) ligands (page 1031). The metal ion must therefore have a 2+ charge (Co^{2+}). The name, listing ligands in alphabetical order, is

dichlorobis(phenanthroline)cobalt(II)

(d) The complex ion has a 2+ charge because it is paired with two uncoordinated Cl^- ions. The cobalt ion is Co^{3+} because it is bonded to two neutral ethylenediamine bidentate ligands, one neutral water, and one Cl^-. The name is

aquachlorobis(ethylenediamine)cobalt(III) chloride

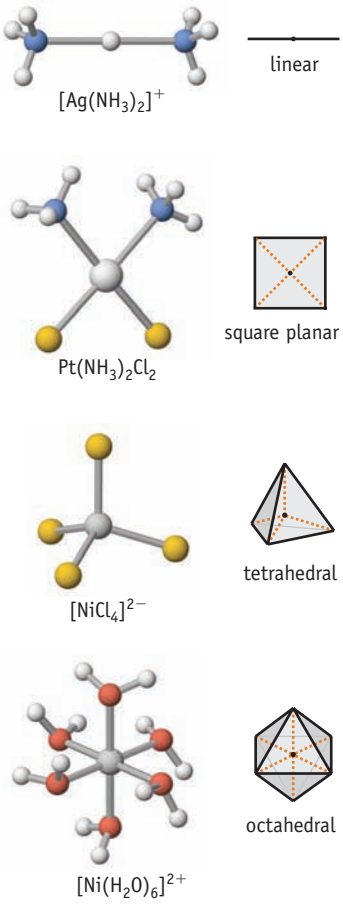
Think about Your Answer The earliest studies of coordination compounds created a colorful array of names, and a few of these are still used (Prussian Blue, mentioned earlier, and Zeise's salt, $K[Pt(C_2H_4)Cl_3]$, are two examples). However, as the depth and breadth of coordination chemistry expands, a systematic nomenclature is essential to communication among scientists working in the area. The rules of nomenclature make it possible for any scientist to derive a formula from the name, or to name a compound given its formula.

Check Your Understanding

Name the following coordination compounds.

(a) $[Ni(H_2O)_6]SO_4$ (b) $[Cr(en)_2(CN)_2]Cl$ (c) $K[Pt(NH_3)Cl_3]$ (d) $K[CuCl_2]$

22.5 Structures of Coordination Compounds



Goals for Section 22.5

- Identify the different types of isomers that are encountered with coordination compounds.
- Given the molecular formula of a complex, determine whether isomers are possible, and draw their structures.

Common Coordination Geometries

The geometry of a coordination complex is defined by the arrangement of donor atoms of the ligands around the central metal ion. Metal ions in coordination compounds can have coordination numbers ranging from 2 to 12. Only complexes with coordination numbers of 2, 4, and 6 are common, however, so we will concentrate on species such as $[ML_2]^{n\pm}$, $[ML_4]^{n\pm}$, and $[ML_6]^{n\pm}$, where M is the metal ion and L is a *monodentate* ligand. For complexes having these stoichiometries, the following geometries are encountered:

- All $[ML_2]^{n\pm}$ complexes are linear. The two ligands are on opposite sides of the metal, and the L—M—L bond angle is 180°. Common examples include $[Ag(NH_3)_2]^+$ and $[CuCl_2]^-$.
- Tetrahedral geometry occurs in many $[ML_4]^{n\pm}$ complexes. Examples include $TiCl_4$, $[CoCl_4]^{2-}$, $[NiCl_4]^{2-}$, and $[Zn(NH_3)_4]^{2+}$.
- Some $[ML_4]^{n\pm}$ complexes have square planar geometry. This geometry is most often found for metal ions that have eight *d* electrons. Examples include $Pt(NH_3)_2Cl_2$, $[Ni(CN)_4]^{2-}$, and the nickel complex with the dimethylglyoximate (dmg^-) ligand in Figure 22.10.
- Octahedral geometry is found in complexes with the stoichiometry $[ML_6]^{n\pm}$ (Figure 22.10).

Common Coordination Geometries

Isomerism

Isomers are compounds with the same molecular formulas but different arrangements of atoms. There are several forms of isomerism.

- *Structural isomers* have the same molecular formula but different bonding arrangements of atoms.
- *Stereoisomers* have the same atom-to-atom bonding sequence, but the atoms differ in their arrangement in space. There are two types of stereoisomerism: *geometric isomerism* and *optical isomerism*.

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

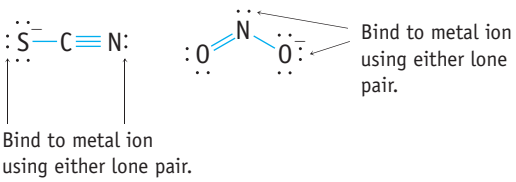
All three types of isomerism—structural, geometric, and optical—are encountered in coordination chemistry.

Structural Isomerism

$[Ag(NH_3)_2]F$ in Dentistry The cation $[Ag(NH_3)_2]^+$ is one of the few linear coordination compounds, and, interestingly, the fluoride-containing salt is the latest in dental care. Brushing $[Ag(NH_3)_2]F$ onto a cavity is found to stop further decay. Particularly with children, this quick, easy, painless treatment of a dental cavity is often preferable to traditional drilling and filling with a mercury amalgam. In addition, silver ions released by the complex ion kill cavity-forming bacteria in the mouth, and the F^- ion promotes fluoroapatite formation.



The two most important types of structural isomerism in coordination chemistry are coordination isomerism and linkage isomerism. **Coordination isomerism** occurs by exchanging a coordinated ligand and the uncoordinated counterion. For example, dark violet $[Co(NH_3)_5Br]SO_4$ and red $[Co(NH_3)_5SO_4]Br$ are coordination isomers. In the first compound, bromide ion is a ligand and sulfate is a counterion; in the second, sulfate is a ligand and bromide is the counterion. A diagnostic test for this kind of isomer is often made based on precipitation reactions. Addition of $Ba^{2+}(aq)$ to a solution of $[Co(NH_3)_5Br]SO_4$ gives a precipitate of $BaSO_4$, indicating the presence of sulfate ion in solution. In contrast, no reaction occurs if $Ba^{2+}(aq)$ is added to a solution of $[Co(NH_3)_5SO_4]Br$. In this complex, sulfate ion is attached to Co^{3+} and is not a free ion in solution.

$$[Co(NH_3)_5Br]SO_4 + Ba^{2+}(aq) \longrightarrow BaSO_4(s) + [Co(NH_3)_5Br]^{2+}(aq)$$

$$[Co(NH_3)_5SO_4]Br + Ba^{2+}(aq) \longrightarrow \text{no reaction}$$

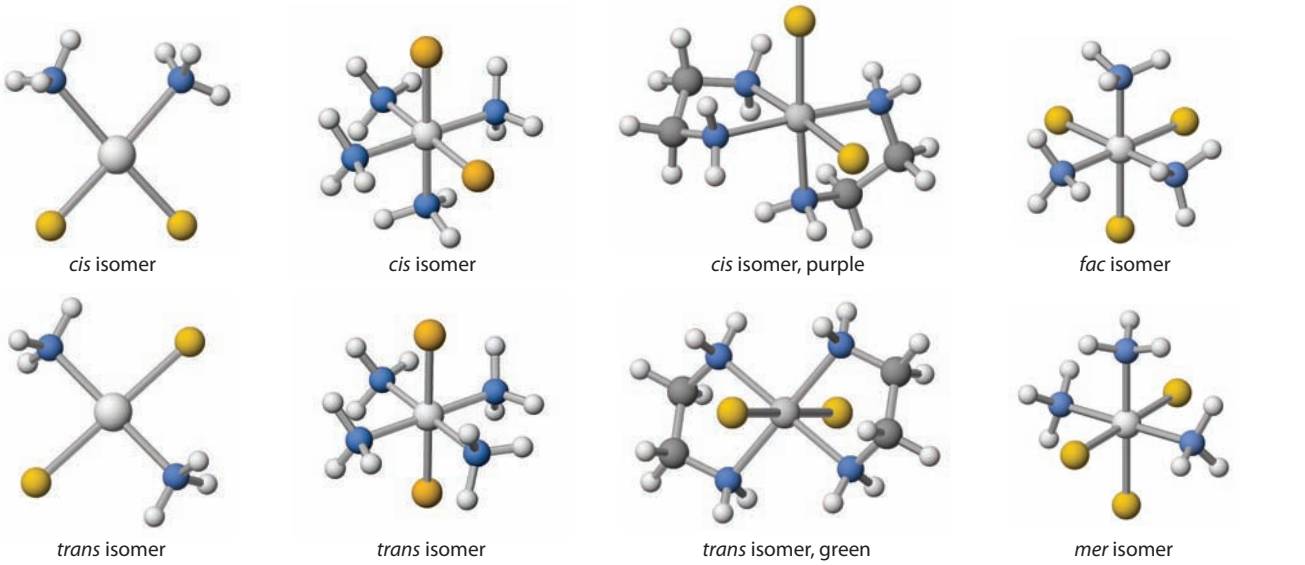
Linkage isomerism occurs when it is possible to attach a ligand to the metal through different atoms. The two most common ligands with which linkage isomerism arises are thiocyanate, SCN^-, and nitrite, NO_2^-. The Lewis structure of the thiocyanate ion shows that there are lone pairs of electrons on sulfur and nitrogen. The ligand can attach to a metal either through a sulfur lone pair (called *S-bonded thiocyanate*) or through a nitrogen lone pair (called *N-bonded thiocyanate*). Nitrite ion can attach either at oxygen or at nitrogen. The former are called nitrito complexes; the latter are nitro complexes (Figure 22.15).

Ligands forming linkage isomers

***Cis–Trans* Isomerism** *Cis–trans* isomerism is not possible for tetrahedral complexes. All L—M—L angles are 109.5°, and all positions are equivalent in this three-dimensional structure.

Geometric Isomerism

Geometric isomerism results when the atoms bonded directly to the metal have a different spatial arrangement. The simplest example of geometric isomerism in coordination chemistry is *cis–trans* isomerism, which occurs in both square-planar and octahedral complexes. The square-planar complex $Pt(NH_3)_2Cl_2$ is an example of



© Cengage Learning/Charles D. Winters

Figure 22.15 Linkage isomers, $[Co(NH_3)_5ONO]^{2+}$ and $[Co(NH_3)_5NO_2]^{2+}$. These complex ions, whose systematic names are pentaamminenitritocobalt(III) and pentaamminenitrocobalt(III), respectively, were the first known examples of this type of isomerism. (The compounds shown in this figure have two chloride ions as counterions.)

(a) The square-planar complex $Pt(NH_3)_2Cl_2$ can exist in two geometries, *cis* and *trans*.

(b) *Cis* and *trans* octahedral isomers for $[Co(NH_3)_4Cl_2]^+$.

(c) *Cis* and *trans* octahedral isomers for $[Co(en)_2Cl_2]^+$.

(d) *Fac* and *mer* isomers of $Cr(NH_3)_3Cl_3$: *fac* isomer, the three identical ligands are arranged at the corners of a triangular face. In the *mer* isomer, the three similar ligands follow a meridian.

Figure 22.16 **Geometric isomers.**

cis–trans isomerism (Figure 22.16a). In this complex, the two Cl^- ions can be either adjacent to each other (*cis*) or on opposite sides of the metal (*trans*). The *cis* isomer is effective in the treatment of testicular, ovarian, bladder, and osteogenic sarcoma cancers, but the *trans* isomer has no effect on these diseases (*Applying Chemical Principles: 22.2 Cisplatin: Accidental Discovery of a Chemotherapy Agent*).

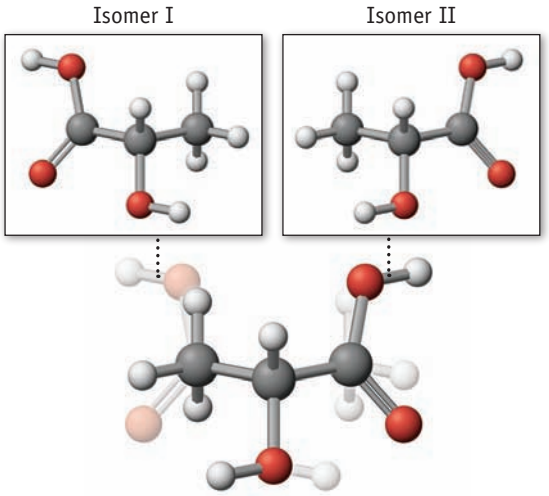
Cis–trans isomerism occurs in octahedral complexes with the formula MA_4B_2. In the complex $[Co(NH_3)_4Cl_2]^+$ the two Cl^- ions can occupy positions that are either adjacent (Cl—Co—Cl angle = 90°) or on opposite sides of the metal (Cl—Co—Cl angle = 180°) (Figure 22.16b).

Cis–trans isomerism in an octahedral complex with two bidentate ethylenediamine ligands is illustrated by $[Co(H_2NCH_2CH_2NH_2)_2Cl_2]^+$. The two Cl^- ions occupy positions that are either adjacent (the purple *cis* isomer) or opposite (the green *trans* isomer) (Figure 22.16c).

Another common type of geometric isomerism occurs for octahedral complexes with the general formula MA_3B_3. A *fac* isomer has three identical ligands lying at the corners of a triangular face of an octahedron defined by the ligands (*fac* = facial), whereas the ligands follow a meridian in the *mer* isomer (*mer* = meridional). *Fac* and *mer* isomers of $Cr(NH_3)_3Cl_3$ are shown in Figure 22.16d.

Optical Isomerism

Optical isomerism is a second type of stereoisomerism. Optical isomers are molecules that have nonsuperimposable mirror images. Molecules that have nonsuperimposable mirror images are termed **chiral**. Pairs of nonsuperimposable, mirror-image molecules are called **enantiomers**.



In chemistry a common model for chirality is a carbon-based compound with four different groups attached to the C atom (Figure 22.17). One enantiomer is a mirror image of the other, and the two enantiomers cannot be superimposed. (Chirality occurs widely in organic and biochemistry chemistry and will be discussed in Chapters 23 and 24.)

There are many examples of chirality in non-chemical contexts. Seashells, for example, may spiral in different directions, giving left-handed and right-handed

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Figure 22.17 **Stereoisomerism in chemistry and nature.**

Lactic acid enantiomers are nonsuperimposable, just as your right hand is not superimposable on your left.

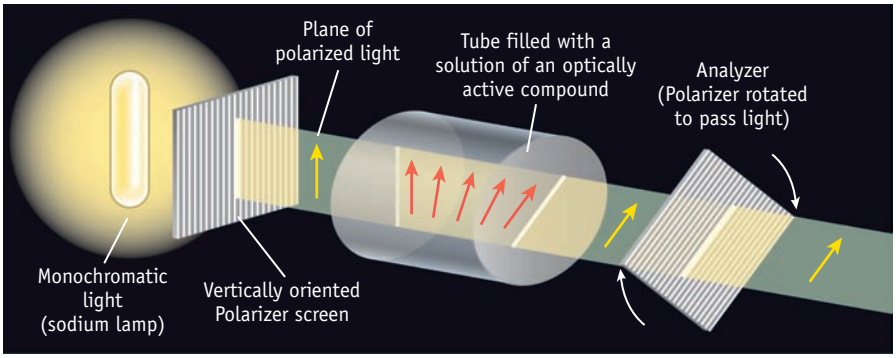
Steven Hyatt

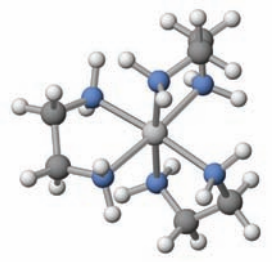
Left- and right-handed seashells (of different species)

shells (Figure 22.17). Bolts and screws can also have left-handed or right-handed threads.

Pure samples of enantiomers have the same physical properties, such as melting point, boiling point, density, and solubility in common solvents, but they differ in a significant way: When a beam of plane-polarized light passes through a solution of a pure enantiomer, the plane of polarization rotates (Figure 22.18). The two enantiomers rotate polarized light to an equal extent, but do so in opposite directions. The term optical isomerism is used because this effect involves light.

Optical isomerism (chirality) occurs for octahedral complexes when the metal ion coordinates to three bidentate ligands or when the metal ion coordinates to two bidentate ligands and two monodentate ligands in a *cis* position. The complexes $[Co(en)_3]^{3+}$ and *cis*-$[Co(en)_2Cl_2]^+$, illustrated in Figure 22.19, are examples of chiral complexes. The diagnostic test for chirality is met with both species: Mirror images of these molecules are not superimposable on one another, and solutions of the optical isomers rotate plane-polarized light in opposite directions.





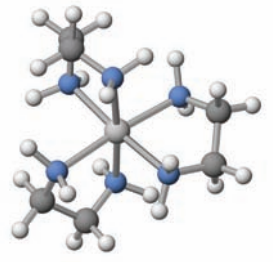


Figure 22.18 **Rotation of plane polarized light by an optical isomer.** Monochromatic light (light of only one wavelength) is produced by a sodium lamp. After it passes through a polarizing filter, the light vibrates in only one direction—it is polarized. A solution of an optical isomer placed between the first and second polarizing filters causes rotation of the plane of polarized light. The second filter is rotated to a point where a maximum of light is transmitted and the angle of rotation is calculated. The magnitude and direction of rotation are unique physical properties of the optical isomer being tested.

EXAMPLE 22.4

Isomerism in Coordination Chemistry

Problem For which of the following compounds or complex ions do isomers exist? If isomers are possible, identify the type of isomerism (structural, geometric, or optical).

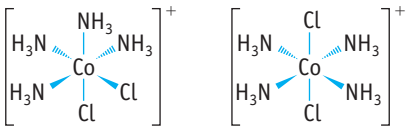
(a) $[Co(NH_3)_4Cl_2]^+$

(b) $Pt(NH_3)_2(CN)_2$ (square-planar)

(c) $Co(NH_3)_3Cl_3$

(d) $K_3[Fe(C_2O_4)_3]$

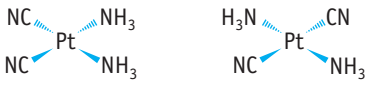
(e) $Zn(NH_3)_2Cl_2$ (tetrahedral)



(f) $[Co(NH_3)_5SCN]^{2+}$

What Do You Know? You can infer coordination number and geometry from the formulas. Structural isomers are those for which there are different attachments of atoms; geometric isomers are those in which the spatial arrangement of atoms is different. Complexes that are optically active have nonsuperimposable mirror images.

Strategy Determine the number of ligands attached to the metal and decide whether the ligands are monodentate or bidentate. Knowing how many donor atoms are coordinated to the metal (the coordination number) will allow you to establish the metal geometry. The only stereoisomerism possible for square-planar complexes is geometric (*cis* and *trans*). Tetrahedral coordination complexes do not have geometric or optical isomers. Six-coordinate complexes of the formula MA_4B_2 can be either *cis* or *trans*. *Mer* and *fac* isomers are possible with a stoichiometry of MA_3B_3. Optical activity arises for metal complexes of the formula *cis*-M(bidentate)$_2X_2$ and M(bidentate)$_3$. Drawing pictures of the molecules will help you visualize the isomers.

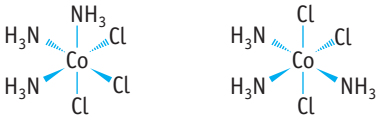


SOLUTION

(a) Two geometric isomers can be drawn for octahedral complexes with a formula of MA_4B_2. One isomer has two Cl^- ions in *cis* positions (adjacent positions, at a 90° angle), and the other isomer has the Cl^- ligands in *trans* positions (with a 180° angle between the ligands). Optical isomers are not possible.

cis isomer *trans* isomer

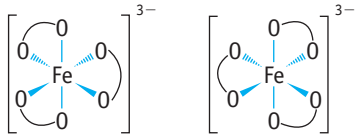
(b) In this square-planar complex, the two NH_3 ligands (and the two CN^- ligands) can be either *cis* or *trans*. These are geometric isomers. Optical isomers are not possible.



cis isomer *trans* isomer

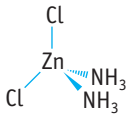
Optical Isomerism Square-planar complexes are incapable of optical isomerism based at the metal center; mirror images are always superimposable. Chiral tetrahedral complexes are possible, but examples of complexes with a metal bonded tetrahedrally to four different monodentate ligands are rare.

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203



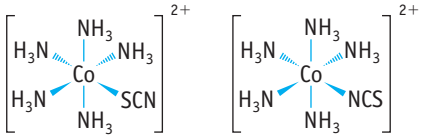
Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

(c) Two geometric isomers of this octahedral complex, with chloride ligands either *fac* or *mer*, are possible. In the *fac* isomer, the three Cl^- ligands are all at 90° to each other; in the *mer* isomer, two Cl^- ligands are at 180°, and the third is 90° from the other two. Optical isomers are not possible.



fac isomer *mer* isomer

(d) Ignore the counterions, K^+. The anion is an octahedral complex. Remember that the bidentate oxalate ion occupies two adjacent coordination sites of the metal, and that three oxalate ligands means that the metal has a coordination number of 6. Mirror images of complexes of the stoichiometry M(bidentate)$_3$ (Figure 22.19) are not superimposable; therefore, two optical isomers are possible. (Here the ligands, $C_2O_4^{2-}$, are drawn abbreviated as O—O.)



nonsuperimposable mirror images of $[Fe(ox)_3]^{3-}$

(e) Only a single structure is possible for tetrahedral complexes such as $Zn(NH_3)_2Cl_2$.

(f) Only linkage isomerism (structural isomerism) is possible for this octahedral cobalt complex. Either the sulfur or the nitrogen of the SCN^- anion can be attached to the cobalt(III) ion in this complex.

S-bonded SCN^- N-bonded SCN^-

Think about Your Answer More complex situations occur when a complex has three or more different ligands. In those instances it is important to be able to visualize the three-dimensional molecule and to organize your approach.

Check Your Understanding

What types of isomers are possible for the following compounds or complex ions?

(a) $K[Co(NH_3)_2Cl_4]$

(b) $Pt(en)Cl_2$ (square-planar)

(c) $[Co(NH_3)_5Cl]^{2+}$

(d) $[Ru(phen)_3]Cl_3$

(e) $Na_2[MnCl_4]$ (tetrahedral)

(f) $[Co(NH_3)_5NO_2]^{2+}$

22.6 Bonding in Coordination Compounds

Goals for Section 22.6

- Use ligand field theory to describe metal-ligand bonding in coordination compounds.
- Draw an energy level diagram representing splitting of the metal *d* orbitals by the ligand field.
- Predict and rationalize magnetism in coordination complexes.

Metal–ligand bonding in a coordination complex was described earlier in this chapter as being covalent, resulting from the sharing of an electron pair between the metal and the ligand donor atom. Although frequently used, this description is not capable of explaining the color and magnetic behavior of these complexes. As a consequence, the covalent bonding picture has now largely been superseded by two other bonding models: molecular orbital theory and ligand field theory.

The bonding model based on molecular orbital theory assumes that the metal and the ligand bond through the molecular orbitals formed by atomic orbital overlap between metal and ligand. The **ligand field model**, in contrast, focuses on repulsion (and destabilization) of electrons in the metal coordination sphere. The ligand field model also assumes that the positive metal ion and the negative ligand lone pair are attracted electrostatically; that is, the bond results from the attraction between a positively charged metal ion and a negative ion or the negative end of a polar molecule. For the most part, the molecular orbital and ligand field models predict similar, qualitative results regarding color and magnetic behavior. Here, we will focus on the ligand field approach and illustrate how it explains the color and magnetic behavior of transition metal complexes.

The *d* Orbitals: Ligand Field Theory

To understand ligand field theory, it is necessary to look at the *d* orbitals (Figure 22.20), specifically with regard to their orientation relative to the positions of ligands in a metal complex.

In an isolated atom or ion, the five *d* orbitals have the same energy. For a metal atom or ion in a coordination complex, however, the *d* orbitals have different energies. According to the ligand field model, repulsion between *d* electrons on the metal and electron pairs of the ligands destabilizes electrons that reside in the *d* orbitals; that is, it causes the orbital energy to increase. Electrons in the various *d* orbitals are not affected equally, however, because of their different orientations in space relative to the position of the ligand lone pairs.

We look first at octahedral complexes. Assume the ligands in an octahedral complex lie along the *x*-, *y*-, and *z*-axes. This results in the five *d* orbitals being subdivided into two sets: the $d_{x^2-y^2}$ and d_{z^2} orbitals in one set and the d_{xy}, d_{xz}, and d_{yz} orbitals in the second (Figure 22.20). The $d_{x^2-y^2}$ and d_{z^2} orbitals are directed along

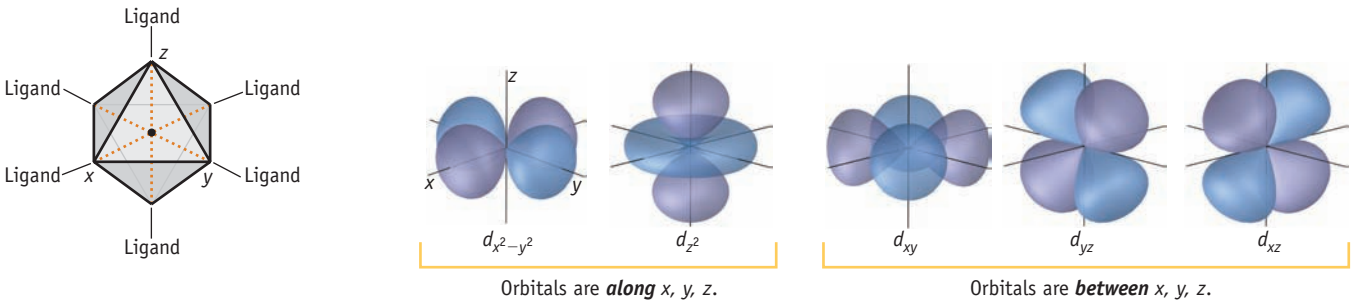

Figure 22.20 The *d* orbitals. The five *d* orbitals and their spatial relation to the ligands on the *x*-, *y*-, and *z*-axes.

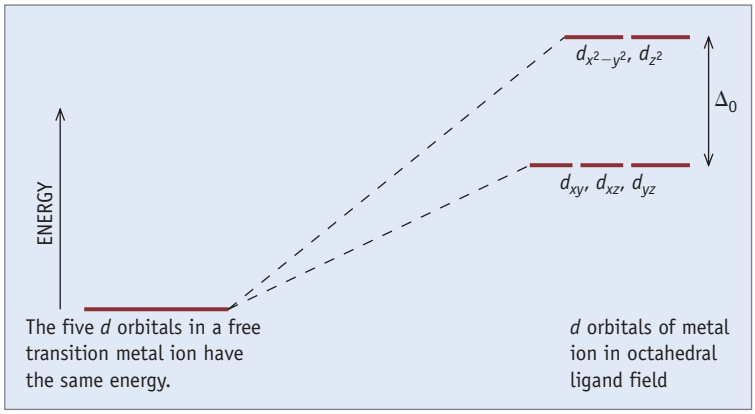

Figure 22.21 Ligand field splitting for an octahedral complex. The *d*-orbital energies increase as the ligands approach the metal along the *x*-, *y*-, and *z*-axes. The d_{xy}, d_{xz}, and d_{yz} orbitals, not pointed toward the ligands, are less destabilized than the $d_{x^2-y^2}$ and d_{z^2} orbitals. Thus, the d_{xy}, d_{xz}, and d_{yz} orbitals are at lower energy. (Δ_0 stands for the splitting of *d* orbital energies in an octahedral ligand field.)

the *x*-, *y*-, and *z*-axes, whereas the orbitals of the second group are aligned between these axes. Electrons in the $d_{x^2-y^2}$ and d_{z^2} orbitals experience a larger repulsion because these orbitals point directly at the ligand electron pairs. A smaller repulsive effect is experienced by electrons in the d_{xy}, d_{xz}, and d_{yz} orbitals. The difference in degree of repulsion means that an energy difference exists between the two sets of orbitals in an octahedral complex (Figure 22.21). This difference, called the **ligand field splitting** and denoted by the symbol Δ_0, is a function of the metal and the ligands and varies predictably from one complex to another.

A different splitting pattern is encountered with square-planar complexes (Figure 22.22). Assume that the four ligands are along the *x*- and *y*-axes. The $d_{x^2-y^2}$ orbital also points along these axes, so it has the highest energy. The d_{xy} orbital (which also lies in the *xy*-plane, but does not point at the ligands) is next highest in energy, followed by the d_{z^2} orbital. The d_{xz} and d_{yz} orbitals, both of which partially point in the *z*-direction, have the lowest energy.

The *d*-orbital splitting pattern for a tetrahedral complex is the reverse of the pattern observed for octahedral complexes. Three orbitals (d_{xz}, d_{xy}, d_{yz}) are higher in energy, whereas the $d_{x^2-y^2}$ and d_{z^2} orbitals are below them in energy (Figure 22.22).

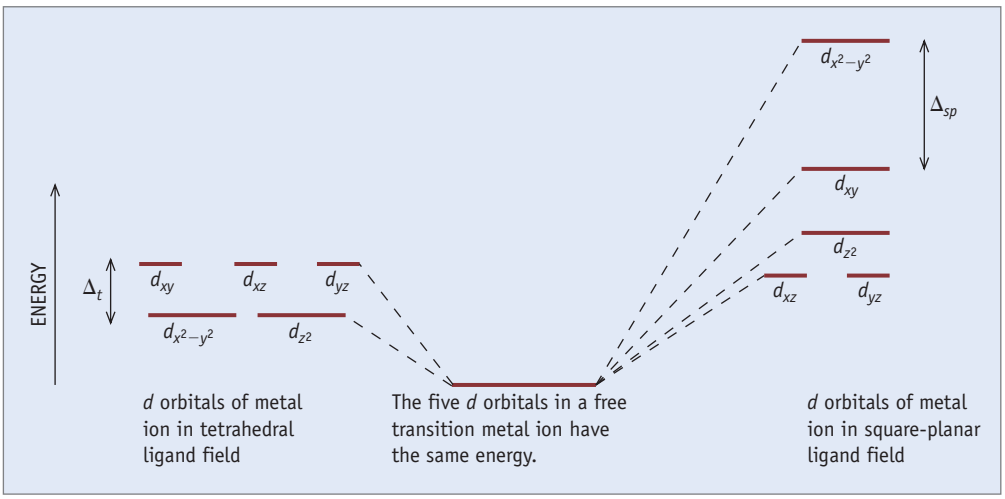

Figure 22.22 Splitting of the *d* orbitals in *(left)* tetrahedral and *(right)* square-planar geometries. (Δ_t and Δ_{sp} are, respectively, the splitting in tetrahedral and square-planar ligand fields.)

Electron Configurations and Magnetic Properties

The *d*-orbital splitting in coordination complexes provides an explanation of both the magnetic behavior and the color of these complexes. To understand this explanation, however, we must first understand how to assign electrons to the various orbitals in each geometry.

A gaseous Cr^{2+} ion has the electron configuration $[Ar]3d^4$. The term *gaseous* in this context is used to denote a single, isolated atom or ion with all other particles located an infinite distance away. In this situation, the five 3*d* orbitals have the same energy. The four electrons reside singly in different *d* orbitals, according to Hund's rule, and the Cr^{2+} ion has four unpaired electrons.

When the Cr^{2+} ion is part of an octahedral complex, the five *d* orbitals do not have identical energies. As illustrated in Figure 22.21, these orbitals divide into two sets, with the d_{xy}, d_{xz}, and d_{yz} orbitals having a lower energy than the $d_{x^2-y^2}$ and d_{z^2} orbitals. Having two sets of orbitals means that two different electron configurations are possible for Cr^{2+} (Figure 22.23). Three of the four *d* electrons in Cr^{2+} are assigned to the lower-energy d_{xy}, d_{xz}, and d_{yz} orbitals. The fourth electron either can be assigned to an orbital in the higher-energy $d_{x^2-y^2}$ and d_{z^2} set or can pair up with an electron already in the lower-energy set. The first arrangement is called **high spin**, because it has the maximum number of unpaired electrons, four in the case of Cr^{2+}. The second arrangement is called **low spin**, because it has the minimum number of unpaired electrons possible.

Paramagnetism Figure 7.4 (page 326) shows the paramagnetic behavior of a compound of Fe^{3+} (a high spin d^5 ion).

At first glance, a high-spin configuration appears to contradict conventional thinking. It seems logical that the most stable situation would occur when electrons occupy the lowest-energy orbitals. A second factor intervenes, however. Because electrons are negatively charged, repulsion increases when they are assigned to the same orbital. This destabilizing effect is due to the **pairing energy (P)**. The preference for an electron to be in the lowest-energy orbital and the pairing energy have opposing effects (Figure 22.23). Low-spin complexes arise when the splitting of the *d* orbitals by the ligand field is large—that is, when Δ_0 has a large value. The energy gained by putting all of the electrons in the lowest-energy level is the dominant effect when $\Delta_0 > P$. In contrast, high-spin complexes occur if the value of Δ_0 is smaller than the energy required to pair electrons ($\Delta_0 < P$).

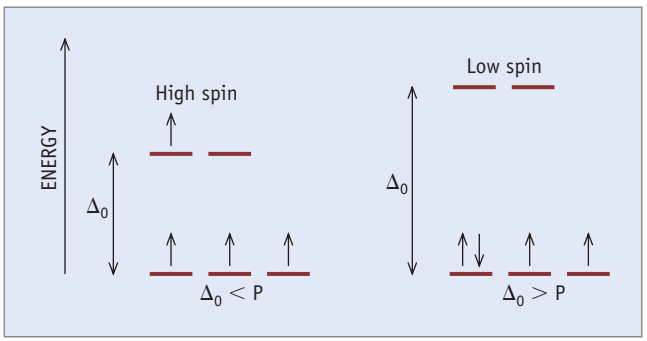

Figure 22.23 High- and low-spin cases for an octahedral chromium(II) complex. *(left, high spin)* If the ligand field splitting (Δ_0) is smaller than the pairing energy (P), the electrons are placed in different orbitals, and the complex has four unpaired electrons. *(right, low spin)* If the splitting is larger than the pairing energy, all four electrons will be in the lower-energy orbital set. This requires pairing two electrons in one of the orbitals, so the complex will have two unpaired electrons.

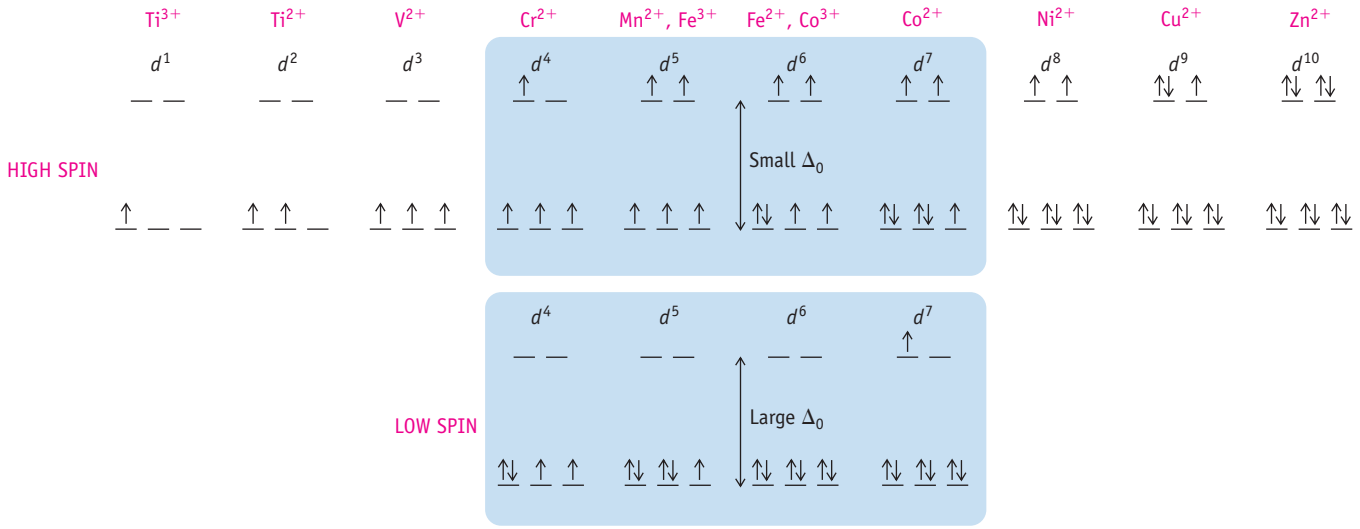

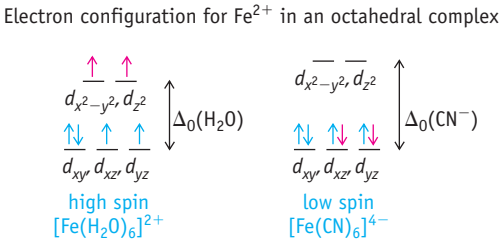

Figure 22.24 High- and low-spin octahedral complexes. *d*-Orbital occupancy for octahedral complexes of metal ions. Only the d^4 through d^7 cases have both high- and low-spin configurations.

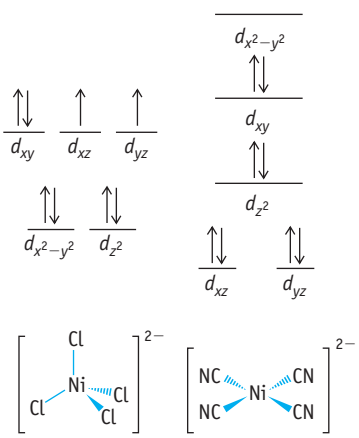

For octahedral complexes, high- and low-spin complexes are possible only for configurations d^4 through d^7 (Figure 22.24). Complexes of the d^6 metal ion, Fe^{2+}, for example, can have either high spin or low spin. The complex formed when the Fe^{2+} ion is placed in water, $[Fe(H_2O)_6]^{2+}$, is high spin, whereas the $[Fe(CN)_6]^{4-}$ complex ion is low spin.

It is possible to tell whether a complex is high or low spin by examining its magnetic behavior. The high-spin complex $[Fe(H_2O)_6]^{2+}$ has four unpaired electrons and is *paramagnetic* (attracted by a magnet), whereas the low-spin $[Fe(CN)_6]^{4-}$ complex has no unpaired electrons and is *diamagnetic* (repelled by a magnet) (Section 7.4).

Most complexes of Pd^{2+} and Pt^{2+} ions are square-planar, the electron configuration of these metals being [noble gas]$(n-1)d^8$. In a square-planar complex, there are four sets of orbitals (Figure 22.22). For square-planar d^8 complexes, all except the highest-energy orbital are filled, and all electrons are paired, resulting in diamagnetic (low-spin) complexes.

Nickel, which is found above palladium in the periodic table, forms both square-planar and tetrahedral complexes (as well as octahedral complexes). For example, the complex ion $[Ni(CN)_4]^{2-}$ is square-planar, whereas the $[NiCl_4]^{2-}$ ion is tetrahedral. Magnetism allows us to differentiate between these two geometries. Based on the ligand field splitting pattern, the cyanide complex is expected to be diamagnetic, whereas the chloride complex is expected to be paramagnetic with two unpaired electrons.

Nickel(II) complexes and magnetism. The anion $[NiCl_4]^{2-}$ is a paramagnetic tetrahedral complex. In contrast, $[Ni(CN)_4]^{2-}$ is a diamagnetic square-planar complex.

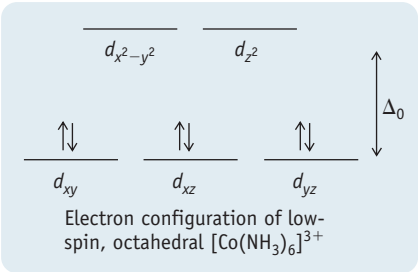
EXAMPLE 22.5

High- and Low-Spin Complexes and Magnetism

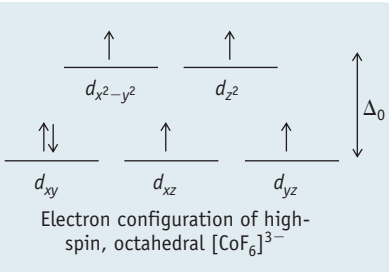
Problem Give the electron configuration for the metal ion in each of the following complexes. How many unpaired electrons are present in each? Are the complexes paramagnetic or diamagnetic?



(a) Low-spin $[Co(NH_3)_6]^{3+}$

(b) High-spin $[CoF_6]^{3-}$

What Do You Know? From their formulas, we know that these have six ligands and we can presume that they have octahedral geometry. Both are complexes of cobalt(III), a metal ion with a d^6 configuration. One complex is low spin, the other high spin.



Strategy Set up an energy-level diagram for an octahedral complex. In low-spin complexes, the electrons are added preferentially to the lower-energy set of orbitals. In high-spin complexes, the first five electrons are added singly to each of the five orbitals, then additional electrons are paired with electrons in orbitals in the lower-energy set.

SOLUTION

Electron configuration of low-spin, octahedral $[Co(NH_3)_6]^{3+}$

(a)

Electron configuration of high-spin, octahedral $[CoF_6]^{3-}$

(b)

(a) The six electrons of the Co^{3+} ion fill the lower-energy set of orbitals entirely. This d^6 complex ion has no unpaired electrons and is diamagnetic.

(b) To obtain the electron configuration in high-spin $[CoF_6]^{3-}$, place one electron in each of the five *d* orbitals, and then place the sixth electron in one of the lower-energy orbitals. The complex has four unpaired electrons and is paramagnetic.

Think about Your Answer The two complexes have different magnetic properties; low-spin $[Co(NH_3)_6]^{3+}$ is diamagnetic and high-spin $[CoF_6]^{3-}$ is paramagnetic to the extent of four unpaired electrons.

Check Your Understanding

For each of the following complex ions, give the oxidation number of the metal, depict possible low- and high-spin configurations, give the number of unpaired electrons in each configuration, and tell whether each is paramagnetic or diamagnetic.

(a) $[Ru(H_2O)_6]^{2+}$

(b) $[Ni(NH_3)_6]^{2+}$

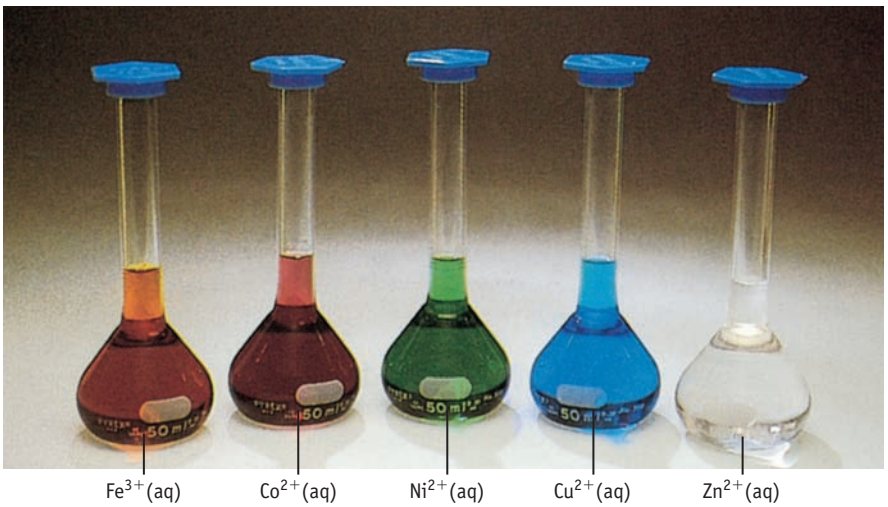
Problem Solving Tip 22.1 Ligand Field Theory

This summary of the concepts of ligand field theory may help you to keep the broader picture in mind.



- Ligand–metal bonding results from the electrostatic attraction between a metal cation and either an anion or a polar molecule.
- The ligands define a coordination geometry. Common geometries are linear (coordination number = 2), tetrahedral and square-planar (coordination number = 4), and octahedral (coordination number = 6).
- The placement of the ligands around the metal causes the *d* orbitals on the metal to have different energies. In an octahedral complex, for example, the *d* orbitals divide into two groups: a higher-energy group ($d_{x^2-y^2}$ and d_{z^2}) and a lower-energy group (d_{xy}, d_{xz}, and d_{yz}).
- Electrons are assigned to metal *d* orbitals in a manner that leads to the lowest total energy. Two competing features determine the placement: the relative energy of the sets of orbitals and the electron pairing energy.
- For the electron configurations of d^4, d^5, d^6, and d^7 in octahedral complexes, two electron configurations are possible: high spin, which occurs when the orbital splitting is small, and low spin, which occurs with a large orbital splitting. To determine whether a complex is high spin or low spin, its magnetism can be measured to determine the number of unpaired electrons.
