Periodic Table of the Elements

Note: Atomic masses are IUPAC values (up to four decimal places). Numbers in parentheses are atomic masses or mass numbers of the most stable isotope of an element.

PART ONE THE BASIC TOOLS OF CHEMISTRY

1 Basic Concepts of Chemistry xxviii

Let's Review: The Tools of Quantitative Chemistry 28

2 Atoms, Molecules, and Ions 58

3 Chemical Reactions 122

4 Stoichiometry: Quantitative Information about Chemical Reactions 172

5 Principles of Chemical Reactivity: Energy and Chemical Reactions 228

PART TWO ATOMS AND MOLECULES

6 The Structure of Atoms 276

7 The Structure of Atoms and Periodic Trends 310

8 Bonding and Molecular Structure 350

9 Bonding and Molecular Structure: Orbital Hybridization and Molecular Orbitals 412

PART THREE STATES OF MATTER

10 Gases and Their Properties 450

11 Intermolecular Forces and Liquids 490

12 The Solid State 526

13 Solutions and Their Behavior 564

PART FOUR THE CONTROL OF CHEMICAL REACTIONS

14 Chemical Kinetics: The Rates of Chemical Reactions 608

15 Principles of Chemical Reactivity: Equilibria 670

16 Principles of Chemical Reactivity: The Chemistry of Acids and Bases 708

17 Principles of Chemical Reactivity: Other Aspects of Aqueous Equilibria 760

18 Principles of Chemical Reactivity: Entropy and Free Energy 814

19 Principles of Chemical Reactivity: Electron Transfer Reactions 858

PART FIVE THE CHEMISTRY OF THE ELEMENTS

20 Environmental Chemistry—Earth's Environment, Energy, and Sustainability 916

21 The Chemistry of the Main Group Elements 958

22 The Chemistry of the Transition Elements 1020

23 Carbon: Not Just Another Element 1064

24 Biochemistry 1116

25 Nuclear Chemistry 1148

List of Appendices

A Using Logarithms and Solving Quadratic Equations A-2

B Some Important Physical Concepts A-6

C Abbreviations and Useful Conversion Factors A-9

D Physical Constants A-13

E A Brief Guide to Naming Organic Compounds A-15

F Values for the Ionization Energies and Electron Attachment Enthalpies of the Elements A-18

G Vapor Pressure of Water at Various Temperatures A-19

H Ionization Constants for Aqueous Weak Acids at 25 °C A-20

I Ionization Constants for Aqueous Weak Bases at 25 °C A-22

J Solubility Product Constants for Some Inorganic Compounds at 25 °C A-23

K Formation Constants for Some Complex Ions in Aqueous Solution at 25 °C A-24

L Selected Thermodynamic Values A-25

M Standard Reduction Potentials in Aqueous Solution at 25 °C A-32

N Answers to Study Questions, Check Your Understanding, and Applying Chemical Principles Questions A-36

Index and Glossary I-1

Contents

Preface xix

PART ONE THE BASIC TOOLS OF CHEMISTRY

1 Basic Concepts of Chemistry xxviii

1.1 **Chemistry and Its Methods** 1
A Scientific Mystery: Ötzi the Iceman 1
Chemistry and Change 2
Hypotheses, Laws, and Theories 3
Goals of Science 4
Dilemmas and Integrity in Science 4
1.2 **Sustainability and Green Chemistry** 5
1.3 **Classifying Matter** 6
States of Matter and Kinetic-Molecular Theory 6
Matter at the Macroscopic and Particulate Levels 7
Pure Substances 7
Mixtures: Heterogeneous and Homogeneous 8
1.4 **Elements** 9
1.5 **Compounds** 10
1.6 **Physical Properties** 12
Extensive and Intensive Properties 14
1.7 **Physical and Chemical Changes** 15
1.8 **Energy: Some Basic Principles** 17
Conservation of Energy 18
APPLYING CHEMICAL PRINCIPLES 1.1: CO_2 in the Oceans 19
CHAPTER GOALS REVISITED 20
KEY EQUATION 21
STUDY QUESTIONS 21

Let's Review: The Tools of Quantitative Chemistry 28

1 **Units of Measurement** 29
Temperature Scales 29
Length, Volume, and Mass 31
Energy Units 33
A Closer Look: Energy and Food 34
2 **Making Measurements: Precision, Accuracy, Experimental Error, and Standard Deviation** 34
Experimental Error 35
Standard Deviation 36
3 **Mathematics of Chemistry** 37
Exponential or Scientific Notation 37
Significant Figures 38
4 **Problem Solving by Dimensional Analysis** 43
5 **Graphs and Graphing** 44
6 **Problem Solving and Chemical Arithmetic** 45
APPLYING CHEMICAL PRINCIPLES 1: Out of Gas! 47
APPLYING CHEMICAL PRINCIPLES 2: Ties in Swimming and Significant Figures 48
CHAPTER GOALS REVISITED 49
KEY EQUATIONS 49
STUDY QUESTIONS 50

2 Atoms, Molecules, and Ions 58

2.1 **Atomic Structure, Atomic Number, and Atomic Mass** 59
Atomic Structure 59
Atomic Number 60
Relative Atomic Mass 60
Mass Number 60

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

2.2 **Isotopes and Atomic Weight** 62
Determining Atomic Mass and Isotope Abundance 62
Atomic Weight 63
Key Experiments: How Do We Know the Nature of the Atom and Its Components? 66
2.3 **The Periodic Table** 68
Features of the Periodic Table 68
A Brief Overview of the Periodic Table and the Chemical Elements 69
A Closer Look: Mendeleev and the Periodic Table 70
2.4 **Molecules, Compounds, and Formulas** 74
Formulas 75
Molecular Models 75
Naming Molecular Compounds 76
2.5 **Ionic Compounds: Formulas, Names, and Properties** 77
Ions 78
Formulas of Ionic Compounds 81
Names of Ions 83
Properties of Ionic Compounds 84
A Closer Look: Hydrated Ionic Compounds 85
2.6 **Atoms, Molecules, and the Mole** 86
A Closer Look: Amedeo Avogadro and His Number 87
Atoms and Molar Mass 87
Molecules, Compounds, and Molar Mass 89
A Closer Look: The Mole, a Counting Unit 90
2.7 **Chemical Analysis: Determining Compound Formulas** 93
Percent Composition 93
Empirical and Molecular Formulas from Percent Composition 94
Determining a Formula from Mass Data 97
2.8 **Instrumental Analysis: Determining Compound Formulas** 99
Determining a Formula by Mass Spectrometry 99
Molar Mass and Isotopes in Mass Spectrometry 100
APPLYING CHEMICAL PRINCIPLES 2.1: Using Isotopes: Ötzi, the Iceman of the Alps 102
APPLYING CHEMICAL PRINCIPLES 2.2: Arsenic, Medicine, and the Formula of Compound 606 103
APPLYING CHEMICAL PRINCIPLES 2.3: Argon—An Amazing Discovery 103
CHAPTER GOALS REVISITED 104
KEY EQUATIONS 106
STUDY QUESTIONS 106

3 **Chemical Reactions** 122

3.1 **Introduction to Chemical Equations** 123
A Closer Look: Antoine Laurent Lavoisier, 1743–1794 124
3.2 **Balancing Chemical Equations** 125
3.3 **Introduction to Chemical Equilibrium** 128
3.4 **Aqueous Solutions** 131
Ions and Molecules in Aqueous Solutions 131
Solubility of Ionic Compounds in Water 133
3.5 **Precipitation Reactions** 135
Net Ionic Equations 137
3.6 **Acids and Bases** 139
Acids and Bases: The Arrhenius Definition 140
A Closer Look: Naming Common Acids 141
Acids and Bases: The Brønsted–Lowry Definition 142
Reactions of Acids and Bases 144
A Closer Look: Sulfuric Acid 145
Oxides of Nonmetals and Metals 146
3.7 **Gas-Forming Reactions** 147
3.8 **Oxidation–Reduction Reactions** 149
Oxidation–Reduction Reactions and Electron Transfer 150
Oxidation Numbers 151
Recognizing Oxidation–Reduction Reactions 153
A Closer Look: Are Oxidation Numbers "Real"? 153
3.9 **Classifying Reactions in Aqueous Solution** 155
A Closer Look: Alternative Organizations of Reaction Types 156
APPLYING CHEMICAL PRINCIPLES 3.1: Superconductors 158
APPLYING CHEMICAL PRINCIPLES 3.2: Sequestering Carbon Dioxide 159
APPLYING CHEMICAL PRINCIPLES 3.3: Black Smokers and Volcanoes 159
CHAPTER GOALS REVISITED 160
STUDY QUESTIONS 162

4 Stoichiometry: Quantitative Information about Chemical Reactions 172

4.1 **Mass Relationships in Chemical Reactions: Stoichiometry** 173

4.2 **Reactions in Which One Reactant Is Present in Limited Supply** 177

A Stoichiometry Calculation with a Limiting Reactant 177

4.3 **Percent Yield** 180

4.4 **Chemical Equations and Chemical Analysis** 183

Quantitative Analysis of a Mixture 183

Determining the Formula of a Compound by Combustion 185

4.5 **Measuring Concentrations of Compounds in Solution** 188

Solution Concentration: Molarity 188

Preparing Solutions of Known Concentration 191

A Closer Look: Serial Dilutions 193

4.6 **pH, a Concentration Scale for Acids and Bases** 194

4.7 **Stoichiometry of Reactions in Aqueous Solution—Fundamentals** 196

4.8 **Stoichiometry of Reactions in Aqueous Solution—Titrations 198**

Titration: A Method of Chemical Analysis 198

Standardizing an Acid or Base 200

Determining Molar Mass by Titration 201

Titrations Using Oxidation–Reduction Reactions 202

4.9 **Spectrophotometry** 203

Transmittance, Absorbance, and the Beer–Lambert Law 204

Spectrophotometric Analysis 205

APPLYING CHEMICAL PRINCIPLES 4.1: Green Chemistry and Atom Economy 207

APPLYING CHEMICAL PRINCIPLES 4.2: Forensic Chemistry—Food Tampering 208

APPLYING CHEMICAL PRINCIPLES 4.3: How Much Salt is There in Seawater? 209

APPLYING CHEMICAL PRINCIPLES 4.4: The Martian 209

CHAPTER GOALS REVISITED 210

KEY EQUATIONS 211

STUDY QUESTIONS 212

5 Principles of Chemical Reactivity: Energy and Chemical Reactions 228

5.1 **Energy: Some Basic Principles** 229

Systems and Surroundings 230

Directionality and Extent of Transfer of Heat: Thermal Equilibrium 230

5.2 **Specific Heat Capacity: Heating and Cooling** 231

A Closer Look: What is Heat? 233

Quantitative Aspects of Energy Transferred as Heat 234

5.3 **Energy and Changes of State** 236

5.4 **The First Law of Thermodynamics** 240

A Closer Look: *P–V* Work 242

Enthalpy 242

State Functions 244

5.5 **Enthalpy Changes for Chemical Reactions** 245

5.6 **Calorimetry** 247

Constant-Pressure Calorimetry, Measuring ΔH 247

Constant-Volume Calorimetry, Measuring ΔU 249

5.7 **Enthalpy Calculations** 251

Hess's Law 251

Energy Level Diagrams 252

Standard Enthalpies of Formation 254

Enthalpy Change for a Reaction 255

A Closer Look: Hess's Law and Equation 5.6 256

5.8 **Product- or Reactant-Favored Reactions and Thermodynamics** 257

APPLYING CHEMICAL PRINCIPLES 5.1: Gunpowder 258

APPLYING CHEMICAL PRINCIPLES 5.2: The Fuel Controversy—Alcohol and Gasoline 259

CHAPTER GOALS REVISITED 260

KEY EQUATIONS 261

STUDY QUESTIONS 262

PART TWO ATOMS AND MOLECULES

6 The Structure of Atoms 276

6.1 **Electromagnetic Radiation** 277

6.2 **Quantization: Planck, Einstein, Energy, and Photons** 279

Planck's Equation 279

Einstein and the Photoelectric Effect 281

6.3 **Atomic Line Spectra and Niels Bohr** 283

The Bohr Model of the Hydrogen Atom 284

The Bohr Theory and the Spectra of Excited Atoms 287

6.4 **Particle–Wave Duality: Prelude to Quantum Mechanics** 289

6.5 **The Modern View of Electronic Structure: Wave or Quantum Mechanics** 291

Quantum Numbers and Orbitals 292

Shells and Subshells 293

6.6 **The Shapes of Atomic Orbitals** 294

s Orbitals 295

p Orbitals 296

d Orbitals 297

f Orbitals 297

6.7 **One More Electron Property: Electron Spin** 297

A Closer Look: More about H Atom Orbital Shapes and Wavefunctions 298

APPLYING CHEMICAL PRINCIPLES 6.1: Sunburn, Sunscreens, and Ultraviolet Radiation 299

APPLYING CHEMICAL PRINCIPLES 6.2: What Makes the Colors in Fireworks? 299

APPLYING CHEMICAL PRINCIPLES 6.3: Chemistry of the Sun 300

CHAPTER GOALS REVISITED 301

KEY EQUATIONS 302

STUDY QUESTIONS 302

7 The Structure of Atoms and Periodic Trends 310

7.1 **The Pauli Exclusion Principle** 311

7.2 **Atomic Subshell Energies and Electron Assignments** 313

Order of Subshell Energies and Assignments 313

Effective Nuclear Charge, *Z** 314

7.3 **Electron Configurations of Atoms** 315

Electron Configurations of the Main Group Elements 317

Elements of Period 3 319

Electron Configurations of the Transition Elements 321

A Closer Look: Orbital Energies, Z*, and Electron Configurations 322

7.4 **Electron Configurations of Ions** 324

Anions and Cations 324

A Closer Look: Questions about Transition Element Electron Configurations 324

Diamagnetism and Paramagnetism 325

A Closer Look: Paramagnetism and Ferromagnetism 327

7.5 **Atomic Properties and Periodic Trends** 328

Atomic Size 328

Ionization Energy 330

Electron Attachment Enthalpy and Electron Affinity 332

A Closer Look: Photoelectron Spectroscopy 333

Trends in Ion Sizes 335

7.6 **Periodic Trends and Chemical Properties** 337

APPLYING CHEMICAL PRINCIPLES 7.1: The Not-So-Rare Earths 338

APPLYING CHEMICAL PRINCIPLES 7.2: Metals in Biochemistry and Medicine 339

CHAPTER GOALS REVISITED 339

STUDY QUESTIONS 340

8 Bonding and Molecular Structure 350

8.1 **Chemical Bond Formation and Lewis Electron Dot Symbols** 351

Valence Electrons and Lewis Symbols for Atoms 353

8.2 **Covalent Bonding and Lewis Structures** 354

Drawing Lewis Electron Dot Structures 355

Predicting Lewis Structures 360

8.3 **Atom Formal Charges in Covalent Molecules and Ions** 363

A Closer Look: Comparing Oxidation Number and Formal Charge 364

8.4 **Resonance** 365

A Closer Look: Resonance 367

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

8.5 **Exceptions to the Octet Rule** 369
Compounds in Which an Atom Has Fewer Than Eight Valence Electrons 369
Compounds in Which an Atom Has More Than Eight Valence Electrons 369
A Closer Look: A Scientific Controversy—Resonance, Formal Charges, and the Question of Double Bonds in Sulfate and Phosphate Ions 370
A Closer Look: Structure and Bonding for Hypervalent Molecules 372
Molecules with an Odd Number of Electrons 372
8.6 **Molecular Shapes** 373
Central Atoms Surrounded Only by Single-Bond Pairs 374
Central Atoms with Single-Bond Pairs and Lone Pairs 375
Multiple Bonds and Molecular Geometry 378
8.7 **Electronegativity and Bond Polarity** 379
Charge Distribution: Combining Formal Charge and Electronegativity 381
8.8 **Molecular Polarity** 384
A Closer Look: Measuring Molecular Polarity 384
A Closer Look: Visualizing Charge Distributions and Molecular Polarity—Electrostatic Potential Surfaces and Partial Charge 387
8.9 **Bond Properties: Order, Length, and Dissociation Enthalpy** 389
Bond Order 389
Bond Length 390
Bond Dissociation Enthalpy 391
8.10 **DNA, Revisited** 395
A Closer Look: DNA—Watson, Crick, Wilkins, and Franklin 396
APPLYING CHEMICAL PRINCIPLES 8.1: Ibuprofen, A Study in Green Chemistry 397
APPLYING CHEMICAL PRINCIPLES 8.2: van Arkel Triangles and Bonding 397
APPLYING CHEMICAL PRINCIPLES 8.3: Linus Pauling and the Origin of the Concept of Electronegativity 398
CHAPTER GOALS REVISITED 399
KEY EQUATIONS 401
STUDY QUESTIONS 401

9 Bonding and Molecular Structure: Orbital Hybridization and Molecular Orbitals 412

9.1 **Valence Bond Theory** 413
The Orbital Overlap Model of Bonding 413
Hybridization Using *s* and *p* Atomic Orbitals 415
Hybrid Orbitals for Molecules and Ions with Trigonal-Planar and Linear Electron-Pair Geometries 418
Valence Bond Theory and Multiple Bonds 421
Benzene: A Special Case of π Bonding 425
Hybridization: A Summary 426
9.2 **Molecular Orbital Theory** 427
Principles of Molecular Orbital Theory 427
A Closer Look: Molecular Orbitals for Molecules Formed from *p*-Block Elements 434
Electron Configurations for Heteronuclear Diatomic Molecules 434
Resonance and MO Theory 434
9.3 **Theories of Chemical Bonding: A Summary** 436
A Closer Look: Three-Center Bonds in HF_2^-, B_2H_6, and SF_6 437
APPLYING CHEMICAL PRINCIPLES 9.1: Probing Molecules with Photoelectron Spectroscopy 438
APPLYING CHEMICAL PRINCIPLES 9.2: Green Chemistry, Safe Dyes, and Molecular Orbitals 439
CHAPTER GOALS REVISITED 440
KEY EQUATION 440
STUDY QUESTIONS 440

PART THREE STATES OF MATTER

10 Gases and Their Properties 450

10.1 **Modeling a State of Matter: Gases and Gas Pressure** 451
A Closer Look: Measuring Gas Pressure 452
10.2 **Gas Laws: The Experimental Basis** 453
Boyle's Law: The Compressibility of Gases 453
The Effect of Temperature on Gas Volume: Charles's Law 455
Combining Boyle's and Charles's Laws: The General Gas Law 457
Avogadro's Hypothesis 458

PART FOUR THE CONTROL OF CHEMICAL REACTIONS

14 **Chemical Kinetics: The Rates of Chemical Reactions** 608

14.1 **Rates of Chemical Reactions** 609

Calculating a Rate 610

Relative Rates and Stoichiometry 612

14.2 **Reaction Conditions and Rate** 614

14.3 **Effect of Concentration on Reaction Rate** 616

Rate Equations 616

The Order of a Reaction 617

The Rate Constant, *k* 617

Determining a Rate Equation 618

14.4 **Concentration–Time Relationships: Integrated Rate Laws** 622

First-Order Reactions 622

Second-Order Reactions 624

Zero-Order Reactions 625

Graphical Methods for Determining Reaction Order and the Rate Constant 626

Half-Life and First-Order Reactions 626

14.5 **A Microscopic View of Reaction Rates** 630

A Closer Look: Rate Laws, Rate Constants, and Reaction Stoichiometry 631

Collision Theory: Concentration and Reaction Rate 631

Collision Theory: Activation Energy 632

A Closer Look: More About Molecular Orientation and Reaction Coordinate Diagrams 633

Collision Theory: Activation Energy and Temperature 634

Collision Theory: Effect of Molecular Orientation on Reaction Rate 635

The Arrhenius Equation 635

14.6 **Catalysts** 638

Effect of Catalysts on Reaction Rate 638

A Closer Look: Thinking About Kinetics, Catalysis, and Bond Energies 638

Enzymes 641

16 **Principles of Chemical Reactivity: The Chemistry of Acids and Bases** 708

16.1 **The Brønsted–Lowry Concept of Acids and Bases** 709
Conjugate Acid–Base Pairs 711
16.2 **Water and the pH Scale** 712
Water Autoionization and the Water Ionization Constant, K_w 712
The pH Scale 714
16.3 **Equilibrium Constants for Acids and Bases** 715
K_a and K_b Values for Polyprotic Acids 719
Logarithmic Scale of Relative Acid Strength, pK_a 719
Relating the Ionization Constants for an Acid and Its Conjugate Base 720
16.4 **Acid–Base Properties of Salts** 720
16.5 **Predicting the Direction of Acid–Base Reactions** 722
16.6 **Types of Acid–Base Reactions** 725
The Reaction of a Strong Acid with a Strong Base 725
The Reaction of a Weak Acid with a Strong Base 726
The Reaction of a Strong Acid with a Weak Base 726
The Reaction of a Weak Acid with a Weak Base 726
16.7 **Calculations with Equilibrium Constants** 727
Determining *K* from Initial Concentrations and Measured pH 727
What Is the pH of an Aqueous Solution of a Weak Acid or Base? 729
16.8 **Polyprotic Acids and Bases** 735
16.9 **Molecular Structure, Bonding, and Acid–Base Behavior** 737
Acid Strength of the Hydrogen Halides, HX 737
Comparing Oxoacids: HNO_2 and HNO_3 738
Why Are Carboxylic Acids Brønsted Acids? 740
A Closer Look: Acid Strengths and Molecular Structure 741

18 **Principles of Chemical Reactivity: Entropy and Free Energy** 814

18.1 **Spontaneity and Dispersal of Energy: Entropy** 815
18.2 **Entropy: A Microscopic Understanding** 817
Dispersal of Energy 817
A Closer Look: Reversible and Irreversible Processes 818
Dispersal of Matter: Dispersal of Energy Revisited 820
A Summary: Entropy, Entropy Change, and Energy Dispersal 821
18.3 **Entropy Measurement and Values** 821
Standard Entropy Values, $S°$ 822
Determining Entropy Changes in Physical and Chemical Processes 824
18.4 **Entropy Changes and Spontaneity** 825
A Closer Look: Entropy and Spontaneity? 827
Spontaneous or Not? 828
How Temperature Affects $\Delta S°$ (universe) 829
18.5 **Gibbs Free Energy** 830
The Change in the Gibbs Free Energy, ΔG 830
Gibbs Free Energy, Spontaneity, and Chemical Equilibrium 830
A Summary: Gibbs Free Energy ($\Delta_r G$ and $\Delta_r G°$), the Reaction Quotient (Q) and Equilibrium Constant (K), and Reaction Favorability 832
What Is "Free" Energy? 833
18.6 **Calculating and Using Standard Free Energies, $\Delta_r G°$** 833
Standard Free Energy of Formation 833
Calculating $\Delta_r G°$, the Free Energy Change for a Reaction Under Standard Conditions 833
Free Energy and Temperature 835
Using the Relationship between $\Delta_r G°$ and K 838

Preface

The first edition of this book was conceived over 35 years ago. Since that time there have been nine editions, and over 1 million students worldwide have used the book to begin their study of chemistry. Over the years, and the many editions, our goals have remained the same: to provide a broad overview of the principles of chemistry, the reactivity of the chemical elements and their compounds, and the applications of chemistry. To reach these goals, we have tried to show the close relation between the observations chemists make of chemical and physical changes in the laboratory and in nature and the way these changes are viewed at the atomic and molecular levels.

John C. Kotz

Hot air balloon. See Chapter 10 on the gas laws.

We have also tried to convey a sense that chemistry not only has a lively history but is also dynamic, with important new developments occurring every year. Furthermore, we want to provide some insight into the chemical aspects of the world around us.

The authors of this text have collectively taught chemistry for over 100 years, and we have engaged in years of fundamental research. As with thousands of scientists before and now, our goal has been to satisfy our curiosity about areas of chemistry, to document what we found, and to convey that to students and other scientists. Our results, and many, many others, are put to use, perhaps only many years later, to make a better material or better pharmaceutical. Every person eventually benefits from the work of the worldwide community of scientists.

Recently, however, science has come under attack. Some distrust what the scientific community has done and dismiss results of carefully done research. Therefore, key among the objectives of this book and of a course in general chemistry is to describe basic chemical "facts"—chemical processes and principles, how chemists came to understand those principles, how they can be applied in industry, medicine, and the environment, and how to think about problems as a scientist. We have tried to provide the tools to help you become a chemically and scientifically literate citizen.

AUDIENCE FOR CHEMISTRY & CHEMICAL REACTIVITY

This textbook (both as a printed book and digital version) is designed for students interested in further study in science, whether that science is chemistry, biology, engineering, geology, physics, or related subjects. Our assumption is that students in a course using this book have had some preparation in algebra and in general science. Although undeniably helpful, a previous exposure to chemistry is neither assumed nor required.

PHILOSOPHY AND APPROACH OF CHEMISTRY & CHEMICAL REACTIVITY

We have had several major, but not independent, objectives since the first edition of the book. The first was to write a book that students would enjoy reading and that would offer, at a reasonable level of rigor, chemistry and chemical principles in a format and organization typical of college and university courses today. Second, we wanted to convey the utility and importance of chemistry by introducing the properties of the elements, their compounds, and their reactions.

The American Chemical Society has been urging educators to put "chemistry" back into introductory chemistry courses. We agree wholeheartedly. Therefore, we have tried to describe the elements, their compounds, and their reactions as early and as often as possible by:

- Bringing **material on the properties of elements and compounds** into the Examples and Study Questions.
- Using numerous **photographs** of the elements and common compounds, of chemical reactions, and of common laboratory operations and industrial processes.
- Using ***Applying Chemical Principles*** study questions in each chapter that delve into the applications of chemistry.

GENERAL ORGANIZATION

Through its many editions, *Chemistry & Chemical Reactivity* has had two broad themes: *Chemical Reactivity* and *Bonding and Molecular Structure*. The chapters on *Principles of Reactivity* introduce the factors that lead chemical reactions to be successful in converting reactants to products: common types of reactions, the energy involved in reactions, and the factors that affect the speed of a reaction. One reason for the enormous advances in chemistry and molecular biology in the last several decades has been an understanding of molecular structure. The sections of the book on *Principles of Bonding and Molecular Structure* lay the groundwork for understanding these developments. Particular attention is paid to an understanding of the structural aspects of such biologically important molecules as hemoglobin, proteins, and DNA.

Flexibility of Chapter Organization

As we look at the introductory chemistry texts currently available and talk with colleagues at other universities, it is evident there is a generally accepted order of topics in the course. With minor variations, we have followed that order. That is not to say that the chapters in our book cannot be used in some other order. We have written this book to be as flexible as possible. An example is the **flexibility of covering the behavior of gases** (Chapter 10). It has been placed with chapters on liquids, solids, and solutions (Chapters 10–13) because it logically fits with those topics. However, it can easily be read and understood after covering only the first four chapters of the book.

Similarly, chapters on atomic and molecular structure (Chapters 6–9) could be used in an ***atoms-first approach*** before the chapters on stoichiometry and common reactions (Chapters 3 and 4). To facilitate this, there is an introduction to energy and its units in Chapter 1.

John C. Kotz

Crystals of rhodochrosite, $MnCO_3$. See Chapters 12 and 17.

Also, the chapters on chemical equilibria (Chapters 15–17) can be covered before those on solutions and kinetics (Chapters 13 and 14).

Organic chemistry (Chapter 23) is one of the final chapters in the textbook. However, the topics of this chapter can also be presented to students following the chapters on structure and bonding.

The order of topics in the text was also devised to introduce as early as possible the background required for the laboratory experiments usually performed in introductory chemistry courses. For this reason, chapters on chemical and physical properties, common reaction types, and stoichiometry begin the book. In addition, because an understanding of energy is so important in the study of chemistry, energy and its units are introduced in Chapter 1, and thermochemistry is introduced in Chapter 5.

ORGANIZATION AND PURPOSES OF THE SECTIONS OF THE BOOK

PART ONE: The Basic Tools of Chemistry

The basic ideas and methods of chemistry are introduced in Part One. Chapter 1 defines important terms, and the accompanying *Let's Review* section reviews units and mathematical methods. Chapter 2 introduces atoms, molecules, and ions, and the most important organizational device in chemistry, the periodic table. In Chapter 3, we begin to discuss the principles of chemical reactivity. Writing chemical equations is covered here, and there is a short introduction to equilibrium. Then, in Chapter 4, we describe the numerical methods used by chemists to extract quantitative information from chemical reactions. Chapter 5 is an introduction to the energy involved in chemical processes.

PART TWO: Atoms and Molecules

The current theories of the arrangement of electrons in atoms are presented in Chapters 6 and 7. This discussion is tied closely to the arrangement of elements in the periodic table and to periodic properties. In Chapter 8 we discuss the details of chemical bonding and the properties of these bonds. In addition, we show how to derive the three-dimensional structure of simple molecules. Finally, Chapter 9 considers the major theories of chemical bonding in more detail.

PART THREE: States of Matter

The behavior of the three states of matter—gases, liquids, and solids—is described in Chapters 10–12. The discussion of liquids and solids is tied to gases through the description of intermolecular forces in Chapter 11, with particular attention given to liquid and solid water. In Chapter 13 we describe the properties of solutions, intimate mixtures of gases, liquids, and solids.

WHAT'S NEW IN THIS EDITION

Numerous changes have been made from the previous edition, some small, some large. A few that stand out are listed here.

- *Goals* for each topic in a chapter are now given at the beginning of each section. A *Chapter Goals Revisited* section at the end of the chapter then links each goal to one or more Study Questions that relate to the goal.
- *Applying Chemical Principles* questions have been expanded from one per chapter to two or three. Some were *A Closer Look* or *Case Study* boxes in the ninth edition.
- We made a change in how significant figures are treated in problem solving (page 41).
- We reorganized the section on naming compounds in Chapter 2.
- A new section has been added to Chapter 2 on *Instrumental Analysis: Determining Compound Formulas.*
- At the suggestion of a user of the book, we added an *A Closer Look* box in Chapter 3 (page 141) on naming common acids and their related anions.
- We changed our approach to solving limiting reactant problems in Chapter 4.
- In Chapter 8 we expanded the discussion of van Arkel diagrams for bonding and added an *Applying Chemical Principles* question on the topic.
- In Chapter 12 we added a section on the Electron Sea Model for bonding in metals.
- The section on alloys in Chapter 12 was expanded.

John C. Kotz

Fireworks. See Chapter 6.

- In Chapter 13 we feature an excerpt from the book *Lab Girl* by Hope Jahren. The *A Closer Look* box on *Hardening Trees* applies to the colligative properties described in the chapter.
- In Chapter 14 a new *Problem Solving Tip* on *Determining a Rate Equation: A Logarithmic Approach* was added, and we expanded the discussion of enzyme catalysis.
- A *Problem Solving Tip* on *A Review of Concepts of Equilibrium* was added to Chapter 15.
- In Chapter 18 there is a new *A Closer Look* box titled *Entropy and Spontaneity?* This is based on some recent papers in the *Journal of Chemical Education*.
- In Chapter 18 there is a new section on *The Interplay of Kinetics and Thermodynamics.*
- Chapter 19 has a new section on *Corrosion: Redox Reactions in the Environment.*
- In Chapter 20 on environmental chemistry, much of the data have been updated, and a new *A Closer Look* box was added on *The Flint, Michigan Water Treatment Problem.*
- New research on understanding the dramatic reactivity of sodium with water is the subject of an *A Closer Look* box in Chapter 21. Other new *A Closer Look* boxes describe advances in boron chemistry, ammonium nitrate explosions, and new fluorine-based compounds. Finally, there are new *Applying Chemical Principles* questions on *Lead in the Environment* and *Hydrogen Storage*.
- For Chapter 24, *Biochemistry*, the section on *The RNA World* was dropped as was a box on *Reverse Transcriptase*. But, given the enormous interest in CRISPR, we added an *A Closer Look* box on *Genetic Engineering with CRISPR-Cas9*.
- Several new elements were added to the periodic table in the past few years. A new *A Closer Look* box in Chapter 25 describes those new elements and their production. There is also a new *A Closer Look* box, *A Real-Life Spy Thriller*, that describes a murder done with radioactive polonium.

PART FOUR: The Control of Chemical Reactions

This section is wholly concerned with the *Principles of Reactivity*. Chapter 14 examines the rates of chemical processes and the factors controlling these rates. Next, Chapters 15–17 describe chemical equilibrium. After an introduction to equilibrium in Chapter 15, we highlight the reactions involving acids and bases in water (Chapters 16 and 17) and reactions leading to slightly soluble salts (Chapter 17). To tie together the discussion of chemical equilibria and thermodynamics, we explore entropy and free energy in Chapter 18. As a final topic in this section we describe in Chapter 19 chemical reactions involving the transfer of electrons and the use of these reactions in electrochemical cells.

PART FIVE: The Chemistry of the Elements

Although the chemistry of many elements and compounds is described throughout the book, Part Five considers this topic in a more systematic way. Chapter 20 brings together many of the concepts in earlier chapters into a discussion of *Environmental Chemistry—Earth's Environment, Energy, and Sustainability.* Chapter 21 is devoted to the chemistry of the main group elements, whereas Chapter 22 is a discussion of the transition elements and their compounds. Chapter 23 is a brief discussion

of organic chemistry with an emphasis on molecular structure, basic reaction types, and polymers. Chapter 24 is an introduction to biochemistry, and Chapter 25 is an overview of nuclear chemistry.

FEATURES OF THE BOOK

Some years ago a student of one of the authors, now an accountant, shared his perspective on finishing general chemistry. He said that, while chemistry was one of his hardest subjects, it was also the most useful course he had taken because it taught him how to solve problems. We were certainly pleased because we have always thought that, for many students, an important goal in general chemistry was not only to teach students chemistry but also to help them learn critical thinking and problem-solving skills. Many of the features of the book are meant to support those goals.

Problem-Solving Approach: Organization and Strategy Maps

Worked-out examples are an essential part of each chapter. To better help students to follow the logic of a solution, all *Examples* are organized around the following outline:

***Problem*:** A statement of the problem.

***What Do You Know?*:** The information given is outlined.

***Strategy*:** The information available is combined with the objective, and we begin to devise a pathway to a solution.

***Solution*:** We work through the steps, both logical and mathematical, to the answer.

***Think About Your Answer*:** We ask if the answer is reasonable or what it means.

***Check Your Understanding*:** This is a similar problem for the student to try. A solution to the problem is in Appendix N.

For many students, a **visual *strategy map*** can be a useful tool in problem solving (as on page 46). There are approximately 60 strategy maps in the book accompanying *Example* problems.

Chapter Goals Revisited

The learning goals for each section are listed at the top of the section. The goals are revisited on the last page of the chapter, and specific end-of-chapter *Study Questions* are listed that can help students determine if they have met those goals.

End-of-Chapter Study Questions

There are 40 to over 150 *Study Questions* for each chapter, and answers to the odd-numbered questions are given in Appendix N. Questions are grouped as follows:

***Practicing Skills*:** These questions are grouped by the topic covered by the questions.

General Questions: There is no indication regarding the pertinent section of the chapter. They generally cover several chapter sections.

***In the Laboratory*:** These are problems that may be encountered in a laboratory experiment on the chapter material.

Summary and Conceptual Questions: These questions use concepts from the current chapter as well as preceding chapters.

Study Questions are available in the OWLv2 online learning system. OWLv2 now has over 1800 of the roughly 2500 *Study Questions* in the book.

Finally, note that some questions are marked with a small red triangle (▲). These are meant to be more challenging than other questions.

A CLOSER LOOK ESSAYS AND PROBLEM SOLVING TIPS

As in the ninth edition, there are boxed essays titled *A Closer Look* that take a more in-depth look at relevant chemistry. A few examples are *Mendeleev and the Periodic Table* (Chapter 2), *Amedeo Avogadro and His Number* (Chapter 2), *Measuring Molecular Polarity* (Chapter 8), *Hydrogen Bonding in Biochemistry* (Chapter 11), and *The Flint, Michigan Water Treatment Problem* (Chapter 20).

From our teaching experience, we have learned some "tricks of the trade" and try to pass on some of those in *Problem Solving Tips*.

Applying Chemical Principles

At the end of each chapter there are two or three longer questions that use the principles learned in the chapter to study examples of forensic chemistry, environmental chemistry, a problem in medicinal chemistry, or some other area. Examples are *Green Chemistry and Atom Economy* (Chapter 4), *What Makes the Colors in Fireworks* (Chapter 6), *A Pet Food Catastrophe* (Chapter 11), and *Lithium and "Green Cars"* (Chapter 12).

ANCHORING CONCEPTS IN CHEMISTRY

The American Chemical Society Examinations Institute has been writing assessment examinations for college chemistry for over 75 years. In 2012 the Institute began publishing papers in the *Journal of Chemical Education* on "anchoring concepts" or "big ideas" in chemistry. The purpose was to provide college instructors with a fine-grained content map of chemistry so that instruction can be aligned better with the content of the American Chemical Society examinations. The ACS map begins with "anchoring concepts," which are subdivided into "enduring understandings" and then further broken down into detailed areas.

We believe these ideas are useful to both teachers and students of chemistry and are important enough to include them in this Preface.

The College Board, the publisher of Advanced Placement (AP®) examinations, has recently redesigned the AP chemistry curriculum along many of the same ideas. We have made sure that the present edition of *Chemistry & Chemical Reactivity* has included material that meets many of the criteria of the College Board curriculum while basing the text largely on the "anchoring concepts" of the Examinations Institute.

AMERICAN CHEMICAL SOCIETY EXAMINATIONS INSTITUTE'S ANCHORING CONCEPTS

The anchoring concepts are listed here with a notation of the chapters that describe or use those concepts.

1. **Atoms (Chapters 1, 2, 6, 7)**
2. **Bonding (Chapters 8, 9, 12, 23)**
3. **Structure and Function (Chapters 11, 12, 16, 24)**
4. **Intermolecular Interactions (Chapters 10, 11, 24)**
5. **Reactions (Chapters 3, 4, 16, 17, 19–24)**
6. **Energy and Thermodynamics (Chapters 1, 5–8, 12, 13, 18, 20)**
7. **Kinetics (Chapter 14, 24)**
8. **Equilibrium (Chapters 3, 15–19)**
9. **Experiments, Measurements, and Data (these appear throughout the book)**
10. **Visualizations (these appear throughout the book)**

Acknowledgments

Preparing this new edition of *Chemistry & Chemical Reactivity* took about two years of continuous effort. As in our work on the first nine editions, we have had the support and encouragement of our colleagues at Cengage and of our families and wonderful friends, faculty colleagues, and students.

CENGAGE

The ninth edition of this book was published by Cengage, and we continue with much of the same excellent team we have had in place for a number of years.

The ninth edition of the book was very successful, in large part owing to the work of Lisa Lockwood as the Product Manager. She has an excellent sense of the market and worked with us in planning this new edition. We have worked with Lisa through several editions and have become good friends.

Peter McGahey has been our Content Developer since he joined us to work on the fifth edition. Peter is blessed with energy, creativity, enthusiasm, intelligence, and good humor. He is a trusted friend and confidant and cheerfully answers our many questions during frequent phone calls and emails.

Our team at Cengage is completed with Teresa Trego, Content Project Manager. Schedules are very demanding in textbook publishing, and Teresa has helped to keep us on schedule. We certainly appreciate her organizational skills and good humor.

We have worked with Graphic World, Inc. for the production of the last several editions, and they have been excellent again. For this edition, Cassie Carey guided the book through months of production.

A team at Lumina Datamatics directed the photo research for the book and was successful in filling our sometimes offbeat requests for particular photos.

No book can be successful without proper marketing, and Janet del Mundo (Marketing Manager) is again involved with this book. She is knowledgeable about the market and has worked tirelessly to bring the book to everyone's attention.

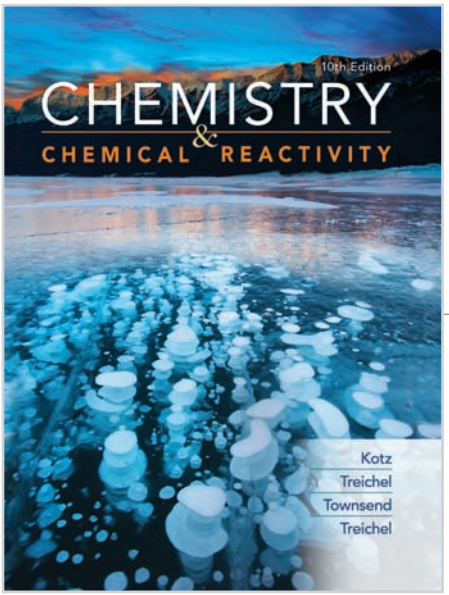
With regard to marketing and sales, over the nine editions of this book we have met in person or through email the people from the company who visit universities and meet the faculty. They have been excellent over the years, work hard for us, and deserve our profound thanks.

Art, Design, and Photography

Many of the color photographs in our book have been beautifully created by Charles D. Winters, and he produced a few new images for this edition. We have worked with him for more than 30 years and have become close friends. We listen to his jokes, both new and old—and always forget them.

When the fifth edition was being planned some years ago, we brought in Patrick Harman as a member of the team. Pat designed the first edition of our *Interactive General Chemistry* CD-ROM (published in the 1990s), and we believe its success is in no small way connected to his design skill. For the fifth through the ninth editions of the book, Pat went over many of the figures to bring a fresh perspective to ways to communicate chemistry. Once again he has worked on designing and producing new illustrations for this edition, and his creativity is obvious in their clarity. Pat is also working with us on the digital version of this book.

Other Collaborators



We have been fortunate to have a number of other colleagues who have played valuable roles in this project. Several who have been important in this edition are:

- Alton Banks (North Carolina State University) has been involved for a number of editions preparing the *Student Solutions Manual*. Alton has been very helpful in ensuring the accuracy of the Study Question answers in the book, as well as in their respective manuals.
- David Shinn of the U.S. Merchant Marine Academy has been the accuracy reviewer for the text.
- David Sadeghi (University of Texas, San Antonio) reviewed the ninth edition and made suggestions that helped in the preparation of this new edition.

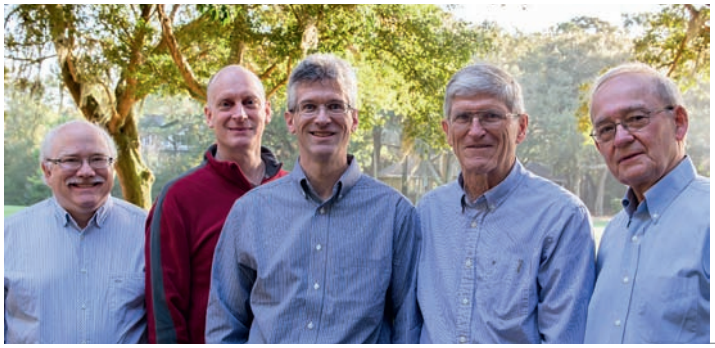
About the Cover

Kevin Schafer/Minden Pictures

Have you ever walked around a shallow lake or pond and watched as bubbles of gas rise to the surface? This is "marsh gas," and it is often responsible for the characteristic smell of a marshy area. This "marsh gas" is mostly methane (CH_4), and it is an extremely important and possibly dangerous feature of the worldwide environment.

Bodies of water are usually surrounded by vegetation, which, over the years or centuries, will fall into the water and decay. The vegetation is consumed by bacteria that release methane as a product of the digestion. Some of the methane bubbles to the surface, and in the winter the bubbles can be trapped in the ice. The white patches you see in the photo on the cover of the book are trapped methane bubbles in a lake in northern Canada.

The methane can also be trapped as "methane hydrate," a white solid in which methane is encased in a lattice of water molecules (pages 925 and 936). Estimates are that there are millions upon millions of tons of methane trapped in the hydrated form under the world's oceans and in the Arctic regions.



Why should methane bubbles and methane hydrate be of interest? Methane hydrates could be a source of needed fuel. But, as we are in an era of climate change, likely brought on by excessive release of carbon dioxide (CO_2), scientists are interested in all possible effects on the climate. Many studies have found that methane is a far more potent "greenhouse gas" than CO_2. Some of the bubbles in a frozen lake come from slow methane release by methane hydrate. But what if methane is released explosively? This is of concern because the Arctic is clearly warming, which destabilizes the buried methane hydrate. The possibility of a catastrophic, explosive methane release is hotly debated by environmental scientists.

There is a lot of interesting information available on this topic from reputable journals and news sources. This would be a good topic for you to watch over the next few years.

About the Authors

Courtesy Katherine Kotz

(*left to right*) John Townsend, Pat Harman, David Treichel, Paul Treichel, John Kotz

John (Jack) Kotz graduated from Washington and Lee University in 1959 and earned a Ph.D. in chemistry at Cornell University in 1963. He was a National Institutes of Health postdoctoral fellow at the University of Manchester in England and at Indiana University. He was an assistant professor of chemistry at Kansas State University before moving to the SUNY College at Oneonta in 1970. He retired from SUNY in 2005 as a *State University of New York Distinguished Teaching Professor of Chemistry*.

He is the author or co-author of 15 chemistry textbooks, among them two in advanced chemistry and two introductory general chemistry books in numerous editions. The general chemistry book has been published as an interactive CD-ROM, as an interactive ebook, and has been translated into five languages. He also published a number of research papers in organometallic chemistry.

He has received a number of awards, among them the *SUNY Award for Research and Scholarship* and the *Catalyst Award in Education* from the Chemical Manufacturers Association. He was the *Estee Lecturer* at the University of South Dakota, the *Squibb Lecturer* at the University of North Carolina-Asheville, and an invited plenary lecturer at numerous chemical society meetings overseas. He was a Fulbright Senior Lecturer in Portugal and a member of Fulbright review boards. In addition, he has been a Mentor for the U.S. National Chemistry Olympiad team and the technical editor for *ChemMatters* magazine. He has served on the boards of trustees for the College at Oneonta Foundation, the Kiawah Nature Conservancy, and Camp Dudley. His email address is johnkotz@mac.com.

Paul M. Treichel received his B.S. degree from the University of Wisconsin in 1958 and a Ph.D. from Harvard University in 1962. After a year of postdoctoral study in London, he assumed a faculty position at the University of Wisconsin–Madison. He served as department chair from 1986 through 1995 and was awarded a Helfaer Professorship in 1996. He has held visiting faculty positions in South Africa (1975) and in Japan (1995). Retiring after 44 years as a faculty member in 2007, he is currently Emeritus Professor of Chemistry. During his faculty career he taught courses in general chemistry, inorganic chemistry, organometallic chemistry, and scientific ethics. Professor Treichel's research in organometallic and metal cluster chemistry and in mass spectrometry, aided by 75 graduate and undergraduate students, has led to more than 170 papers in scientific journals. He may be contacted by email at treichelpaul@me.com.

John R. Townsend, Professor of Chemistry at West Chester University of Pennsylvania, completed his B.A. in Chemistry as well as the Approved Program for Teacher Certification in Chemistry at the University of Delaware. After a career teaching high school science and mathematics, he earned his M.S. and Ph.D. in biophysical chemistry at Cornell University, where he also received the DuPont Teaching Award for his work as a teaching assistant. After teaching at Bloomsburg University, he joined the faculty at West Chester University, where he coordinates the chemistry education program for prospective high school teachers and the general chemistry lecture program for science majors. He has been the university supervisor for more than 70 prospective high school chemistry teachers during their student teaching semester. His research interests are in the fields of chemical education and biochemistry. He may be contacted by email at jtownsend@wcupa.edu.

David A. Treichel, Professor of Chemistry at Nebraska Wesleyan University, received a B.A. degree from Carleton College. He earned a M.S. and a Ph.D. in analytical chemistry at Northwestern University. After postdoctoral research at the University of Texas in Austin, he joined the faculty at Nebraska Wesleyan University. His research interests are in the fields of electrochemistry and surface-laser spectroscopy. He may be contacted by email at dat@nebrwesleyan.edu.

Patrick Harman is an Information and Graphics Designer specializing in media development for scientific education. He studied communication design, film, and animation as an undergraduate and graduate student at the University of Illinois, and also taught a variety of communication design and motion graphics courses at the University of Illinois at Chicago. For over 35 years Patrick has produced graphic design, animation, sound design, interface design, content development, and distance learning solutions for a wide variety of scientific educational applications and disciplines, most recently with researchers in arctic climate research and Alaskan native languages. He also designed a number of the illustrations in this book over several editions.

CHAPTER OUTLINE

1.1 Chemistry and Its Methods

1.2 Sustainability and Green Chemistry

1.3 Classifying Matter

1.4 Elements

1.5 Compounds

1.6 Physical Properties

1.7 Physical and Chemical Changes

1.8 Energy: Some Basic Principles

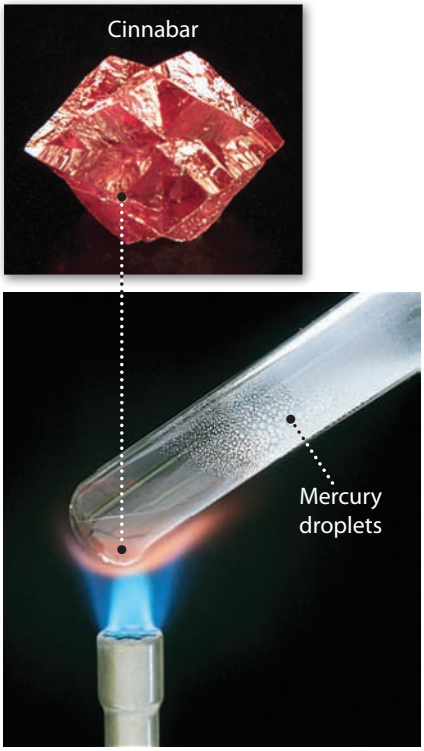
1.1 Chemistry and Its Methods

Goal for Section 1.1

- Recognize the difference between a hypothesis and a theory and understand how laws are established.

A Scientific Mystery: Ötzi the Iceman

In 1991 a hiker in the Alps on the Austrian-Italian border found a well-preserved human body encased in ice. It was first thought to be a person who had recently died, but a number of scientific studies over more than a decade concluded the man had lived 53 centuries ago and was about 46 years old when he died. He became known as Ötzi the Iceman.



The discovery of the Iceman's body, one of the oldest naturally-formed mummies, set off many scientific studies that brought together chemists, biologists, anthropologists, paleontologists, and others from all over the world. These studies give us a marvelous view of how science is done and the role that chemistry plays. Among the many discoveries made about the Iceman were the following:

- Some investigators looked for food residues in the Iceman's intestines. In addition to finding a few particles of grain, they located tiny flakes of mica believed to come from stones used to grind the grain the man ate. Their composition was like that of mica in a small area south of the Alps, thus establishing where the man lived in his later years. And, by analyzing animal fibers in his stomach, they determined his last meal was the meat of an Alpine ibex.

◀ **Ötzi the Iceman.** In 1991 a well-preserved body was found by a hiker in the Alps. The name "Ötzi" comes from the Ötz valley, the region of Europe (on the Austrian-Italian border) where the man was found. This discovery sparked a large number of studies, many involving chemistry, to discover how the Iceman lived and died.

Figure 1.1 Cinnabar and mercury. Heating cinnabar (mercury(II) sulfide) in air changes it into orange mercury(II) oxide, which, on further heating, decomposes to the elements mercury and oxygen gas.

- High levels of copper and arsenic were incorporated into his hair. These observations, combined with the discovery that his ax was nearly pure copper, led the investigators to conclude he had been involved in copper smelting.
- One fingernail was still present on his body. Based on its condition, scientists concluded that he had been sick three times in the 6 months before he died and his last illness had lasted for 2 weeks. Finally, images of his teeth showed severe periodontal disease and cavities.
- Australian scientists took samples of blood residues from his stone-tipped knife, his arrows, and his coat. Using techniques developed to study ancient DNA, they found the blood came from four individuals. The blood on one arrow tip was from two individuals, suggesting that the man had killed or wounded two people using this arrow tip. Perhaps he had killed or wounded one person, retrieved the arrow, and used it again.

The many different methods used to reveal the life of the Iceman and his environment are used by scientists around the world, including present-day forensic scientists in their study of accidents and crimes. As you study chemistry and the chemical principles in this book, keep in mind that many areas of science depend on chemistry and that many different careers in the sciences are available.

Chemistry and Change

Chemistry is about change. It was once only about changing one natural substance into another—wood and oil burn, grape juice turns into wine, and cinnabar (Figure 1.1), a red mineral, ultimately changes into shiny quicksilver (mercury) when heated. The emphasis was largely on finding a recipe to carry out a desired change with little understanding of the underlying structure of the materials or explanations for why particular changes occurred. Chemistry is still about change, but now chemists focus on the change of one pure substance, whether natural or synthetic, into another and on understanding that change (Figure 1.2). As you will see, in modern chemistry, we now picture an exciting world of submicroscopic atoms and molecules interacting with each other. We have also developed ways to predict whether or not a particular reaction may occur.

Although chemistry is endlessly fascinating—at least to chemists—why should you study chemistry? Each person probably has a different answer, but many students take a chemistry course because someone else has decided it is an important part of preparing for a particular career. Chemistry is especially useful because it is central to our understanding of disciplines as diverse as biology, geology, materials science, medicine, physics, and some branches of engineering. In addition, chemistry plays a major role in the economy of developed nations, and chemistry and chemicals affect our daily lives in a wide variety of ways. A course in chemistry can also help you see how a scientist thinks about the world and how to solve problems. The knowledge and skills developed in such a course will benefit you in many career paths and will help you become a better informed citizen in a world that is becoming technologically more complex—and more interesting.

Hypotheses, Laws, and Theories

As scientists, we study questions of our own choosing or ones that someone else poses in the hope of finding an answer or discovering some useful information. When the Iceman was discovered, there were many questions that scientists could try to answer, such as where he lived. Considering what was known about humans living in that age, it seemed reasonable to assume that he was from an area on the border of what is now Austria and Italy. That is, regarding his origins, the scientists formed a **hypothesis**, a tentative explanation or prediction in accord with current knowledge.

After formulating one or more hypotheses, scientists perform experiments designed to give results that confirm or invalidate these hypotheses. In chemistry this usually requires that both quantitative and qualitative information be collected. **Quantitative** information is numerical data, such as the mass of a substance (Figure 1.3) or temperature at which it melts. **Qualitative** information, in contrast, consists of nonnumerical observations, such as the color of a substance or its physical appearance.

In the case of the Iceman, scientists assembled a great deal of qualitative and quantitative information on his body, his clothing, and his weapons. Among this was information on the ratio of oxygen isotopes in his tooth enamel and bones. Scientists know that the ratio of oxygen isotopes in water and plants differs from place to place. This ratio of isotopes showed that the Iceman must have consumed water from a relatively small location within what is now Italy.

This analysis using oxygen isotopes could be done because it is well known that oxygen isotopes in water vary with altitude in predictable ways. That is, the variation in isotope composition with location can be considered a law of science. After numerous experiments by many scientists over an extended period of time, these results have been summarized as a **law**—a concise verbal or mathematical statement of a behavior or a relation that seems always to be the same under the same conditions.

Figure 1.4 The metallic element sodium reacts with water.

We base much of what we do in science on laws because they help us predict what may occur under a new set of circumstances. For example, we know from experience that if the chemical element sodium comes in contact with water, a violent reaction occurs and new substances are formed (Figure 1.4), and we know that the mass of the substances produced in the reaction is exactly the same as the mass of sodium and water used in the reaction. That is, *mass is always conserved in chemical reactions,* the **law of conservation of matter**.

Once enough reproducible experiments have been conducted and experimental results have been generalized as a law or general rule, it may be possible to conceive a theory to explain the observation. A **theory** is a well-tested, unifying principle that explains a body of facts and the laws based on them. It is capable of suggesting new hypotheses that can be tested experimentally.

Sometimes nonscientists use the word *theory* to imply that someone has made a guess and that an idea is not yet substantiated. To scientists, however, a theory is based on carefully determined and reproducible evidence. Theories are the cornerstone of our understanding of the natural world at any given time. Remember, though, that theories are inventions of the human mind. Theories can and do change as new facts are uncovered.

Goals of Science

Scientists, including chemists, have several goals. Two of these are *prediction* and *control*. We do experiments and look for generalities because we want to be able to predict what may occur under other circumstances. We also want to know how we might control the outcome of a chemical reaction or process.

Understanding and *explaining* are two other important goals. We know, for example, that certain elements such as sodium react vigorously with water. But why should this be true? To explain and understand this, we need a background in chemical concepts.

Dilemmas and Integrity in Science

You may think research in science is straightforward: Do experiments, collect information, and draw a conclusion. But, research is seldom that easy. Frustrations and disappointments are common enough, and results can be inconclusive. Experiments often contain some level of uncertainty, and contradictory data can be collected. For example, suppose you do an experiment expecting to find a direct relation between two experimental quantities. You collect six data sets. When plotted on a graph, four of the sets lie on a straight line, but two others lie far away from the line. Should you ignore the last two sets of data? Or should you do more experiments when you know the time they take will mean someone else could publish their results first and thus get the credit for a new scientific principle? Or should you consider that the two points not on the line might indicate that your original hypothesis is wrong and that you will have to abandon a favorite idea you have worked on for many months? Scientists have a responsibility to remain objective in these situations, but sometimes it is hard to do.

It is important to remember that a scientist is subject to the same moral pressures and dilemmas as any other person. To help ensure integrity in science, some simple principles have emerged over time that guide scientific practice:

- Experimental results should be reproducible. Furthermore, these results should be reported in the scientific literature in enough detail so that they can be used or reproduced by others.
- Research reports should be reviewed before publication by experts in the field to make sure that the experiments have been conducted properly and that the conclusions are logical. (Scientists refer to this as "peer review.")
- Conclusions should be reasonable and unbiased.
- Credit should be given where it is due.

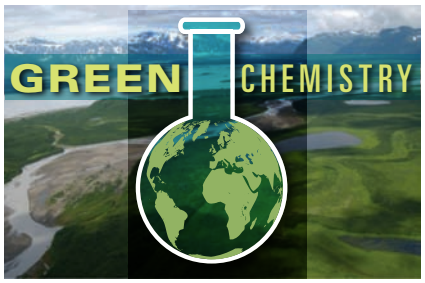
1.2 Sustainability and Green Chemistry

Goal for Section 1.2



- Understand the principles of green chemistry.

The world's population is about 7.5 billion people, with about 80 million added per year. Each new person needs shelter, food, and medical care, and each uses increasingly scarce resources like fresh water and energy. And each produces by-products in the act of living and working that can affect our environment. With such a large population, these individual effects can have large consequences for our planet. The focus of scientists, planners, and politicians is increasingly turning to a concept of "sustainable development."

James Cusumano, a chemist and former president of a chemical company, said that "On one hand, society, governments, and industry seek economic growth to create greater value, new jobs, and a more enjoyable and fulfilling lifestyle. Yet, on the other, regulators, environmentalists, and citizens of the globe demand that we do so with *sustainable development*—meeting today's global economic and environmental needs while preserving the options of future generations to meet theirs. How do nations resolve these potentially conflicting goals?" This conflict is even more evident now than it was in 1995 when Dr. Cusumano made this statement in the *Journal of Chemical Education*.

Much of the increase in life expectancy and quality of life, at least in the developed world, is derived from advances in science. But we have paid an environmental price for it, with increases in gases such as nitrogen oxides and sulfur oxides in the atmosphere, acid rain falling in many parts of the world, and waste pharmaceuticals entering the water supply. Among many others, chemists are seeking answers to these problems, and one response has been to practice *green chemistry.*

The concept of green chemistry began to take root more than 20 years ago and is now leading to new ways of doing things and to lower pollutant levels. Paul Anastas and John Warner stated the principles of green chemistry in their book *Green Chemistry: Theory and Practice* (Oxford, 1998). Among these are the ones stated below.

© Cengage Learning/Charles D. Winters

- "It is better to prevent waste than to treat or clean up waste after it is formed."
- New pharmaceuticals or consumer chemicals are synthesized by a large number of chemical processes. "Synthetic methods should be designed to maximize the incorporation of all materials used in the final product."
- Synthetic methods "should be designed to use and generate substances that possess little or no toxicity to human health or the environment."
- "Chemical products should be designed to [function effectively] while still reducing toxicity."
- "Energy requirements should be recognized for their environmental and economic impacts and should be minimized. Synthetic methods should be conducted at ambient temperature and pressure."
- Raw materials "should be renewable whenever technically and economically practical."
- "Chemical products should be designed so that at the end of their function, they do not persist in the environment or break down into dangerous products."
- "Substances used in a chemical process should be chosen to minimize the potential for chemical accidents, including releases, explosions, and fires."

As you read *Chemistry & Chemical Reactivity,* we will remind you of these principles, and others, and how they can be applied. As you can see, they are simple ideas. The challenge is to put them into practice.

1.3 Classifying Matter

Goals for Section 1.3

- Understand the basic ideas of kinetic-molecular theory.
- Recognize the importance of representing matter at the macroscopic, microscopic, and symbolic levels.
- Recognize the different states of matter (solids, liquids, and gases) and give their characteristics.
- Recognize the difference between pure substances and mixtures and the difference between homogeneous and heterogeneous mixtures.

This chapter begins our discussion of how chemists think about science in general and about matter in particular. After looking at a way to classify matter, we will turn to some basic ideas about elements, atoms, compounds, and molecules and describe how chemists characterize these building blocks of matter.

States of Matter and Kinetic-Molecular Theory

An easily observed property of matter is its **state**—that is, whether a substance is a solid, liquid, or gas (Figure 1.5). You recognize a material as a solid because it has a rigid shape and a fixed volume that changes little as temperature and pressure change. Like solids, liquids have a fixed volume, but a liquid is fluid—it takes on the shape of its container and has no definite shape of its own. Gases are fluid as well, but the volume of a gas is determined by the size of its container. The volume of a gas varies more than the volume of a liquid with changes in temperature and pressure.

At low enough temperatures, virtually all matter is found in the solid state. As the temperature is raised, solids usually melt to form liquids. Eventually, if the temperature is high enough, liquids evaporate to form gases. Volume changes typically accompany changes in state. For a given mass of material, there is usually a small increase in volume on melting—water being a significant exception—and then a large increase in volume occurs upon evaporation.

The **kinetic-molecular theory of matter** helps us interpret the properties of solids, liquids, and gases. According to this theory, all matter consists of extremely tiny particles (atoms, molecules, or ions) in constant motion.

- In solids, particles are packed closely together, usually in a regular pattern. The particles vibrate back and forth about their average positions, but seldom do particles in a solid squeeze past their immediate neighbors to come into contact with a new set of particles.
- The particles in liquids are arranged randomly rather than in the regular patterns found in solids. Liquids and gases are fluid because the particles are not confined to specific locations and can move past one another.
- Under normal conditions, the particles in a gas are far apart. Gas molecules move extremely rapidly and are not constrained by their neighbors. The molecules of a gas fly about, colliding with one another and with the container walls. This random motion allows gas molecules to fill their container, so the volume of the gas sample is the volume of the container.
- There are net forces of attraction between particles in all states—generally small in gases and large in liquids and solids. These forces have a significant role in determining the properties of matter.

An important aspect of the kinetic-molecular theory is that *the higher the temperature, the faster the particles move*. The energy of motion of the particles (their **kinetic energy**, Section 1.8) acts to overcome the forces of attraction between particles. A solid melts to form a liquid when the temperature of the solid is raised to the point at which the particles vibrate fast enough and far enough to push one

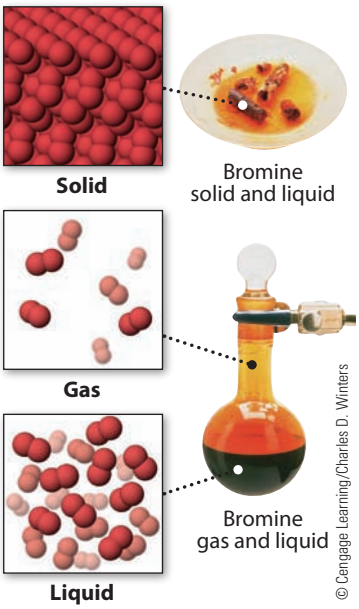

Figure 1.5 States of matter—solid, liquid, and gas. Elemental bromine exists in all three states near room temperature.

another out of the way and move out of their regularly spaced positions. As the temperature increases even more, the particles move faster still until finally they can escape the clutches of their neighbors and enter the gaseous state.

Matter at the Macroscopic and Particulate Levels

The characteristic properties of gases, liquids, and solids can be observed by the unaided human senses. They are determined using samples of matter large enough to be seen, measured, and handled. You can determine, for example, the color of a substance, whether it dissolves in water, whether it conducts electricity, and if it reacts with oxygen. Observations such as these generally take place in the **macroscopic** world of chemistry (Figure 1.6). This is the world of experiments and observations.

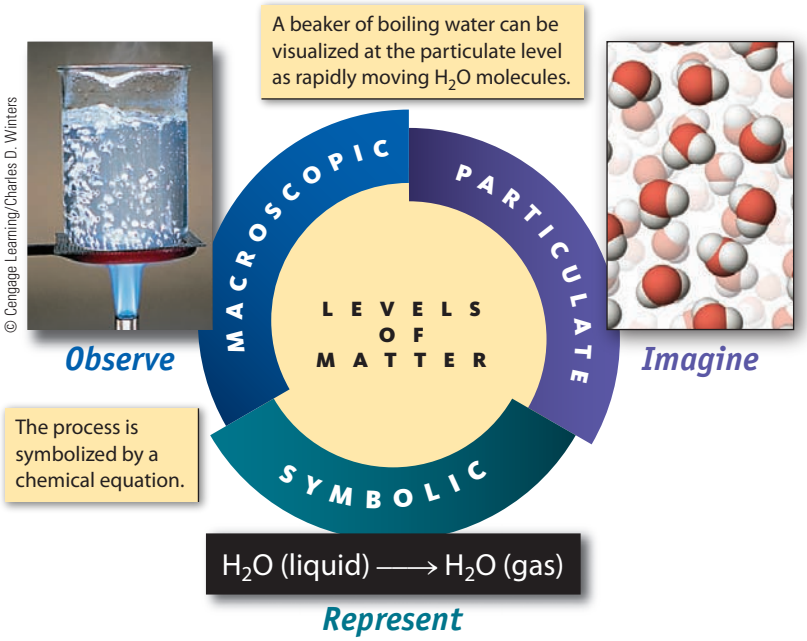

Figure 1.6 Levels of matter. We observe chemical and physical processes at the macroscopic level. To understand or illustrate these processes, scientists often imagine what has occurred at the particulate atomic and molecular levels and write symbols to represent these observations.

Now let us move to the level of atoms, molecules, and ions—a world of chemistry we cannot see. Take a macroscopic sample of material and divide it, again and again, past the point where the amount of sample can be seen by the naked eye, past the point where it can be seen using an optical microscope. Eventually you reach the level of individual particles that make up all matter, a level that chemists refer to as the **submicroscopic** or **particulate** world of atoms and molecules (Figures 1.5 and 1.6).

Chemists are interested in the structure of matter at the particulate level. Atoms, molecules, and ions cannot be "seen" in the same way that one views the macroscopic world, but they are no less real. Chemists imagine what atoms must look like and how they might fit together to form molecules. They create models to represent atoms and molecules (Figures 1.5 and 1.6)—where tiny spheres are used to represent atoms—and then use these models to think about chemistry and to explain the observations they have made about the macroscopic world.

Chemists carry out experiments at the macroscopic level, but they think about chemistry at the particulate level. They then write down their observations as "symbols," the formulas (such as H_2O for water or NH_3 for ammonia molecules) and drawings that represent the elements and compounds involved. This is a useful perspective that will help you as you study chemistry. Indeed, one of our goals is to help you make the connections in your own mind among the symbolic, particulate, and macroscopic worlds of chemistry.

Pure Substances

A chemist looks at a glass of drinking water and sees a liquid. This liquid could be the pure chemical compound water. However, it is also possible the liquid is actually a homogeneous mixture of water and dissolved substances—that is, a **solution**. Specifically, we can classify a sample of matter as being either a pure substance or a mixture (Figure 1.7).

A pure substance has a set of unique properties by which it can be recognized. Pure water, for example, is colorless and odorless. If you want to identify a substance conclusively as water, however, you would have to examine its properties more carefully and compare them against the known properties of pure water. Melting point and boiling point serve the purpose well here. If you could show that the substance melts at 0 °C and boils at 100 °C at atmospheric pressure, you can be certain it is water. No other known substance melts and boils at precisely those temperatures.

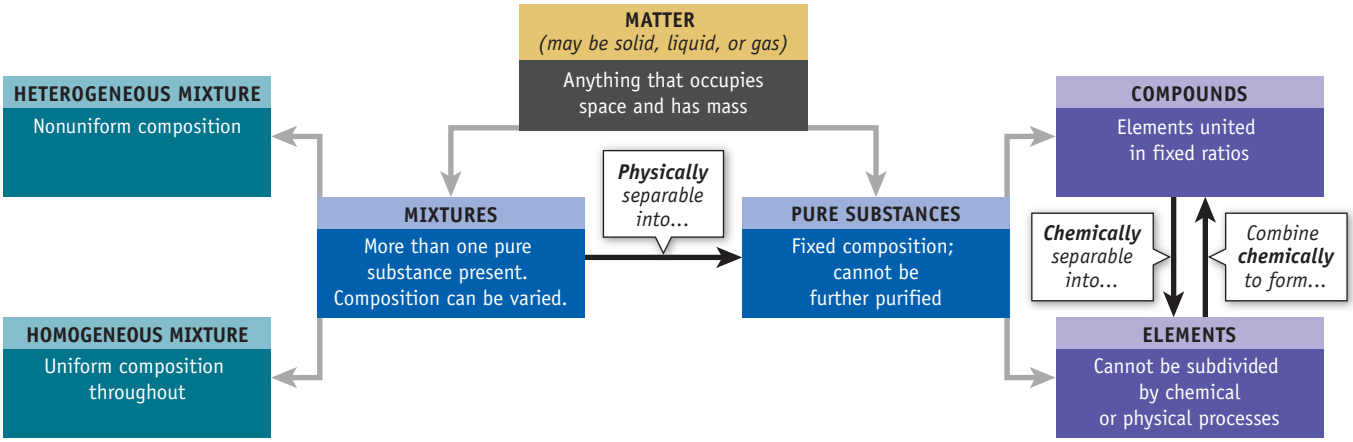

Figure 1.7 Classifying matter.

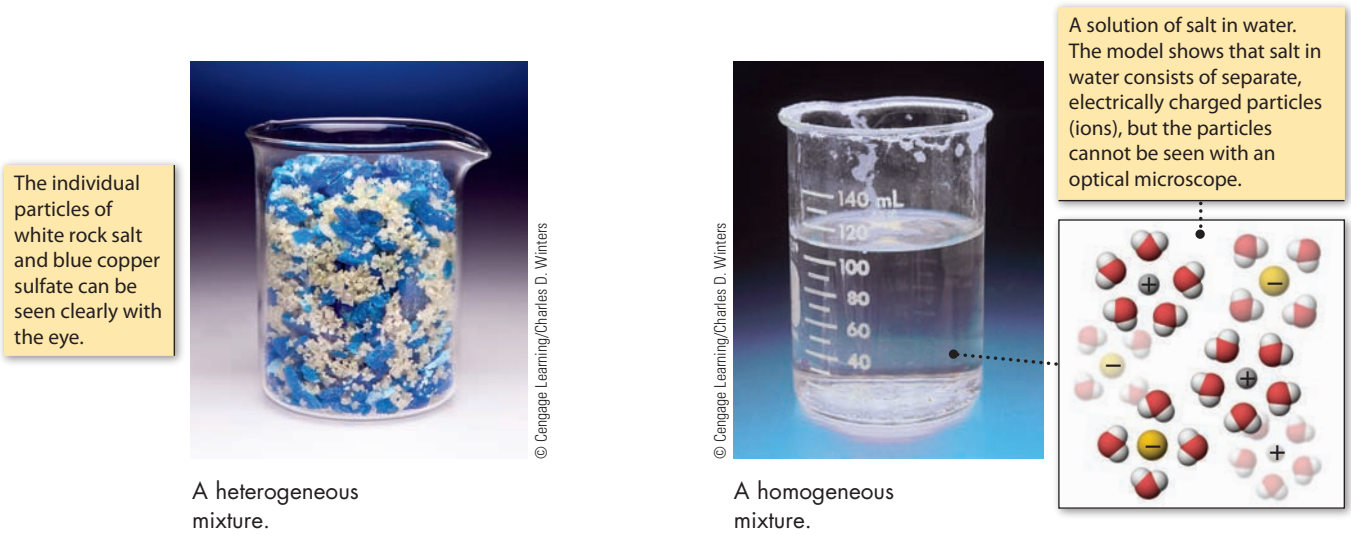
A second feature of a pure substance is that it cannot be separated into two or more different species by any physical technique at ordinary temperatures. If it could be separated, our sample would be classified as a mixture.

Mixtures: Heterogeneous and Homogeneous

A mixture consists of two or more pure substances that can be separated by physical techniques. In a **heterogeneous** mixture the uneven texture of the material can often be detected by the naked eye (Figure 1.8). However, keep in mind there are heterogeneous mixtures that may appear completely uniform but on closer examination are not. Milk, for example, appears smooth in texture to the unaided eye, but magnification would reveal fat and protein globules within the liquid. In a heterogeneous mixture the properties in one region are different from those in another region.

A **homogeneous** mixture consists of two or more substances in the same phase (Figure 1.8). No amount of optical magnification will reveal a homogeneous mixture to have different properties in different regions. Homogeneous mixtures are often called **solutions**. Common examples include air (mostly a mixture of nitrogen and oxygen gases), gasoline (a mixture of carbon- and hydrogen-containing compounds called *hydrocarbons*), and a soft drink in an unopened container.

When a mixture is separated into its pure components, the components are said to be **purified**. Efforts at separation are often not complete in a single step, however,



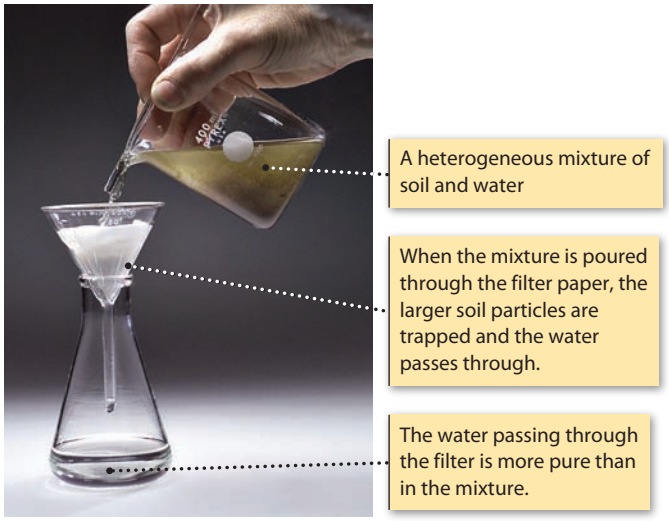


Figure 1.8 Heterogeneous and homogeneous mixtures.

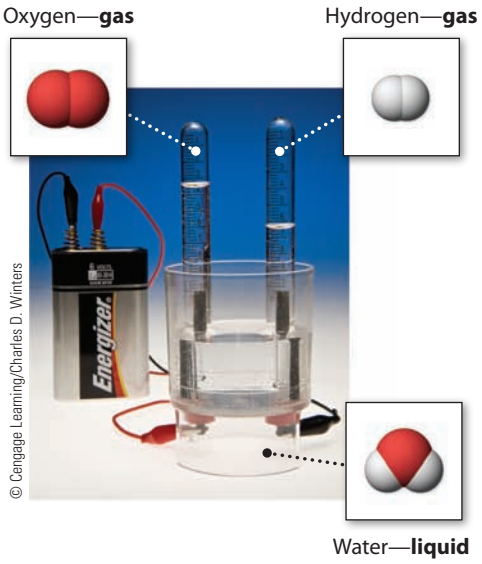
Figure 1.9 Purifying a heterogeneous mixture by filtration.

and repetition almost always gives an increasingly pure substance. For example, soil particles can be separated from water by filtration (Figure 1.9). When the mixture is passed through a filter, many of the particles are removed. Repeated filtrations will give water with a higher and higher state of purity. This purification process uses a property of the mixture, its clarity, to measure the extent of purification. When a perfectly clear sample of water is obtained, all of the soil particles are assumed to have been removed.



1.4 Elements

Goals for Section 1.4

- Identify the name or symbol for an element, given its symbol or name, respectively.
- Use the terms atom, element, and molecule correctly.

Passing an electric current through water can decompose it to gaseous hydrogen and oxygen (Figure 1.10). Substances like hydrogen and oxygen that are composed of *only one type of atom* are classified as **elements**. Currently 118 elements are known. Of these, only about 90—a few of which are illustrated in Figure 1.11—are found in nature. The remainder have been created by scientists. *Names and symbols for the elements are listed in the tables at the front and back of this book.* Carbon (C), sulfur (S), iron (Fe), copper (Cu), silver (Ag), tin (Sn), gold (Au), mercury (Hg), and lead (Pb) were known to the early Greeks and Romans and to the alchemists of ancient China, the Arab world, and medieval Europe. However, many other elements—such as aluminum (Al), silicon (Si), iodine (I), and helium (He)—were not discovered until the 18th and 19th centuries. Finally, scientists in the 20th and 21st centuries have made elements that do not exist in nature, such as technetium (Tc) and plutonium (Pu).

The stories behind some of the names of the elements are fascinating. Many elements have names and symbols with Latin or Greek origins. Examples include helium (He), from the Greek word *helios* meaning "sun," and lead, whose symbol, Pb, comes from the Latin word for "heavy," *plumbum*. More recently discovered elements have been named for their place of discovery or place of significance. Americium (Am),

Figure 1.11 Elements.
Chemical elements can often be distinguished by their color and their state at room temperature.

californium (Cf), scandium (Sc), europium (Eu), francium (Fr), and polonium (Po) are examples.

A number of elements are named for their discoverers or famous scientists: curium (Cm), einsteinium (Es), fermium (Fm), mendelevium (Md), nobelium (No), seaborgium (Sg), and meitnerium (Mt), among others. A recently named element, element 112, was given its official name, copernicium (Cn), in 2010. It was named after Nicolaus Copernicus (1473–1543), who first proposed that Earth and the other planets orbit the Sun. Some say his work was the beginning of the scientific revolution.

When writing the symbol for an element, notice that the first letter (but not the second) of an element's symbol is capitalized. For example, cobalt is Co, not co or CO. The notation co has no chemical meaning, whereas CO represents the chemical compound carbon monoxide. Also note that the element name is not capitalized, except at the beginning of a sentence.

The table inside the front cover of this book, in which the symbol and other information for the elements are enclosed in a box, is called the **periodic table**. We will describe this important tool of chemistry in more detail beginning in Chapter 2.

An **atom** is the smallest particle of an element that retains the characteristic chemical properties of that element. Some elements, such as neon and argon, are found in nature as isolated atoms. Others are found as **molecules**, particles consisting of more than one atom in which the atoms are held together by **chemical bonds.** Examples of molecular elements are the colorless gases of the air, nitrogen (N_2) and oxygen (O_2) as well as deep purple iodine (I_2) and orange liquid bromine (Br_2). Yet other elements consist of infinite networks of atoms; an example of this is diamond, one of the forms of the element carbon.

© Cengage Learning/Charles D. Winters

Diamond. A diamond consists of a network of carbon atoms linked by chemical bonds.

1.5 Compounds

Goals for Section 1.5

- Use the term *compound* correctly.
- Understand the law of definite proportions (law of constant composition).

A pure substance like sugar, salt, or water, which is composed of two or more different elements held together by chemical bonds, is referred to as a **chemical compound**. Even though only 118 elements are known, there appears to be no limit to the number of compounds that can be made from those elements. In mid-2016, over 100 million different compounds were identified in *Chemical Abstracts*, a database created by the American Chemical Society.

Number of Substances About 15,000 new substances are added to the *Chemical Abstracts* Registry each day.

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

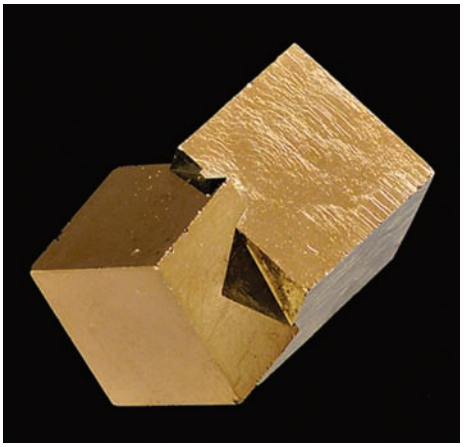
The properties of a compound, such as its color, hardness, and melting point, are different than those of its constituent elements. Consider common table salt (sodium chloride), which is composed of two elements (Figure 1.2):



- Sodium is a shiny metal that reacts violently with water. Its solid-state structure has sodium atoms tightly packed together.
- Chlorine is a light yellow gas that has a distinctive, suffocating odor and is a powerful irritant to lungs and other tissues. The element is composed of Cl_2 molecules in which two chlorine atoms are tightly bound together.
- Sodium chloride, or common salt (NaCl), is a colorless, crystalline solid composed of sodium and chlorine ions bound tightly together. Its properties are completely unlike those of the two elements from which it is made.

It is important to distinguish between a mixture of elements and a chemical compound of two or more elements. Pure metallic iron and yellow, powdered sulfur can be mixed in varying proportions. In the chemical compound iron pyrite, however, there is no variation in composition. Not only does iron pyrite exhibit properties unique to itself and different from those of either iron or sulfur, or a mixture of these two elements, it also has a definite percentage composition by mass (46.55% Fe and 53.45% S). That a compound has a definite composition (by mass) of its combining elements is a basic principle of chemistry and is often referred to as the **law of definite proportions** or the **law of constant composition**. Thus, two major differences exist between a mixture and a pure compound: A compound has distinctly different characteristics from its parent elements, and it has a definite percentage composition (by mass) of its combining elements.

© Cengage Learning/Charles D. Winters

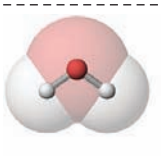
The material in the dish is a **mixture** of elements, iron and sulfur. The iron can be separated easily from the sulfur by using a magnet.

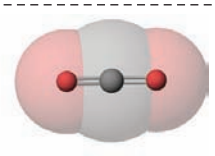
© Cengage Learning/Charles D. Winters

Iron pyrite is a **chemical compound** composed of iron and sulfur. It is often found in nature as perfect, golden cubes.

Some compounds—such as table salt, NaCl—are composed of **ions**, which are electrically charged atoms or groups of atoms (Section 2.5). Other compounds—such as water and sugar—consist of molecules.

The composition of any compound is represented by its **chemical formula**. In the formula for water, H_2O, for example, the symbol for hydrogen, H, is followed by a subscript 2, indicating that two atoms of hydrogen occur in a single water molecule. The symbol for oxygen appears without a subscript, indicating that one oxygen atom occurs in the molecule.





Name	Water	Methane	Ammonia	Carbon dioxide
Formula	H_2O	CH_4	NH_3	CO_2
Model				

Figure 1.12 Names, formulas, and models of some common molecular compounds. A common color scheme is that C atoms are gray, H atoms are white, N atoms are blue, and O atoms are red.

As you shall see throughout this text, molecules can be represented with models that depict their composition and structure. Figure 1.12 illustrates the names, formulas, and models of the structures of four common molecular compounds.

EXAMPLE 1.1

Elements and Compounds

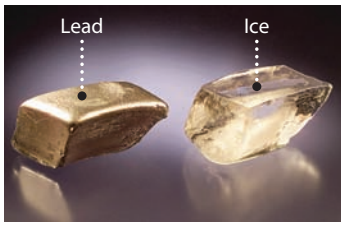
Problem Identify whether each of the following is an element or compound: bromine, Br_2 and hydrogen peroxide, H_2O_2.

What Do You Know? Elements and compounds are both pure substances. An element is composed of only one type of atom. A compound is composed of more than one type of atom, where the atoms are connected by chemical bonds and occur in a definite proportion by mass.

Strategy Look at each formula given and use the guidelines above to determine whether the formula is that for an element or a compound.

SOLUTION Bromine, Br_2, is an element because both of the atoms present in the molecule are the same type, bromine atoms. H_2O_2 is a compound. In H_2O_2, there are two different types of atoms present, hydrogen atoms and oxygen atoms. They are bonded together in hydrogen peroxide molecules that have a definite composition by mass; each molecule of H_2O_2 has two atoms of hydrogen and two atoms of oxygen.

Think about Your Answer If all of the atoms in a molecule are the same type, such as in Br_2, then it is a molecule of an element.



Check Your Understanding

Identify whether white phosphorus (P_4) and carbon monoxide (CO) are elements or compounds.

1.6 Physical Properties

Goals for Section 1.6

- Identify several physical properties of common substances.
- Relate density to the volume and mass of a substance.
- Understand the difference between extensive and intensive properties and give examples of them.

© Cengage Learning/ Charles D. Winters

You recognize your friends by their physical appearance: their height and weight and the color of their eyes and hair. The same is true of chemical substances. You can tell the difference between an ice cube and a cube of lead of the same size not only because of their appearance (one is clear and colorless, and the other is a lustrous metal), but also because one is more dense (lead) than the other (ice). Properties such as these, which can be observed and measured without changing the composition of a substance, are called **physical properties**. The chemical elements in Figure 1.11, for example, clearly differ in terms of their color, appearance, and state (solid, liquid, or gas). Physical properties allow us to classify and identify substances. Table 1.1 lists a few physical properties of matter that chemists commonly use.

Density, the ratio of the mass of an object to its volume, is a physical property useful for identifying substances.

$$\text{Density} = \frac{\text{mass}}{\text{volume}} \qquad (1.1)$$

Units of Density The decimal system of units in the sciences is called Le Système International d'Unités, often referred to as SI units. The SI unit of density is kg/m^3. In chemistry, the more commonly used unit is g/cm^3. To convert from kg/m^3 to g/cm^3, divide by 1000.

TABLE 1.1 Some Physical Properties

Property	Using the Property to Distinguish Substances
Color	Is the substance colored or colorless? What is the color, and what is its intensity?
State of matter	Is it a solid, liquid, or gas? If it is a solid, what is the shape of the particles?
Melting point	At what temperature does a solid melt?
Boiling point	At what temperature does a liquid boil (at 1 atmosphere pressure)?
Density	What is the substance's density (mass per unit volume)?
Solubility	What mass of substance can dissolve in a given volume of water or other solvent?
Electric conductivity	Does the substance conduct electricity?
Malleability	How easily can a solid be deformed?
Ductility	How easily can a solid be drawn into a wire?
Viscosity	How easily will a liquid flow?

TABLE 1.2

Temperature Dependence of Water Density

Temperature (°C)	Density of Water (g/cm^3)
0 (ice)	0.917
0 (liq water)	0.99984
2	0.99994
4	0.99997
10	0.99970
25	0.99707
100	0.95836

© Cengage Learning/Charles D. Winters

Figure 1.13 Temperature dependence of physical properties. The density of water and other substances changes with temperature.

For example, you can readily tell the difference between an ice cube and a cube of lead of identical size because lead has a high density, 11.35 g/cm^3 (11.35 grams per cubic centimeter), whereas ice has a density slightly less than 0.917 g/cm^3. An ice cube with a volume of 16.0 cm^3 has a mass of 14.7 g, whereas a cube of lead with the same volume has a mass of 182 g.

The **temperature** of a sample of matter often affects the numerical values of its properties. Density is a particularly important example. Although the change in water density with temperature seems small (Table 1.2), it affects our environment profoundly. For example, as the water in a lake cools, the density of the water increases and the denser water sinks as you see in Figure 1.13. This continues until the water temperature reaches 3.98 °C, the point at which water has its maximum density (0.999973 g/cm^3). If the water temperature drops farther, the density decreases slightly and the colder water floats on top of water at 3.98 °C. If water is cooled below about 0 °C, solid ice forms. Water has a rare property: Its solid form is less dense than its liquid form, so ice floats on water.

The volume of a given mass of liquid changes with temperature, so its density does as well. This is the reason laboratory glassware used to measure precise volumes of solutions always specifies the temperature at which it was calibrated (Figure 1.14).

© Cengage Learning/Charles D. Winters

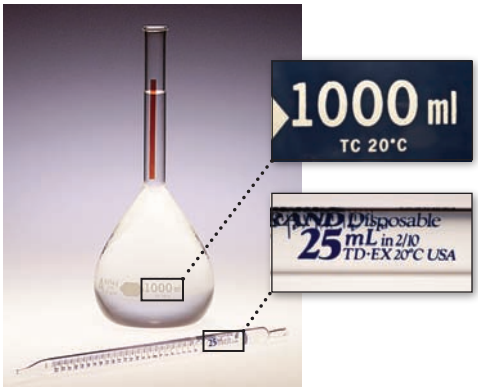

Figure 1.14 Dependence of density on temperature. Water and other substances change in density with temperature so laboratory apparatus is calibrated for a particular temperature.

EXAMPLE 1.2

Density

Problem A piece of a polypropylene rope (used for water skiing) floats on water, whereas a terephthalate polymer from a soda bottle sinks in water. Place polypropylene, the terephthalate polymer, and water in order of increasing density.

What Do You Know? Density is given by Equation 1.1. An object with a higher density will sink in a liquid of lower density, whereas an object with a lower density will float in a liquid of higher density.

Strategy Use the observations as to whether a material sinks or floats in water to determine the order of the densities.

SOLUTION The polypropylene rope floats in water, therefore polypropylene is less dense than water. The soda bottle plastic sinks in water; therefore the soda bottle plastic is more dense than the water. This gives the overall order of densities: polypropylene < water < soda bottle plastic.

Think about Your Answer In a material with a greater density, the matter is more tightly packed for a given mass than in materials of lower density.

Check Your Understanding

Some salad dressings are made from a mixture of olive oil and vinegar. These two liquids are not significantly soluble in each other. If this mixture is allowed to sit, the two liquids separate from each other with the olive oil floating on top of the vinegar. Which liquid has the greater density?

Extensive and Intensive Properties

Extensive properties depend on the amount of a substance present. The mass and volume of samples of elements or compounds or the amount of energy transferred as heat from burning gasoline are extensive properties, for example.

In contrast, **intensive properties** do *not* depend on the amount of substance. A sample of ice will melt at 0 °C, no matter whether you have an ice cube or an iceberg.

Although mass and volume are extensive properties, it is interesting that density (the quotient of these two quantities) is an intensive property. The density of gold, for example, is the same (19.3 g/cm^3 at 20 °C) whether you have a flake of pure gold or a solid gold ring.

Intensive properties are often useful in identifying a material. For example, the temperature at which a material melts (its melting point) is often so characteristic that it can be used to identify the solid (Figure 1.15).

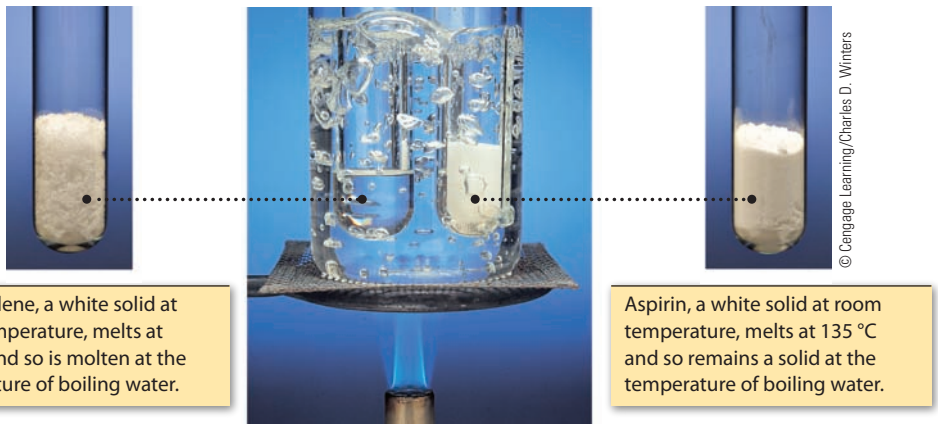

Figure 1.15 A physical property used to distinguish compounds.

EXAMPLE 1.3

Extensive and Intensive Properties

Problem A sample of liquid mercury has a shiny surface, melts at 234 K, has a mass of 27.2 g, has a volume of 2.00 cm^3, and has a density of 13.6 g/cm^3. Which of these properties are extensive properties and which are intensive properties?

What Do You Know? Extensive properties depend on the amount of a substance present. Intensive properties do not depend on the amount of substance present.

Strategy Determine which of the properties listed depend on the amount of material present and which do not.

SOLUTION The mass and volume of the sample each depend on the amount of material present; the greater the amount of material present, the greater will be the mass and the volume. Mass and volume are extensive properties. The shininess of the surface, the melting point, and the density are properties that are the same regardless of the amount of material present, so they are intensive properties.

Think about Your Answer Mass and volume are both extensive properties, but their quotient, density, is an intensive property.

Check Your Understanding

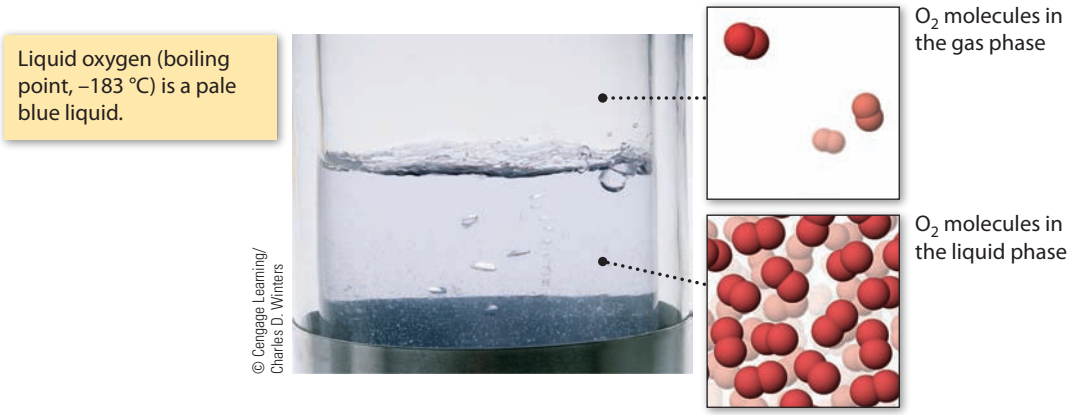
Identify whether each of the following properties is extensive or intensive: boiling point, hardness, volume of a solution, number of atoms, number of atoms dissolved per volume of solution.

1.7 Physical and Chemical Changes

Goals for Section 1.7

- Explain the difference between chemical and physical changes.
- Identify several chemical properties of common substances.

Changes in physical properties are called **physical changes**. In a physical change the identity of a substance is preserved even though it may have changed its physical state or the gross size and shape of its pieces. A physical change does not result in a new chemical substance being produced. The particles (atoms, molecules, or ions) present before and after the change are the same. An example of a physical change is the melting of a solid (Figure 1.15) or the evaporation of a liquid (Figure 1.16). In either case, the same molecules are present both before and after the change. Their chemical identities have not changed.



A physical property of hydrogen gas (H_2) is its low density, so a balloon filled with H_2 floats in air. Suppose, however, that a lighted candle is brought up to the balloon. When the heat causes the skin of the balloon to rupture, the hydrogen mixes with the oxygen (O_2) in the air, and the heat of the burning candle sets off a chemical reaction, producing water, H_2O (Figure 1.16). This reaction is an example of a **chemical change**, in which one or more substances (the **reactants**) are transformed into one or more different substances (the **products**).

A chemical change at the particulate level is also illustrated in Figure 1.16 by the reaction of hydrogen and oxygen molecules to form water molecules. The representation of the change using chemical formulas is called a **chemical equation**. It shows that the substances on the left (the reactants) produce the substances on the right (the products). This equation illustrates an important principle of chemical

Physical Change • The same molecules are present both before and after the change.

A symbolic and particulate view • The reaction of O_2 and H_2

Chemical change • One or more substances (reactants) are transformed into one or more different substances (products)

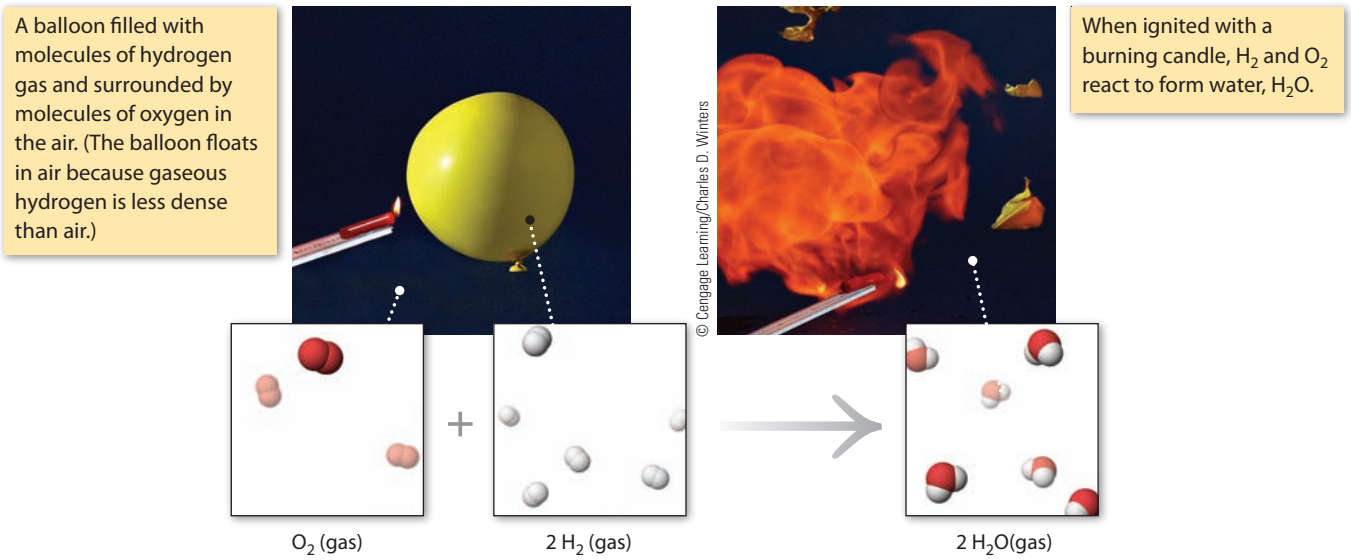

Figure 1.16 **Physical and chemical change.**

reactions: *matter is conserved*. The number and identity of the atoms found in the reactants are the same as in the products. Here, there are four atoms of H and two atoms of O before *and* after the reaction, but the molecules before the reaction are different from those after the reaction.

The term **chemical property** refers to chemical reactions that a substance might undergo. For example, a chemical property of hydrogen gas is that it reacts with oxygen gas, and quite vigorously so.

EXAMPLE 1.4

Physical and Chemical Changes

Problem Identify each of the following as being either a physical or a chemical change: boiling water and rusting of an iron nail.

What Do You Know? In a physical change, the chemical identities of the materials do not change, whereas in a chemical change, they do.

Strategy Examine each of the changes to determine if the chemical identities of the materials change.

SOLUTION In liquid water, the chemical species present is H_2O molecules. When water boils, molecules move to the gaseous state. The chemical species is still H_2O molecules; the molecules have merely changed states. Boiling water is thus a physical change. Rusting of an iron nail is a chemical change because we begin with iron and oxygen and end up with rust, which is predominantly the chemical compound iron(III) oxide, Fe_2O_3. The substance at the end of the process is a different chemical species than the ones with which we started.

Think about Your Answer Students sometimes confuse changes of state with chemical changes; changes of state are physical changes.

Check Your Understanding

Identify whether each of the following is a physical change or a chemical change: (a) melting butter, (b) burning wood, (c) dissolving sugar in water.

1.8 Energy: Some Basic Principles

Goals for Section 1.8

- Identify types of potential and kinetic energy.
- Recognize and apply the law of conservation of energy.

Energy, a crucial part of many chemical and physical changes, is defined as the capacity to do work. You do work against the force of gravity when carrying yourself and hiking equipment up a mountain. The energy to do this is provided by the food you have eaten. Food is a source of chemical energy—energy stored in chemical compounds and released when the compounds undergo the chemical reactions of metabolism in your body. Chemical reactions almost always either release or absorb energy.

Units of Energy Energy in chemistry is measured in units of joules. (See The Tools of Quantitative Chemistry (page 28) and Chapter 5 for calculations involving energy units.)

Energy can be classified as kinetic or potential. **Kinetic energy** is energy associated with motion, such as:

- The motion of atoms, molecules, or ions at the submicroscopic (particulate) level (*thermal energy*). All matter has thermal energy.
- The motion of macroscopic objects such as a moving tennis ball or automobile (*mechanical energy*).
- The movement of electrons in a conductor (*electrical energy*).
- The compression and expansion of the spaces between molecules in the transmission of sound (*acoustic energy*).

(a) Potential energy is converted to mechanical energy.

www.flickr.com

(b) Chemical potential energy of a fuel and oxygen is converted to thermal and mechanical energy in a jet engine.

Igor Zh./Shutterstock.com

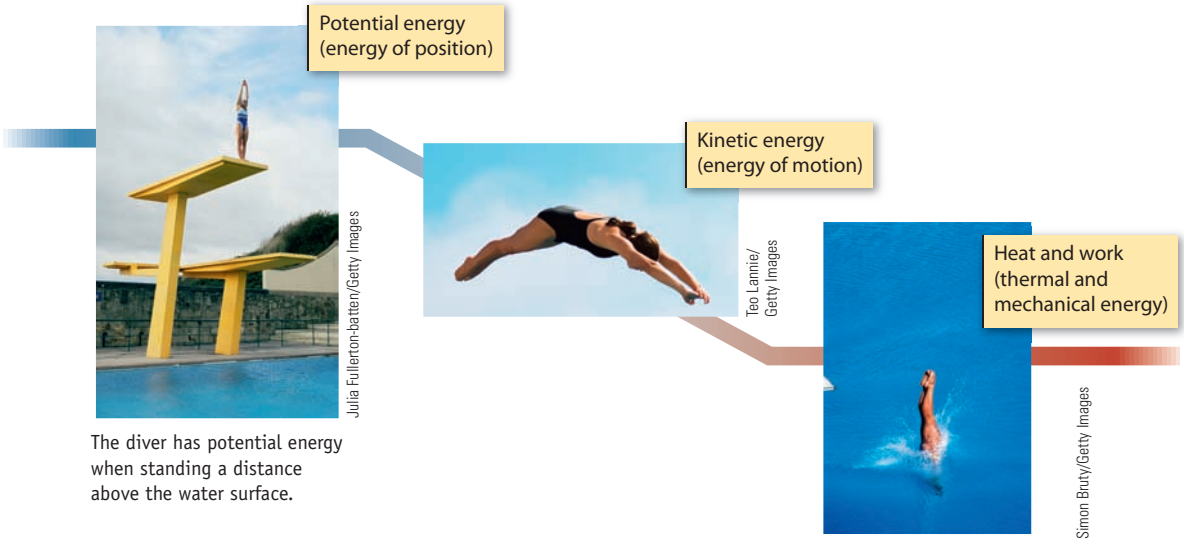
(c) Electrostatic energy is converted into radiant and thermal energy.

Figure 1.17 **Energy and its conversion.**

Potential energy results from an object's position or state and includes:

- Energy possessed by a ball held above the floor and by water at the top of a water wheel (*gravitational energy*) (Figure 1.17a).
- Energy stored in an extended spring.
- Energy stored in fuels (*chemical energy*) (Figure 1.17b).
- Energy associated with the separation of electrical charges (*electrostatic energy*) (Figure 1.17c).

Potential energy and kinetic energy can be interconverted. For example, as water falls over a waterfall, its potential energy is converted into kinetic energy. Similarly, kinetic energy can be converted into potential energy: The kinetic energy of falling water can turn a turbine to produce electricity, which can then be used to convert water into H_2 and O_2 by electrolysis. Hydrogen gas contains stored chemical potential energy because it can be burned to produce heat and light or electricity.



Conservation of Energy

Standing on a diving board, you have considerable potential energy because of your position above the water. Once you dive off the board, some of that potential energy is converted into kinetic energy (Figure 1.18). During the dive, the force of gravity accelerates your body so that it moves faster and faster. Your kinetic energy increases and your potential energy decreases. At the moment you hit the water, your velocity is abruptly reduced and much of your kinetic energy is transferred to the water as your body moves it aside. Eventually you float to the surface, and the water becomes still again. If you could see them, however, you would find that the water molecules are moving a little faster in the vicinity of your entry into the water; that is, the kinetic energy of the water molecules is slightly higher.

This series of energy conversions illustrates the **law of conservation of energy**, which states that *energy can neither be created nor destroyed.* Or, to state this law differently, *the total energy of the universe is constant.* The law of conservation of energy summarizes the results of many experiments in which the amounts of energy transferred have been measured and in which the total energy content has been found to be the same before and after an event.

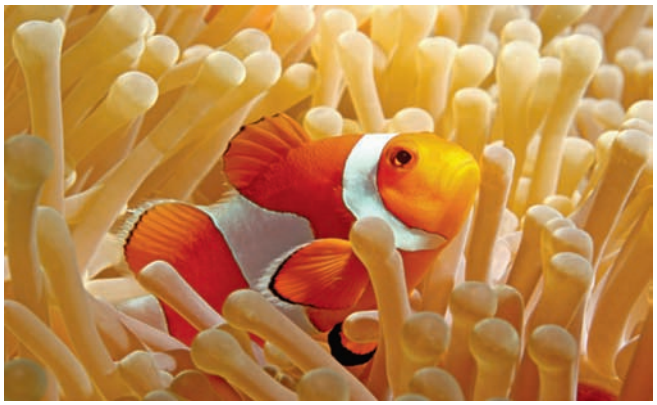
The diver has potential energy when standing a distance above the water surface.

The diver's potential energy is first converted to kinetic energy, which is then transferred to the water.

Figure 1.18 **The law of energy conservation.**

Let us examine this law in the case of a chemical reaction, the reaction of hydrogen and oxygen to form water (Figure 1.16). In this reaction, the reactants (hydrogen and oxygen) have a certain amount of energy associated with them. When they react, some of this energy is released to their surroundings. If we were to add up all of the energy present before the reaction and all of the energy present after the reaction, we would find that the energy has only been redistributed; the total amount of energy in the universe has remained constant. Energy has been conserved.

APPLYING CHEMICAL PRINCIPLES



1.1 CO_2 in the Oceans

"Over the past 200 years, the oceans have absorbed approximately 550 billion tons of CO_2 from the atmosphere, or about a third of the total amount of anthropogenic emissions over that period." This amounts to about 22 million tons *per day*. This statement was made by R. A. Feely, a scientist at the National Oceanographic and Atmospheric Administration, in connection with studies on the effects of carbon dioxide on ocean chemistry.

The amount of CO_2 dissolved in the oceans is of great concern and interest because it affects the pH of the water, that is, its level of acidity. This in turn can affect the growth of marine organisms such as corals and sea urchins and microscopic coccolithophores (single-cell phytoplankton).

Recent studies have indicated that, in water with a high CO_2 content, the spines of sea urchins are greatly impaired, the larvae of orange clown fish lose their homing ability, and the concentrations of calcium, copper, manganese, and iron in sea water are affected, sometimes drastically.

A recent investigation of the history of ocean acidification ended with the statement that "the current rate of (mainly fossil fuel) CO_2 release stands out as capable of driving a combination and magnitude of ocean geochemical changes potentially unparalleled in at least the last 300 million years of Earth history, raising the possibility that we are entering an unknown territory of marine ecosystem change."

Questions:

1. Much has been written about CO_2. What is its name?
2. Give the symbols for the four metals mentioned in this article.
3. Of the four metals mentioned here, which is the most dense? The least dense? (Use an Internet tool such as www.ptable.com to find this information.)
4. The spines of the sea urchin, corals, and coccolithophores all are built of the compound $CaCO_3$. What elements are involved in this compound? Do you know its name?

CHAPTER GOALS REVISITED

The goals for this chapter are keyed to specific Study Questions to help you organize your review.

1.1 Chemistry and Its Methods

- Recognize the difference between a hypothesis and a theory and understand how laws are established. 1, 2.

1.2 Sustainability and Green Chemistry

- Understand the principles of green chemistry. 3–6.

1.3 Classifying Matter

- Understand the basic ideas of kinetic-molecular theory. 41, 42.
- Recognize the importance of representing matter at the macroscopic, microscopic, and symbolic levels. 35, 36.
- Recognize the different states of matter (solids, liquids, and gases) and give their characteristics. 29, 41, 51.
- Recognize the difference between pure substances and mixtures and the difference between homogeneous and heterogeneous mixtures. 31, 32, 42.

1.4 Elements

- Identify the name or symbol for an element, given its symbol or name, respectively. 7–10, 29, 30.
- Use the terms atom, element, and molecule correctly. 11, 12, 39, 40.

1.5 Compounds

- Use the term compound correctly. 11, 12, 39, 40.
- Understand the law of definite proportions (law of constant composition). 13, 14.

1.6 Physical Properties

- Identify several physical properties of common substances. 15, 17, 18, 30, 44, 46.
- Relate density to the volume and mass of a substance. 25, 26, 37, 38, 43, 45, 47, 48, 49, 52, 53, 56.
- Understand the difference between extensive and intensive properties and give examples of them. 25, 26.

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

1.7 Physical and Chemical Changes

- Explain the difference between chemical and physical changes. **16, 33, 34, 51, 55.**
- Identify several chemical properties of common substances. **15, 17, 18, 27, 28.**

1.8 Energy: Some Basic Principles

- Identify types of potential and kinetic energy. **19–22.**
- Recognize and apply the law of conservation of energy. **23, 24.**

KEY EQUATION

Equation 1.1 (page 12) Density: In chemistry the common unit of density is g/cm^3, whereas kg/m^3 is commonly used in geology and oceanography.

$$\text{Density} = \frac{\text{mass}}{\text{volume}}$$

STUDY QUESTIONS

▲ denotes challenging questions. **Blue-numbered questions** have answers in Appendix N and fully worked solutions in the *Student Solutions Manual.*

Practicing Skills

Nature of Science

(See Section 1.1.)

1. In the following scenario, identify which of the statements represents a theory, law, or hypothesis. (a) A student exploring the properties of gases proposes that if she decreases the volume of a sample of gas then the pressure exerted by the sample will increase. (b) Many scientists over time have conducted similar experiments and have concluded that pressure and volume are inversely proportional. (c) She proposes that the reason this occurs is that if the volume is decreased, more molecules will collide with a given area of the container walls, causing the pressure to be greater.
2. State whether the following is a hypothesis, theory, or law of science. Global climate change is occurring because of human-generated carbon dioxide. Explain.

Green Chemistry

(See Section 1.2.)

3. What is meant by the phrase "sustainable development"?
4. What is meant by the phrase "green chemistry"?
5. One of the winners of the 2016 Presidential Green Chemistry Challenge Awards was a process for making a high octane feedstock for gasoline. The traditional process uses higly corrosive acids such as hydrofluoric acid or sulfuric acid. Once used, the remaining acid must be regenerated or sent for disposal, requiring additional energy and generating waste. The new process uses a safer solid catalyst that can be regenerated and reused. It also leads to minimal by-products. Which principles of green chemistry are being followed by this new process compared to the older process?
6. One of the winners of the 2016 Presidential Green Chemistry Challenge Awards was a process to generate dodecanedioic acid (DDA), a chemical used in making certain nylons. The older process uses chemicals from fossil fuels, uses nitric acid, and produces a greenhouse gas, dinitrogen monoxide. This process also requires high temperatures and pressures. The new process uses a modified yeast strain to manufacture DDA from an acid derived from palm kernel oil or coconut oil, is run near room temperature and pressure, avoids the use of nitric acid, does not generate dinitrogen monoxide, and leads to a higher purity product. Which principles of green chemistry are being followed by this new process compared to the older process?

Matter: Elements and Atoms, Compounds, and Molecules

(See Example 1.1.)

7. Give the name of each of the following elements:
   (a) C (d) P
   (b) K (e) Mg
   (c) Cl (f) Ni

8. Give the name of each of the following elements:
   (a) Mn (d) Br
   (b) Cu (e) Xe
   (c) Na (f) Fe

9. Give the symbol for each of the following elements:
   (a) barium (d) lead
   (b) titanium (e) arsenic
   (c) chromium (f) zinc

10. Give the symbol for each of the following elements:
    (a) silver (d) tin
    (b) aluminum (e) technetium
    (c) plutonium (f) krypton

11. In each of the following pairs, decide which is an element and which is a compound.
    (a) Na or NaCl
    (b) sugar or carbon
    (c) gold or gold chloride

12. In each of the following pairs, decide which is an element and which is a compound.
    (a) $Pt(NH_3)_2Cl_2$ or Pt
    (b) copper or copper(II) oxide
    (c) silicon or sand

13. An 18 g sample of water is decomposed into 2 g of hydrogen gas and 16 g of oxygen gas. What masses of hydrogen and oxygen gases would have been prepared from 27 g of water? What law of chemistry is used in solving this problem?

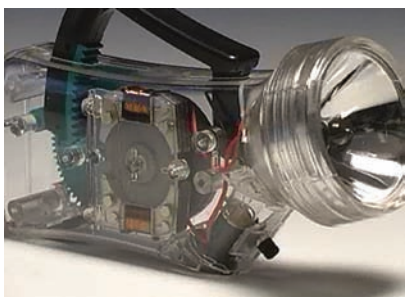
14. A sample of the compound magnesium oxide is synthesized as follows. 60. g of magnesium is burned and produces 100. g of magnesium oxide, indicating that the magnesium combined with 40. g of oxygen in the air. If 30. g of magnesium had been used, what mass of oxygen would have combined with it? What law of chemistry is used in solving this problem?

Physical and Chemical Properties

(See Sections 1.6 and 1.7.)

15. In each case, decide if the underlined property is a physical or chemical property.
    (a) The color of elemental bromine is orange-red.
    (b) Iron turns to rust in the presence of air and water.
    (c) Hydrogen can explode when ignited in air (Figure 1.16).
    (d) The density of titanium metal is 4.5 g/cm^3.
    (e) Tin metal melts at 505 K.
    (f) Chlorophyll, a plant pigment, is green.

16. In each case, decide if the change is a chemical or physical change.
    (a) A cup of household bleach changes the color of your favorite T-shirt from purple to pink.
    (b) Water vapor in your exhaled breath condenses in the air on a cold day.
    (c) Plants use carbon dioxide from the air to make sugar.
    (d) Butter melts when placed in the Sun.



17. Which part of the description of a compound or element refers to its physical properties and which to its chemical properties?
    (a) The colorless liquid ethanol burns in air.
    (b) The shiny metal aluminum reacts readily with orange-red bromine.

18. Which part of the description of a compound or element refers to its physical properties and which to its chemical properties?
    (a) Calcium carbonate is a white solid with a density of 2.71 g/cm^3. It reacts readily with an acid to produce gaseous carbon dioxide.
    (b) Gray, powdered zinc metal reacts with purple iodine to give a white compound.

Energy

(See Section 1.8.)

19. The flashlight in the photo does not use batteries. Instead, you move a lever, which turns a geared mechanism and finally results in light from the bulb. What type of energy is used to move the lever? What type or types of energy are produced?

© Cengage Learning/Charles D. Winters

A hand-operated flashlight

20. A solar panel is pictured in the photo. When light shines on the panel, it generates an electric current that can be used to recharge the batteries in an electric car. What types of energy are involved in this setup?

© Cengage Learning/Charles D. Winters

A solar panel

21. Determine which of the following represent potential energy and which represent kinetic energy.

(a) thermal energy

(b) gravitational energy

(c) chemical energy

(d) electrostatic energy

22. Determine whether kinetic energy is being converted to potential energy, or vice versa, in the following processes.

(a) Water cascades downward in a waterfall.

(b) A player kicks a football.

(c) An electric current is generated by a chemical reaction in a battery.

(d) Water boils when heated on a gas stove.

23. A hot metal block is plunged into water in a well-insulated container. The temperature of the metal block goes down, and the temperature of the water goes up until their temperatures are the same. A total of 1500 J of energy is lost by the metal object. By how much did the energy of the water increase? What law of science is illustrated by this problem?

24. A book is held at a height above the floor. It has a certain amount of potential energy. When the book is released, its potential energy is converted to kinetic energy as it falls to the floor. The book hits the floor and comes to rest. According to the law of conservation of energy the amount of energy in the universe is constant. Where has the energy gone?

General Questions

These questions are not designated as to type or location in the chapter. They may combine several concepts.

25. A piece of turquoise is a blue-green solid; it has a density of 2.65 g/cm^3 and a mass of 2.5 g.

(a) Which of these observations are qualitative and which are quantitative?

(b) Which of the observations are extensive and which are intensive?

(c) What is the volume of the piece of turquoise?

26. Iron pyrite (fool's gold, page 11) has a shiny golden metallic appearance. Crystals are often in the form of perfect cubes. A cube 0.40 cm on each side has a mass of 0.064 g.

(a) Which of these observations are qualitative and which are quantitative?

(b) Which of the observations are extensive and which are intensive?

(c) What is the density of the sample of iron pyrite?

27. Which observations below describe chemical properties?

(a) Sugar is soluble in water.

(b) Water boils at 100 °C.

(c) Ultraviolet light converts O_3 (ozone) to O_2 (oxygen).

(d) Ice is less dense than water.

28. Which observations below describe chemical properties?

(a) Sodium metal reacts violently with water.

(b) The combustion of octane (a compound in gasoline) gives CO_2 and H_2O.

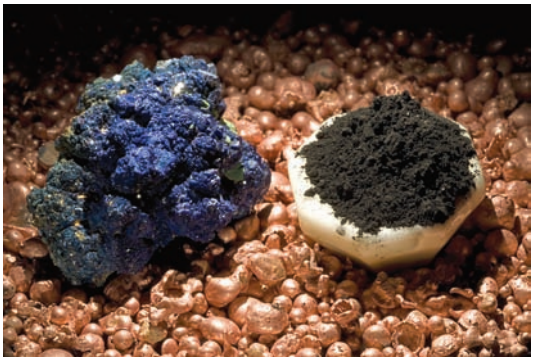
(c) Chlorine is a green gas.

(d) Heat is required to melt ice.

29. The mineral fluorite contains the elements calcium and fluorine and can have various colors, including blue, violet, green, and yellow.

© Cengage Learning/Charles D. Winters

The mineral fluorite, calcium fluoride



(a) What are the symbols of these elements?

(b) How would you describe the shape of the fluorite crystals in the photo? What can this tell us about the arrangement of the particles (ions) inside the crystal?

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

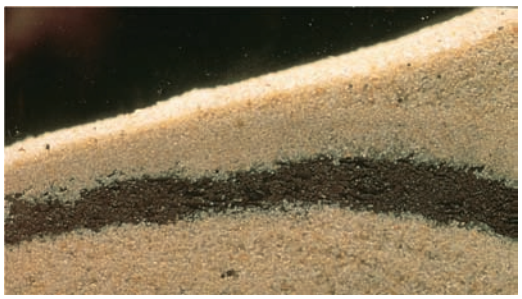
30. Azurite, a blue, crystalline mineral, is composed of copper, carbon, and oxygen.

© Cengage Learning/Charles D. Winters



Azurite is a deep blue crystalline mineral. It is surrounded by copper pellets and powdered carbon (in the dish).

(a) What are the symbols of the three elements that combine to make the mineral azurite?

(b) Based on the photo, describe some of the physical properties of the elements and the mineral. Are any the same? Are any properties different?

31. You have a solution of NaCl dissolved in water. Describe a method by which these two compounds could be separated.

32. Small chips of iron are mixed with sand (see photo). Is this a homogeneous or heterogeneous mixture? Suggest a way to separate the iron from the sand.

© Cengage Learning/Charles D. Winters

Chips of iron mixed with sand

33. Identify the following as either physical changes or chemical changes.

(a) Dry ice (solid CO_2) sublimes (converts directly from solid to gaseous CO_2).

(b) Mercury's density decreases as the temperature increases.

(c) Energy is given off as heat when natural gas (mostly methane, CH_4) burns.

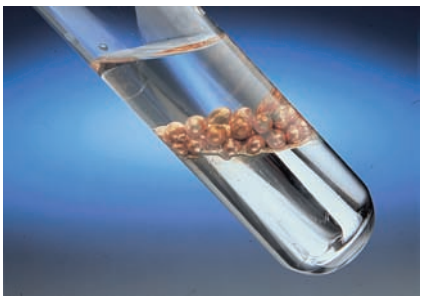
(d) NaCl dissolves in water.

34. Identify the following as either physical changes or chemical changes.

(a) The desalination of sea water (separation of pure water from dissolved salts).

(b) The formation of SO_2 (an air pollutant) when coal containing sulfur is burned.

(c) Silver tarnishes.



(d) Iron is heated to red heat.

35. In Figure 1.2 you see a piece of salt and a representation of its internal structure. Which is the macroscopic view and which is the particulate view? How are the macroscopic and particulate views related?

36. In Figure 1.5 you see macroscopic and particulate views of the element bromine. Which are the macroscopic views and which are the particulate views? Describe how the particulate views explain properties of this element related to the state of matter.

37. Carbon tetrachloride, CCl_4, a common liquid compound, has a density of 1.58 g/cm^3. If you place a piece of a plastic soda bottle (d = 1.37 g/cm^3) and a piece of aluminum (d = 2.70 g/cm^3) in liquid CCl_4, will the plastic and aluminum float or sink?

38. The following photo shows copper balls, immersed in water, floating on top of mercury. What are the liquids and solids in this photo? Which substance is most dense? Which is least dense?

© Cengage Learning/Charles D. Winters

Water, copper, and mercury

39. Categorize each of the following as an element, a compound, or a mixture.

(a) sterling silver

(b) carbonated mineral water

(c) tungsten

(d) aspirin

40. Categorize each of the following as an element, a compound, or a mixture.

(a) air

(b) fluorite

(c) brass

(d) 18-carat gold

41. ▲ Make a drawing, based on the kinetic-molecular theory and the ideas about atoms and molecules presented in this chapter, of the arrangement of particles in each of the cases listed here. For each case, draw 10 particles of each substance. It is acceptable for your diagram to be two dimensional. Represent each atom as a circle, and distinguish each different kind of atom by shading.
   (a) a sample of solid iron (which consists of iron atoms)
   (b) a sample of liquid water (which consists of H_2O molecules)
   (c) a sample of water vapor

42. ▲ Make a drawing, based on the kinetic-molecular theory and the ideas about atoms and molecules presented in this chapter, of the arrangement of particles in each of the cases listed here. For each case, draw 10 particles of each substance. It is acceptable for your diagram to be two dimensional. Represent each atom as a circle, and distinguish each different kind of atom by shading.
   (a) a homogeneous mixture of water vapor and helium gas (which consists of helium atoms)
   (b) a heterogeneous mixture consisting of liquid water and solid aluminum; show a region of the sample that includes both substances
   (c) a sample of brass (which is a homogeneous solid mixture of copper and zinc)

43. Hexane (C_6H_{14}, density = 0.766 g/cm^3), perfluorohexane (C_6F_{14}, density = 1.669 g/cm^3), and water are immiscible liquids; that is, they do not dissolve in one another. You place 10 mL of each in a graduated cylinder, along with pieces of high-density polyethylene (HDPE, density = 0.97 g/cm^3), polyvinyl chloride (PVC, density = 1.36 g/cm^3), and Teflon (density = 2.3 g/cm^3). None of these common plastics dissolves in these liquids. Describe what you expect to see.

44. ▲ You have a sample of a white crystalline substance from your kitchen. You know that it is either salt or sugar. Although you could decide by taste, suggest another property that you could use to decide. (*Hint:* You may use the World Wide Web or a handbook of chemistry in the library to find some information.)

45. You can figure out whether a solid floats or sinks if you know its density and the density of the liquid. In which of the liquids listed below will high-density polyethylene (HDPE) float? (HDPE, a common plastic, has a density of 0.97 g/cm^3. It does not dissolve in any of these liquids.)

Substance	Density (g/cm^3)	Properties, Uses
Ethylene glycol	1.1088	Toxic; major component of automobile antifreeze
Water	0.9997	
Ethanol	0.7893	Alcohol in alcoholic beverages
Methanol	0.7914	Toxic; gasoline additive to prevent gas line freezing
Acetic acid	1.0492	Component of vinegar
Glycerol	1.2613	Solvent used in home care products

46. You are given a sample of a silvery metal. What information could you use to prove the metal is silver?

47. Milk in a glass bottle was placed in the freezing compartment of a refrigerator overnight. By morning, a column of frozen milk emerged from the bottle. Explain this observation.

© Cengage Learning/Charles D. Winters

Frozen milk in a glass bottle

48. Describe an experimental method that can be used to determine the density of an irregularly shaped piece of metal.

49. Diabetes can alter the density of urine, so urine density can be used as a diagnostic tool. Diabetics can excrete too much sugar or excrete too much water. What do you predict will happen to the density of urine under each of these conditions? (*Hint:* Water containing dissolved sugar is more dense than pure water.)

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

50. Suggest a way to determine if the colorless liquid in a beaker is water. How could you discover if there is salt dissolved in the water?

51. The following photo shows the element potassium reacting with water to form the element hydrogen, a gas, and a solution of the compound potassium hydroxide.

© Cengage Learning/Charles D. Winters

Potassium reacting with water to produce hydrogen gas and potassium hydroxide.

(a) What states of matter are involved in the reaction?

(b) Is the observed change chemical or physical?

(c) What are the reactants in this reaction, and what are the products?

(d) What qualitative observations can be made concerning this reaction?

52. Three liquids of different densities are mixed. Because they are not miscible (do not form a homogeneous solution with one another), they form discrete layers, one on top of the other. Sketch the result of mixing carbon tetrachloride (CCl_4, d = 1.58 g/cm^3), mercury (d = 13.546 g/cm^3), and water (d = 1.00 g/cm^3).

53. Four balloons are each filled with a different gas, each having a different density:

helium, d = 0.164 g/L neon, d = 0.825 g/L

argon, d = 1.633 g/L krypton, d = 4.425 g/L

If the density of dry air is 1.12 g/L, which balloon or balloons float in air?

54. A copper-colored metal is found to conduct an electric current. Can you say with certainty that it is copper? Why or why not? Suggest additional information that could provide unequivocal confirmation that it is copper.

55. The photo below shows elemental iodine dissolving in ethanol to give a solution. Is this a physical or chemical change?

© Cengage Learning/Charles D. Winters

Elemental iodine dissolving in ethanol.

56. ▲ You want to determine the density of a compound but have only a tiny crystal, and it would be difficult to measure mass and volume accurately. There is another way to determine density, however, called the *flotation method.* If you placed the crystal in a liquid whose density is precisely that of the substance, it would be suspended in the liquid, neither sinking to the bottom of the beaker nor floating to the surface. However, for such an experiment you would need to have a liquid with the precise density of the crystal. You can accomplish this by mixing two liquids of different densities to create a liquid having the desired density.

(a) Consider the following: you mix 10.0 mL of $CHCl_3$ (d = 1.492 g/mL) and 5.0 mL of $CHBr_3$ (d = 2.890 g/mL), giving 15.0 mL of solution. What is the density of this mixture?

(b) Suppose now that you wanted to determine the density of a small yellow crystal to confirm that it is sulfur. From the literature, you know that sulfur has a density of 2.07 g/cm^3. How would you prepare 20.0 mL of the liquid mixture having that density from pure samples of $CHCl_3$ and $CHBr_3$? (*Note:* 1 mL = 1 cm^3.)

57. A few years ago a young chemist in Vienna, Austria, wanted to see just how permanent the gold was in his wedding band. The ring was 18-carat gold. (18-carat gold is 75% gold with the remainder copper and silver.) One week after his wedding day he took off the ring, cleaned it carefully, and weighed it. It had a mass of 5.58387 g. He weighed it weekly from then on, and after 1 year it had lost 6.15 mg just from normal wear and tear. He found that the activities that took the greatest toll on the gold were vacationing on a sandy beach and gardening.

(a) What are the symbols of the elements that make up 18-carat gold?

(b) The density of gold is 19.3 g/cm^3. Use one of the periodic tables on the Internet (such as www.ptable.com) to find out if gold is the most dense of all of the known elements. If it is not gold, then what element is the most dense [considering only the elements from hydrogen (H) through uranium (U)]?

(c) If a wedding band is 18-carat gold and has a mass of 5.58 g, what mass of gold is contained within the ring?

(d) Assume there are 56 million married couples in the United States, and each person has an 18-carat gold ring. What mass of gold is lost by all the wedding rings in the United States in 1 year (in units of grams) if each ring loses 6.15 mg of mass per year? Assuming gold is $1620 per troy ounce (where 1 troy ounce = 31.1 g), what is the lost gold worth?

CHAPTER OUTLINE

1 Units of Measurement

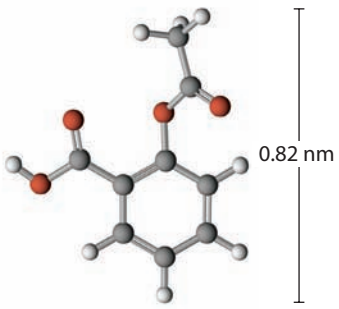
2 Making Measurements: Precision, Accuracy, Experimental Error, and Standard Deviation

3 Mathematics of Chemistry

4 Problem Solving by Dimensional Analysis

5 Graphs and Graphing

6 Problem Solving and Chemical Arithmetic



1 Units of Measurement

Goal for Section 1

- Use the common units for measurements in chemistry and make unit conversions (such as from liters to milliliters).

Doing chemistry requires observing chemical reactions and physical changes. We make qualitative observations—such as changes in color or the evolution of heat—and quantitative measurements of temperature, time, volume, mass, and length or size. To record and report measurements, the scientific community has chosen a modified version of the **metric system**. This decimal system is called the Système International d'Unités (International System of Units), abbreviated **SI**.

All SI units are derived from base units, listed in Table 1. Larger and smaller quantities are expressed by using appropriate prefixes with the base unit (Table 2). The nanometer (nm), for example, is 1 billionth of a meter, that is, 1×10^{-9} m (meter). Dimensions on the nanometer scale are common in chemistry and biology because, for example, a typical molecule (such as aspirin) is about 1 nm in length and a bacterium is about 1000 nm in length. Indeed, the prefix *nano-* is also used in the name for a whole area of science, *nanotechnology*, which involves the synthesis and study of materials having this tiny size.

Structure of the aspirin molecule

Temperature Scales

Two temperature scales are commonly used in scientific work: Celsius and Kelvin (Figure 1). The Celsius scale is generally used worldwide for measurements in the laboratory. When calculations incorporate temperature data, however, the Kelvin scale is almost always used.

◀ **Scientific Instruments and Glassware.** Chemistry is a quantitative science. Many different instruments and pieces of glassware have been invented to measure the properties of matter.

Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

The Kilogram, a New Standard Needed? Unlike the second and the meter, the kilogram is defined by a physical object: a block of platinum-iridium alloy in a building in Paris, France. The block has been mysteriously losing mass, so there is great interest in the scientific community to find a better way to define the kilogram. In 2011, the International Committee for Weights and Measures agreed to try to define the kilogram based on a fundamental constant of nature called Planck's constant, provided that sufficient agreement on the value of Planck's constant to a certain precision can be reached. Scientists are hoping that the issue may be resolved soon.

TABLE 1 The Seven SI Base Units

Measured Property	Name of Unit	Abbreviation
Mass	kilogram	kg
Length	meter	m
Time	second	s
Temperature	kelvin	K
Amount of substance	mole	mol
Electric current	ampere	A
Luminous intensity	candela	cd

The Celsius Temperature Scale

The size of the Celsius degree is defined by assigning zero as the freezing point of pure water (0 °C) and 100 as its boiling point (100 °C). You may recognize that a comfortable room temperature is around 20 °C and your normal body temperature is 37 °C. The warmest water you can stand to immerse a finger in is probably about 60 °C.

The Kelvin Temperature Scale

Lord Kelvin William Thomson (1824–1907), known as Lord Kelvin, was a professor of natural philosophy at the University in Glasgow, Scotland, from 1846 to 1899. He was best known for his study of heat and work, from which came the concept of the absolute temperature scale.

William Thomson, known as Lord Kelvin (1824–1907), first suggested the temperature scale that now bears his name. The Kelvin scale assigns zero as the lowest temperature that can be achieved, a point called **absolute zero**. Many experiments have found that this limiting temperature is −273.15 °C. *Kelvin units and Celsius degrees are the same size.* Thus, the freezing point of water is reached at 273.15 K; that is, 0 °C = 273.15 K. The normal boiling point of pure water is 373.15 K. Temperatures in Celsius degrees are readily converted to kelvins, and vice versa, using the relation

$$T\ (\mathrm{K}) = \frac{1\ \mathrm{K}}{1\ ^\circ\mathrm{C}}\ (T\ ^\circ\mathrm{C} + 273.15\ ^\circ\mathrm{C}) \qquad (1)$$

Common Conversion Factors
1000 g = 1 kg
1×10^9 nm = 1 m
10 mm = 1 cm
100 cm = 10 dm = 1 m
1000 m = 1 km
Conversion factors for SI units are given in Appendix C and inside the back cover of this book.

TABLE 2 Selected Prefixes Used in the Metric System

Prefix	Abbreviation	Meaning	Example
Giga-	G	10^9 (billion)	1 gigahertz = 1×10^9 Hz
Mega-	M	10^6 (million)	1 megaton = 1×10^6 tons
Kilo-	k	10^3 (thousand)	1 kilogram (kg) = 1×10^3 g
Deci-	d	10^{-1} (tenth)	1 decimeter (dm) = 1×10^{-1} m
Centi-	c	10^{-2} (one hundredth)	1 centimeter (cm) = 1×10^{-2} m
Milli-	m	10^{-3} (one thousandth)	1 millimeter (mm) = 1×10^{-3} m
Micro-	μ	10^{-6} (one millionth)	1 micrometer (μm) = 1×10^{-6} m
Nano-	n	10^{-9} (one billionth)	1 nanometer (nm) = 1×10^{-9} m
Pico-	p	10^{-12}	1 picometer (pm) = 1×10^{-12} m
Femto-	f	10^{-15}	1 femtometer (fm) = 1×10^{-15} m

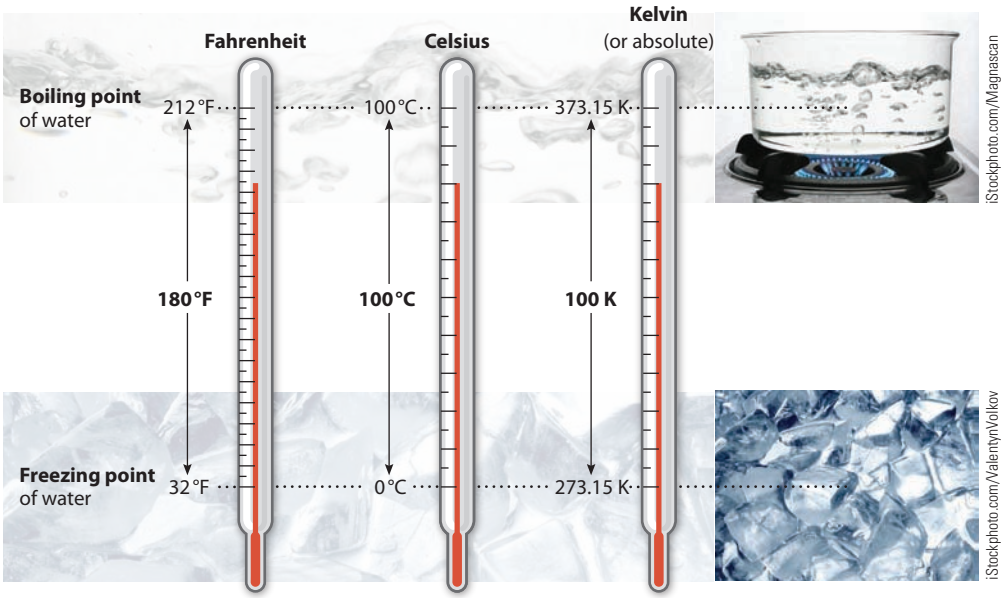

Figure 1 Comparison of Fahrenheit, Celsius, and Kelvin scales. Note that the degree sign (°) is not used with the Kelvin scale.

Using this equation, you can show that a common room temperature of 23.5 °C is equivalent to 296.7 K.

$$T\ (\text{K}) = \frac{1\ \text{K}}{1\ \text{°C}}(23.5\ \text{°C} + 273.15\ \text{°C}) = 296.7\ \text{K}$$

Three things to notice about the Kelvin scale are that the degree symbol (°) is not used with Kelvin temperatures, the name of the unit on this scale is the *kelvin* (not capitalized), and such temperatures are designated with a capital K.

Length, Volume, and Mass

The meter is the standard unit of *length*, but objects observed in chemistry are frequently smaller than 1 meter. Measurements are often reported in units of centimeters (cm), millimeters (mm), or micrometers (μm), and objects on the atomic and molecular scale have dimensions of nanometers (nm; 1 nm = 1×10^{-9} m) or picometers (pm; 1 pm = 1×10^{-12} m) (Figure 2).

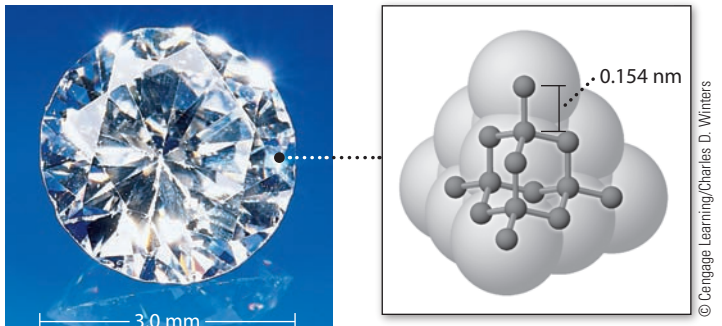

Figure 2 Dimensions in the molecular world. Dimensions on the molecular scale are often given in terms of nanometers (1 nm = 1×10^{-9} m) or picometers (1 pm = 1×10^{-12} m). Here, the distance between C atoms in diamond is 0.154 nm.

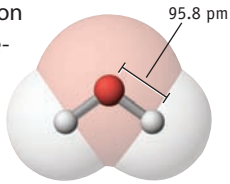
To illustrate the range of dimensions used in science, let us look at a study of the glassy skeleton of a sea sponge. The sea sponge in Figure 3 is about 20 cm long and a few centimeters in diameter. A closer look shows more detail of the lattice-like structure. Scientists at Bell Laboratories found that each strand of the lattice is a ceramic-fiber composite of silica (SiO_2) and protein less than 100 μm in diameter. These strands are composed of "spicules," which consist of silica nanoparticles 50–200 nanometers in diameter.

EXAMPLE 1

Distances on the Molecular Scale

Problem The distance between an O atom and an H atom in a water molecule is 95.8 pm. What is this distance in nanometers (nm)?



What Do You Know? You are given the interatomic O–H distance. You will need to know (or look up) the relationships of the metric units.

Ångstrom Units An older but often-used non-SI unit for molecular distances is the Ångstrom unit (Å), where 1 Å = 1.0×10^{-10} m. The distance between two carbon atoms in diamond would be 1.54 Å.

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

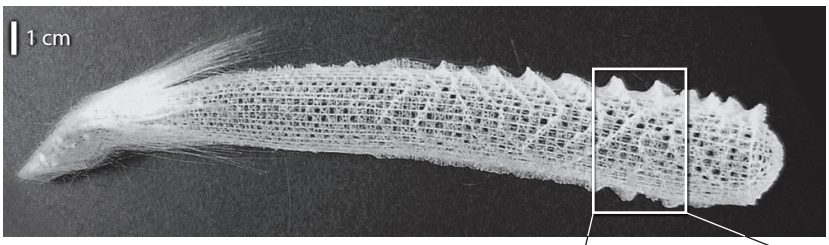
Strategy You can solve this problem by knowing the conversion factor between the units in the information you are given (picometers) and the desired units (meters or nanometers). (For more about conversion factors and their use in problem solving, see page 43.) There is no conversion factor given in Table 2 to change nanometers to picometers directly, but relationships are listed between meters and picometers and between meters and nanometers. Therefore, we first convert picometers to meters and then convert meters to nanometers.

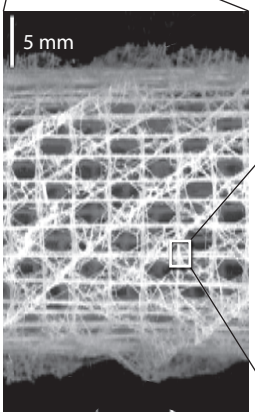
$$\text{picometers} \xrightarrow{x\ {}^{\text{m}}/_{\text{pm}}} \text{meters} \xrightarrow{y\ {}^{\text{nm}}/_{\text{m}}} \text{nanometers}$$

SOLUTION Using the appropriate conversion factors ($1\ \text{pm} = 1 \times 10^{-12}\ \text{m}$ and $1\ \text{nm} = 1 \times 10^{-9}\ \text{m}$), we have



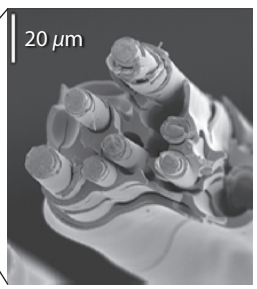
$$95.8\ \text{pm} \times \frac{1 \times 10^{-12}\ \text{m}}{1\ \text{pm}} = 9.58 \times 10^{-11}\ \text{m}$$

$$9.58 \times 10^{-11}\ \text{m} \times \frac{1\ \text{nm}}{1 \times 10^{-9}\ \text{m}} = 9.58 \times 10^{-2}\ \text{nm} \text{ or } 0.0958\ \text{nm}$$



Think about Your Answer A nanometer is a larger unit than a picometer, so the same distance expressed in nanometers will have a smaller numerical value. Our answer agrees with this. Notice how the units cancel in the calculation to leave an answer whose unit is that of the numerator of the conversion factor. The process of using units to guide a calculation is called *dimensional analysis*. It is explored further on pages 43–44.

Check Your Understanding



The distance between two carbon atoms in diamond (Figure 2) is 0.154 nm. What is this distance in picometers (pm)? In centimeters (cm)?

(a) Photograph of the glassy sea sponge *Euplectella*. Scale bar = 1 cm.

(b) Fragment of the structure showing the square grid of the lattice with diagonal supports. Scale bar = 5 mm.

(c) Scanning electron microscope (SEM) image of a single strand showing its ceramic-composite structure. Scale bar = 20 μm.

Chemists often use glassware such as beakers, flasks, pipets, graduated cylinders, and burets, which are marked in volume units (Figure 4). Because the SI unit of volume [the cubic meter (m^3)] is too large for everyday laboratory use, chemists usually use the liter (L) or the milliliter (mL) for volume measurements. One liter is equivalent to the volume of a cube with sides equal to 10 cm [$V = (0.1\ m)^3 = 0.001\ m^3$].

$$1\ \text{liter (L)} = 1000\ cm^3 = 1000\ mL = 0.001\ m^3$$

Because there are exactly 1000 mL (= 1000 cm^3) in a liter, this means that

$$1\ mL = 0.001\ L = 1\ cm^3$$

The units *milliliter and cubic centimeter* (or "cc") *are interchangeable.* Therefore, a flask that contains exactly 125 mL has a volume of 125 cm^3.

© Cengage Learning/Charles D. Winters

Figure 4 Some common laboratory glassware. Volumes are marked in units of milliliters (mL). Remember that 1 mL is equivalent to 1 cm^3.

Although not widely used in the United States, the cubic decimeter (dm^3) is a common unit in the rest of the world. A length of 10 cm is called a decimeter (dm), a tenth of a meter. Because a cube 10 cm on a side defines a volume of 1 liter, *a liter is equivalent to a cubic decimeter:* 1 L = 1 dm^3. Products in Europe, Africa, and other parts of the world are often sold by the cubic decimeter.

The *deciliter, dL,* which is exactly equivalent to 1/10 of a liter (0.100 L) or 100 mL, is widely used in medicine. Standards for concentrations of environmental contaminants are often set as a certain mass per deciliter. For example, the U.S. Centers for Disease Control and Prevention recommends that children with more than 5 micrograms (5×10^{-6} g) of lead per deciliter of blood undergo further testing for lead poisoning.

Finally, when chemists prepare chemicals for reactions, they often take given masses of materials. *Mass* is the fundamental measure of the quantity of matter, and the SI unit of mass is the kilogram (kg). Smaller masses are expressed in grams (g) or milligrams (mg).

$$1\ kg = 1000\ g\ \textit{and}\ 1\ g = 1000\ mg$$

Energy Units

When expressing energy quantities, most chemists (and much of the world outside the United States) use the **joule** (J), the SI unit. The joule is related directly to the units used for mechanical energy: 1 J equals 1 kg · m^2/s^2. Because the joule is inconveniently small for most uses in chemistry, the kilojoule (kJ), equivalent to 1000 joules, is often the unit of choice.

To give you some feeling for joules, suppose you drop a six-pack of soft-drink cans, each full of liquid, on your foot. Although you probably will not take time to calculate the kinetic energy at the moment of impact is 10 or more joules.

The calorie (cal) is an older energy unit. It is defined as the energy transferred as heat that is required to raise the temperature of 1.00 g of pure liquid water from 14.5 °C to 15.5 °C. A kilocalorie (kcal) is equivalent to 1000 calories. The conversion factor relating joules and calories is

1 calorie (cal) = 4.184 joules (J)

The dietary Calorie (with a capital C) is often used in the United States to represent the energy content of foods. The dietary Calorie (Cal) is equivalent to the kilocalorie or 1000 calories. Thus, a breakfast cereal that gives you 100.0 Calories of nutritional energy per serving provides 100.0 kcal or 418.4 kJ.

Oesper Collection in the History of Chemistry/ University of Cincinnati

James Joule The joule is named for James P. Joule (1818–1889), the son of a wealthy brewer in Manchester, England. The family wealth and a workshop in the brewery gave Joule the opportunity to pursue scientific studies. Among the topics that Joule studied was whether heat was a massless fluid. Scientists at that time referred to this idea as the caloric hypothesis. Joule's careful experiments showed that heat and mechanical work are related, providing evidence that heat is not a fluid. See Chapter 5 for more on this important topic.

A CLOSER LOOK

Energy and Food

The U.S. Food and Drug Administration (FDA) mandates that nutritional data, including energy content, be included on almost all packaged food. The Nutrition Labeling and Education Act of 1990 requires that the total energy from protein, carbohydrates, fat, and alcohol be specified. How is this determined? Initially, the method used was calorimetry. In this method (described in Chapter 5), a food product is burned, and the energy transferred as heat in the combustion is measured. Now, however, energy contents are estimated using the Atwater system. This specifies the following average values for energy sources in foods:

1 g protein = 4 kcal (17 kJ)
1 g carbohydrate = 4 kcal (17 kJ)
1 g fat = 9 kcal (38 kJ)
1 g alcohol = 7 kcal (29 kJ)

Because carbohydrates may include some indigestible fiber, the mass of fiber is subtracted from the mass of carbohydrate when calculating the energy from carbohydrates.

As an example, one serving of cashew nuts (about 28 g) has

14 g fat = 126 kcal
6 g protein = 24 kcal
7 g carbohydrates − 1 g fiber = 24 kcal
Total = 174 kcal (728 kJ)

A value of 170 kcal is reported on the package.

You can find data on more than 6000 foods at the U.S. Department of Agriculture website.

Energy and food labels. All packaged foods must have labels specifying nutritional values, with energy given in Calories (where 1 Cal = 1 kilocalorie).

2 Making Measurements: Precision, Accuracy, Experimental Error, and Standard Deviation

Goal for Section 2

- Recognize and express uncertainties in measurements.

The **precision** of a measurement indicates how well several determinations of the same quantity agree. This is illustrated by the results of throwing darts at a target. In Figure 5a, the dart thrower was apparently not skillful, and the precision of the darts' placement on the target is low. In Figures 5b and 5c, the darts are clustered together, indicating much better consistency on the part of the thrower—that is, greater precision.

Figure 5
Precision and accuracy.

(a) Poor precision and poor accuracy

(b) Good precision and poor accuracy

(c) Good precision and good accuracy

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Accuracy is the agreement of a measurement with the accepted value of the quantity. Figure 5c shows that our thrower was accurate as well as precise—the average of all shots is close to the targeted position, the bull's eye.

Figure 5b shows it is possible to be precise without being accurate—the thrower has consistently missed the bull's eye, although all the darts are clustered precisely around one point on the target. This is analogous to an experiment with some flaw (either in design or in a measuring device) that causes all results to differ from the correct value by the same amount.

The accuracy of a result in the laboratory is often expressed in terms of percent error relative to a standard or accepted value, whereas the precision is expressed as a standard deviation.

Accuracy and NIST The National Institute of Standards and Technology (NIST) is an important resource for standards and data used in science. Comparison with NIST data is a test of the accuracy of the measurement (see www.nist.gov).

Experimental Error

If you measure a quantity in the laboratory, you may be required to report the error in the result, the difference between your result and the accepted value,

$$\text{Error in measurement} = \text{experimentally determined value} - \text{accepted value} \tag{2}$$

or the **percent error.**

$$\text{Percent error} = \frac{\text{error in measurement}}{\text{accepted value}} \times 100\% \tag{3}$$

EXAMPLE 2

Precision, Accuracy, and Error

Problem Suppose a coin has an "accepted" diameter of 28.054 mm. In an experiment, two students measure this diameter. Student A makes four measurements of the diameter of the coin using a precision tool called a micrometer. Student B measures the same coin using a simple plastic ruler. The two students report the following results:

Student A	Student B
28.246 mm	27.9 mm
28.244	28.0
28.246	27.8
28.248	28.1

What is the average diameter and percent error obtained in each case? Which student's data are more accurate?

Percent Error Percent error can be positive or negative, indicating whether the experimental value is too high or too low compared to the accepted value. In Example 2, Student B's percent error is −0.4%, indicating it is 0.4% lower than the accepted value.

What Do You Know? You know the data collected by the two students and want to compare them with the "accepted" value by calculating the percent error.

Strategy For each set of values, we calculate the average of the four measurements and the percent error.

SOLUTION The average for each set of data is obtained by summing the four values and dividing by 4.

$$\text{Average value for Student A} = 28.246 \text{ mm}$$

$$\text{Average value for Student B} = 28.0 \text{ mm}$$

$$\text{Percent error for Student A} = \frac{28.246 \text{ mm} - 28.054 \text{ mm}}{28.054 \text{ mm}} \times 100\% = 0.684\%$$

Student B's measurement has a percent error of only about −0.4%.

Student B's average is more accurate because it is closer to the accepted value, and thus it has a smaller percent error.

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Think about Your Answer Although Student A had less accurate results than Student B, they were more precise; the standard deviation for Student A is 2×10^{-3} mm (calculated as described below), in contrast to Student B's larger value (standard deviation = 0.13 mm). Possible reasons for the error in Student A's result are incorrect use of the micrometer or a flaw in the instrument.

Check Your Understanding

A student checked the accuracy of two standard top-loading balances by testing them with a standard 5.000-g mass. The results were as follows:

Balance 1: 4.99 g, 5.04 g, 5.03 g, 5.01 g

Balance 2: 4.97 g, 4.99 g, 4.95 g, 4.96 g

Calculate the average values for balances 1 and 2 and calculate the percent error for each. Which balance is more accurate?

Standard Deviation

Laboratory measurements can be in error for two basic reasons. First, "determinate" errors are caused by faulty instruments or human errors such as incorrect record keeping. Second, indeterminate (or random) errors arise from uncertainties in a measurement. One way to judge the indeterminate error in a result is to calculate the standard deviation.

The **standard deviation** of a series of measurements is *equal to the square root of the sum of the squares of the deviations for each measurement from the average, divided by one less than the number of measurements*. It has a precise statistical significance: Assuming a large number of measurements is used to calculate the average, slightly more than 68% of the values collected are expected to be within one standard deviation of the value determined, and 95% are within two standard deviations.

Suppose you carefully measured the mass of water delivered by a 10-mL pipet. (A pipet containing a green solution is shown in Figure 4.) For five attempts at the measurement (shown in column 2 of the following table), the standard deviation is found as follows. First, the average of the measurements is calculated (here, 9.984). Next, the deviation of each individual measurement from this value is determined (column 3). These values are squared, giving the values in column 4, and the sum of these values is determined. The standard deviation is then calculated by dividing this sum by 4, the number of determinations minus 1, and taking the square root of the result.

Determination	Measured Mass (g)	Difference Between Measurement and Average (g)	Square of Difference
1	9.990	0.006	4×10^{-5}
2	9.993	0.009	8×10^{-5}
3	9.975	−0.009	8×10^{-5}
4	9.980	−0.004	2×10^{-5}
5	9.982	−0.002	0.4×10^{-5}

$$\text{Average mass} = 9.984 \text{ g}$$

$$\text{Sum of squares of differences} = 22 \times 10^{-5}$$

$$\text{Standard deviation} = \sqrt{\frac{22 \times 10^{-5}}{4}} = 0.007$$

The standard deviation calculation would tell a reader that if this experiment were repeated, a majority of the values would fall in the range from 9.977 g to 9.991 g (±0.007 g from the average value).

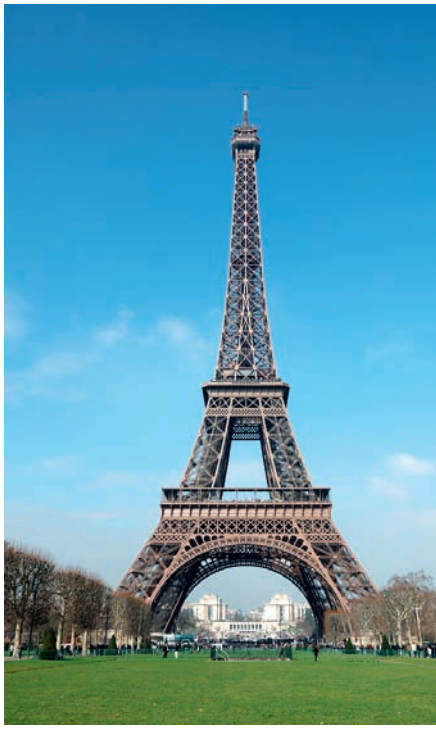
3 Mathematics of Chemistry



Goals for Section 3

- Express and use numbers in exponential or scientific notation.
- Report the answer of a calculation to the correct number of significant figures.

Exponential or Scientific Notation

The Eiffel Tower, built in 1889, is the tallest building in Paris. It was designed by the French architect Gustave Eiffel to mark the centennial of the French Revolution. The Tower, constructed of very pure iron, is as tall as an 81-story building. It was supposed to be dismantled in 1909, but the building still stands as a symbol of Paris. Some quantitative information on the structure is collected in the following table:

Eiffel Tower Characteristics	Quantitative Information
Height	324 meters (m)
Mass of iron	7.3×10^6 kilograms (kg)
Volume of iron	930 cubic meters (m^3)
Number of iron pieces	1.8×10^4 pieces
Approximate number of visitors annually	7×10^6 people

Brian A Jackson/Shutterstock.com

Eiffel Tower (Paris, France).

Some of the data on the Tower are expressed in **fixed notation** (324 meters), whereas other data are expressed in **exponential,** or **scientific, notation** (7.3×10^6 kilograms). Scientific notation is a way of presenting very large or very small numbers in a compact and consistent form that simplifies calculations. Because of its convenience, scientific notation is widely used in sciences.

In scientific notation a number is expressed as the product of two numbers: $N \times 10^n$. N is the *digit term* and is a number between 1 and 9.9999. . . . The second number, 10^n, the *exponential term*, is some integer power of 10. For example, 1234 is written in scientific notation as 1.234×10^3, or 1.234 multiplied by 10 three times:

$$1234 = 1.234 \times 10^1 \times 10^1 \times 10^1 = 1.234 \times 10^3$$

Conversely, a number less than 1, such as 0.01234, is written as 1.234×10^{-2}. This notation tells us that 1.234 should be divided twice by 10 to obtain 0.01234:

$$0.01234 = \frac{1.234}{10^1 \times 10^1} = 1.234 \times 10^{-1} \times 10^{-1} = 1.234 \times 10^{-2}$$

When converting a number to scientific notation, notice that the exponent n is positive if the number is greater than 1 and negative if the number is less than 1. The value of n is the number of places by which the decimal is shifted to obtain the number in scientific notation:

$$1\overset{\curvearrowleft}{2}\,3\,4\,5. = 1.2345 \times 10^4$$

(a) Decimal shifted four places to the left. Therefore, n is positive and equal to 4.

$$0.0\,0\,1\overset{\curvearrowright}{,}\,2 = 1.2 \times 10^{-3}$$

(b) Decimal shifted three places to the right. Therefore, n is negative and equal to 3.

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

If you wish to convert a number in scientific notation to one using fixed notation (that is, not using powers of 10), the procedure is reversed:

$$6.27 \times 10^{2} = 627.3$$

(a) Decimal point moved two places to the right because n is positive and equal to 2.

$$6.273 \times 10^{-3} = 0.006273$$

(b) Decimal point shifted three places to the left because n is negative and equal to 3.

Comparing Earth and a Plant Cell—Powers of 10

Earth
= 12,760,000 meters wide
= 12.76 million meters
= 1.276×10^{7} meters

Plant cell
= 0.00001276 meter wide
= 12.76 millionths of a meter
= 1.276×10^{-5} meters

In chemistry, you will often have to use numbers in exponential notation in mathematical operations. The following five operations are important:

- *Adding and Subtracting Numbers Expressed in Scientific Notation*
  When adding or subtracting two numbers, first convert them to the same powers of 10. The digit terms are then added or subtracted as appropriate:

$$(1.234 \times 10^{-3}) + (5.623 \times 10^{-2}) = (0.1234 \times 10^{-2}) + (5.623 \times 10^{-2})$$
$$= 5.746 \times 10^{-2}$$

- *Multiplication of Numbers Expressed in Scientific Notation*
  The digit terms are multiplied in the usual manner, and the exponents are added. The result is expressed with a digit term with only one nonzero digit to the left of the decimal place:

$$(6.0 \times 10^{23}) \times (2.0 \times 10^{-2}) = (6.0)(2.0 \times 10^{23-2}) = 12 \times 10^{21} = 1.2 \times 10^{22}$$

- *Division of Numbers Expressed in Scientific Notation*
  The digit terms are divided in the usual manner, and the exponents are subtracted. The quotient is written with one nonzero digit to the left of the decimal in the digit term:

$$\frac{7.60 \times 10^{3}}{1.23 \times 10^{2}} = \frac{7.60}{1.23} \times 10^{3-2} = 6.18 \times 10^{1}$$

- *Powers of Numbers Expressed in Scientific Notation*
  When raising a number in exponential notation to a power, treat the digit term in the usual manner. The exponent is then multiplied by the number indicating the power:

$$(5.28 \times 10^{3})^{2} = (5.28)^{2} \times 10^{3\times 2} = 27.9 \times 10^{6} = 2.79 \times 10^{7}$$

- *Roots of Numbers Expressed in Scientific Notation*
  Unless you use an electronic calculator, the number must first be put into a form in which the exponent is exactly divisible by the root. For example, for a square root, the exponent should be divisible by 2. The root of the digit term is found in the usual way, and the exponent is divided by the desired root:

$$\sqrt{3.6 \times 10^{7}} = \sqrt{36 \times 10^{6}} = \sqrt{36} \times \sqrt{10^{6}} = 6.0 \times 10^{3}$$

Significant Figures

In most experiments, several kinds of measurements must be made, and some can be made more precisely than others. It is common sense that a result calculated from experimental data can be no more precise than the least precise piece of information that went into the calculation. This is where the rules for significant figures come in. **Significant figures** are the digits in a measured quantity that are known exactly plus one digit that is inexact.

Determining Significant Figures

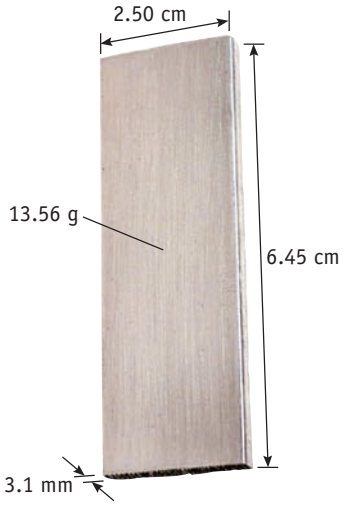
Suppose we place a new U.S. dime on the pan of an analytical laboratory balance such as the one pictured in Figure 6 and observe a mass of 2.2653 g. This number has five significant figures or digits because all five numbers are observed. However, you will learn from experience that the final digit (3) is somewhat uncertain because you may notice the balance readings can change slightly and give masses of 2.2652, 2.2653, and 2.2654, with the mass of 2.2653 observed most of the time. Thus, of the five significant digits (2.2653) the last (3) is uncertain. In general, *in a number representing a scientific measurement, the last digit to the right is taken to be inexact*. Unless stated otherwise, it is common practice to assign an uncertainty of ± 1 to the last significant digit.

Suppose you want to calculate the density of a piece of metal (Figure 7). The mass and dimensions were determined by standard laboratory techniques. Most of these data have two digits to the right of the decimal, but they have different numbers of significant figures.

© Cengage Learning/Charles D. Winters

Figure 6 Analytical laboratory balance and significant figures. Such balances can determine the mass of an object to the nearest tenth of a milligram.

Measurement	Data Collected	Significant Figures
Mass of metal	13.56 g	4
Length	6.45 cm	3
Width	2.50 cm	3
Thickness	3.1 mm = 0.31 cm	2



The quantity 0.31 cm has two significant figures. The 3 in 0.31 is exactly known, but the 1 is uncertain. That is, the thickness of the metal piece may have been as small as 0.30 cm or as large as 0.32 cm. In the case of the width of the piece, you found it to be 2.50 cm, where 2.5 is known with certainty, but the final 0 is uncertain. There are three significant figures in 2.50.

When you read a number in a problem or collect data in the laboratory (Figure 8), how do you determine which digits are significant?

First, is the number an exact number or a measured quantity? If it is an exact number, you don't have to worry about the number of significant figures. For example, there are exactly 100 cm in 1 m. We could add as many zeros after the decimal place as we want, and the expression would still be true. Using this relationship in a calculation will not affect how many significant figures you can report in your answer.

If, however, the number is a measured value, you must take into account significant figures. The number of significant figures in our data above is clear, with the possible exception of 0.31 and 2.50. Are the zeroes significant?

1. *Zeroes between two other significant digits are significant.* For example, the zero in 103 is significant.
2. *Zeroes to the right of a nonzero number, and also to the right of a decimal place, are significant.* For example, in the number 2.50 cm, the zero is significant.
3. *Zeroes that are placeholders are not significant.* There are two types of numbers that fall under this rule.
   (a) The first are decimal numbers with zeroes that occur *before* the first nonzero digit. For example, in 0.0013, only the 1 and the 3 are significant; the zeroes are not. This number has two significant figures.
   (b) The second are *numbers with trailing zeroes* that must be there to indicate the magnitude of the number. For example, the zeroes in the number 13,000 may or may not be significant; it depends on whether they were measured or not. To avoid confusion with regard to such numbers, *we shall assume in this book that trailing zeroes are significant when there is a decimal point to the right of the last zero.* Thus, we would say that 13,000 has only two significant

The 10-mL graduated cylinder is marked in 0.1-mL increments; its contents would normally be estimated to 0.01 mL. However, graduated cylinders are not precision glassware. You can expect no more than 2 significant figures when reading a volume with this cylinder.

A 50-mL buret is marked in 0.10-mL increments, but it may be read with greater precision (0.01 mL).

A volumetric flask is meant to be filled to the mark on the neck. For a 250-mL flask, the volume is known to the nearest 0.1 mL, so the flask contains 250.0 ± 0.1 mL when full to the mark (four significant figures).

A pipet is like a volumetric flask in that it is filled to the mark on its neck. For a 20-mL pipet the volume is known to the nearest 0.02 mL.

Figure 8 **Glassware and significant figures.**

Zeroes and Common Laboratory Mistakes Students often find the mass of a chemical on a balance and fail to write down trailing zeroes. For example, if the balance reading gives a mass is 2.340 g, the final zero is significant and must be reported as part of the measured value. The number 2.34 g has only three significant figures and implies the 4 is uncertain, when in fact the balance reading indicated the 4 is certain.

figures but that 13,000. has five. The best way to be unambiguous when writing numbers with trailing zeroes is to use scientific notation. For example 1.300×10^4 indicates four significant figures, whereas 1.3×10^4 indicates two.

Using Significant Figures in Calculations

When doing calculations using measured quantities, we follow some basic rules so that the results reflect the precision of all the measurements that go into the calculations. *The rules used for significant figures in this book are as follows:*

Rule 1. When adding or subtracting numbers, the number of decimal places in the answer is equal to the number of decimal places in the number with the fewest digits after the decimal.

0.12	2 decimal places
+ 1.9	1 decimal place
+10.925	3 decimal places
12.945	3 decimal places

The sum should be reported as 12.9, a number with one decimal place, because 1.9 has only one decimal place.

Rule 2. In multiplication or division, the number of significant figures in the answer is determined by the quantity with the fewest significant figures.

$$\frac{0.01208}{0.0236} = 0.512, \text{ or in scientific notation, } 5.12 \times 10^{-1}$$

Because 0.0236 has only three significant digits, while 0.01208 has four, the answer should have three significant digits.

Rule 3. When a number is rounded off, the last digit to be retained is increased by one only if the following digit is 5 or greater.

Problem Solving Tip 1 Using Your Calculator

You will be performing a number of calculations in general chemistry, most of them using an electronic calculator. Many different types of calculators are available, so be sure to consult your calculator manual for specific instructions to enter scientific notation and to find powers and roots of numbers.

1. Scientific Notation

When entering a number such as 1.23×10^{-4} into your calculator, you first enter 1.23 and then press a key marked EE or EXP (or something similar). This enters the "$\times 10$" portion of the notation for you. You then complete the entry by keying in the exponent of the number, 4. (To change the exponent from $+4$ to -4, press the "+/−" key.)

A common error made by students is to enter 1.23, press the multiply key ($\times$), and then key in 10 before finishing by pressing EE or EXP followed by -4. This gives you an entry that is 10 times too large.

Two final points should be made concerning scientific notation. First, be aware that calculators and computers often express a number such as 1.23×10^3 as 1.23E3 or 6.45×10^{-5} as 6.45E-5. Second, some electronic calculators can readily convert numbers in fixed notation to scientific notation.

2. Powers of Numbers

Electronic calculators often offer two methods of raising a number to a power. To square a number, enter the number and then press the x^2 key. To raise a number to any power, use the y^x (or similar key such as ^). For example, to raise 1.42×10^2 to the fourth power:

1. Enter 1.42×10^2.
2. Press y^x.
3. Enter 4 (this should appear on the display).
4. Press =, and 4.0659×10^8 appears on the display.

3. Roots of Numbers

A general procedure for finding any root is to use the y^x key. For a square root, x is 0.5 (or 1/2), whereas x is 0.3333 (or 1/3) for a cube root, 0.25 (or 1/4) for a fourth root, and so on. For example, to find the fourth root of 5.6×10^{-10}:

1. Enter the number.
2. Press the y^x key.
3. Enter the desired root. Because we want the fourth root, enter 0.25.
4. Press =. The answer here is 4.9×10^{-3}.

To make sure you are using your calculator correctly, try these sample calculations:

1. $(6.02 \times 10^{23})(2.26 \times 10^{-5})/367$ (Answer = 3.71×10^{16})
2. $(4.32 \times 10^{-3})^3$ (Answer = 8.06×10^{-8})
3. $(4.32 \times 10^{-3})^{1/3}$ (Answer = 0.163)

Full Number	Number Rounded to Three Significant Digits
12.696	12.7
16.349	16.3
18.35	18.4
18.351	18.4

Now let us apply these rules to calculate the density of the piece of metal in Figure 7.

$$\text{Length} \times \text{width} \times \text{thickness} = \text{volume}$$

$$\text{Density} = \frac{\text{mass (g)}}{\text{volume (cm}^3\text{)}} = \frac{13.56\ \text{g}}{6.45\ \text{cm} \times 2.50\ \text{cm} \times 0.31\ \text{cm}} = 2.7\ \text{g/cm}^3$$

The calculated density has two significant figures because *a calculated result can be no more precise than the least precise data used,* and here the thickness has only two significant figures.

One last word on significant figures and calculations: When working problems, you should do the calculation with all the digits allowed by your calculator and round off only at the end of the calculation. *Rounding off in the middle of a calculation can introduce errors.* In Example problems in this book, the answer to each intermediate step is given to the correct number of significant figures *plus one extra digit for that*

Who Is Right—You or the Book? If your answer to a problem in this book does not quite agree with the answers in Appendix N, the discrepancy may be the result of your rounding the answer after each step and then using that rounded answer in the next step.

step, so that round-off errors do not propagate in the significant figures. The final answers to numerical problems result from retaining several digits more than the number required by the rules of significant figures and rounding to the correct number of significant figures only at the end.

EXAMPLE 3

Using Significant Figures

Problem An example of a calculation you will do later in the book (Chapter 10) is

$$\text{Volume of gas (L)} = \frac{(0.120)(0.08206)(273.15 + 5)}{(230/760.0)}$$

Calculate the final answer to the correct number of significant figures.

What Do You Know? You know the rules for determining the number of significant figures for each number in the equation.

Strategy First decide on the number of significant figures represented by each number and then apply Rules 1–3.

SOLUTION

Number	Number of Significant Figures	Comments
0.120	3	The trailing 0 is significant.
0.08206	4	The first 0 to the immediate right of the decimal is not significant.
273.15 + 5 = 278	3	5 has no decimal places, so the sum can have none.
230/760.0 = 0.30	2	230 has two significant figures because the last zero is not significant. In contrast, there is a decimal point in 760.0, so there are four significant digits. The quotient will have only two significant digits.

Multiplication and division gives 9.0506 ... L. However, analysis shows that one of the pieces of information is known to only two significant figures. Therefore, you should report the volume of gas as 9.1 L, a number with two significant figures.

Think about Your Answer Be especially careful when you add or subtract two numbers because it is easy to make significant figure errors when doing so. Notice that in the addition portion of this calculation (273.15 + 5 = 278) the sum has three significant figures.

Check Your Understanding

What is the result of the following calculation?

$$x = \frac{(110.7 - 64)}{(0.056)(0.00216)}$$

4 Problem Solving by Dimensional Analysis

Goal for Section 4

- Solve problems using dimensional analysis.

Figure 7 illustrated the data that were collected to determine the density of a piece of metal. The thickness was measured in millimeters, whereas the length and width were measured in centimeters. To find the volume of the sample in cubic centimeters, we first had to have the length, width, and thickness in the same units, so we converted the thickness to centimeters.

$$3.1 \text{ mm} \times \frac{1 \text{ cm}}{10 \text{ mm}} = 0.31 \text{ cm}$$

Here, we multiplied the number we wished to convert (3.1 mm) by a *conversion factor* (1 cm/10 mm) to produce the result in the desired unit (0.31 cm). Notice that units are treated like numbers. Because the unit "mm" is in both the numerator and the denominator, the units are said to "cancel out." This leaves the answer in centimeters, the desired unit.

This approach to problem solving is often called **dimensional analysis** (or sometimes the **factor-label method**). *It is a general problem-solving approach that uses the dimensions or units of each value to guide us through calculations.*

A **conversion factor** expresses the equivalence of a measurement in two different units (1 cm ≡ 10 mm; 1 g ≡ 1000 mg; 12 eggs ≡ 1 dozen; 12 inches ≡ 1 foot). Because the numerator and the denominator describe the same quantity, the conversion factor is equivalent to the number 1. Therefore, multiplication by this factor does not change the measured quantity, only its units. A conversion factor is always written so that it has the form "new units divided by units of original number."

$$\text{Number in original unit} \left[\frac{\text{new unit}}{\text{original unit}}\right] = \text{new number in new unit}$$

- Number in original unit: Quantity to express in new units
- $\left[\frac{\text{new unit}}{\text{original unit}}\right]$: Conversion factor
- new number in new unit: Quantity now expressed in new units

Using Conversion Factors and Doing Calculations As you work problems in this book and read Example problems, notice that proceeding from given information to an answer very often involves a series of multiplications. That is, we multiply the given data by a conversion factor, multiply the answer of that step by another factor, and so on, to get the answer.

EXAMPLE 4

Using Conversion Factors and Dimensional Analysis

Problem Oceanographers often express the density of sea water in units of kilograms per cubic meter. If the density of sea water is 1.025 g/cm^3 at 15 °C, what is its density in kilograms per cubic meter?

What Do You Know? You know the density in a unit involving mass in grams and volume in cubic centimeters. Each of these has to be changed to its equivalent in kilograms and cubic meters, respectively.

Strategy To simplify this problem, break it into three steps. First, change the mass in grams to kilograms. Next, convert the volume in cubic centimeters to cubic meters. Finally, calculate the density by dividing the mass in kilograms by the volume in cubic meters.

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

SOLUTION First convert the mass in grams to a mass in kilograms.

$$1.025\ \text{g} \times \frac{1\ \text{kg}}{1000\ \text{g}} = 1.025 \times 10^{-3}\ \text{kg}$$

Our given information is known to four significant figures. The conversion factor is an exact number, so using it will not affect the number of significant figures. No conversion factor is available in one of our tables to directly change units of cubic centimeters to cubic meters. You can find one, however, by cubing (raising to the third power) the relation between the meter and the centimeter:

$$1\ \text{cm}^3 \times \left(\frac{1\ \text{m}}{100\ \text{cm}}\right)^3 = 1\ \text{cm}^3 \times \left(\frac{1\ \text{m}^3}{1 \times 10^6\ \text{cm}^3}\right) = 1 \times 10^{-6}\ \text{m}^3$$

This conversion involves only numbers that are known exactly, so we don't need to worry about significant figures for this step. We now know that 1 cm^3 is equivalent to 1×10^{-6} m^3. Therefore, the density of sea water is

$$\text{Density} = \frac{1.025 \times 10^{-3}\ \text{kg}}{1 \times 10^{-6}\ \text{m}^3} = 1025\ \text{kg/m}^3$$

Think about Your Answer The number of significant figures reported for the final answer is determined by our given information, 1.025 g, which has four significant figures. Our final answer therefore has four significant figures. Densities in units of kg/m^3 can often be large numbers. For example, the density of platinum is 21,450 kg/m^3, and dry air has a density of 1.204 kg/m^3.

Check Your Understanding

The density of gold is 19,320 kg/m^3. What is this density in g/cm^3?

5 Graphs and Graphing

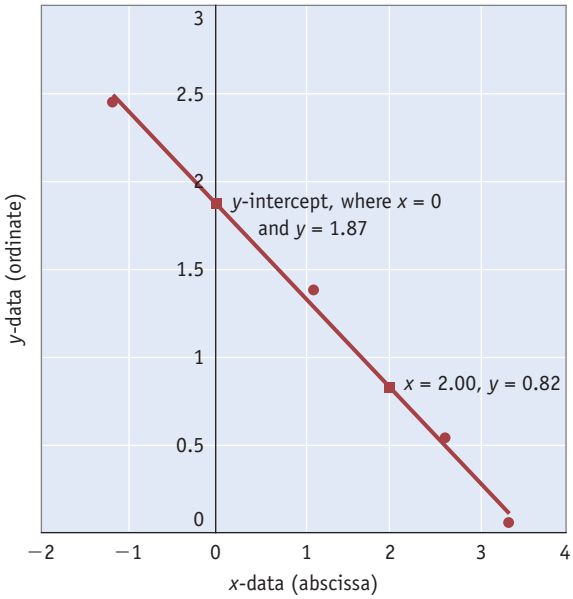
Goals for Section 5

- Read information from graphs.
- Prepare and interpret graphs of numerical information, and, if a graph produces a straight line, find the slope and equation of the line.

In a number of instances in this text, graphs are used when analyzing experimental data with a goal of obtaining a mathematical equation that may help us predict new results. The procedure used will often result in a straight line, which has the equation

$$y = mx + b$$

Determining the Slope with a Computer Program—Least-Squares Analysis Generally, the easiest method of determining the slope and intercept of a straight line (and thus the line's equation) is to use a program such as Microsoft Excel or Apple's Numbers. These programs perform a "least-squares" or "linear regression" analysis and give the best straight line based on the data. (This line is referred to in Excel or Numbers as a trendline.)



In this equation, y is usually referred to as the dependent variable; its value is determined from (that is, is dependent on) the values of x, m, and b. In this equation, x is called the independent variable, and m is the slope of the line. The parameter b is the y-intercept—that is, the value of y when $x = 0$. Let us use an example to investigate two things: (1) how to construct a graph from a set of data points and (2) how to derive an equation for the line generated by the data.

A set of data points to be graphed is presented in Figure 9. We first mark off each axis in increments of the values of x and y. Here, our x-data are within the range from -2 to 4, so the x-axis is marked off in increments of 1 unit. The *y-data fall within the range from 0 to 2.5, so we mark off the* y-axis in increments of 0.5. Each data point is marked as a circle on the graph.

After plotting the points on the graph (round circles), we draw a straight line that comes as close as possible to representing the trend in the data. (Do not just

Experimental data

x	y
3.35	0.0565
2.59	0.520
1.08	1.38
−1.19	2.45

Using the points marked with a square, the slope of the line is:

$$\text{Slope} = \frac{\Delta y}{\Delta x} = \frac{0.82 - 1.87}{2.00 - 0.00} = -0.525$$

Figure 9 Plotting data. Using Microsoft Excel with these data and doing a linear regression analysis, we find $y = -0.525x + 1.87$.

connect the dots!) Because there is always some inaccuracy in experimental data, the straight line we draw is unlikely to pass exactly through every point.

To identify the specific equation corresponding to our data, we must determine the y-intercept (b) and slope (m) for the equation $y = mx + b$. The y-intercept is the point at which $x = 0$ and thus is the point where the line intersects the y-axis. The slope is determined by selecting two points *on the line* (marked with squares in Figure 9) and calculating the difference in values of y ($\Delta y = y_2 - y_1$) and x ($\Delta x = x_2 - x_1$). The slope of the line is then the ratio of these differences, $m = \Delta y/\Delta x$. With the slope and intercept now known, we can write the equation for the line

$$y = -0.525x + 1.87$$

and we can use this equation to calculate y-values for points that are not part of our original set of x–y data. For example, when $x = 1.50$, we find $y = 1.08$.

6 Problem Solving and Chemical Arithmetic

Goals for Section 6

- Solve problems using a systematic approach.
- Incorporate quantitative information into an algebraic expression and solve that expression.

Many aspects of chemistry involve analyzing quantitative information, so problem solving will be important in your success. In every chapter we will demonstrate how to work through problems step by step. However, as in anything you do, careful planning is important, and students usually find it helpful to follow a definite plan as illustrated in all of the examples in the book.

Step 1 *State the Problem.* Read it carefully—and then read it again.

Step 2 *What Do You Know? Determine specifically what you are trying to calculate or conclude and what information you are given.* What key principles are involved? What information is known or not known? What information might be there just to place the question in the context of chemistry? Organize the information to see what is required and to discover the relationships among the data given. Try writing the information down in table form. If the information is numerical, be sure to include units.

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Strategy Maps Many Example problems in this book are accompanied by a Strategy Map that outlines a route to a solution.

General Strategy Map

State the Problem: *Read the problem carefully.*

↓

Data/Information: *What do you know?*

↓

Strategy: *Develop a plan.*

↓

Solution: *Execute the plan.*

STEPS 1, 2, 3... Sequence of operations needed to solve this problem.

Answer: *Is your answer reasonable and in the correct units?*

Step 3 *Strategy.* One of the greatest difficulties for a student in introductory chemistry is picturing what is being asked for. Try sketching a picture of the situation involved. For example, we sketched a picture of the piece of metal whose density we wanted to calculate and put the dimensions on the drawing (Figure 7).

Develop a plan. Have you done a problem of this type before? If not, perhaps the problem is really just a combination of several simpler ones you have seen before. Break it down into those simpler components. Try reasoning backward from the units of the answer. What data do you need to find an answer in those units? Drawing a strategy map such as that shown in the margin may help you in planning how you will go about solving the problem.

Step 4 *Solution.* Execute the plan. Carefully write down each step of the problem, being sure to keep track of the units on each number. (Do the units cancel to give you the answer in the desired units?) Don't skip steps. Don't do anything except the simplest steps in your head. Students often say they got a problem wrong because they "made a stupid mistake." Your instructors—and book authors—also make them, and it is usually because they don't take the time to write down the steps of the problem clearly.

Step 5 *Think about Your Answer.* Ask yourself whether the answer is reasonable and if you obtained an answer in the correct units.

Step 6 *Check Your Understanding.* In this text each Example is followed by another problem for you to try. (The solutions to those questions are given by chapter in Appendix N.) When doing homework Study Questions, try one of the *Practicing Skills* questions to see if you understand the basic ideas.

The steps we outline for problem solving are ones that many students have found to be successful, so try to conscientiously follow this scheme. But also be flexible. The "What Do You Know?" and "Strategy" steps often blend into a single set of ideas.

Strategy Map for Example 5

PROBLEM

How thick will an oil layer be when a **given mass** covers a **given area**?

↓

DATA/INFORMATION

Mass and **density** of the oil and **diameter** of the circular surface to be covered.

STEP 1. Calculate the **volume** of oil from **mass** and **density**.

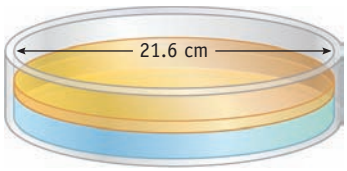
Volume of oil in **cm^3**

STEP 2. Calculate the **surface area** from the **diameter**.

Area to be covered in **cm^2**

STEP 3. Divide the oil **volume** by the **surface area** to calculate the thickness in **cm**.

Thickness of oil layer in **cm**



EXAMPLE 5

Problem Solving

Problem A mineral oil has a density of 0.875 g/cm^3. Suppose you spread 0.75 g of this oil over the surface of water in a large dish with an inner diameter of 21.6 cm. How thick is the oil layer? Express the thickness in centimeters.

What Do You Know? You know the mass and density of the oil and the diameter of the surface to be covered.

Strategy It is often useful to begin solving such problems by sketching a picture of the situation.

This helps you recognize that the solution to the problem is to find the volume of the oil on the water. If you know the volume, then you can find the thickness because

$$\text{Volume of oil layer} = (\text{thickness of layer}) \times (\text{area of oil layer})$$

So, you need two things: (1) the volume of the oil layer and (2) the area of the layer. The volume can be found using the mass and density of the oil. The area can be found because the oil will form a circle, which has an area equal to $\pi \times r^2$ (where r is the radius of the dish).

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

SOLUTION First, calculate the volume of oil. The mass of the oil layer is known, so combining the mass of oil with its density gives the volume of the oil used:

$$0.75 \text{ g} \times \frac{1 \text{ cm}^3}{0.875 \text{ g}} = 0.857 \text{ cm}^3$$

Next, calculate the area of the oil layer. The oil is spread over a circular surface, whose area is given by

$$\text{Area} = \pi \times (\text{radius})^2$$

The radius of the oil layer is half its diameter (= 21.6 cm) or 10.8 cm, so

$$\text{Area of oil layer} = (\pi)(10.8 \text{ cm})^2 = 366.4 \text{ cm}^2$$

With the volume and the area of the oil layer known, the thickness can be calculated.

$$\text{Thickness} = \frac{\text{volume}}{\text{area}} = \frac{0.857 \text{ cm}^3}{366.4 \text{ cm}^2} = 0.0023 \text{ cm}$$

Think about Your Answer In the volume calculation, the calculator shows 0.857143. . . . The quotient should have two significant figures because 0.75 has two significant figures, so the result of this step is reported as 0.857 cm^3, containing one extra digit. In the area calculation, the calculator shows 366.435. . . . The answer to this step should have three significant figures because 10.8 has three; again, this value is reported to one extra digit. When these interim results are combined in calculating thickness, the final result can have only two significant figures. Remember that premature rounding can lead to errors.

Check Your Understanding

A particular paint has a density of 0.914 g/cm^3. You need to cover a wall that is 7.6 m long and 2.74 m high with a paint layer 0.13 mm thick. What volume of paint (in liters) is required? What is the mass (in grams) of the paint layer?

APPLYING CHEMICAL PRINCIPLES

1 Out of Gas!

On July 23, 1983, a new Boeing 767 jet aircraft was flying at 26,000 ft from Montreal to Edmonton as Air Canada Flight 143. Warning buzzers sounded in the cockpit. One of the world's largest planes was now a glider—the plane had run out of fuel!

How did this happen? A simple mistake had been made in calculating the amount of fuel required for the flight because of a mixup of units of measurement!

Like all Boeing 767s, this plane had a sophisticated fuel gauge, but it was not working properly. The plane was still allowed to fly, however, because there is an alternative method of determining the quantity of fuel in the tanks. Mechanics can use a stick, much like the oil dipstick in an automobile engine, to measure the fuel level in each of the three tanks. The mechanics in Montreal read the dipsticks, which were

Wayne Glowacki/Winnipeg Free Press

The Gimli glider. After running out of fuel, Air Canada Flight 143 glided 29 minutes before landing on an abandoned airstrip at Gimli, Manitoba, near Winnipeg.

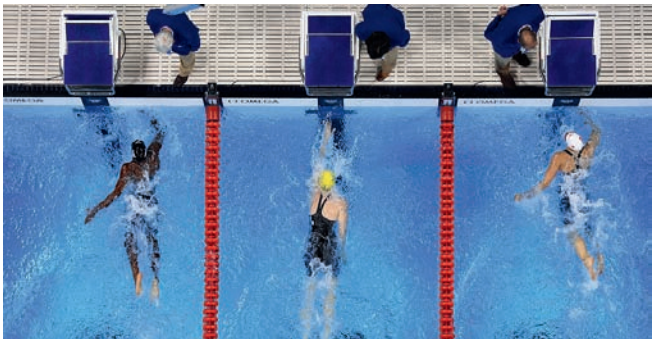
calibrated in centimeters, and translated those readings to a volume in liters. According to this, the plane had a total of 7682 L of fuel.

Pilots always calculate fuel quantities in units of mass because they need to know the total mass of the plane before take-off. Air Canada pilots had always calculated the quantity of fuel in pounds, but the new 767's fuel consumption was given in kilograms. The pilots knew that 22,300 kg of fuel was required for the trip. If 7682 L of fuel remained in the tanks, how much had to be added? This involved using the fuel's density to convert 7682 L to a mass in kilograms. The mass of fuel to be added could then be calculated, and that mass converted to a volume of fuel to be added.

The First Officer of the plane asked a mechanic for the conversion factor to do the volume-to-mass conversion, and the mechanic replied "1.77." Using that number, the First Officer and the mechanics calculated that 4917 L of fuel should be added. But later calculations showed that this is only about one fourth of the required amount of fuel! Why? Because no one thought about the units of the number 1.77. They realized later that 1.77 has units of pounds per liter and not kilograms per liter.

Out of fuel, the plane could not make it to Winnipeg, so controllers directed them to the town of Gimli and to a small airport abandoned by the Royal Canadian Air Force. After gliding for almost 30 minutes, the plane approached the Gimli runway. The runway, however, had been converted to a race course for cars, and a race was underway. Furthermore, a steel barrier had been erected across the runway. Nonetheless, the pilot managed to touch down very near the end of the runway. The plane sped down the concrete strip; the nose wheel collapsed; several tires blew—and the plane skidded safely to a stop just before the barrier. The Gimli glider had made it! And somewhere an aircraft mechanic is paying more attention to units on numbers.



Questions:

1. What is the fuel density in units of kg/L?
2. What mass and what volume of fuel should have been loaded? (1 lb = 453.6 g)

2 Ties in Swimming and Significant Figures

Have you ever noticed that there are many ties in swimming competitions? For example, in the 2016 Summer Olympics, there was a two-way tie for the gold medal in the women's 100-m freestyle and a three-way tie for the silver medal in the men's 100-m butterfly. Olympic competitions are timed to one hundredth of a second. You might wonder why the officials don't simply time the events out to a thousandth of a second, something that is technologically feasible and done in some sports, and eliminate most of these ties. The reason relates to the topic of how many digits in a swimming competition are really significant.

Let's consider a 50-m Olympic-sized swimming pool and a 50-m freestyle swimming contest. The current world record of 20.91 seconds for this event was set by César Cielo of Brazil in 2009. Assuming a person is swimming at this rate, the maximum distance traveled in one thousandth of a second is 2.4 mm. The problem arises with the necessary specifications in the dimensions of the pool. There will always be some variation in the lengths of the different lanes due to limitations in the construction of pools. Current specifications allow a lane to be up to 3 cm longer than the stated length of 50.00 m. It would thus not be fair to penalize a swimmer in a lane that could be 3 cm longer for a difference in time that would amount to at most 2.4 mm, and so timing out to thousandths of a second is not done.

Richard Heathcote/Getty Images

A Tie for Gold. Simone Manuel and Penny Oleksiak tie for gold in the 100 m freestyle event at the 2016 Summer Olympics held in Rio de Janeiro, Brazil.

Questions:

1. Confirm that a person swimming at the world record rate for the 50-m freestyle would travel 2.4 mm in one thousandth of a second.
2. At this world record rate, how long would it take for a swimmer to travel 3.0 cm?
3. Consider a lane that is 3 cm longer than the stated 50.00 m. What is the percent error in this lane's length?

CHAPTER GOALS REVISITED

The goals for this chapter are keyed to specific Study Questions to help you organize your review.

1 Units of Measurement

- Use the common units for measurements in chemistry and make unit conversions (such as from liters to milliliters). 1–12, 17–20, 35–37.

2 Making Measurements: Precision, Accuracy, Experimental Error, and Standard Deviation

- Recognize and express uncertainties in measurements. 21, 22, 46, 56–58, 62, 67.

3 Mathematics of Chemistry

- Express and use numbers in exponential or scientific notation. 23, 24.
- Report the answer of a calculation to the correct number of significant figures. 25, 26.

4 Problem Solving by Dimensional Analysis

- Solve problems using dimensional analysis. 13–16, 39–40, 53.

5 Graphs and Graphing

- Read information from graphs. 28, 29.
- Prepare and interpret graphs of numerical information, and, if a graph produces a straight line, find the slope and equation of the line. 27, 30, 65, 66.

6 Problem Solving and Chemical Arithmetic

- Solve problems using a systematic approach. 38, 44, 47–52, 54, 59–61.
- Incorporate quantitative information into an algebraic expression and solve that expression. 31–34.

KEY EQUATIONS

Equation 1 (page 30) Converting a temperature from °C to K.

$$T\ (\mathrm{K}) = \frac{1\ \mathrm{K}}{1\ ^\circ\mathrm{C}}\ (T\ ^\circ\mathrm{C} + 273.15\ ^\circ\mathrm{C})$$

Equation 2 (page 35) Error in measurement.

$$\text{Error in measurement} = \text{experimentally determined value} - \text{accepted value}$$

Equation 3 (page 35) Percent error.

$$\text{Percent error} = \frac{\text{error in measurement}}{\text{accepted value}} \times 100\%$$

STUDY QUESTIONS

▲ denotes challenging questions. **Blue-numbered questions** have answers in Appendix N and fully worked solutions in the *Student Solutions Manual.*

Practicing Skills

Temperature Scales

1. Many laboratories use 25 °C as a standard temperature. What is this temperature in kelvins?
2. The temperature on the surface of the Sun is 5.5×10^3 °C. What is this temperature in kelvins?
3. Make the following temperature conversions:

	°C	K
(a)	16	_____
(b)	_____	370
(c)	40	_____

4. Make the following temperature conversions:

	°C	K
(a)	_____	77
(b)	63	_____
(c)	_____	1450

Length, Volume, Mass, and Density

(See Example 1.)

5. A marathon distance race covers a distance of 42.195 km. What is this distance in meters? In miles?
6. The average lead pencil, new and unused, is 19 cm long. What is its length in millimeters? In meters?
7. A standard U.S. postage stamp is 2.5 cm long and 2.1 cm wide. What is the area of the stamp in square centimeters? In square meters?
8. A compact disc has a diameter of 11.8 cm. What is the surface area of the disc in square centimeters? In square meters? [Area of a circle = $(\pi)(\text{radius})^2$]
9. A typical laboratory beaker has a volume of 250. mL. What is its volume in cubic centimeters? In liters? In cubic meters? In cubic decimeters?
10. Some soft drinks are sold in bottles with a volume of 1.5 L. What is this volume in milliliters? In cubic centimeters? In cubic decimeters?
11. A book has a mass of 2.52 kg. What is this mass in grams?
12. A new U.S. dime has a mass of 2.265 g. What is its mass in kilograms? In milligrams?
13. Ethylene glycol, $C_2H_6O_2$, is an ingredient of automobile antifreeze. Its density is 1.11 g/cm^3 at 20 °C. If you need 500. mL of this liquid, what mass of the compound, in grams, is required?
14. A piece of silver metal has a mass of 2.365 g. If the density of silver is 10.5 g/cm^3, what is the volume of the silver?
15. You can identify a metal by carefully determining its density (d). An unknown piece of metal, with a mass of 2.361 g, is 2.35 cm long, 1.34 cm wide, and 1.05 mm thick. Which of the following is the element?
    (a) nickel, $d = 8.91$ g/cm^3
    (b) titanium, $d = 4.50$ g/cm^3
    (c) zinc, $d = 7.14$ g/cm^3
    (d) tin, $d = 7.23$ g/cm^3
16. Which occupies a larger volume, 600 g of water (with a density of 0.995 g/cm^3) or 600 g of lead (with a density of 11.35 g/cm^3)?

Energy Units

17. You are on a diet that calls for eating no more than 1200 Cal/day. What is this energy in joules?
18. A 2-in. piece of chocolate cake with frosting provides 1670 kJ of energy. What is this in dietary Calories (Cal)?
19. One food product has an energy content of 170 kcal per serving, and another has 280 kJ per serving. Which food provides the greater energy per serving?
20. A can of soft drink (335 mL) provides 130 Calories. A bottle of mixed berry juice (295 mL) provides 630 kJ. Which provides the greater total energy? Which provides the greater energy per milliliter?

Accuracy, Precision, Error, and Standard Deviation

(See Example 2.)

21. You and your lab partner are asked to determine the density of an aluminum bar. The mass is known accurately (to four significant figures). You use a simple metric ruler to measure its dimensions and obtain the results for Method A. Your partner uses a precision micrometer and obtains the results for Method B.

Method A (g/cm^3)	Method B (g/cm^3)
2.2	2.703
2.3	2.701
2.7	2.705
2.4	5.811

The accepted density of aluminum is 2.702 g/cm^3.

(a) Calculate the average density for each method. Should all the experimental results be included in your calculations? If not, justify any omissions.

(b) Calculate the percent error for each method's average value.

(c) Calculate the standard deviation for each set of data.

(d) Which method's average value is more precise? Which method is more accurate?

22. The accepted value of the melting point of pure aspirin is 135 °C. Trying to verify that value, you obtain 134 °C, 136 °C, 133 °C, and 138 °C in four separate trials. Your partner finds 138 °C, 137 °C, 138 °C, and 138 °C.

(a) Calculate the average value and percent error for your data and your partner's data.

(b) Which of you is more precise? More accurate?

Exponential Notation and Significant Figures

(See Example 3.)

23. Express the following numbers in exponential or scientific notation, and give the number of significant figures in each.

(a) 0.054 g (c) 0.000792 g

(b) 5462 g (d) 1600 mL

24. Express the following numbers in fixed notation (e.g., $1.23 \times 10^2 = 123$), and give the number of significant figures in each.

(a) 1.623×10^3 (c) 6.32×10^{-2}

(b) 2.57×10^{-4} (d) 3.404×10^3

25. Carry out the following operations. Provide the answer with the correct number of significant figures.

(a) $(1.52)(6.21 \times 10^{-3})$

(b) $(6.217 \times 10^3) - (5.23 \times 10^2)$

(c) $(6.217 \times 10^3) \div (5.23 \times 10^2)$

(d) $(0.0546)(16.0000)\left[\dfrac{7.779}{55.85}\right]$

26. Carry out the following operations. Provide the answer with the correct number of significant figures.

(a) $(6.25 \times 10^2)^3$

(b) $\sqrt{2.35 \times 10^{-3}}$

(c) $(2.35 \times 10^{-3})^{1/3}$

(d) $(1.68)\left[\dfrac{23.56 - 2.3}{1.248 \times 10^3}\right]$

Graphing

27. To determine the average mass of a popcorn kernel, you collect the following data:

Number of Kernels	Mass (g)
5	0.836
12	2.162
35	5.801

Plot the data with number of kernels on the *x*-axis and mass on the *y*-axis. Draw the best straight line using the points on the graph (or do a least-squares or linear regression analysis using a computer program), and then write the equation for the resulting straight line. What is the slope of the line? What does the slope of the line signify about the mass of a popcorn kernel? What is the mass of 20 popcorn kernels? How many kernels are there in a handful of popcorn with a mass of 20.88 g?

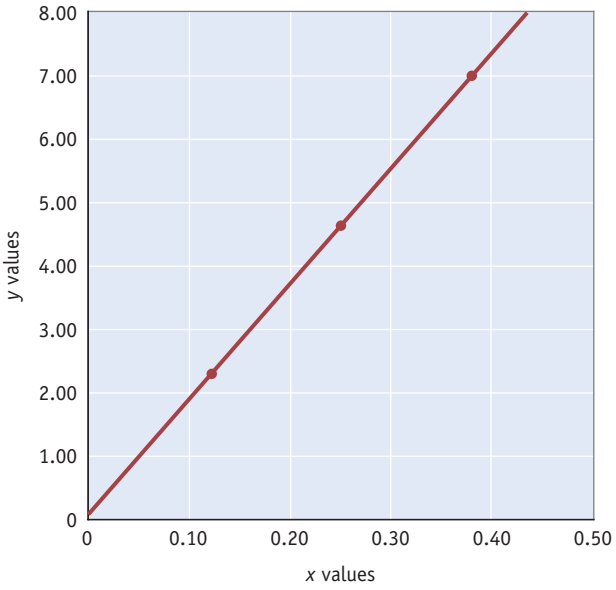
Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

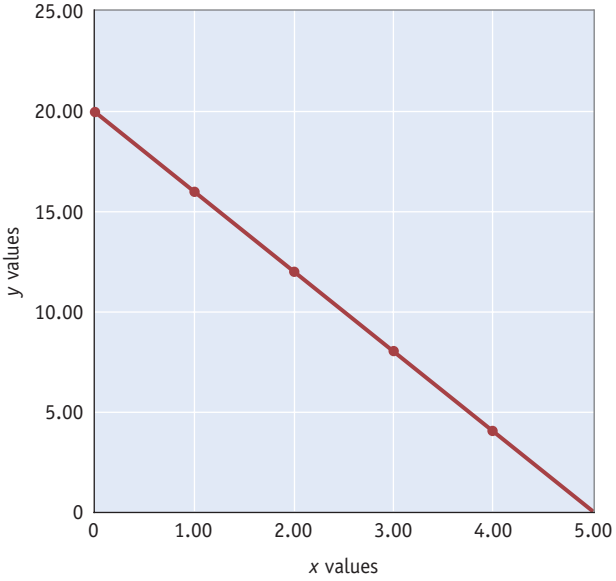


28. Use the following graph to answer the following questions:

(a) What is the value of x when $y = 4.0$?

(b) What is the value of y when $x = 0.30$?

(c) What are the slope and the y-intercept of the line?



(d) What is the value of y when $x = 1.0$?

29. Use the graph below to answer the following questions.

(a) Derive the equation for the straight line, $y = mx + b$.

(b) What is the value of y when $x = 6.0$?

30. The following data were collected in an experiment to determine how an enzyme works in a biochemical reaction.

Amount of H_2O_2	Reaction Speed (amount/second)
1.96	4.75×10^{-5}
1.31	4.03×10^{-5}
0.98	3.51×10^{-5}
0.65	2.52×10^{-5}
0.33	1.44×10^{-5}
0.16	0.585×10^{-5}

(a) Plot these data as 1/amount on the x-axis and 1/speed on the y-axis. Draw the best straight line to fit these data points.

(b) Determine the equation for the data, and give the values of the y-intercept and the slope. (*Note:* In biochemistry this is known as a Lineweaver-Burk plot, and the y-intercept is related to the maximum speed of the reaction.)

Solving Equations

31. Solve the following equation for the unknown value, C.

$$(0.502)(123) = (750.)C$$

32. Solve the following equation for the unknown value, n.

$$(2.34)(15.6) = n(0.0821)(273)$$

33. Solve the following equation for the unknown value, T.

$$(4.184)(244)(T - 292.0) + (0.449)(88.5)(T - 369.0) = 0$$

34. Solve the following equation for the unknown value, n.

$$-246.0 = 1312\left[\frac{1}{2^2} - \frac{1}{n^2}\right]$$

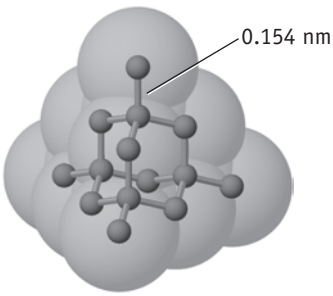
General Questions



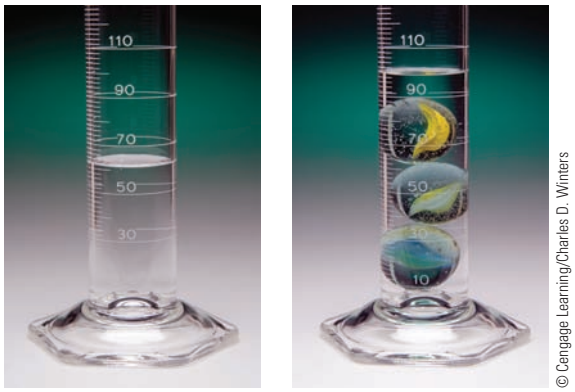
These questions are not designated as to type or location in the chapter. They may combine several concepts.

35. Molecular distances are usually given in nanometers (1 nm = 1×10^{-9} m) or in picometers (1 pm = 1×10^{-12} m). However, the angstrom (Å) unit is sometimes used, where 1 Å = 1×10^{-10} m. (The angstrom unit is not an SI unit.) If the distance between the Pt atom and the N atom in the cancer chemotherapy drug cisplatin is 1.97 Å, what is this distance in nanometers? In picometers?

Cisplatin

36. The separation between carbon atoms in diamond is 0.154 nm. What is their separation in meters? In picometers (pm)? In Angstroms (Å)?

A portion of the diamond structure



37. A red blood cell has a diameter of 7.5 μm (micrometers). What is this dimension in (a) meters, (b) nanometers, and (c) picometers?

38. The platinum-containing cancer drug cisplatin (Study Question 35) contains 65.0 mass-percent of the metal. If you have 1.53 g of the compound, what mass of platinum (in grams) is contained in this sample?

39. The anesthetic procaine hydrochloride is often used to deaden pain during dental surgery. The compound is packaged as a 10.% solution (by mass; d = 1.0 g/mL) in water. If your dentist injects 0.50 mL of the solution, what mass of procaine hydrochloride (in milligrams) is injected?

40. You need a cube of aluminum with a mass of 7.6 g. What must be the length of the cube's edge (in cm)? (The density of aluminum is 2.698 g/cm^3.)

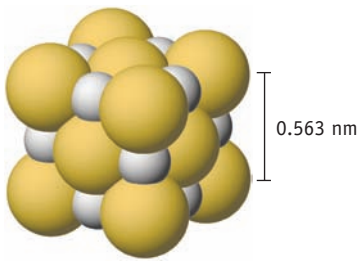
41. You have a 250.0-mL graduated cylinder containing some water. You drop three marbles with a total mass of 95.2 g into the water. What is the average density of a marble?

(a) **(b)**

Determining density. **(a)** A graduated cylinder with 61 mL of water. **(b)** Three marbles are added to the cylinder.

© Cengage Learning/Charles D. Winters

42. You have a white crystalline solid, known to be one of the potassium compounds listed below. To determine which, you measure its density. You measure out 18.82 g and transfer it to a graduated cylinder containing kerosene (in which these compounds will not dissolve). The level of liquid kerosene rises from 8.5 mL to 15.3 mL. Calculate the density of the solid, and identify the compound from the following list.



(a) KF, d = 2.48 g/cm^3

(b) KCl, d = 1.98 g/cm^3

(c) KBr, d = 2.75 g/cm^3

(d) KI, d = 3.13 g/cm^3

43. ▲ The smallest repeating unit of a crystal of common salt is a cube (called a unit cell) with an edge length of 0.563 nm.

Sodium chloride, NaCl

(a) What is the volume of this cube in cubic nanometers? In cubic centimeters?

(b) The density of NaCl is 2.17 g/cm^3. What is the mass of this smallest repeating unit ("unit cell")?

(c) Each repeating unit is composed of four NaCl units. What is the mass of one NaCl formula unit?

44. Diamond has a density of 3.513 g/cm^3. The mass of diamonds is often measured in "carats," where 1 carat equals 0.200 g. What is the volume (in cubic centimeters) of a 1.50-carat diamond?

45. The element gallium has a melting point of 29.8 °C. If you hold a sample of gallium in your hand, should it melt? Explain briefly.

© Cengage Learning/Charles D. Winters

Gallium metal

46. ▲ The density of pure water at various temperatures is given below.

T(°C)	d (g/cm^3)
4	0.99997
15	0.99913
25	0.99707
35	0.99406

Suppose your laboratory partner tells you the density of water at 20 °C is 0.99910 g/cm^3. Is this a reasonable number? Why or why not?

47. When you heat popcorn, it pops because it loses water explosively. Assume a kernel of corn, with a mass of 0.125 g, has a mass of only 0.106 g after popping.
   (a) What percentage of its mass did the kernel lose on popping?
   (b) Popcorn is sold by the pound in the United States. Using 0.125 g as the average mass of a popcorn kernel, how many kernels are there in a pound of popcorn? (1 lb = 453.6 g)

48. ▲ The aluminum in a package containing 75 ft^2 of kitchen foil weighs approximately 12 ounces. Aluminum has a density of 2.70 g/cm^3. What is the approximate thickness of the aluminum foil in millimeters? (1 ounce = 28.4 g)

49. ▲ Fluoridation of city water supplies has been practiced in the United States for several decades. It is done by continuously adding sodium fluoride to water as it comes from a reservoir. Assume you live in a medium-sized city of 150,000 people and that 660 L (170 gal) of water is used per person per day. What mass of sodium fluoride (in kilograms) must be added to the water supply each year (365 days) to have the required fluoride concentration of 1 ppm (part per million)—that is, 1 kilogram of fluoride per 1 million kilograms of water? (Sodium fluoride is 45.0% fluoride, and water has a density of 1.00 g/cm^3.)

50. ▲ About two centuries ago, Benjamin Franklin showed that 1 teaspoon of oil would cover about 0.5 acre of still water. If you know that 1.0×10^4 m^2 = 2.47 acres and that there is approximately 5 cm^3 in a teaspoon, what is the thickness of the 0.5-acre layer of oil? How might this thickness be related to the sizes of molecules?

51. ▲ Automobile batteries are filled with an aqueous solution of sulfuric acid. What is the mass of the acid (in grams) in 500. mL of the battery acid solution if the density of the solution is 1.285 g/cm^3 and the solution is 38.08% sulfuric acid by mass?

52. A 26-meter-tall statue of Buddha in Tibet is covered with 279 kg of gold. If the gold was applied to a thickness of 0.0015 mm, what surface area is covered (in square meters)? (Gold density = 19.3 g/cm^3)

53. At 25 °C, the density of water is 0.997 g/cm^3, whereas the density of ice at −10 °C is 0.917 g/cm^3.
   (a) If a soft-drink can (volume = 250. mL) is filled completely with pure water at 25 °C and then frozen at −10 °C, what volume does the ice occupy?
   (b) Can the ice be contained within the can?

54. Suppose your bedroom is 18 ft long and 15 ft wide, and the distance from floor to ceiling is 8 ft 6 in. You need to know the volume of the room in metric units for some scientific calculations.
   (a) What is the room's volume in cubic meters? In liters?
   (b) What is the mass of air in the room in kilograms? In pounds? (Assume the density of air is 1.2 g/L and that the room is empty of furniture.)

55. A spherical steel ball has a mass of 3.475 g and a diameter of 9.40 mm. What is the density of the steel? [The volume of a sphere = $(4/3)\pi r^3$ where r = radius.]

56. ▲ You are asked to identify an unknown liquid that is known to be one of the liquids listed below. You pipet a 3.50-mL sample into a beaker. The empty beaker had a mass of 12.20 g, and the beaker plus the liquid weighed 16.08 g.

Substance	Density at 25 °C (g/cm^3)
Ethylene glycol	1.1088 (major component of automobile antifreeze)
Water	0.9971
Ethanol	0.7893 (alcohol in alcoholic beverages)
Acetic acid	1.0492 (active component of vinegar)
Glycerol	1.2613 (solvent used in home care products)

(a) Calculate the density and identify the unknown.

(b) If you were able to measure the volume to only two significant figures (that is, 3.5 mL, not 3.50 mL), will the results be sufficiently accurate to identify the unknown? Explain.

57. ▲ You have an irregularly shaped piece of an unknown metal. To identify it, you determine its density and then compare this value with known values that you look up in the chemistry library. The mass of the metal is 74.122 g. Because of the irregular shape, you measure the volume by submerging the metal in water in a graduated cylinder. When you do this, the water level in the cylinder rises from 28.2 mL to 36.7 mL.

(a) What is the density of the metal? (Use the correct number of significant figures in your answer.)

(b) The unknown is one of the seven metals listed below. Is it possible to identify the metal based on the density you have calculated? Explain.

Metal	Density (g/cm^3)	Metal	Density (g/cm^3)
Zinc	7.13	Nickel	8.90
Iron	7.87	Copper	8.96
Cadmium	8.65	Silver	10.50
Cobalt	8.90		

58. ▲ There are five hydrocarbon compounds (compounds of C and H) that have the formula C_6H_{14}. (These are isomers; they differ in the way that C and H atoms are attached. Chapter 23.) All are liquids at room temperature but have slightly different densities.

Hydrocarbon	Density (g/mL)
Hexane	0.6600
2,3-Dimethylbutane	0.6616
1-Methylpentane	0.6532
2,2-Dimethylbutane	0.6485
2-Methylpentane	0.6645

(a) You have a pure sample of one of these hydrocarbons, and to identify it you decide to measure its density. You determine that a 5.0-mL sample (measured in a graduated cylinder) has a mass of 3.2745 g (measured on an analytical balance). Assume that the accuracy of the values for mass and volume is plus or minus one (± 1) in the last significant figure. What is the density of the liquid?

(b) Can you identify the unknown hydrocarbon based on your experiment?

(c) Can you eliminate any of the five possibilities based on the data? If so, which one(s)?

(d) You need a more accurate volume measurement to solve this problem, and you redetermine the volume to be 4.93 mL. Based on this new information, what is the unknown compound?

59. ▲ Suppose you have a cylindrical glass tube with a thin capillary opening, and you wish to determine the diameter of the opening. You can do this experimentally by weighing a piece of the tubing before and after filling a portion of the capillary with mercury. Using the following information, calculate the diameter of the opening.

Mass of tube before adding mercury = 3.263 g

Mass of tube after adding mercury = 3.416 g

Length of capillary filled with mercury = 16.75 mm

Density of mercury = 13.546 g/cm^3

Volume of cylindrical capillary filled with mercury = $(\pi)(\text{radius})^2(\text{length})$

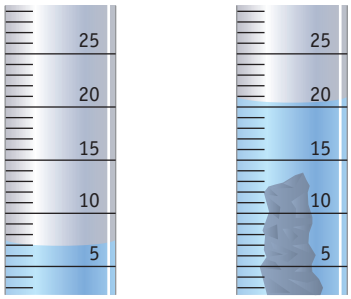
60. Copper: Copper has a density of 8.96 g/cm^3. An ingot of copper with a mass of 57 kg (126 lb) is drawn into wire with a diameter of 9.50 mm. What length of wire (in meters) can be produced? [Volume of wire = (π)(radius)^2(length)]

61. ▲ Copper:

(a) Suppose you have a cube of copper metal that is 0.236 cm on a side with a mass of 0.1206 g. If you know that each copper atom (radius = 128 pm) has a mass of 1.055×10^{-22} g (you will learn in Chapter 2 how to find the mass of one atom), how many atoms are there in this cube? What fraction of the cube is filled with atoms? (Or conversely, how much of the lattice is empty space?) Why is there "empty" space in the lattice?

(b) Now look at the smallest, repeating unit of the crystal lattice of copper.

Cube of copper atoms Smallest repeating unit



Knowing that an edge of this cube is 361.47 pm and the density of copper is 8.960 g/cm^3, calculate the number of copper atoms in this smallest, repeating unit.

62. You set out to determine the density of lead in the laboratory. Using a top loading balance to determine the mass and the water displacement method (Study Question 41) to determine the volume of a variety of pieces of lead, you calculate the following densities: 11.6 g/cm^3, 11.8 g/cm^3, 11.5 g/cm^3, and 12.0 g/cm^3. You consult a reference book and find that the accepted value for the density of lead is 11.3 g/cm^3. Calculate your average value, percent error, and standard deviation of your results.

In the Laboratory

63. A sample of unknown metal is placed in a graduated cylinder containing water. The mass of the sample is 37.5 g, and the water levels before and after adding the sample to the cylinder are as shown in the figure. Which metal in the following list is most likely the sample? (d is the density of the metal.)

(a) Mg, d = 1.74 g/cm^3
(b) Fe, d = 7.87 g/cm^3
(c) Ag, d = 10.5 g/cm^3
(d) Al, d = 2.70 g/cm^3
(e) Cu, d = 8.96 g/cm^3
(f) Pb, d = 11.3 g/cm^3

Graduated cylinders with unknown metal *(right)*

64. Iron pyrite is often called "fool's gold" because it looks like gold (see page 11). Suppose you have a solid that looks like gold, but you believe it to be fool's gold. The sample has a mass of 23.5 g. When the sample is lowered into the water in a graduated cylinder (Study Question 63), the water level rises from 47.5 mL to 52.2 mL. Is the sample fool's gold (d = 5.00 g/cm^3) or "real" gold (d = 19.3 g/cm^3)?

65. You can analyze for a copper compound in water using an instrument called a spectrophotometer. [A spectrophotometer is a scientific instrument that measures the amount of light (of a given wavelength) that is absorbed by the solution.] The amount of light absorbed at a given wavelength of light (A) depends directly on the mass of compound per liter of solution. To calibrate the spectrophotometer, you collect the following data:

Absorbance (A)	Mass per Liter of Copper Compound (g/L)
0.000	0.000
0.257	1.029×10^{-3}
0.518	2.058×10^{-3}
0.771	3.087×10^{-3}
1.021	4.116×10^{-3}

Plot the absorbance (A) against the mass of copper compound per liter (g/L), and find the slope (m) and intercept (b) (assuming that A is y and the amount in solution is x in the equation for a straight line, $y = mx + b$). What is the mass of copper compound in the solution in g/L and mg/mL when the absorbance is 0.635?

66. A gas chromatograph is calibrated for the analysis of isooctane (a major gasoline component) using the following data:

Percent Isooctane (*x*-data)	Instrument Response (*y*-data)
0.352	1.09
0.803	1.78
1.08	2.60
1.38	3.03
1.75	4.01

If the instrument response is 2.75, what percentage of isooctane is present? (Data are taken from *Analytical Chemistry, An Introduction*, by D.A. Skoog, D.M. West, F.J. Holler, and S.R. Crouch, Cengage Learning, Brooks/Cole, Belmont, CA, 7th Edition, 2000.)

67. A general chemistry class carried out an experiment to determine the percentage (by mass) of acetic acid in vinegar. Ten students reported the following values: 5.22%, 5.28%, 5.22%, 5.30%, 5.19%, 5.23%, 5.33%, 5.26%, 5.15%, 5.22%. Determine the average value and the standard deviation from these data. How many of these results fell within one standard deviation of this average value?

CHAPTER OUTLINE

2.1 Atomic Structure, Atomic Number, and Atomic Mass

2.2 Isotopes and Atomic Weight

2.3 The Periodic Table

2.4 Molecules, Compounds, and Formulas

2.5 Ionic Compounds: Formulas, Names, and Properties

2.6 Atoms, Molecules, and the Mole

2.7 Chemical Analysis: Determining Compound Formulas

2.8 Instrumental Analysis: Determining Compound Formulas

2.1 Atomic Structure, Atomic Number, and Atomic Mass

Goals for Section 2.1

- Describe electrons, protons, and neutrons, and the general structure of the atom.
- Define the terms atomic number and mass number.

Atomic Structure

This chapter begins our exploration of the chemistry of the elements, the building blocks of chemistry, and the compounds they form. Around 1900 a series of experiments done by scientists in England such as Sir Joseph John Thomson (1856–1940) and Ernest Rutherford (1871–1937) established a model of the atom that is still the basis of modern atomic theory.

Atoms are made of subatomic particles: electrically positive protons, electrically negative electrons, and, in all except one type of hydrogen atom, electrically neutral neutrons. The model places the more massive protons and neutrons in a very small nucleus (Figure 2.1), which contains all the positive charge and almost all the mass of an atom. Electrons, with a much smaller mass than protons or neutrons, surround the nucleus and occupy most of the volume. In an electrically neutral atom, the number of electrons equals the number of protons.

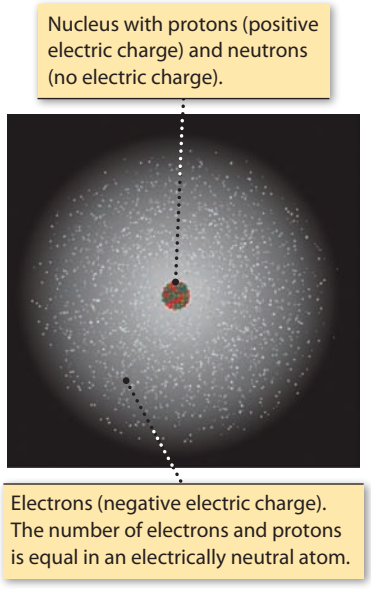

FIGURE 2.1 The structure of the atom. This figure is not drawn to scale. If the nucleus were really the size depicted here, the electron cloud would extend over 200 m. The atom is mostly empty space! In this illustration, the electrons are depicted as a "cloud" around the nucleus. The most accurate model of the atom represents electrons as waves, not particles. Chemists, reluctant to dismiss the idea of an electron as a particle, often use the cloud picture to represent electrons in atoms.

◀ **Some of the 118 known elements.**

The chemical properties of elements and molecules depend largely on the electrons in atoms. We shall look more carefully at their arrangement and how they influence atomic properties in Chapters 6 and 7. In this chapter, however, we first want to describe how the composition of the atom relates to its mass and then to the mass of compounds. This is crucial information when we consider the quantitative aspects of chemical reactions in later chapters.

Atomic Number

All atoms of a given element have the same number of protons in the nucleus. Hydrogen is the simplest element, with one nuclear proton. All helium atoms have two protons, all lithium atoms have three protons, and all beryllium atoms have four protons. The number of protons in the nucleus of an element is given by its **atomic number**, which is generally indicated by the symbol Z.

The 118 currently known elements are listed in the periodic table inside the front cover of this book and on the list inside the back cover. The integer number at the top of the box for each element in the periodic table is its atomic number. A copper atom (Cu), for example, has an atomic number of 29, so its nucleus contains 29 protons. A uranium atom (U) has 92 nuclear protons and $Z = 92$.

Relative Atomic Mass

Historical Perspective on the Development of Our Understanding of Atomic Structure A brief history of important experiments and the scientists involved in developing the modern view of the atom is given on pages 66–67.

With the quantitative work of the great French chemist Antoine Laurent Lavoisier (1743–1794), chemistry began to change from medieval alchemy to a modern field of study (Section 3.1). As 18th- and 19th-century chemists tried to understand how the elements combined, they carried out increasingly quantitative studies aimed at learning, for example, how much of one element would combine with another. Based on this work, they learned that the substances they produced had a constant composition, so they could define the relative masses of elements that would combine to produce a new substance. At the beginning of the 19th century, John Dalton (1766–1844) suggested that the combinations of elements involve atoms, and he proposed a relative scale of atom masses. Apparently for simplicity, Dalton chose a mass of 1 for hydrogen on which to base his scale.

The atomic mass scale has changed since 1800. Like the 19th-century chemists, we still use *relative* masses, but the standard today is carbon. A carbon atom having six protons and six neutrons in the nucleus is assigned a mass value of exactly 12. From chemical experiments and physical measurements, we know an oxygen atom having eight protons and eight neutrons has 1.33291 times the mass of carbon, so it has a relative mass of 15.9949. Masses of atoms of other elements are assigned in a similar manner.

Masses of fundamental atomic particles are often expressed in **unified atomic mass units (u)**. *One atomic mass unit, 1 u, is one-twelfth of the mass of an atom of carbon with six protons and six neutrons*. Thus, such a carbon atom has a mass of exactly 12 u. The unified atomic mass unit can be related to other units of mass using the conversion factor 1 atomic mass unit (u) $= 1.66054 \times 10^{-24}$ g.

Mass Number

How Small Is an Atom? The radius of the typical atom is between 30 and 300 pm (3×10^{-11} m to 3×10^{-10} m). To get a feeling for the incredible smallness of an atom, consider that 1 cm^3 of water contains about three times as many atoms as the Atlantic Ocean contains teaspoons of water.

Because proton and neutron masses are so close to 1 u, while the mass of an electron is only about 1/2000 of this value (Table 2.1), the approximate mass of an atom can be estimated if the number of neutrons and protons is known. The sum of the number of protons and neutrons for an atom is called its **mass number** and is given the symbol A.

$$A = \text{mass number} = \text{number of protons} + \text{number of neutrons}$$

For example, a sodium atom, which has 11 protons and 12 neutrons in its nucleus, has a mass number of 23 ($A = 11\text{ p} + 12\text{ n}$). The most common atom of uranium

TABLE 2.1 Properties of Subatomic Particles*

Particle	MASS		Charge	Symbol
	Grams	*Atomic Mass Units*		
Electron	9.109383×10^{-28}	0.0005485799	1−	$-{}^{0}_{1}e$ or e^-
Proton	1.672622×10^{-24}	1.007276	1+	${}^{1}_{1}p$ or p^+
Neutron	1.674927×10^{-24}	1.008665	0	${}^{1}_{0}n$ or n

*These values and others in the book are taken from the National Institute of Standards and Technology website at http://physics.nist.gov/cuu/Constants/index.html

has 92 protons and 146 neutrons, and a mass number of $A = 238$. We often symbolize atoms with the following notation:

Mass number → ${}^{A}_{Z}X$ ← Element symbol
Atomic number → ${}^{A}_{Z}X$

The subscript Z is optional because the element's symbol tells us what the atomic number must be. For example, the atoms described previously have the symbols ${}^{23}_{11}Na$ and ${}^{238}_{92}U$, or just ${}^{23}Na$ and ${}^{238}U$. In words, we say "sodium-23" or "uranium-238."

EXAMPLE 2.1

Atomic Composition

Problem What is the composition of an atom of phosphorus with 16 neutrons? What is its mass number? What is the symbol for such an atom? If the atom has an actual mass of 30.9738 u, what is its mass in grams? Finally, what is the mass of this phosphorus atom relative to the mass of a carbon atom with a mass number of 12?

What Do You Know? You know the name of the element and the number of neutrons. You also know the actual mass, so you can determine its mass relative to carbon-12.

Strategy The number of protons in an atom is given by the atomic number shown on the periodic table. The mass number is the sum of the number of protons and neutrons. The mass of the atom in grams can be obtained from the mass in unified atomic mass units using the conversion factor $1\ u = 1.66054 \times 10^{-24}$ g. The relative mass of an atom of P compared to ${}^{12}C$ can be determined by dividing the mass of the P atom in unified atomic mass units by the mass of a ${}^{12}C$ atom, 12.0000 u.

SOLUTION A phosphorus atom has 15 protons and 15 electrons. A phosphorus atom with 16 neutrons has a mass number of 31.

$$\text{Mass number} = \text{number of protons} + \text{number of neutrons} = 15 + 16 = 31$$

The atom's complete symbol is ${}^{31}_{15}P$.

$$\text{Mass of one } {}^{31}P \text{ atom} = (30.9738\ u) \times (1.66054 \times 10^{-24}\ g/u) = 5.14332 \times 10^{-23}\ g$$

Mass of ${}^{31}P$ relative to the mass of an atom of ${}^{12}C$: $30.9738/12.0000 = 2.58115$

Think about Your Answer Because phosphorus has an atomic number greater than carbon's, you expect its mass to be greater than 12.

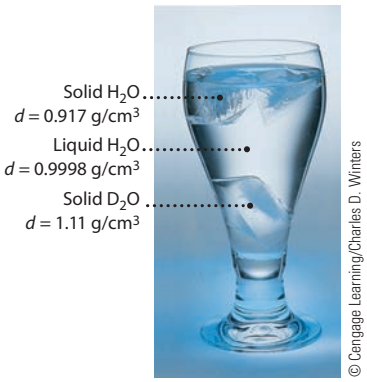
Check Your Understanding

1. What is the mass number of an iron atom with 30 neutrons?
2. A nickel atom with 32 neutrons has a mass of 59.930788 u. What is its mass in grams?
3. How many protons, neutrons, and electrons are in a ^{64}Zn atom?

2.2 Isotopes and Atomic Weight

Goals for Section 2.2



- Define isotopes and give the mass number and number of neutrons for a specific isotope.
- Perform calculations that relate the atomic weight (atomic mass) of an element and isotopic abundances and masses.

All the atoms in a naturally occurring sample of a given element have the same mass in only a few instances (for example, aluminum, fluorine, and phosphorus). Most elements consist of atoms having several different mass numbers. For example, there are two kinds of boron atoms, one with a mass of about 10 (^{10}B) and a second with a mass of about 11 (^{11}B). Atoms of tin can have any of 10 different masses ranging from 112 to 124. Atoms with the same atomic number but different mass numbers are called **isotopes**.

All atoms of an element have the same number of protons. To have different masses, isotopes must have different numbers of neutrons. The nucleus of a ^{10}B atom (Z = 5) contains five protons and five neutrons, whereas the nucleus of a ^{11}B atom contains five protons and six neutrons.

Scientists often refer to a particular isotope by giving its mass number (for example, uranium-238, ^{238}U), but the isotopes of hydrogen are so important that they have special names and symbols. All hydrogen atoms have one proton. When that is the only nuclear particle, the isotope is called *protium*, or just "hydrogen." The isotope of hydrogen with one neutron, $^{2}_{1}H$, is called *deuterium*, or "heavy hydrogen" (symbol = D). The nucleus of radioactive hydrogen-3, $^{3}_{1}H$, or *tritium* (symbol = T), contains one proton and two neutrons.

The substitution of one isotope of an element for another isotope of the same element in a compound sometimes can have an effect on chemical and physical properties (Figure 2.2). This is especially true when deuterium is substituted for hydrogen because the mass of deuterium is double that of hydrogen.

© Cengage Learning/Charles D. Winters

FIGURE 2.2 Ice made from "heavy water" sinks in "ordinary" water. Water containing ordinary hydrogen ($^{1}_{1}H$, protium) forms a solid that is less dense than liquid H_2O, so it floats in the liquid. D_2O-ice is denser than liquid H_2O, so solid D_2O sinks in liquid H_2O.

Determining Atomic Mass and Isotope Abundance

The masses of isotopes and their abundances are determined experimentally by mass spectrometry (Figure 2.3). Modern spectrometers can measure isotopic masses to as many as nine significant figures.

Except for carbon-12, whose mass is defined to be exactly 12 u, isotopic masses do not have integer values. Isotopic masses are, however, always close to the mass numbers for the isotope. For example, the mass of an atom of boron-11 (^{11}B, 5 protons and 6 neutrons) is 11.0093 u, and the mass of an atom of iron-58 (^{58}Fe, 26 protons and 32 neutrons) is 57.9333 u.

A sample of water from a lake will consist almost entirely of H_2O where the H atoms are the ^{1}H isotope. A few molecules, however, will have deuterium (^{2}H) substituted for ^{1}H. We can predict this outcome because we know that 99.985% of all hydrogen atoms on Earth are ^{1}H atoms. That is, the abundance of ^{1}H atoms is 99.985%.

$$\text{Percent abundance} = \frac{\text{number of atoms of a given isotope}}{\text{total number of atoms of all isotopes of that element}} \times 100\% \quad (2.1)$$

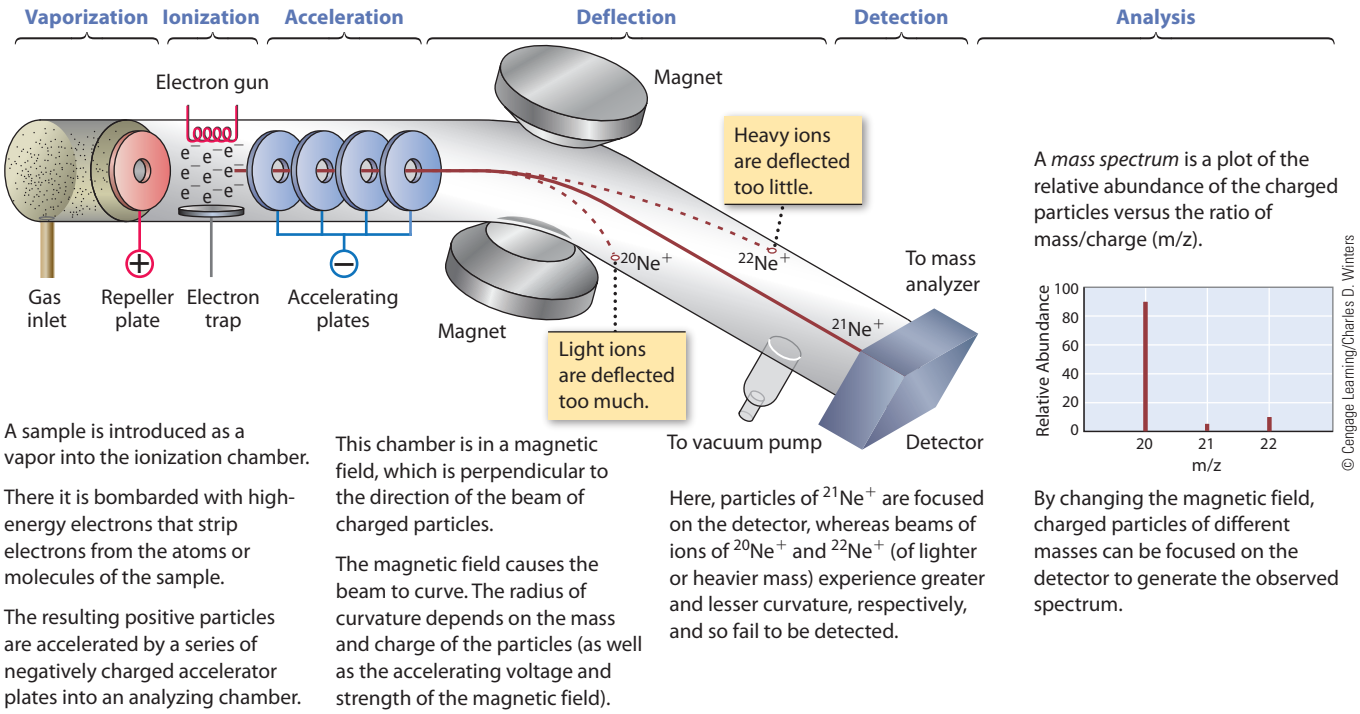

FIGURE 2.3 Mass spectrometer. A mass spectrometer will separate ions of different mass and charge in a gaseous sample of ions. The instrument allows the researcher to determine the accurate mass of each ion.

The remainder of naturally occurring hydrogen is deuterium, whose abundance is only 0.015%. Tritium, the radioactive ^3H isotope, occurs naturally in only trace amounts.

Consider the two isotopes of boron. The boron-10 isotope has an abundance of 19.91%; the abundance of boron-11 is 80.09%. Among 10,000 boron atoms from an "average" natural sample, 1991 would be boron-10 atoms and 8009 of them would be boron-11 atoms.

Isotopic Masses and the Mass Defect Actual masses of atoms are always less than the sum of the masses of the subatomic particles composing that atom. This is called the *mass defect,* and the reason for it is discussed in Chapter 25.

Atomic Weight

Every sample of boron has some atoms with a mass of 10.0129 u and others with a mass of 11.0093 u. The **atomic weight** of the element, the average mass of a representative sample of boron atoms, is somewhere between these values. For boron, for example, the atomic weight is 10.811. If isotope masses and abundances are known, the atomic weight of an element can be calculated using Equation 2.2.

$$\text{Atomic weight} = \left(\frac{\%\text{ abundance isotope 1}}{100}\right)(\text{mass of isotope 1}) + \left(\frac{\%\text{ abundance isotope 2}}{100}\right)(\text{mass of isotope 2}) + \ldots \quad (2.2)$$

For boron with two isotopes (^{10}B, abundance = 19.91%; ^{11}B, abundance = 80.09%), we find

$$\text{Atomic weight} = \left(\frac{19.91}{100}\right) \times 10.0129 + \left(\frac{80.09}{100}\right) \times 11.0093 = 10.811$$

Equation 2.2 gives an average mass, weighted in terms of the abundance of each isotope for the element. As illustrated by the data in Table 2.2, *the atomic weight of an element is typically close to the mass of the most abundant isotope or isotopes.*

TABLE 2.2 Isotope Abundance and Atomic Weight

Element	Symbol	Atomic Weight	Mass Number	Isotopic Mass	Natural Abundance (%)
Hydrogen	H	1.00794	1	1.0078	99.985
	D*		2	2.0141	0.015
	T†		3	3.0161	0
Boron	B	10.811	10	10.0129	19.91
			11	11.0093	80.09
Neon	Ne	20.1797	20	19.9924	90.48
			21	20.9938	0.27
			22	21.9914	9.25
Magnesium	Mg	24.3050	24	23.9850	78.99
			25	24.9858	10.00
			26	25.9826	11.01

*D = deuterium; †T = tritium, radioactive.

For each stable element the atomic weight is given in the periodic table. For unstable (radioactive) elements, the atomic weight or mass number of the most stable isotope is given in parentheses.

© Cengage Learning/Charles D. Winters

Elemental bromine. Bromine is a deep orange-red, volatile liquid at room temperature. It consists of Br_2 molecules in which two bromine atoms are chemically bonded together. There are two, stable, naturally occurring isotopes of bromine atoms: ^{79}Br (50.69% abundance) and ^{81}Br (49.31% abundance).

EXAMPLE 2.2

Calculating Atomic Weight from Isotope Abundance

Problem Bromine has two naturally occurring isotopes. One has a mass of 78.918338 u and an abundance of 50.69%. The other isotope has a mass of 80.916291 u and an abundance of 49.31%. Calculate the atomic weight of bromine.

What Do You Know? You know the mass and abundance of each of the two isotopes.

Strategy The atomic weight of any element is the weighted average of the masses of the isotopes in a representative sample. Use Equation 2.2 to calculate the atomic weight.

SOLUTION

$$\text{Atomic weight of bromine} = (50.69/100)(78.918338) + (49.31/100)(80.916291) = 79.90$$

Think about Your Answer You can also estimate the atomic weight from the data given. There are two isotopes, mass numbers of 79 and 81, in approximately equal abundance. From this, we would expect the average mass to be about 80, midway between the two mass numbers. The calculation bears this out.

Check Your Understanding

Verify that the atomic weight of chlorine is 35.45, given the following information:

^{35}Cl mass = 34.96885 u; percent abundance = 75.77%

^{37}Cl mass = 36.96590 u; percent abundance = 24.23%

EXAMPLE 2.3

Calculating Isotopic Abundances

Problem Antimony, Sb, has two stable isotopes: ^{121}Sb, 120.904 u, and ^{123}Sb, 122.904 u. What are the relative abundances of these isotopes?

What Do You Know? You know the masses of the two isotopes of the element and know that their weighted average, the atomic weight, is 121.760 (see the periodic table).

Strategy To calculate the abundances recognize there are two unknown but related quantities, and you can write the following expression (where the fractional abundance of an isotope is the percent abundance of the isotope divided by 100)

$$\text{Atomic weight} = 121.760 = (\text{fractional abundance of } ^{121}\text{Sb})(120.904) + (\text{fractional abundance of } ^{123}\text{Sb})(122.904)$$

or

$$121.760 = x(120.904) + y(122.904)$$

where x = fractional abundance of ^{121}Sb and y = fractional abundance of ^{123}Sb. Because you know that the sum of fractional abundances of the isotopes must equal 1 ($x + y = 1$), you can solve the two equations simultaneously for x and y.

SOLUTION Because y = fractional abundance of ^{123}Sb $= 1 - x$, you can make a substitution for y.

$$121.760 = x(120.904) + (1 - x)(122.904)$$

Expanding this equation, you have

$$121.760 = 120.904x + 122.904 - 122.904x$$

Finally, solving for x, you find

$$121.760 - 122.904 = (120.904 - 122.904)x$$

$$x = 0.5720$$

The fractional abundance of ^{121}Sb is 0.5720 and its percent abundance is 57.20%. This means that the percent abundance of ^{123}Sb must be 42.80%.

Think about Your Answer You might have predicted that the lighter isotope (^{121}Sb) must be the more abundant because the atomic weight is closer to 121 than to 123.

Check Your Understanding

Neon has three stable isotopes, one with a small abundance. What are the abundances of the other two isotopes?

^{20}Ne, mass = 19.992435 u; percent abundance = ?

^{21}Ne, mass = 20.993843 u; percent abundance = 0.27%

^{22}Ne, mass = 21.991383 u; percent abundance = ?

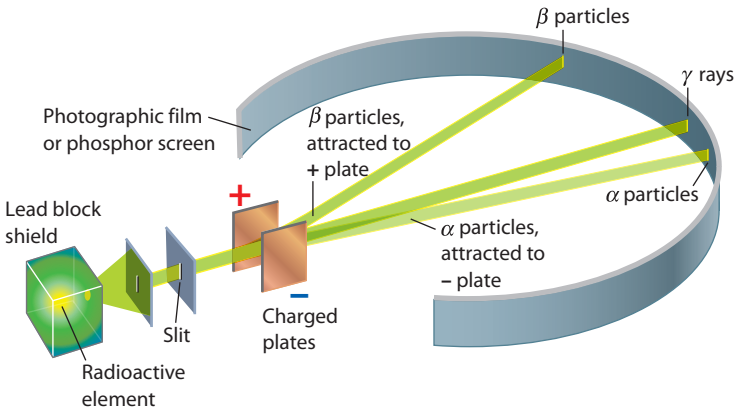
KEY EXPERIMENTS

How Do We Know the Nature of the Atom and Its Components?

The idea that atoms are the building blocks for matter was set on the right track by the English chemist John Dalton in the early 1800s, but little was known about atoms at that time and for a long time after. Dalton proposed that an atom was a "solid, massy, hard, impenetrable, moveable particle," far from the description we have today. To reach the current model involving a nuclear atom with protons, neutrons, and electrons required ingenious experiments, carried out in the late 1800s and early 1900s. This section describes the main ideas for a few of these experiments.

A beam of electrons (cathode rays) is accelerated through two focusing slits.



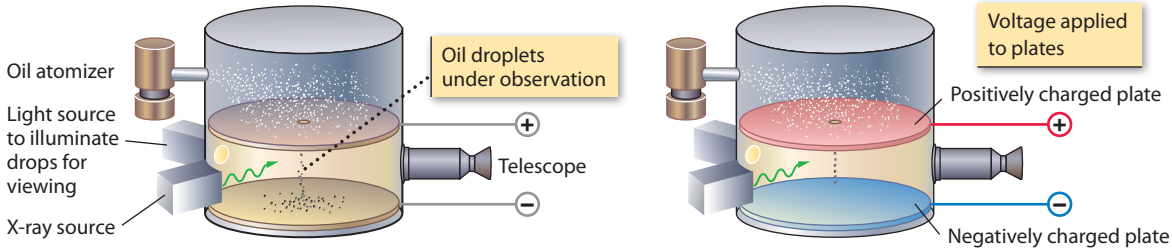
When passing through an electric field the beam of electrons is deflected.

The experiment is arranged so that the electric field causes the beam of electrons to be deflected in one direction. The magnetic field deflects the beam in the opposite direction.

By balancing the effects of the electrical and magnetic fields, the charge-to-mass ratio of the electron can be determined.

FIGURE 1 Cathode rays. Thomson's experiment to measure the electron's charge-to-mass ratio. The second half of the 19th century saw a series of experiments involving cathode ray tubes. First described in 1869 by William Crookes (1832–1919), a cathode ray tube is an evacuated container with two electrodes. When a high voltage is applied, particles (cathode rays) flow from the negative electrode (the cathode) to the anode. These particles were deflected by electric and magnetic fields, and by balancing these effects, it was possible to determine their charge-to-mass ratio (e/m). In 1897, J. J. Thomson (1856–1940) at the University of Cambridge in England estimated that these particles had about 3 orders of magnitude less mass than a hydrogen atom. They became known as electrons, a term already in use to describe the smallest particle of electricity. Thomson reasoned that electrons must originate from the atoms of the cathode, and he speculated that an atom was a uniform sphere of positively charged matter in which negative electrons were embedded, a model that we now know is incorrect.

FIGURE 2 Radioactivity. Evidence that atoms were made up from smaller particles was also inferred from the discovery of radioactivity. In 1896 Henri Becquerel (1852–1908) found that uranium emitted invisible rays that caused a covered photographic plate to darken. Further study showed that pitchblende (a common uranium ore) contained substances that gave off more of this invisible radiation than could be explained by the uranium it contained. This led Pierre Curie (1859–1906) and Marie Curie (1867–1934), working in an old shed in Paris, to extract and isolate the previously unknown elements polonium and radium from uranium ore. Radioactivity was the word the Curies invented to describe the new phenomenon of invisible rays, and they concluded the radiation was the result of the disintegration of atoms.



Identification of the radiation emanating from radioactive substances soon followed. Three types of radiation were observed and given the labels alpha, beta, and gamma. Charge-to-mass studies revealed that alpha rays are helium nuclei (He^{2+}) and beta rays are electrons. Gamma rays have neither mass nor charge; they are now known to be a highly energetic form of electromagnetic radiation.

Marie Curie is one of very few people and the only woman to have ever received two Nobel Prizes. She was born in Poland but studied and carried out her research in Paris. In 1903, she shared the Nobel Prize in Physics with H. Becquerel and her husband Pierre for their discovery of radioactivity. In 1911 she received the Nobel Prize in Chemistry for the discovery of two new chemical elements, radium and polonium (the latter named for her homeland, Poland). A unit of radioactivity (curie, Ci) and an element (curium, Cm) are named in her honor. Pierre, who died in an accident in 1906, was also well known for his research on magnetism. One of their daughters, Irène, married Frédèric Joliot, and they shared in the 1935 Nobel Prize in Chemistry for their discovery of artificial radioactivity.

A fine mist of oil drops is introduced into one chamber.

The droplets fall one by one into the lower chamber under the force of gravity.

Gas molecules in the bottom chamber are ionized (split into electrons and a positive fragment) by a beam of x-rays. The electrons adhere to the oil drops, some droplets having one electron, some two, and so on.

These negatively charged droplets continue to fall due to gravity.

By carefully adjusting the voltage on the plates, the force of gravity on the droplet is exactly counterbalanced by the attraction of the negative droplet to the upper, positively charged plate.

Analysis of these forces leads to a value for the charge on the electron.

FIGURE 3 Millikan's experiment to determine the electron charge. Cathode ray experiments allow measurement of the charge-to-mass ratio of a charged particle, but not the charge or mass individually. In 1908, the American physicist Robert Millikan (1868–1953), at California Institute of Technology, carried out an experiment to measure the charge on the electron. In his experiment, tiny oil droplets were sprayed into a chamber and then subjected to x-rays, causing them to take on a negative charge. The drops could be suspended in air if the force of gravity was balanced against an electric field, and from an analysis of these forces on the droplet the charge could be calculated. Millikan determined that the electronic charge was 1.592×10^{-19} coulombs (C), not far from today's accepted value of 1.602×10^{-19} C. Millikan correctly assumed this was the fundamental unit of charge. Knowing this value and the charge-to-mass ratio determined by Thomson, the mass of an electron could be calculated.

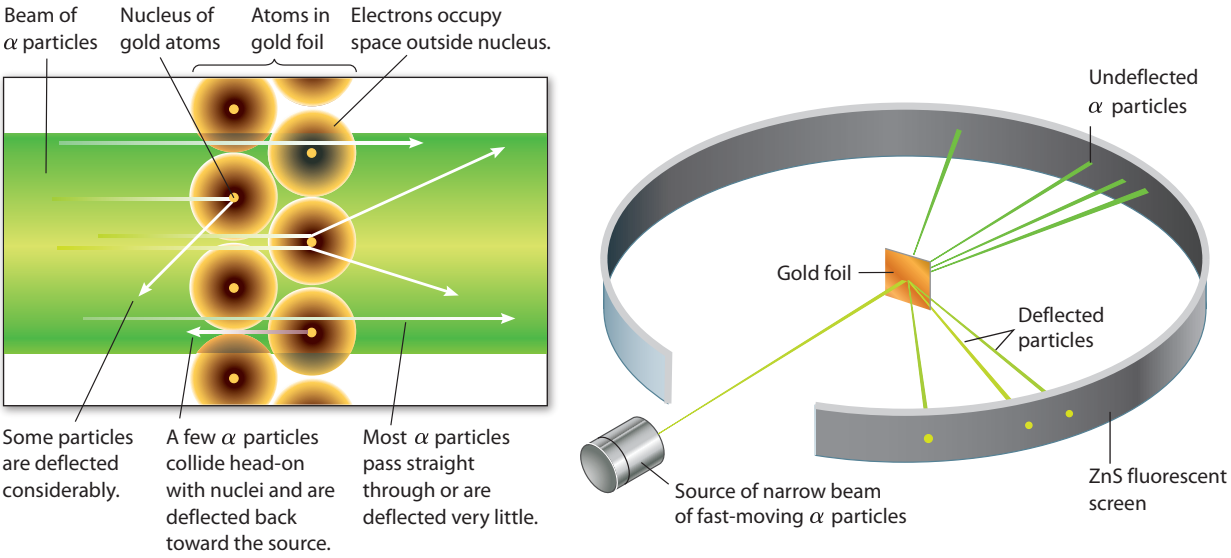

FIGURE 4 Rutherford's experiment to determine the structure of the atom. Although it was recognized that atoms were made up of smaller particles, it was not clear how these particles fit together. Around 1910, Ernest Rutherford (1871–1937) established the model that we now accept. Rutherford interpreted an experiment conducted by two colleagues, Hans Geiger (1882–1945) and Ernest Marsden (1889–1970), in which they bombarded thin gold foil with α particles. Almost all the particles passed straight through the gold foil as if there was nothing there. However, a few α particles were deflected sideways and some even bounced right back. This experiment proved that an atom of gold is mostly empty space with a tiny nucleus at its center. The electrons surround the nucleus and account for most of the volume of the atom. Rutherford calculated that the central nucleus of an atom occupied only 1/10,000th of its volume. He also estimated that a gold nucleus had a positive charge of around 100 units and a radius of about 10^{-12} cm. (The values are now known to be +79 for atomic charge and 10^{-13} cm for the radius.)

The final piece of the picture of atomic structure was not established for another decade. It had been known for some time that there had to be something else in the nucleus, and it had to be a heavy particle to account for the mass of the element. In 1932, the British physicist James Chadwick (1891–1974) found the missing particle. These particles, now known as neutrons, have no electric charge and a mass of 1.675×10^{-24} g, slightly greater than the mass of a proton.

2.3 The Periodic Table

Goals for Section 2.3

- Know the terminology of the periodic table (periods, groups) and know how to use the information given in the periodic table.
- Recognize similarities and differences in properties of some of the common elements of a group.

Features of the Periodic Table

The main organizational features of the periodic table are the following (Figure 2.4):

- Elements with similar chemical and physical properties lie in vertical columns called **groups** or **families**. The periodic table commonly used in the United States has groups numbered 1 through 8, with each number followed by the letter A or B. The A groups are often called the **main group elements** and the B groups are the **transition elements**. In other parts of the world, the groups are numbered 1–18.
- The horizontal rows of the table are called **periods**, and they are numbered beginning with 1 for the period containing only H and He. Currently, 118 elements are known filling periods 1 through 7.

Silicon—a metalloid. Only six elements are generally classified as metalloids or semimetals. This photograph shows solid silicon in various forms, including a wafer that holds printed electronic circuits.

The periodic table can be divided into several regions according to the properties of the elements. On the table inside the cover of this book (and in Figure 2.4), *metals* are indicated in shades of blue, *nonmetals* are indicated in orange, and elements called *metalloids* appear in green. Elements gradually become less metallic as one moves from left to right across a period, and the metalloids lie along the metal-nonmetal boundary.

You are probably familiar with many properties of **metals** from your own experience. At room temperature and normal atmospheric pressure metals are solids (except for mercury), can conduct electricity, are usually ductile (can be drawn into wires) and malleable (can be rolled into sheets), and can form alloys (mixtures of one or more metals with another metal). Iron (Fe) and aluminum (Al) are used in automobile parts because of their ductility, malleability, and low cost relative to other metals. Copper (Cu) is used in electric wiring because it conducts electricity better than most other metals.

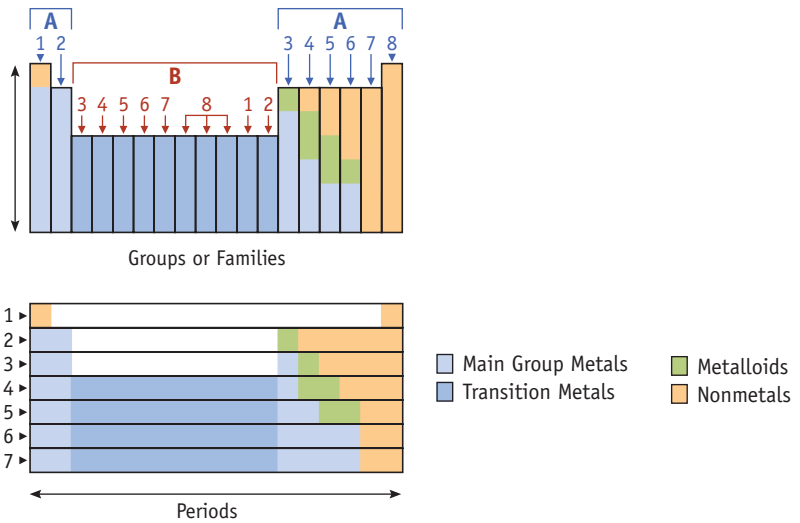

FIGURE 2.4 Periods and groups in the periodic table. An alternative to this labeling system numbers the groups from 1 to 18 going from left to right. This notation is generally used outside the United States.

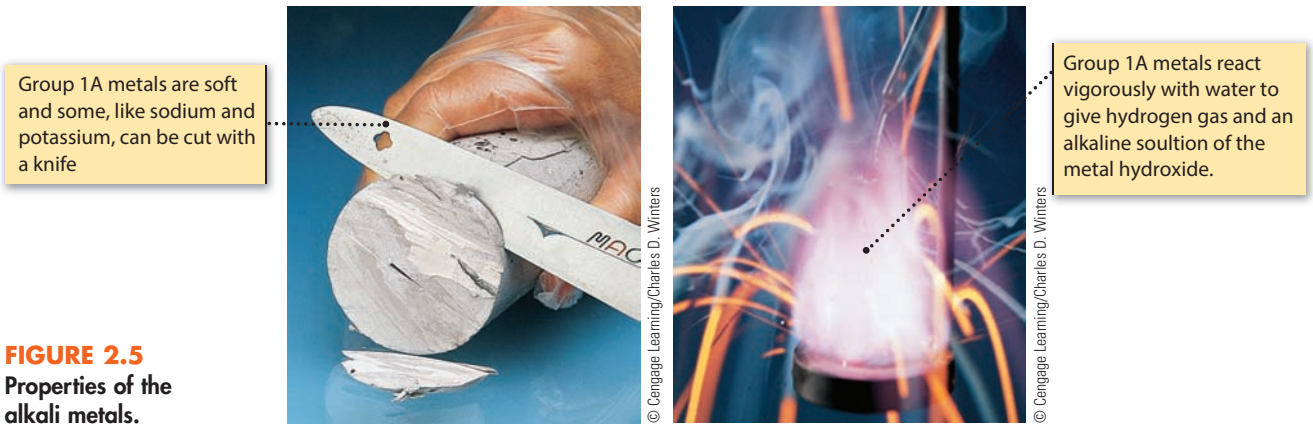

FIGURE 2.5
Properties of the alkali metals.

The **nonmetals**, which lie to the right of a diagonal line that stretches from B to Te in the periodic table, have a wide variety of properties. Some are solids (carbon, sulfur, phosphorus, and iodine). Ten elements are gases at room temperature (hydrogen, oxygen, nitrogen, fluorine, chlorine, helium, neon, argon, krypton, and xenon). One nonmetal, bromine, is a liquid at room temperature. With the exception of carbon in the form of graphite, nonmetals do not conduct electricity, which is one of the main features that distinguishes them from metals.

The elements along the diagonal line from boron (B) to tellurium (Te) have properties that make them difficult to classify as metals or nonmetals. Chemists call them **metalloids** or, sometimes, **semimetals**. You should know, however, that chemists disagree about which elements fit this category. We will define a metalloid as an element that has some of the physical characteristics of a metal but some of the chemical characteristics of a nonmetal; we include only B, Si, Ge, As, Sb, and Te in this category. This definition reflects the ambiguity in the behavior of these elements. Antimony (Sb), for example, conducts electricity as well as many metals. Its chemistry, however, resembles that of phosphorus, an element also in Group 5A.

Placing H in the Periodic Table
Where to place H? Tables often show it in Group 1A even though it is clearly not an alkali metal. However, in its reactions it forms a 1+ ion just like the alkali metals. For this reason, H is often placed in Group 1A.

A Brief Overview of the Periodic Table and the Chemical Elements

Elements in the leftmost column, **Group 1A**, are known as the **alkali metals** (except H). The word *alkali* comes from Arabic. Ancient Arabian chemists discovered that ashes of certain plants, which they called al-qali, gave water solutions that felt slippery and burned the skin. We now know these ashes contain compounds of Group 1A elements that produce alkaline (basic) solutions.

All the alkali metals are solids at room temperature and all are reactive. For example, they react with water to produce hydrogen and alkaline solutions (Figure 2.5). Because of their reactivity, these metals are only found in nature combined in compounds (such as NaCl), never as free elements.

The second group in the periodic table, **Group 2A**, is also composed entirely of metals that occur naturally only in compounds. Except for beryllium (Be), these elements react with water to produce alkaline solutions, and most of their oxides (such as lime, CaO) form alkaline solutions; hence, they are known as the **alkaline earth metals**. Magnesium (Mg) and calcium (Ca) are the seventh and fifth most abundant elements in the Earth's crust, respectively (Table 2.3). Calcium, one of the important elements in teeth and bones, occurs naturally in vast limestone deposits. Calcium carbonate ($CaCO_3$) is the chief constituent of limestone and of corals, sea shells, marble, and chalk. Radium (Ra), the heaviest alkaline earth element, is radioactive.

TABLE 2.3
The 10 Most Abundant Elements in the Earth's Crust

Rank	Element	Abundance (ppm)*
1	Oxygen	474,000
2	Silicon	277,000
3	Aluminum	82,000
4	Iron	41,000
5	Calcium	41,000
6	Sodium	23,000
7	Magnesium	23,000
8	Potassium	21,000
9	Titanium	5,600
10	Hydrogen	1,520

*ppm = parts per million = g per 1000 kg.

A CLOSER LOOK

Mendeleev and the Periodic Table

Although the arrangement of elements in the periodic table is now understood on the basis of atomic structure, the table was originally developed from many experimental observations of the chemical and physical properties of elements and is the result of the ideas of a number of chemists in the 18th and 19th centuries.

In 1869, at the University of St. Petersburg in Russia, Dmitri Ivanovitch Mendeleev (1834–1907) wrote a textbook on chemistry. As he pondered the chemical and physical properties of the elements, he realized that, if the elements were arranged in order of increasing atomic mass, elements with similar properties appeared in a regular pattern. That is, he saw a **periodicity** or periodic repetition of the properties of elements. Mendeleev organized the known elements into a table by lining them up in horizontal rows in order of increasing atomic mass. When he came to an element with properties similar to one already in the row, he started a new row. For example, the elements Li, Be, B, C, N, O, and F were in a row. Sodium was the next element then known; because its properties closely resembled those of Li, Mendeleev started a new row. As more and more elements were added to the table, new rows were begun, and elements with similar properties (such as Li, Na, and K) were placed in the same vertical column.

The original Mendeleev table showing the places he left for as yet-undiscovered elements.

An important feature of Mendeleev's table—and a mark of his genius—was that he left an empty space in a column when he believed an unknown element should exist. He deduced that these spaces would be filled by undiscovered elements. For example, he left a space between Si (silicon) and Sn (tin) in Group 4A for an element he called *eka-silicon*. Based on the progression of properties in this group, Mendeleev was able to predict the properties of the missing element. With the discovery of germanium (Ge) in 1886, Mendeleev's prediction was confirmed.

In Mendeleev's table the elements were ordered by increasing mass. A glance at a modern table, however, shows that, if listed in order of increasing mass, three pairs of elements (Ni and Co, Ar and K, and Te and I) would be out of order. Mendeleev assumed the atomic masses known at that time were inaccurate—not a bad assumption based on the analytical methods then in use. In fact, his order is correct and his assumption that element properties were a function of their mass was wrong.

In 1913 H. G. J. Moseley (1887–1915), a young English scientist working with Ernest Rutherford (1871–1937), bombarded many different metals with electrons in a cathode-ray tube (see "Key Experiments") and examined the x-rays emitted in the process. Moseley realized the wavelength of the x-rays emitted by a given element was related in a precise manner to the positive charge in the nucleus of the element and that this provided a way to experimentally determine the atomic number of a given element. Indeed, once atomic numbers could be determined, chemists recognized that organizing the elements in a table by increasing atomic number corrected the inconsistencies in Mendeleev's table. The **law of chemical periodicity** is now stated as *the properties of the elements are periodic functions of atomic number.*

John C. Kotz

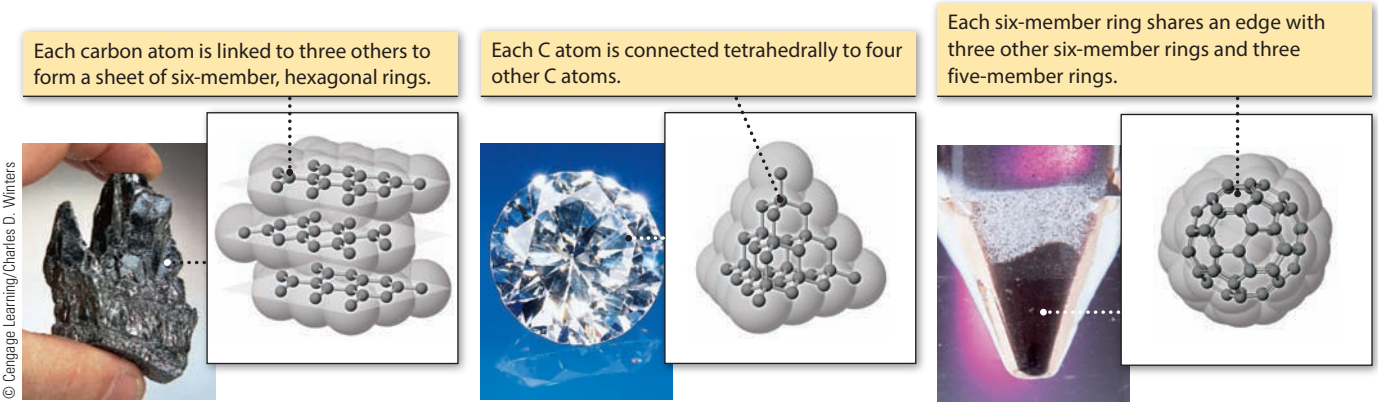
Aluminum is in **Group 3A**. This element along with gallium (Figure 2.6), indium, and thallium are metals, whereas boron is a metalloid. Aluminum (Al) is the most abundant metal in the Earth's crust at 8.2% by mass. It is exceeded in abundance only by the nonmetal oxygen and metalloid silicon and is usually found in minerals and clays. Boron (B) occurs in the mineral borax, a compound used as a cleaning agent, antiseptic, and flux for metal work.

As a metalloid, boron has a different chemistry than the other elements of Group 3A, all of which are metals. Nonetheless, all form compounds with analogous formulas such as BCl_3 and $AlCl_3$, and this similarity marks them as members of the same periodic group.



© Cengage Learning/Charles D. Winters

Figure 2.6 Liquid gallium. Bromine and mercury are the only elements that are liquids under ambient conditions. Gallium and cesium melt slightly above room temperature.

In Group 4A there is a nonmetal, carbon (C), two metalloids, silicon (Si) and germanium (Ge), and two metals, tin (Sn) and lead (Pb). Because of the change from nonmetallic to metallic behavior, more variation occurs in the properties of the elements of this group than in most others. Nonetheless, there are similarities. For example, these elements form compounds with analogous formulas such as CO_2, SiO_2, GeO_2, and PbO_2.

One interesting aspect of the chemistry of the nonmetals is that a particular element can often exist in several different and distinct forms, called **allotropes**, each having its own properties. Carbon has many allotropes, the best known of which are graphite and diamond. Graphite consists of flat sheets in which each carbon atom is connected to three others (Figure 2.7a). Because the sheets of carbon atoms cling only weakly to one another, one layer can slip easily over another. This explains why graphite is soft, is a good lubricant, and is used in pencil lead. [Pencil "lead" is not the element lead (Pb) but a composite of clay and graphite that leaves a trail of graphite on the page as you write.]

In diamond each carbon atom is connected to four others at the corners of a tetrahedron, and this extends throughout the solid (Figure 2.7b). This structure causes diamonds to be extremely hard, denser than graphite ($d = 3.51$ g/cm^3 for diamond versus $d = 2.22$ g/cm^3 for graphite), and chemically less reactive. Because diamonds are not only hard but are excellent conductors of heat, they are used on the tips of metal- and rock-cutting tools.

© Cengage Learning/Charles D. Winters

(a) Graphite. Graphite consists of layers of carbon atoms.

(b) Diamond. In diamond the carbon atoms are also arranged in six-member rings, but the rings are not planar.

(c) Buckyballs. A member of the family called buckminsterfullerenes, C_{60} is an allotrope of carbon. Sixty carbon atoms are arranged in a spherical cage that resembles a hollow soccer ball. Chemists call this molecule a "buckyball." C_{60} is a black powder; it is shown here in the tip of a pointed glass tube.

FIGURE 2.9 Sulfur. The most common allotrope of sulfur consists of S atoms arranged in eight-member, crown-shaped rings.

In the late 1980s another form of carbon was identified as a component of black soot, the stuff that collects when carbon-containing materials are burned in a deficiency of oxygen. This substance is made up of molecules with 60 carbon atoms arranged as a spherical "cage" (Figure 2.7c). The surface is made up of five- and six-member rings and resembles a hollow soccer ball. The shape also reminded its discoverers of an architectural dome conceived over 50 years ago by the American philosopher and engineer, R. Buckminster Fuller. This led to the official name of the allotrope, buckminsterfullerene, although chemists often just call these molecules "buckyballs."

Oxides of silicon are the basis of many minerals such as clay, quartz, and beautiful gemstones like amethyst. Tin and lead have been known for centuries because they are easily smelted from their ores. Tin alloyed with copper makes bronze, which was used in ancient times in utensils and weapons. Lead has been used in water pipes and paint, even though the element is toxic to humans.

Nitrogen in **Group 5A** occurs naturally in the form of the diatomic molecule N_2 (Figures 2.8) and makes up about three-fourths of Earth's atmosphere. It is also found in biochemically important substances such as chlorophyll, proteins, and DNA. Scientists have long studied ways to make compounds from atmospheric nitrogen, a process referred to as "nitrogen fixation." Nature accomplishes this easily in some prokaryotic organisms, but severe conditions (high temperatures, for example) must be used in the laboratory and in industry to cause N_2 to react with other elements (such as H_2 to make ammonia, NH_3, which is widely used as a fertilizer).

Phosphorus is also essential to life. It is an important constituent in bones, teeth, and DNA. The element glows in the dark if it is in the air (owing to its reaction with O_2), and its name is based on Greek words meaning "light-bearing." This element has several allotropes, the most important being white and red phosphorus. White phosphorus (composed of P_4 molecules) ignites spontaneously in air, so it is normally stored under water. When it reacts with air, it forms P_4O_{10}, which can react with water to form phosphoric acid (H_3PO_4), a compound used in food products such as soft drinks. Red phosphorus is used in the striking strips on match books. When a match is struck, potassium chlorate in the match head mixes with some red phosphorus on the striking strip, and the friction is enough to ignite the mixture.

As with Group 4A, we again see nonmetals (N and P), metalloids (As and Sb), and a metal (Bi) in Group 5A. In spite of these variations, they also form analogous compounds such as the oxides N_2O_5, P_4O_{10}, and As_2O_5.

Oxygen, which constitutes about 20% of Earth's atmosphere and which combines readily with most other elements, is at the top of **Group 6A**. Most of the energy that powers life on Earth is derived from reactions in which oxygen combines with other substances.

Sulfur has been known in elemental form since ancient times as brimstone or "burning stone" (Figure 2.9). Sulfur, selenium, and tellurium are often referred to collectively as *chalcogens* (from the Greek word, *khalkos*, for copper) because most copper ores contain these elements. Their compounds can be foul-smelling and poisonous; nevertheless, sulfur and selenium are essential components of the human diet. By far the most important compound of sulfur is sulfuric acid (H_2SO_4), which is manufactured in larger amounts than any other compound.

As in Group 5A, the second- and third-period elements of Group 6A have different structures. Like nitrogen, oxygen is also a diatomic molecule (see Figure 2.8). Unlike nitrogen, however, oxygen has an allotrope, the triatomic molecule ozone, O_3. Sulfur, which can be found in nature as a yellow solid, has many allotropes, the most common of which consists of eight-member, crown-shaped rings of sulfur atoms (see Figure 2.9).

Polonium, the radioactive element in Group 6A, was isolated in 1898 by Marie and Pierre Curie, who separated a small amount from tons of a uranium-containing ore and named it for Madame Curie's native country, Poland.

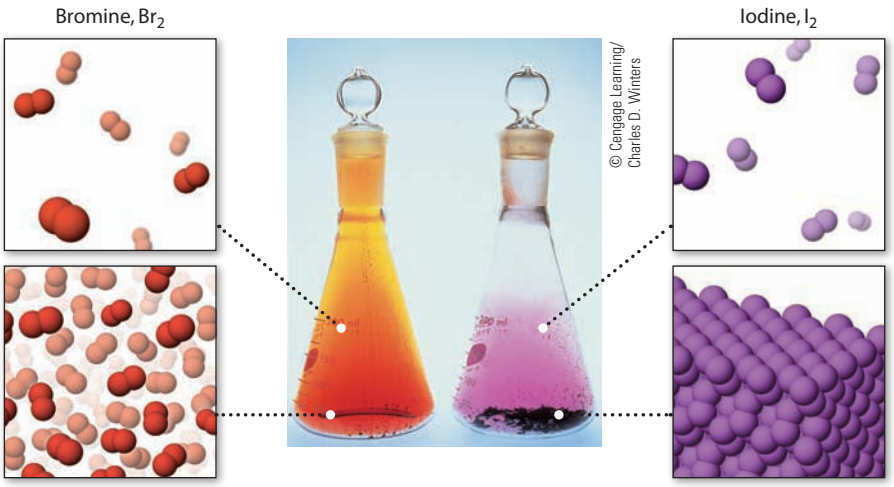

FIGURE 2.10 Bromine and iodine. These and other Group 7A elements are commonly called halogens.

In Group 6A we once again observe a variation of properties. Oxygen, sulfur, and selenium are nonmetals, tellurium is a metalloid, and polonium is a metal. Nonetheless, there is a family resemblance in their chemistries. All of oxygen's fellow group members form oxygen-containing compounds (SO_2, SeO_2, and TeO_2), and all form sodium-containing compounds (Na_2O, Na_2S, Na_2Se, and Na_2Te).

At the far right of the periodic table are two groups composed entirely of nonmetals. The **Group 7A** elements—fluorine, chlorine, bromine, iodine, and radioactive astatine—are nonmetals and all exist as diatomic molecules. At room temperature fluorine (F_2) and chlorine (Cl_2) are gases. Bromine (Br_2) is a liquid and iodine (I_2) is a solid, but bromine and iodine vapor are clearly visible over the liquid or solid (Figure 2.10).

Special Group Names Some groups have widely used common names.

Group 1A: Alkali metals
Group 2A: Alkaline earth metals
Group 7A: Halogens
Group 8A: Noble gases

The Group 7A elements are among the most reactive of all elements, and all combine violently with alkali metals to form salts such as table salt, NaCl. The name for this group, the **halogens**, comes from the Greek words *hals*, meaning "salt," and *genes*, for "forming."

The **Group 8A** elements—helium, neon, argon, krypton, xenon, and radioactive radon—are the least reactive elements. All are gases, and none is abundant on Earth or in the Earth's atmosphere (although argon is the third most abundant gas in dry air at 0.9%). Because of this, they were not discovered until the end of the 19th century (see page 103). A common name for this group, the **noble gases**, denotes their general lack of reactivity.

Helium, the second most abundant element in the universe after hydrogen, was detected in the Sun in 1868 by analysis of the solar spectrum but was not found on Earth until 1895. It is now widely used, with worldwide production in 2015 of about 175 billion liters of the gas. The biggest single use of helium is to cool the magnets found in MRI units in hospitals, and nuclear magnetic resonance spectrometers in research laboratories (Figure 2.11). These magnets need to be cooled with liquid helium to 4 K because, at this extremely low temperature, the magnets are superconductors of electricity. They can then generate the high magnetic fields needed to produce an image of your body. In addition, helium gas is used to fill weather balloons (and party balloons) and in the semiconductor industry. The United States supplies most of the helium, but there are periodic shortages that seriously disrupt commerce and research.

FIGURE 2.11 Helium, a noble gas, and MRI units. The magnets of MRI units need to be cooled to 4 K with liquid helium in order to be able to generate the high magnetic field required. This is the largest use of this noble gas.

Stretching between Groups 2A and 3A in the periodic table is a series of elements called the **transition elements**. These fill the B-groups (1B through 8B) in the fourth through the seventh periods in the center of the periodic table. All are metals, and 13 of them are in the top 30 elements in terms of abundance in the Earth's crust. Most occur naturally in combination with other elements, but a few—copper (Cu), silver (Ag), gold (Au), and platinum (Pt)—can be found in nature as pure elements.

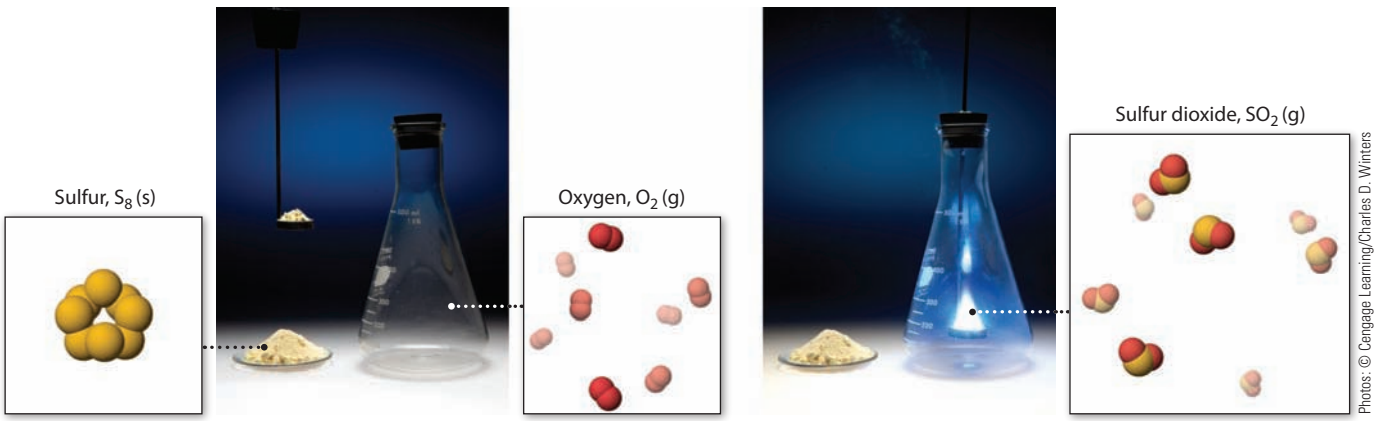
© Heinrich Pniok (www.pse-mendelejew.de)

FIGURE 2.12 The rare earth element europium. Among the rarest of the lanthanides, its abundance on Earth is about the same as tin and uranium.

Virtually all of the transition elements have commercial uses. They are used as structural materials (iron, titanium, chromium, copper); in paints (titanium, chromium); in the catalytic converters in automobile exhaust systems (platinum and rhodium); in coins (copper, nickel, zinc); and in batteries (manganese, nickel, zinc, cadmium, mercury).

Two rows at the bottom of the table accommodate the **lanthanides** [the series of elements between the elements lanthanum ($Z = 57$) and hafnium ($Z = 72$)] and the **actinides** [the series of elements between actinium ($Z = 89$) and rutherfordium ($Z = 104$)]. The lanthanides are often referred to as **rare earth elements** (Figure 2.12). In fact, they are not that rare but are geologically widely dispersed. In spite of the difficulty in mining rare earth–containing minerals, they have become very important commercially. They are used in magnets (neodymium), in LCD screens, in hybrid car batteries, and in polishing glass. Minerals containing rare earth elements are presently mined largely in China, and there is concern that a worldwide shortage looms.

2.4 Molecules, Compounds, and Formulas



Goals for Section 2.4

- Recognize and interpret molecular formulas, condensed formulas, and structural formulas.
- Remember formulas and names of common molecular compounds.
- Name and write formulas for binary molecular compounds.

A molecule is the smallest identifiable unit into which some pure substances like sugar and water can be divided and still retain the composition and chemical properties of the substance. Such substances are composed of identical molecules consisting of two or more atoms bound firmly together. In the reaction below and in Figure 2.13, molecules of sulfur, S_8, combine with molecules of oxygen, O_2, to produce molecules of the compound sulfur dioxide, SO_2.

$$S_8(s) + 8\ O_2(g) \rightarrow 8\ SO_2(g)$$
$$\text{sulfur} + \text{oxygen} \rightarrow \text{sulfur dioxide}$$

To describe this chemical change (or chemical reaction), the composition of each element and compound is represented by a symbol or formula. Here one molecule of SO_2 is composed of one S atom and two O atoms.

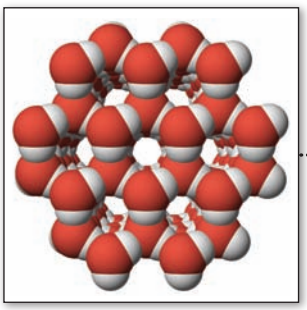
NAME	MOLECULAR FORMULA	CONDENSED FORMULA	STRUCTURAL FORMULA	MOLECULAR MODEL
Ethanol	C_2H_6O	CH_3CH_2OH		
Dimethyl ether	C_2H_6O	CH_3OCH_3		

FIGURE 2.14 Four approaches to showing molecular formulas. Here the two molecules have the same molecular formula. Condensed or structural formulas, or a molecular model, clearly show these molecules are different.

Formulas

There is often more than one way to write the formula of a compound, depending on the information we want to convey. For example, the formula of ethanol (also called ethyl alcohol) can be represented as C_2H_6O (Figure 2.14). This **molecular formula** describes the composition of ethanol molecules—two carbon atoms, six hydrogen atoms, and one atom of oxygen per molecule—but it gives us no structural information. Structural information—how the atoms are connected and how the molecule fills space—is important because it helps us understand how a molecule can interact with other molecules.

To provide some structural information, it is useful to write a **condensed formula**, which indicates how certain atoms are grouped together. For example, the condensed formula of ethanol, CH_3CH_2OH (Figure 2.14), tells us that the molecule consists of three "groups": a CH_3 group, a CH_2 group, and an OH group. Writing the formula as CH_3CH_2OH also shows that the compound is not dimethyl ether, CH_3OCH_3, a compound with the same molecular formula but with a different structure and distinctly different properties.



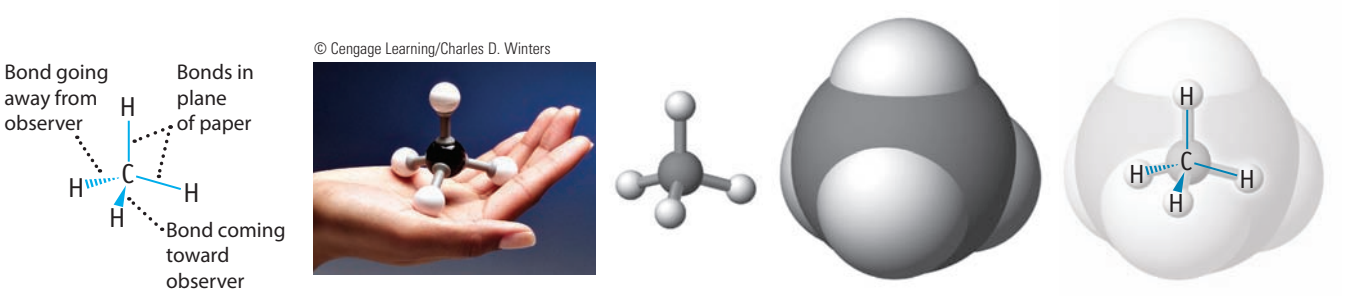
That ethanol and dimethyl ether are different molecules is also clear from their **structural formulas** (Figure 2.14). This type of formula gives us an even higher level of structural detail, showing how all of the atoms are attached within a molecule. The lines between atoms represent the chemical bonds that hold atoms together in this molecule.

Writing Formulas When writing molecular formulas of organic compounds (compounds with C, H, and other elements) the convention is to write C first, then H, and finally other elements in alphabetical order. For example, acrylonitrile, a compound used to make consumer plastics, has the condensed formula CH_2CHCN. Its molecular formula would be C_3H_3N.

Molecular Models

The physical and chemical properties of compounds are often closely related to their structures (which is why you will see so many molecular models in this book). For example, two well-known features of ice are related to its underlying molecular structure (Figure 2.15). The first is the shape of ice crystals: The sixfold symmetry of

Ice consists of six-sided rings formed by water molecules, in which each side of a ring consists of two O atoms and an H atom.



The six-sided structure of a snowflake is a reflection of the underlying molecular structure of ice.

- carbon atoms
- hydrogen atoms
- oxygen atoms
- nitrogen atoms
- chlorine atoms

macroscopic ice crystals also appears at the particulate level in the form of six-sided rings of hydrogen and oxygen atoms. The second is water's unusual property of being less dense when it is solid than when it is liquid. The lower density of ice, which has enormous consequences for Earth's climate, results from the fact that molecules of water are not packed together tightly in ice.

Because molecules are three dimensional, it is often difficult to represent their structures on paper. Certain conventions have been developed, however, that help represent three-dimensional structures on two-dimensional surfaces. Simple perspective drawings are often used (Figure 2.16).

Molecular models are very useful for visualizing structures. These models make it easy to see how atoms are attached to one another and show the molecule's overall three-dimensional structure. In the **ball-and-stick model**, spheres of different colors represent the atoms, and sticks represent the bonds holding them together. Molecules can also be represented using **space-filling models**. These models are a better representation of relative sizes of atoms and their proximity to each other. A disadvantage of pictures of space-filling models is that atoms can often be hidden from view.

Naming Molecular Compounds

There are many simple compounds you will encounter often, and you should understand how to name them and, in many cases, know their formulas. Let us look first at molecules formed from combinations of two nonmetals. These "two-element" or **binary compounds** of nonmetals can be named in a systematic way.

Hydrogen forms binary compounds with all of the nonmetals except the noble gases. For compounds of oxygen, sulfur, and the halogens, the H atom is generally written first in the formula and is named first. The other nonmetal is named by adding *-ide* to the stem of the name.

Compound	Name
HF	Hydrogen fluoride
HCl	Hydrogen chloride
H_2S	Hydrogen sulfide

Although there are exceptions, *most binary molecular compounds are a combination of nonmetallic elements from Groups 4A–7A with one another or with hydrogen.* The formula is generally written by putting the elements in order of increasing group number. When naming the compound, the number of atoms of a given

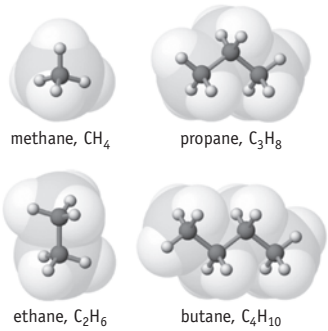
type in the compound is designated with a prefix, such as "di-," "tri-," "tetra-," "penta-," and so on.



Compound	Systematic Name
NF_3	Nitrogen trifluoride
NO	Nitrogen monoxide
NO_2	Nitrogen dioxide
N_2O	Dinitrogen monoxide
N_2O_4	Dinitrogen tetraoxide
PCl_5	Phosphorus pentachloride
SF_6	Sulfur hexafluoride
S_2F_{10}	Disulfur decafluoride

Formulas of Binary Nonmetal Compounds Containing Hydrogen Simple hydrocarbons (compounds of C and H) such as methane (CH_4) and ethane (C_2H_6) have formulas written with H following C, and the formulas of ammonia and hydrazine have H following N. Water and the hydrogen halides, however, have the H atom preceding O or the halogen atom. Tradition is the only explanation for such irregularities in writing formulas.

Finally, many of the binary compounds of nonmetals were discovered years ago and have common names.

Compound	Common Name	Compound	Common Name
CH_4	Methane	N_2H_4	Hydrazine
C_2H_6	Ethane	PH_3	Phosphine
C_3H_8	Propane	NO	Nitric oxide
C_4H_{10}	Butane	N_2O	Nitrous oxide ("laughing gas")
NH_3	Ammonia	H_2O	Water

Hydrocarbons Compounds such as methane, ethane, propane, and butane belong to a class of hydrocarbons called *alkanes*.

2.5 Ionic Compounds: Formulas, Names, and Properties

Goals for Section 2.5

- Recognize that metal atoms commonly lose one or more electrons to form positive ions, called cations, and nonmetal atoms often gain electrons to form negative ions, called anions.
- Predict the charge on monatomic cations and anions based on Group number.
- Write formulas for ionic compounds by combining ions in the proper ratio to give no overall charge.
- Give the names of formulas of ions and ionic compounds.
- Understand the importance of Coulomb's law in chemistry, which describes the electrostatic forces of attraction and repulsion of ions.

The compounds you have encountered so far in this chapter are **molecular compounds**, that is, compounds that consist of discrete molecules at the particulate level. **Ionic compounds** make up another major class of compounds, and many are probably familiar to you (Figure 2.17). Table salt, or sodium chloride (NaCl), and lime (CaO) are just two. It is important for you to be able to recognize ionic compounds, to name them, and to write their formulas.

FIGURE 2.17 **Some common ionic compounds.**

© Cengage Learning/Charles D. Winters

Common Name	Name	Formula	Ions Involved
Calcite	Calcium carbonate	$CaCO_3$	Ca^{2+}, CO_3^{2-}
Fluorite	Calcium fluoride	CaF_2	Ca^{2+}, F^-
Gypsum	Calcium sulfate dihydrate	$CaSO_4 \cdot 2\ H_2O$	Ca^{2+}, SO_4^{2-}
Hematite	Iron(III) oxide	Fe_2O_3	Fe^{3+}, O^{2-}
Orpiment	Arsenic(III) sulfide	As_2S_3	As^{3+}, S^{2-}

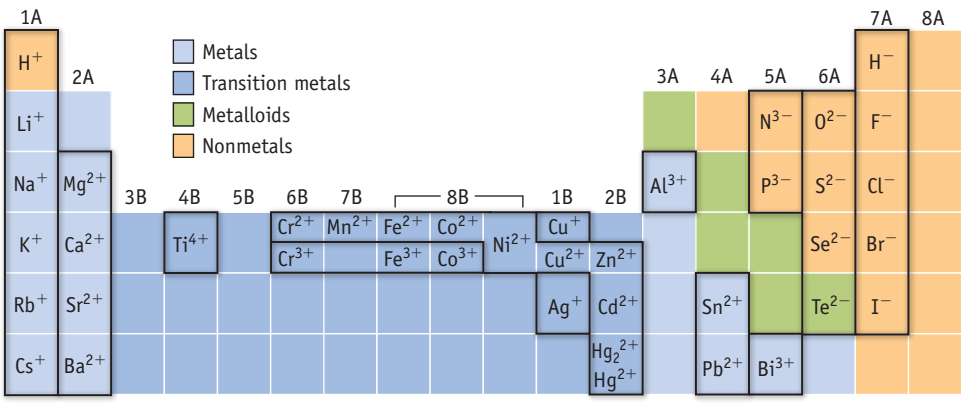
Ions

Ionic compounds consist of **ions**, that is, atoms or groups of atoms that bear a positive or negative electric charge. Atoms of many elements can lose or gain electrons to form monatomic ions, and commonly encountered ions are listed in Figure 2.18. How do you know if an atom is likely to gain or lose electrons? It depends on whether the element is a metal or nonmetal. In reactions,

- Metals generally lose one or more electrons.
- Nonmetals frequently gain one or more electrons.

Monatomic Cations

If an atom loses an electron (which is transferred to an atom of another element in the course of a reaction), the atom now has one less negative electron than it has positive protons in the nucleus. The result is a positively charged ion called a **cation** (Figure 2.19). (The name is pronounced "cat'-i-on.") For example, the loss of an electron from the Group 1A element lithium results in the formation of the Li^+ ion.



$$\underset{\text{(3 protons and 3 electrons)}}{\text{Li atom}} \rightarrow \text{e}^- + \underset{\text{(3 protons and 2 electrons)}}{\text{Li}^+ \text{ cation}}$$

Writing Ion Formulas When writing the formula of an ion, the charge on the ion **must** be included.

Elements of Group 2A will lose two electrons in reactions,

$$\underset{\text{(20 protons and 20 electrons)}}{\text{Ca atom}} \rightarrow 2\ \text{e}^- + \underset{\text{(20 protons and 18 electrons)}}{\text{Ca}^{2+} \text{ cation}}$$

FIGURE 2.18 **Charges on some common monatomic cations and anions.** Metals usually form cations and nonmetals usually form anions. (The boxed areas show ions of identical charge.) **NOTE:** It is important to recognize that transition metals (and a few main group metals) form cations of several charges. Examples include Cr^{2+} and Cr^{3+}, Fe^{2+} and Fe^{3+}, and Cu^+ and Cu^{2+}. As explained in the text, their names must reflect this.

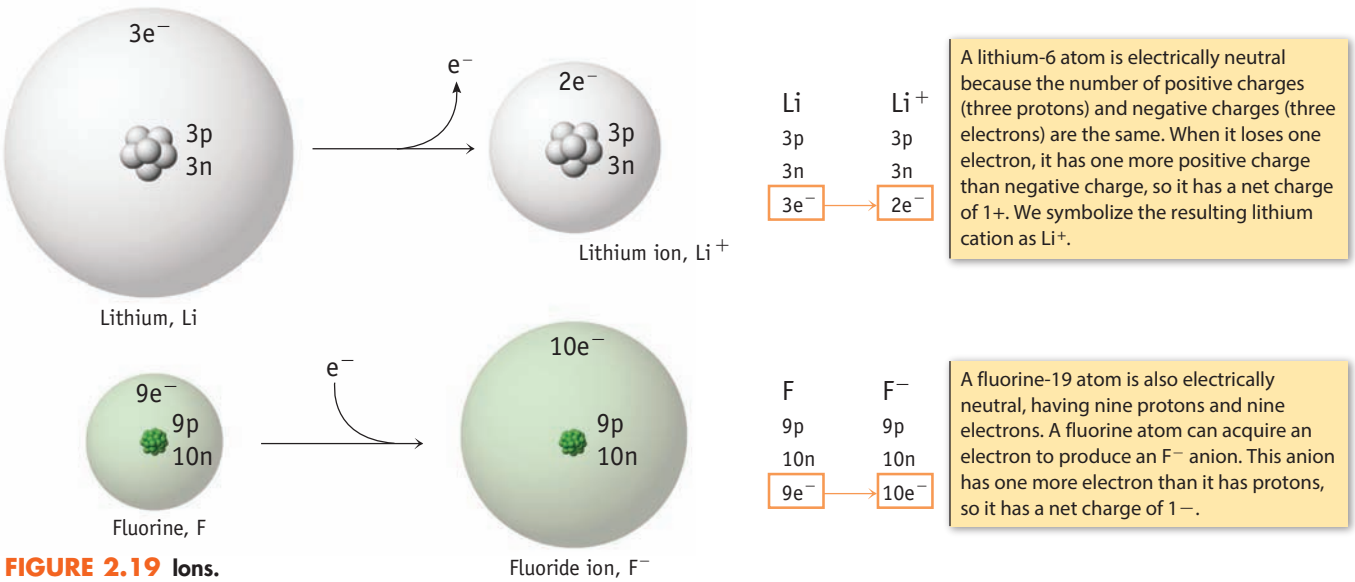

FIGURE 2.19 Ions.

and elements of Group 3A will lose three electrons.

$$\underset{\text{(13 protons and 13 electrons)}}{\text{Al atom}} \rightarrow 3\ e^- + \underset{\text{(13 protons and 10 electrons)}}{Al^{3+}\ \text{cation}}$$

How can you predict the number of electrons gained or lost in reactions of elements in Groups 1A through 3A?

- Metals of Groups 1A–3A lose one or more electrons to form positive ions having a charge equal to the group number of the metal.
- The number of electrons remaining on the cation is the same as the number of electrons in an atom of the noble gas that precedes it in the periodic table.

Transition metals (B-group elements) also form cations, but unlike the A-group metals, there is no easily predictable pattern of behavior. In addition, transition metals often form several different ions. Iron, for example, may form either Fe^{2+} or Fe^{3+} ions in its reactions. Copper may form a 1+ or 2+ ion, but silver forms only a 1+ ion.

Monatomic Anions

Nonmetals can gain electrons to form negatively charged ions. If an atom gains one or more electrons, there will now be more negatively charged electrons than protons (Figure 2.19). A negatively charged ion is called an anion (pronounced "an'-i-on"). An oxygen atom, for example, can gain two electrons in a reaction to form an ion with the formula O^{2-}:

$$\underset{\text{(8 protons and 8 electrons)}}{\text{O atom}} + 2\ e^- \rightarrow \underset{\text{(8 protons and 10 electrons)}}{O^{2-}\ \text{anion}}$$

A chlorine atom can add a single electron to form Cl^-.

$$\underset{\text{(17 protons and 17 electrons)}}{\text{Cl atom}} + e^- \rightarrow \underset{\text{(17 protons and 18 electrons)}}{Cl^-\ \text{anion}}$$

We can make two general observations concerning the formation of anions from nonmetals.

- Nonmetals of Groups 5A–7A form negative ions having a charge equal to the group number of the nonmetal minus 8.
- The number of electrons on the anion is the same as the number of electrons in an atom of the noble gas that follows it in the periodic table.

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Notice that hydrogen appears at two locations in Figure 2.18. The H atom can either lose or gain electrons, depending on the other atoms it encounters.

Electron lost: H (1 proton, 1 electron) $\rightarrow$ H^+ (1 proton, 0 electrons) + e^-

Electron gained: H (1 proton, 1 electron) + e^- $\rightarrow$ H^- (1 proton, 2 electrons)

Finally, the noble gases very rarely form monatomic cations and never form monatomic anions in chemical reactions.

Polyatomic Ions

Polyatomic ions are made up of two or more atoms, and the collection has an electric charge (Figure 2.20 and Table 2.4). For example, carbonate ion, CO_3^{2-}, a common polyatomic anion, consists of one C atom and three O atoms. The ion has two units of negative charge because there are two more electrons (a total of 32) in the ion than there are protons (a total of 30) in the nuclei of one C atom and three O atoms.

The ammonium ion, NH_4^+, is a common polyatomic cation. In this case, four H atoms surround an N atom, and the ion has a 1+ electric charge. This ion has 10 electrons, but there are 11 positively charged protons in the nuclei of the N and H atoms (7 for N, 1 for each H).

Polyatomic anion names To be successful in your study of chemistry you must know the names and formulas (including the ion charges) of the common ions listed in this table.

TABLE 2.4 Formulas and Names of Some Common Polyatomic Ions

Formula	Name	Formula	Name
Cation: Positive Ion			
NH_4^+	Ammonium ion		
Anions: Negative Ions			
Based on a Group 4A element		**Based on a Group 7A element**	
CN^-	Cyanide ion	ClO^-	Hypochlorite ion
$CH_3CO_2^-$	Acetate ion	ClO_2^-	Chlorite ion
CO_3^{2-}	Carbonate ion	ClO_3^-	Chlorate ion
HCO_3^-	Hydrogen carbonate ion (or bicarbonate ion)	ClO_4^-	Perchlorate ion
$C_2O_4^{2-}$	Oxalate ion		
Based on a Group 5A element		**Based on a transition metal**	
NO_2^-	Nitrite ion	CrO_4^{2-}	Chromate ion
NO_3^-	Nitrate ion	$Cr_2O_7^{2-}$	Dichromate ion
PO_4^{3-}	Phosphate ion	MnO_4^-	Permanganate ion
HPO_4^{2-}	Hydrogen phosphate ion		
$H_2PO_4^-$	Dihydrogen phosphate ion		
Based on a Group 6A element			
OH^-	Hydroxide ion		
SO_3^{2-}	Sulfite ion		
SO_4^{2-}	Sulfate ion		
HSO_4^-	Hydrogen sulfate ion (or bisulfate ion)

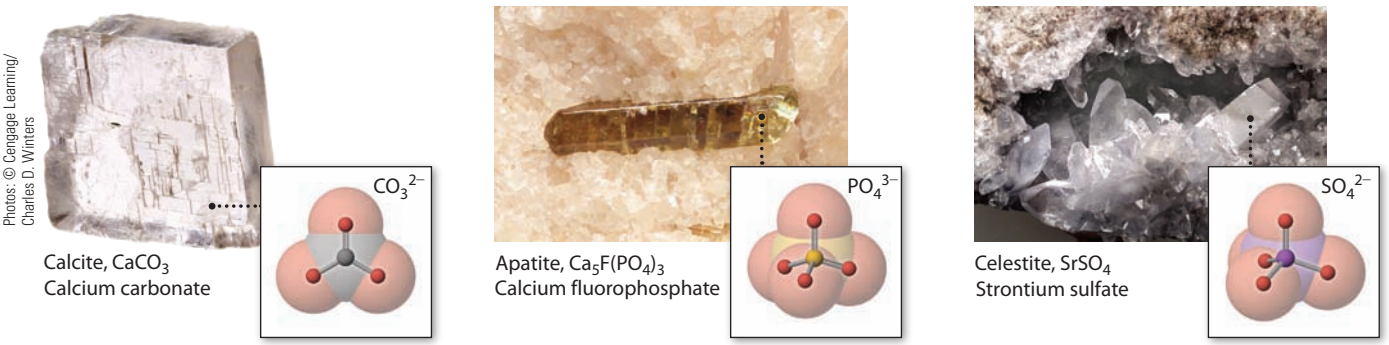

FIGURE 2.20 **Common ionic compounds containing polyatomic ions.**

Formulas of Ionic Compounds

Compounds are electrically neutral; that is, they have no net electric charge. Thus, in an ionic compound the numbers of positive and negative ions must be such that the positive and negative charges balance. In sodium chloride, the sodium ion has a 1+ charge (Na^+) and the chloride ion has a 1− charge (Cl^-). These ions must be present in a 1:1 ratio, and so the formula is NaCl.

The gemstone ruby is largely the compound formed from aluminum ions (Al^{3+}) and oxide ions (O^{2-}). To have a compound with the same number of positive and negative charges, two Al^{3+} ions [total charge = $2 \times (3+) = 6+$] must combine with three O^{2-} ions [total charge = $3 \times (2-) = 6-$] to give a formula of Al_2O_3.

Calcium, a Group 2A metal, forms a cation having a 2+ charge. It can combine with a variety of anions to form ionic compounds such as those in the following table:

Compound	Ion Combination	Overall Charge on Compound
$CaCl_2$	$Ca^{2+} + 2\ Cl^-$	$(2+) + 2 \times (1-) = 0$
$CaCO_3$	$Ca^{2+} + CO_3^{2-}$	$(2+) + (2-) = 0$
$Ca_3(PO_4)_2$	$3\ Ca^{2+} + 2\ PO_4^{3-}$	$3 \times (2+) + 2 \times (3-) = 0$

The Color of Rubies The beautiful red color of a ruby comes from a trace of Cr^{3+} ions that take the place of a few of the Al^{3+} ions in the solid.

In writing formulas of ionic compounds, the convention is that *the symbol of the cation is given first, followed by the anion symbol.* Also notice the use of parentheses when more than one polyatomic ion of a given kind is present [as in $Ca_3(PO_4)_2$]. (None, however, are used when only one polyatomic ion is present, as in $CaCO_3$.)

EXAMPLE 2.4

Ionic Compound Formulas

Problem For each of the following ionic compounds, write the symbols for the ions present and give the relative number of each: (a) Li_2CO_3, and (b) $Fe_2(SO_4)_3$.

What Do You Know? You know the formulas of the ionic compounds, the predicted charges on monatomic ions (see Figure 2.18), and the formulas and charges of polyatomic ions (see Table 2.4).

Strategy Divide the formula of the compound into the cations and anions. To accomplish this you will have to *recognize, and remember, the formulas of common monatomic and polyatomic ions*.

Identifying Charges on Transition Metal Cations Because ionic compounds are electrically neutral, the charges on transition metal cations can be determined if anion charges are known.

SOLUTION

(a) Li_2CO_3 is composed of two lithium ions, Li^+, for each carbonate ion, CO_3^{2-}. Li is a Group 1A element and always has a 1+ charge in its compounds. Because the two 1+ charges balance the negative charge of the carbonate ion, the latter must be 2−.

(b) $Fe_2(SO_4)_3$ contains two iron(III) ions, Fe^{3+}, for every three sulfate ions, SO_4^{2-}. The way to recognize this is to recall that sulfate has a 2− charge. Because three sulfate ions are present (with a total charge of 6−), the two iron cations must have a total charge of 6+. This is possible only if each iron cation has a charge of 3+.

Think about Your Answer Remember that the formula for an ion must include its composition and its charge. Formulas for ionic compounds are always written with the cation first and then the anion, but ion charges are ***not*** included.

Check Your Understanding

Give the number and identity of the constituent ions in each of the following ionic compounds: NaF, $Cu(NO_3)_2$, and $NaCH_3CO_2$.

EXAMPLE 2.5

Ionic Compound Formulas

Problem Write formulas for ionic compounds composed of an aluminum cation and each of the following anions: (a) fluoride ion, (b) sulfide ion, and (c) nitrate ion.

What Do You Know? You know the names of the ions involved, the predicted charges on monatomic ions (see Figure 2.18), and the names, formulas, and charges of polyatomic ions (see Table 2.4).

Strategy First decide on the formula of the Al cation and the formula of each anion. Combine the Al cation with each type of anion to form electrically neutral compounds.

SOLUTION An aluminum cation is predicted to have a charge of 3+ because Al is a metal in Group 3A.

(a) Fluorine is a Group 7A element. The charge of the fluoride ion is predicted to be 1− (from $7 - 8 = 1-$). Therefore, we need 3 F^- ions to combine with one Al^{3+}. The formula of the compound is AlF_3.

(b) Sulfur is a nonmetal in Group 6A, so it forms a 2− anion. Thus, we need to combine two Al^{3+} ions [total charge is $6+ = 2 \times (3+)$] with three S^{2-} ions [total charge is $6- = 3 \times (2-)$]. The compound has the formula Al_2S_3.

(c) The nitrate ion has the formula NO_3^- (see Table 2.4). The answer here is therefore similar to the AlF_3 case, and the compound has the formula $Al(NO_3)_3$. Here we place parentheses around NO_3 to show that three polyatomic NO_3^- ions are involved.

Think about Your Answer The most common error students make is not knowing the correct charge on an ion.

Check Your Understanding

(a) Write the formulas of all neutral ionic compounds that can be formed by combining the cations Na^+ and Ba^{2+} with the anions S^{2-} and PO_4^{3-}.

(b) Iron forms ions having 2+ and 3+ charges. Write the formulas of the compounds formed between chloride ions and these two different iron cations.

Names of Ions

Naming Positive Ions (Cations)

With a few exceptions (such as NH_4^+), the positive ions described in this text are metal ions. Positive ions are named by the following rules:

1. For a monatomic positive ion (that is, a metal cation) the name is that of the metal plus the word "cation." For example, we have already referred to Al^{3+} as the aluminum cation.
2. In the transition series, a metal can often form more than one type of positive ion. So that the name specifies which ion is involved, the charge of transition metal cations is indicated by a Roman numeral in parentheses immediately following the ion's name. For example, Co^{2+} is the cobalt(II) cation, and Co^{3+} is the cobalt(III) cation.

Finally, you will encounter the ammonium cation, NH_4^+, many times in this book and in the laboratory. Do not confuse the ammonium cation with the ammonia molecule, NH_3, which has no electric charge and one less H atom.

Elements with Multiple Ion Charges These occur especially in the transition metals. However, some main group metals such as tin (Sn^{2+} and Sn^{4+}) and lead (Pb^{2+} and Pb^{4+}) can also have multiple ion charges. It is our practice to always indicate the ion charge with a Roman numeral when naming compounds of the transition metal elements and in other cases when multiple charges are possible.

Naming Negative Ions (Anions)

There are two types of negative ions: those having only one atom (*monatomic*) and those having several atoms (*polyatomic*).

1. A monatomic negative ion is named by adding *-ide* to the stem of the name of the nonmetal element from which the ion is derived (Figure 2.21). The anions of the Group 7A elements, the halogens, are known as fluoride, chloride, bromide, and iodide ions and as a group are called **halide ions**.
2. Polyatomic negative ions are common, especially those containing oxygen (called **oxoanions**). The names of some of the most common oxoanions are given in Table 2.4. Although most of these names must simply be learned, some guidelines can help. For example, consider the following pairs of ions:

NO_3^- is the nitrate ion, whereas NO_2^- is the nitrite ion.

SO_4^{2-} is the sulfate ion, whereas SO_3^{2-} is the sulfite ion.

The oxoanion having the greater number of oxygen atoms is given the suffix -ate, and the oxoanion having the smaller number of oxygen atoms has the suffix -ite. For a series of oxoanions having more than two members, the ion with the largest number of oxygen atoms has the prefix *per-* and the suffix *-ate*. The ion having the smallest number of oxygen atoms has the prefix *hypo-* and the suffix *-ite*. The chlorine oxoanions are the most commonly encountered example.

		increasing oxygen content ↑
ClO_4^-	*Per*chlor*ate* ion	per . . . ate
ClO_3^-	Chlor*ate* ion	. . . ate
ClO_2^-	Chlor*ite* ion	. . . ite
ClO^-	*Hypo*chlor*ite* ion	hypo . . . ite

Oxoanions that contain hydrogen are named by adding the word "hydrogen" before the name of the oxoanion. If two hydrogens are in the anion, we say "dihydrogen." Some hydrogen-containing oxoanions also have common names. For example, the hydrogen carbonate ion, HCO_3^-, is called the bicarbonate ion.

Ion	Systematic Name	Common Name
HPO_4^{2-}	Hydrogen phosphate ion	
$H_2PO_4^-$	Dihydrogen phosphate ion	
HCO_3^-	Hydrogen carbonate ion	Bicarbonate ion
HSO_4^-	Hydrogen sulfate ion	Bisulfate ion
HSO_3^-	Hydrogen sulfite ion	Bisulfite ion

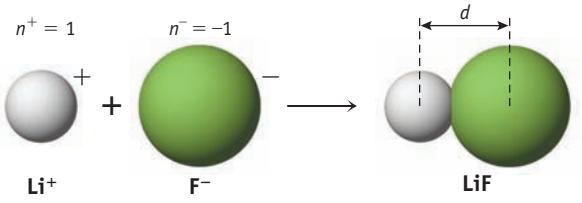
Problem Solving Tip 4.1 Formulas for Ions and Ionic Compounds

Writing formulas for ionic compounds requires that you know the formulas and charges of the most common ions. The charges on monatomic ions are often evident from the position of the element in the periodic table, but *you simply have to remember the formulas and charges of polyatomic ions*, especially the most common ones such as nitrate, sulfate, carbonate, phosphate, and acetate.

If you cannot remember the formula of a polyatomic ion or if you encounter an ion you have not seen before, you may be able to figure out its formula. For example, suppose you are told that the formula for sodium formate is $NaCHO_2$. You know that the sodium ion is Na^+, so the formate ion must be the remaining portion of the compound; it must have a charge of 1− to balance the 1+ charge on the sodium ion. Thus, the formate ion must be CHO_2^-.

Finally, when writing the formulas of ions, you *must* include the charge on the ion (except in the formula of an ionic compound). Writing Na when you mean sodium ion is incorrect. There is a vast difference in the properties of the element sodium (Na) and those of its ion (Na^+).

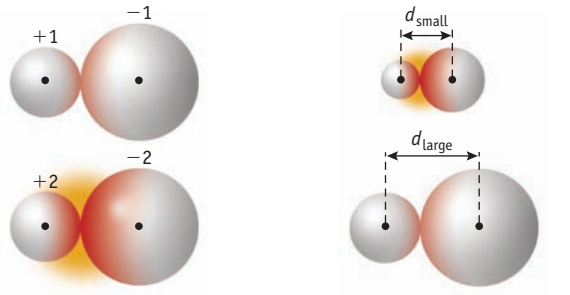
Names of Ionic Compounds



Names of Compounds Containing Transition Metal Cations Be sure to notice that the charge on a transition metal cation is indicated by a Roman numeral and is included in the name.

The name of an ionic compound is built from the names of the positive and negative ions in the compound. The name of the positive cation is given first, followed by the name of the negative anion. Examples of ionic compound names are given below.

Ionic Compound	Ions Involved	Name
$CaBr_2$	Ca^{2+} and 2 Br^-	Calcium bromide
$NaHSO_4$	Na^+ and HSO_4^-	Sodium hydrogen sulfate
$(NH_4)_2CO_3$	2 NH_4^+ and CO_3^{2-}	Ammonium carbonate
$Mg(OH)_2$	Mg^{2+} and 2 OH^-	Magnesium hydroxide
$TiCl_2$	Ti^{2+} and 2 Cl^-	Titanium(II) chloride
Co_2O_3	2 Co^{3+} and 3 O^{2-}	Cobalt(III) oxide



Properties of Ionic Compounds

When a particle having a negative electric charge is brought near another particle having a positive electric charge, there is a force of attraction between them (Figure 2.22). In contrast, there is a repulsive force when two particles with the same charge—both positive or both negative—are brought together. These forces are

Ions such as Li^+ and F^- are held together by a coulombic force of attraction. Here a lithium ion is attracted to a fluoride ion, and the distance between the nuclei of the two ions is *d*.

(a)

As **ion charge** increases, **force of attraction** increases

As **distance** increases, **force of attraction** decreases

(b)

A CLOSER LOOK

Hydrated Ionic Compounds

If ionic compounds are prepared in water solution and then isolated as solids, the crystals often retain molecules of water. These compounds are called **hydrated compounds**. For example, crystals of the red cobalt(II) compound in the Figure have six water molecules per $CoCl_2$. By convention, the formula for this compound is written as $CoCl_2 \cdot 6\ H_2O$. The dot between $CoCl_2$ and $6\ H_2O$ indicates that 6 molecules of water are associated with every $CoCl_2$. The name of the compound is cobalt(II) chloride hexahydrate.

Hydrated cobalt(II) chloride, the red solid in the Figure, turns purple and then deep blue as it is heated and loses water to form anhydrous $CoCl_2$; "anhydrous" means without water. On exposure to moist air, anhydrous $CoCl_2$ takes up water and is converted back into the red hydrated compound. It is this property that allows crystals of the blue compound to be used as a humidity indicator. You may have seen them in small bags packed with a piece of electronic equipment.

Hydrated compounds are common. The walls of your home are probably covered with wallboard, or "plaster board," which contains hydrated calcium sulfate (gypsum, $CaSO_4 \cdot 2\ H_2O$), as well as anhydrous $CaSO_4$, sandwiched between paper. If gypsum is heated between 120 and 180 °C, the water is partly driven off to give $CaSO_4 \cdot 1/2\ H_2O$, a compound commonly called "plaster of Paris." If you have ever broken an arm or leg and had to have a cast, the cast may have been made of this compound. It is an effective casting material because, when added to water, it forms a thick slurry that can be poured into a mold or spread out over a part of the body. As it takes on more water, the material increases in volume and forms a hard, inflexible solid. Plaster of Paris is also a useful material for artists, because the expanding compound fills a mold completely and makes a high-quality reproduction.

Cobalt(II) chloride hexahydrate [$CoCl_2 \cdot 6\ H_2O$] is deep red.

When it is heated, the compound loses some of the water of hydration.

Heating ultimately leads to the deep blue compounds $CoCl_2 \cdot 2\ H_2O$ and $CoCl_2$. Experiments show that some also decomposes to black CoO and HCl.

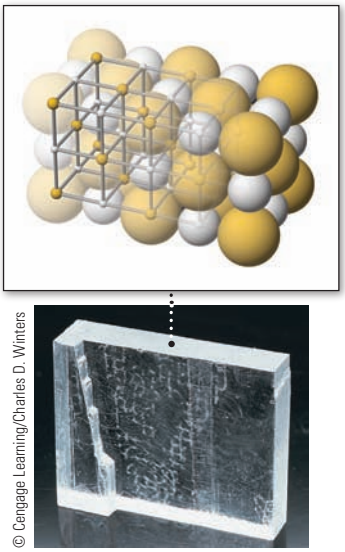
called **electrostatic** forces, and the force of attraction (or repulsion) between ions is given by **Coulomb's law** (Equation 2.3):

$$\text{Force} = -k\,\frac{(n^+e)(n^-e)}{d^2} \qquad (2.3)$$

(charge on + and − ions; charge on electron; proportionality constant; distance between ions)

where, for example, n^+ is $+3$ for Al^{3+} and n^- is -2 for O^{2-}. Based on Coulomb's law, the force of attraction (Figure 2.22) between oppositely charged ions increases

- as the ion charges (n^+ and n^-) increase. Thus, the attraction between ions having charges of 2+ and 2− is greater than that between ions having 1+ and 1− charges.
- as the distance between the ions becomes smaller.



The simplest ratio of cations to anions in an ionic compound is represented by its formula. However, ionic compounds do not consist of simple pairs or small groups of positive and negative ions. Instead, an ionic solid consists of millions upon millions of ions arranged in an extended three-dimensional network called a **crystal lattice**. A portion of the lattice for NaCl, illustrated in Figure 2.23, represents a common way of arranging ions for compounds that have a 1 : 1 ratio of cations to anions.

The Importance of Coulomb's Law Coulomb's law is the basis for understanding many fundamental concepts of chemistry. Among the chapters where this is important are:

Chapter 3: dissolving compounds in water.
Chapters 6 & 7: the interaction of electrons and the atomic nucleus.
Chapters 8 & 9: the interaction of atoms to form molecules.
Chapter 11: the interactions between molecules (intermolecular forces).
Chapter 12: the formation of ionic solids.
Chapter 13: the solution process.

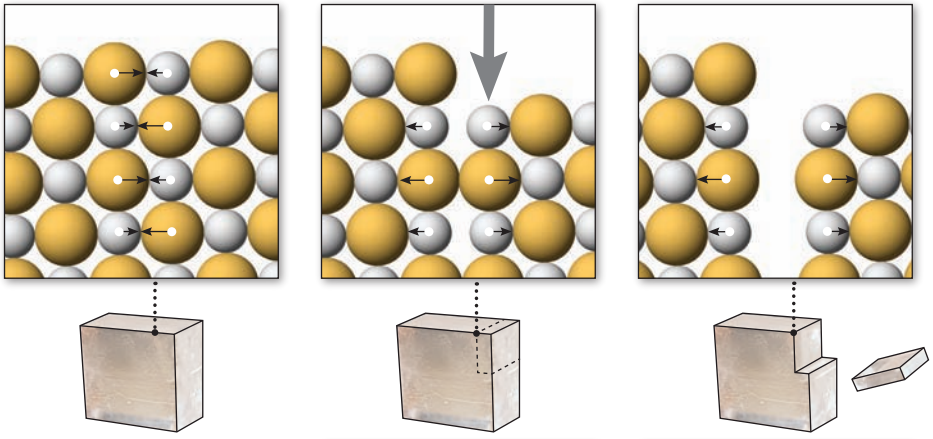
Figure 2.23 Sodium chloride. A crystal of NaCl consists of an extended lattice of sodium ions and chloride ions in a 1 : 1 ratio. When melted, the crystal lattice collapses and the ions move freely and can conduct an electrical current.

Ionic compounds have characteristic properties that can be understood in terms of the charges of the ions and their arrangement in the lattice. Because each ion is surrounded by oppositely charged nearest neighbors, it is held tightly in its allotted location. At room temperature each ion can move just a bit around its average position, but considerable energy must be added before an ion can escape the attraction of its neighboring ions. Only if enough energy is added will the lattice structure collapse and the substance melt. Greater attractive forces mean that ever more energy—and higher and higher temperatures—is required to cause melting. Thus, Al_2O_3, composed of Al^{3+} and O^{2-} ions, melts at a much higher temperature (2072 °C) than NaCl (801 °C), composed of Na^+ and Cl^- ions.

Most ionic compounds are "hard" solids. That is, the solids are not pliable or soft. The reason for this is again related to the lattice of ions. The nearest neighbors of a cation in a lattice are anions, and the force of attraction makes the lattice rigid. However, a blow with a hammer can cause the lattice to break cleanly along a sharp boundary. The hammer blow displaces layers of ions just enough to cause ions of like charge to become nearest neighbors, and the repulsion between these like-charged ions forces the lattice apart (Figure 2.24).

2.6 Atoms, Molecules, and the Mole

Goals for Section 2.6



- Understand the mole concept and molar mass and their application.
- Use the molar mass of an element and Avogadro's number in calculations.
- Calculate the molar mass of a compound from its formula and a table of atomic weights.
- Calculate the amount (= number of moles) of a compound represented by a given mass, and vice versa.
- Use Avogadro's number to calculate the number of atoms or ions in a compound.

When two chemicals react with each other, we want to know how many atoms or molecules of each are used so that formulas can be established for the reaction's

© Cengage Learning/Charles D. Winters

An ionic solid is rigid owing to the forces of attraction between oppositely charged ions. When struck sharply, however, the crystal can cleave cleanly.

When a crystal is struck, layers of ions move slightly, and ions of like charge become nearest neighbors.

Repulsions between ions of similar charge cause the crystal to cleave.

FIGURE 2.24 Ionic solids.

A CLOSER LOOK

Amedeo Avogadro and His Number

Amedeo Avogadro, conte di Quaregna (1776–1856), was an Italian nobleman and a lawyer. In about 1800, he turned to science and was the first professor of mathematical physics in Italy.

Avogadro did not himself propose the notion of a fixed number of particles in a chemical unit. Rather, the number was named in his honor because he had performed experiments in the 19th century that laid the groundwork for the concept.

Just how large is Avogadro's number? One mole of unpopped popcorn kernels would cover the continental United States to a depth of about 9 miles.

Is the number a unique value like π? No. It is fixed by the definition of the mole as exactly 12 g of carbon-12. If one mole of carbon were defined to have some other mass, then Avogadro's number would have a different value. Furthermore, it is determined experimentally, and, as experimental techniques improve, the value is determined with more and more accuracy. From the 9th edition of this book to this edition the value changed slightly in the 7th and later digits.

Edgar Fahs Smith Collection

Amedeo Avogadro

products. To do this, we need a method of counting atoms and molecules. That is, we need a way of connecting the macroscopic world, the world we can see, with the particulate world of atoms, molecules, and ions. The solution to this problem is to define a unit of matter that contains a known number of particles. That chemical unit is the mole.

The **mole** (abbreviated mol) is the SI base unit for measuring an *amount of a substance* (Table 1, page 30) and is defined as follows:

> A **mole** is the amount of a substance that contains as many elementary entities (atoms, molecules, or other particles) as there are atoms in exactly 12 g of the carbon-12 isotope.

The "Mole" The term *mole* was introduced about 1895 by Wilhelm Ostwald (1853–1932), who derived the term from the Latin word *moles*, meaning a "heap" or a "pile."

The key to understanding the concept of the mole is recognizing that *one mole always contains the same number of particles, no matter what the substance*. One mole of sodium contains the same number of atoms as one mole of iron and the same as the number of molecules in one mole of water. How many particles? Many experiments over the years have established that number as

$$1 \text{ mole} = 6.022140857 \times 10^{23} \text{ particles}$$

This value is known as **Avogadro's number** (symbolized by N_A) in honor of Amedeo Avogadro, an Italian lawyer and physicist (1776–1856) who conceived the basic idea (but never determined the number).

Atoms and Molar Mass

The mass in grams of one mole of any element ($6.022140857 \times 10^{23}$ atoms of that element) is the **molar mass** of that element. Molar mass is abbreviated with a capital italicized *M* and has units of grams per mole (g/mol). *An element's molar mass is the quantity in grams numerically equal to its atomic weight.* Using copper as an example,

$$\begin{aligned} \text{Molar mass of copper (Cu)} &= \text{mass of 1.000 mol of Cu atoms} \\ &= 63.55 \text{ g/mol} \\ &= \text{mass of } 6.022 \times 10^{23} \text{ Cu atoms} \end{aligned}$$

An Important Difference Between the Terms *Amount* and *Quantity* The terms "amount" and "quantity" are used in a specific sense by chemists. The amount of a substance is the number of moles of that substance. In contrast, quantity refers, for example, to the mass or volume of the substance.

Figure 2.25 shows one mole of some common elements. Although each of these "piles of atoms" has a different volume and different mass, each contains 6.022×10^{23} atoms.

The mole concept is the cornerstone of quantitative chemistry. It is essential to be able to convert from moles to mass and from mass to moles. Dimensional analysis,

FIGURE 2.25 One mole of common elements. (*Left to right*) Sulfur powder, magnesium chips, tin, and silicon. (*Above*) Copper beads.

which is described in Let's Review, page 43, shows that this can be done in the following way:

MASS ⟷ MOLES CONVERSION

Moles to Mass

$$\text{Moles} \times \frac{\text{grams}}{1\ \text{mol}} = \text{grams}$$

(molar mass)

Mass to Moles

$$\text{Grams} \times \frac{1\ \text{mol}}{\text{grams}} = \text{moles}$$

(1/molar mass)

For example, what mass, in grams, is represented by 0.35 mol of aluminum? Using the molar mass of aluminum (27.0 g/mol), you can determine that 0.35 mol of Al has a mass of 9.5 g.

$$0.35\ \text{mol Al} \times \frac{27.0\ \text{g Al}}{1\ \text{mol Al}} = 9.5\ \text{g Al}$$

Molar masses of the elements are generally known to at least four significant figures. The convention followed in calculations in this book is to use a value of the molar mass with at least one more significant figure than in any other number in the problem. For example, if you weigh out 16.5 g of carbon, you use 12.01 g/mol for the molar mass of C to find the amount of carbon present.

$$16.5\ \text{g C} \times \frac{1\ \text{mol C}}{12.01\ \text{g C}} = 1.37\ \text{mol C}$$

Note that four significant figures are used in the molar mass, but there are three in the sample mass.

Using one more significant figure for the molar mass than in the data means the accuracy of this value will not affect the accuracy of the result.

EXAMPLE 2.6

Mass, Moles, and Atoms

Problem Consider two elements in the same vertical column of the periodic table, lead and tin.

(a) What mass of lead, in grams, is equivalent to 2.50 mol of lead (Pb)?

(b) What amount of tin, in moles, is represented by 36.6 g of tin (Sn)? How many atoms of tin are in the sample?

What Do You Know? You know the amount of lead and the mass of tin. You also know, from the periodic tables in this book, the molar masses of lead (207.2 g/mol) and tin (118.7 g/mol). For part (b) Avogadro's number is needed.

Strategy

Part (a) Multiply the amount of Pb by the molar mass.

Part (b) Multiply the mass of tin by (1/molar mass). To determine the number of atoms, multiply the amount of tin by Avogadro's number.

SOLUTION

(a) Convert the amount of lead in moles to mass in grams.

$$2.50 \text{ mol Pb} \times \frac{207.2 \text{ g}}{1 \text{ mol Pb}} = 518 \text{ g Pb}$$

(b) Convert the mass of tin to the amount in moles,

$$36.6 \text{ g Sn} \times \frac{1 \text{ mol Sn}}{118.7 \text{ g Sn}} = 0.3083 \text{ mol Sn} = 0.308 \text{ mol Sn}$$

and then use Avogadro's number to find the number of atoms in the sample.

$$0.3083 \text{ mol Sn} \times \frac{6.022 \times 10^{23} \text{ atoms Sn}}{1 \text{ mol Sn}} = 1.86 \times 10^{23} \text{ atoms Sn}$$

Think about Your Answer These problems were solved using *g/mol* or *mol/g* as conversion factors. To be sure you have used them correctly you should keep track of the units of each term (page 43). Also, you should think about your answers. For example, in part (b), if you had inverted the conversion factor (*mol/atoms* instead of *atoms/mol*), you would have calculated that there was less than one atom in 0.308 mol of Sn, clearly an unreasonable answer.

Check Your Understanding

What mass of gold, Au, contains 2.6×10^{24} atoms?

© Cengage Learning/Charles D. Winters

Lead. A 150-mL beaker containing 2.50 mol or 518 g of lead.

© Cengage Learning/Charles D. Winters

Tin. A sample of tin having a mass of 36.6 g (or 1.86×10^{23} atoms).

Molecules, Compounds, and Molar Mass

The formula of a compound tells you the type of atoms or ions in the compound and the relative number of each. For example, one molecule of methane, CH_4, is made up of one atom of C and four atoms of H. But suppose you have Avogadro's number of C atoms (6.022×10^{23}) combined with the proper number of H atoms. (For CH_4 this means there are $4 \times 6.022 \times 10^{23}$ H atoms per mole of

Molecular Weight and Molar Mass The old term *molecular weight* is sometimes encountered. This is the sum of the atomic weights of the constituent elements.

A CLOSER LOOK

The Mole, a Counting Unit

Students studying chemistry for the first time are often perplexed by the idea of the mole. But you should recognize it is just a counting unit with an odd name. Pairs and dozens are two other common counting units. For example, a pair of objects has two of the same things (two shoes or two gloves), and there are 12 eggs or apples in a dozen. In the same way, a mole of atoms or a mole of jelly beans has 6.022×10^{23} objects.

The great advantage of counting units is that if you know the number of units you also know the number of objects. If you know there are 3.5 dozen apples in a box, you know there are 42 apples. And, if you have 0.308 mol of tin (36.6 g), you know you have 1.86×10^{23} atoms of tin.

In the chemistry lab when we do a reaction, we need to know how many "chemical units" of an element are involved. Atoms obviously cannot be counted out one by one. Instead, we weigh a given mass of the element, and, from the molar mass, we know the number of "chemical units" or moles. And, if we really wanted to know the information, we could calculate the number of atoms involved.

© Cengage Learning/Charles D. Winters

Counting Units. The unit "dozen," which refers to 12 objects, is a common counting unit. Similarly, the mole is a chemical counting unit. Just as a dozen always has 12 objects, a mole always has 6.022×10^{23} objects.

C atoms.) What masses of atoms are combined, and what is the mass of this many CH_4 molecules?

C	+	4 H	→	CH_4
6.022×10^{23} C atoms		$4 \times 6.022 \times 10^{23}$ H atoms		6.022×10^{23} CH_4 molecules
= 1.000 mol of C		= 4.000 mol of H atoms		= 1.000 mol of CH_4 molecules
= 12.01 g of C atoms		= 4.032 g of H atoms		= 16.04 g of CH_4 molecules

Because you know the number of moles of C and H atoms in 1 mol of CH_4, you can calculate the masses of carbon and hydrogen that must be combined. It follows that the mass of CH_4 is the sum of these masses. That is, 1 mol of CH_4 has a mass equal to the mass of 1 mol of C atoms (12.01 g) plus 4 mol of H atoms (4.032 g). Thus, the *molar mass, M,* of CH_4 is 16.04 g/mol.

Because you know the mass of one mole of methane, 16.04 g, and that there are 6.022×10^{23} molecules present in one mole, you can also calculate the mass of an average molecule of CH_4. (This is an average mass; because there are several isotopes of carbon and hydrogen, and the mass of a given molecule will be determined by which isotopes make up that molecule.)

$$\text{Average molecular mass} = \frac{16.04 \text{ g}}{\text{mol}} \times \frac{1 \text{ mol}}{6.022 \times 10^{23} \text{ molecule}} = 2.664 \times 10^{-23} \text{ g/molecule}$$

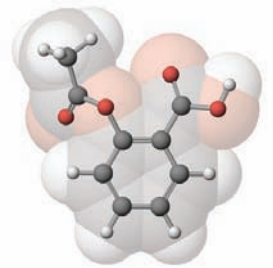

Figure 2.26 illustrates 1-mol quantities of several common compounds. To find the molar mass of any compound, you need only to add up the atomic masses for each element in the compound, taking into account any subscripts on elements. As an example, let us find the molar mass of aspirin, $C_9H_8O_4$. In one mole of aspirin there are 9 mol of carbon atoms, 8 mol of hydrogen atoms, and 4 mol of oxygen atoms, which add up to 180.15 g/mol of aspirin.

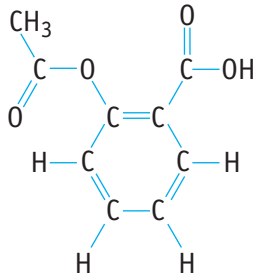
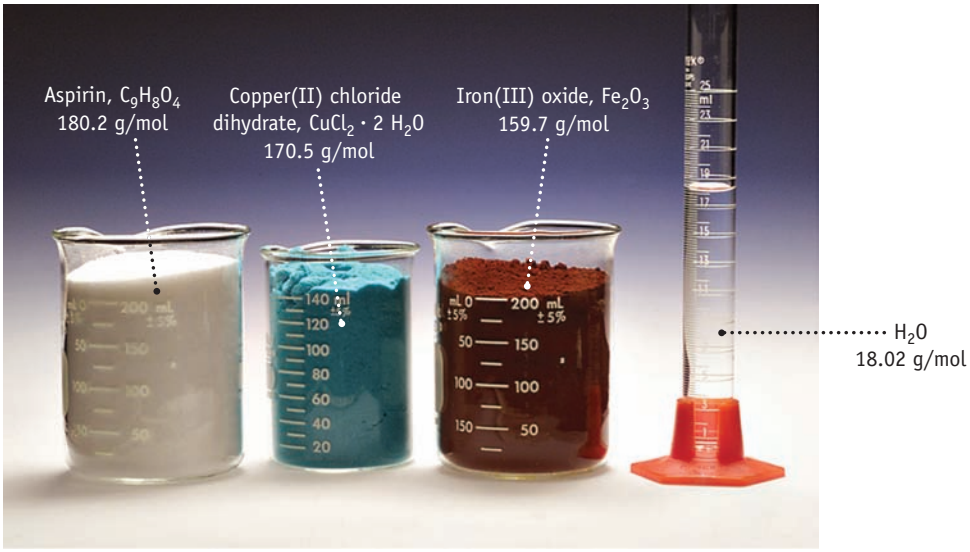


$$\text{Mass of C in 1 mol } C_9H_8O_4 = 9 \text{ mol C} \times \frac{12.01 \text{ g C}}{1 \text{ mol C}} = 108.09 \text{ g C}$$

$$\text{Mass of H in 1 mol } C_9H_8O_4 = 8 \text{ mol H} \times \frac{1.008 \text{ g H}}{1 \text{ mol H}} = 8.064 \text{ g H}$$

$$\text{Mass of O in 1 mol } C_9H_8O_4 = 4 \text{ mol O} \times \frac{16.00 \text{ g O}}{1 \text{ mol O}} = 64.00 \text{ g O}$$

$$\text{Total mass of 1 mol of } C_9H_8O_4 = \text{molar mass of } C_9H_8O_4 = 180.15 \text{ g}$$



Aspirin Formula Aspirin has the molecular formula $C_9H_8O_4$ and a molar mass of 180.2 g/mol. Aspirin is the common name of the compound acetylsalicylic acid.

FIGURE 2.26 One mole of some compounds. In the second compound, $CuCl_2 \cdot 2\ H_2O$, one "formula unit" consists of one Cu^{2+} ion, two Cl^- ions, and two water molecules. The molar mass is the sum of the mass of 1 mol of Cu, 2 mol of Cl, and 2 mol of H_2O.

As was the case with elements, it is important to be able to convert between amounts (moles) and mass (grams). For example, if you take 325 mg (0.325 g) of aspirin in one tablet, what amount of the compound have you ingested? Based on a molar mass of 180.15 g/mol, there is 0.00180 mol of aspirin per tablet.

$$0.325\ \text{g aspirin} \times \frac{1\ \text{mol aspirin}}{180.15\ \text{g aspirin}} = 0.001804\ \text{mol aspirin} = 0.00180\ \text{mol aspirin}$$

Using the molar mass of a compound it is possible to determine the number of molecules in any sample from the sample mass and to determine the mass of one molecule. For example, the number of aspirin molecules in one tablet is

$$0.001804\ \text{mol aspirin} \times \frac{6.022 \times 10^{23}\ \text{molecules}}{1\ \text{mol aspirin}} = 1.09 \times 10^{21}\ \text{molecules}$$

and the mass of one molecule is

$$\frac{180.15\ \text{g aspirin}}{1\ \text{mol aspirin}} \times \frac{1\ \text{mol aspirin}}{6.022 \times 10^{23}\ \text{molecules}} = 2.992 \times 10^{-22}\ \text{g/molecule}$$

Ionic compounds such as NaCl do not exist as individual molecules. Thus, for ionic compounds we write the simplest formula that shows the relative number of each kind of atom in a "formula unit" of the compound, and the molar mass is calculated from this formula (M for NaCl = 58.44 g/mol). To differentiate substances like NaCl that do not contain molecules, chemists sometimes refer to their *formula mass* instead of their molar mass.

Strategy Map 2.7

PROBLEM

Find **amount of oxalic acid** in a **given mass.** Then find **number of molecules** and **number of C atoms** in the sample.

↓

DATA/INFORMATION KNOWN

- **Mass** of sample
- **Formula** of compound
- **Avogadro's number**

↓ STEP 1. Calculate **molar mass** of oxalic acid.

Molar mass of oxalic acid **(g/mol)**

↓ STEP 2. Use molar mass to calculate **amount** (multiply **mass** by **1/molar mass**).

Amount (mol) of oxalic acid

↓ STEP 3. Multiply by **Avogadro's number.**

Number of molecules

↓ STEP 4. Multiply by number of **C atoms** per molecule.

Number of **C** atoms in sample

EXAMPLE 2.7

Molar Mass and Moles

Problem You have 16.5 g of oxalic acid, $H_2C_2O_4$.

(a) What amount is represented by 16.5 g of oxalic acid?

(b) How many molecules of oxalic acid are in 16.5 g of the acid?

(c) How many atoms of carbon are in 16.5 g of oxalic acid?

What Do You Know? You know the mass and formula of oxalic acid. The molar mass of the compound can be calculated based on the formula.

Strategy The strategy is outlined in the strategy map.

- The molar mass is the sum of the masses of the component atoms.
- Part (a) Use the molar mass to convert mass to amount.
- Part (b) Use Avogadro's number to calculate the number of molecules from the amount.
- Part (c) From the formula you know there are two atoms of carbon in each molecule.

SOLUTION

(a) *Moles represented by 16.5 g* Let us first calculate the molar mass of oxalic acid:

$$2 \text{ mol C per mol } H_2C_2O_4 \times \frac{12.01 \text{ g C}}{1 \text{ mol C}} = 24.02 \text{ g C per mol } H_2C_2O_4$$

$$2 \text{ mol H per mol } H_2C_2O_4 \times \frac{1.008 \text{ g H}}{1 \text{ mol H}} = 2.016 \text{ g H per mol } H_2C_2O_4$$

$$4 \text{ mol O per mol } H_2C_2O_4 \times \frac{16.00 \text{ g O}}{1 \text{ mol O}} = 64.00 \text{ g O per mol } H_2C_2O_4$$

$$\text{Molar mass of } H_2C_2O_4 = 90.04 \text{ g per mol } H_2C_2O_4$$

Now calculate the amount in moles. The molar mass (expressed here in units of 1 mol/90.04 g) is used in all mass-mole conversions.

$$16.5 \text{ g } H_2C_2O_4 \times \frac{1 \text{ mol}}{90.04 \text{ g } H_2C_2O_4} = 0.1833 \text{ g } H_2C_2O_4 = 0.183 \text{ mol } H_2C_2O_4$$

(b) *Number of molecules* Use Avogadro's number to find the number of oxalic acid molecules in 0.1833 mol of $H_2C_2O_4$.

$$0.1833 \text{ mol} \times \frac{6.022 \times 10^{23} \text{ molecules}}{1 \text{ mol}} = 1.104 \times 10^{23} \text{ molecules}$$

$$= 1.10 \times 10^{23} \text{ molecules}$$

(c) *Number of C atoms* Because each molecule contains two carbon atoms, the number of carbon atoms in 16.5 g of the acid is

$$1.104 \times 10^{23} \text{ molecules} \times \frac{2 \text{ C atoms}}{1 \text{ molecule}} = 2.21 \times 10^{23} \text{ C atoms}$$

Think about Your Answer The mass of oxalic acid is 16.5 g, much less than the mass of a mole, so check to make sure your answer reflects this. The number of molecules of the acid should be many fewer than in one mole of molecules.

Check Your Understanding

If you have 454 g of citric acid ($H_3C_6H_5O_7$), what amount (moles) does this represent? How many molecules? How many atoms of carbon?

2.7 Chemical Analysis: Determining Compound Formulas

Goals for Section 2.7

- Express the composition of a compound in terms of percent composition.
- Determine the empirical and molecular formula of a compound using percent composition or other experimental data.

Given a sample of an unknown compound, how can its formula be determined? The answer lies in *chemical analysis*, a major branch of chemistry that deals with the determination of formulas and structures.

Percent Composition

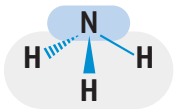
A central principle of chemistry is that any sample of a pure compound always consists of the same elements combined in the same proportion by mass. Suppose you have 1.0000 mol of NH_3 or 17.031 g. This mass of NH_3 is composed of 14.007 g of N (1.0000 mol) and 3.0237 g of H (3.0000 mol). If you compare the mass of N to the total mass of compound, 82.244% of the total mass is N and 17.755% is H.

$$\text{Mass percent N in } NH_3 = \frac{\text{mass of N in 1 mol } NH_3}{\text{mass of 1 mol } NH_3} \times 100\%$$

$$= \frac{14.007 \text{ g N}}{17.031 \text{ g } NH_3} \times 100\%$$

$$= 82.244\% \text{ (or 82.244 g N in 100.000 g } NH_3)$$

$$\text{Mass percent H in } NH_3 = \frac{\text{mass of H in 1 mol } NH_3}{\text{mass of 1 mol } NH_3} \times 100\%$$



$$= \frac{3.0237 \text{ g H}}{17.031 \text{ g } NH_3} \times 100\%$$

$$= 17.755\% \text{ (or 17.755 g H in 100.000 g } NH_3)$$

These values tell you that in a 100.00-g sample there are 82.244 g of N and 17.755 g of H.

Molecular Composition Molecular composition can be expressed as a percent (mass of an element in a 100-g sample). For example, NH_3 is 82.244% N. Therefore, it has 82.244 g of N in 100.000 g of compound.

82.244% of NH_3 mass is **nitrogen.**

17.755% of NH_3 mass is **hydrogen.**

EXAMPLE 2.8

Using Percent Composition

Problem What is the mass percent of each element in propane, C_3H_8? What mass of carbon is contained in 454 g of propane?

What Do You Know? You know the formula of propane. You will need the atomic weights of C and H to calculate the mass percent of each element.

Strategy

(a) Calculate the molar mass of propane.

(b) The percent of each element is the mass of the element in one mole of the compound divided by the molar mass of the compound and multiplied by 100.

(c) The mass of C in 454 g of C_3H_8 is obtained by multiplying this mass by the % C and dividing by 100.

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

SOLUTION

(a) The molar mass of C_3H_8 is 44.10 g/mol.

(b) Mass percent of C and H in C_3H_8:

$$\frac{3 \text{ mol C}}{1 \text{ mol } C_3H_8} \times \frac{12.01 \text{ g C}}{1 \text{ mol C}} = 36.03 \text{ g C}/1 \text{ mol } C_3H_8$$

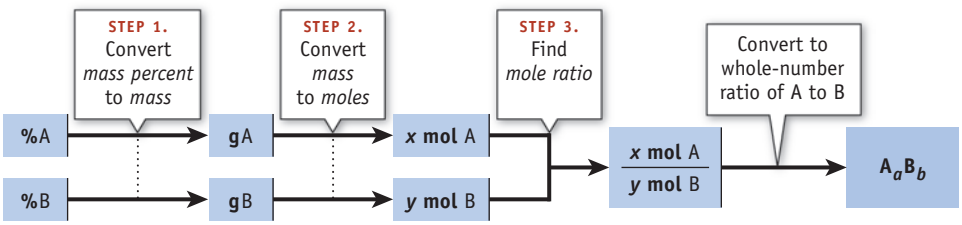
$$\text{Mass percent of C in } C_3H_8 = \frac{36.03 \text{ g C}}{44.10 \text{ g } C_3H_8} \times 100\% = 81.70\% \text{ C}$$

$$\frac{8 \text{ mol H}}{1 \text{ mol } C_3H_8} \times \frac{1.008 \text{ g H}}{1 \text{ mol H}} = 8.064 \text{ g H}/1 \text{ mol } C_3H_8$$

$$\text{Mass percent of H in } C_3H_8 = \frac{8.064 \text{ g H}}{44.10 \text{ g } C_3H_8} \times 100\% = 18.29\% \text{ H}$$

(c) Mass of C in 454 g of C_3H_8:

$$454 \text{ g } C_3H_8 \times \frac{81.70 \text{ g C}}{100.0 \text{ g } C_3H_8} = 371 \text{ g C}$$



Think about Your Answer Once you know the percent C in the sample, you could calculate the percent H from it knowing that %H = 100% − %C.

Check Your Understanding

1. Express the composition of ammonium carbonate, $(NH_4)_2CO_3$, in terms of the mass of each element in 1.00 mol of compound and the mass percent of each element.
2. What is the mass of carbon in 454 g of octane, C_8H_{18}?

Empirical and Molecular Formulas from Percent Composition

Now consider the reverse of the procedure just described. That is, use relative mass or percent composition data to find a molecular formula. Suppose you know the identity of the elements in a sample and have determined the mass of each element in a given mass of compound by chemical analysis (Section 4.4). You can then calculate the relative amount (moles) of each element, *which is also the relative number of atoms of each element in the formula of the compound.* For example, for a compound composed of atoms of A and B, the steps from percent composition to a formula are as follows:

Deriving a Formula Percent composition gives the mass of an element in 100 g of a sample. However, in deriving a formula, any amount of sample is appropriate if you know the mass of each element in that sample mass.

As an example, let us derive the formula for hydrazine, a compound used to remove oxygen from water in heating and cooling systems and a close relative of ammonia. Hydrazine is composed of 87.42% N and 12.58% H.

Step 1 *Convert mass percent to mass.* The mass percentages of N and H in hydrazine tell us there are 87.42 g of N and 12.58 g of H in a 100.00-g sample.

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Step 2 *Convert the mass of each element to moles.* The amount of each element in the 100.00-g sample is

$$87.42 \text{ g N} \times \frac{1 \text{ mol N}}{14.007 \text{ g N}} = 6.2412 \text{ mol N}$$

$$12.58 \text{ g H} \times \frac{1 \text{ mol H}}{1.0079 \text{ g H}} = 12.481 \text{ mol H}$$

Step 3 *Find the mole ratio of elements.* Use the amount (moles) of each element in the 100.00-g sample to find the amount of one element relative to the other. (To do this it is usually best to divide the larger amount by the smaller amount.) For hydrazine, this ratio is 2 mol of H to 1 mol of N,

$$\frac{12.481 \text{ mol H}}{6.2412 \text{ mol N}} = \frac{2.000 \text{ mol H}}{1.000 \text{ mol N}} \longrightarrow \text{NH}_2$$

showing that there are 2 mol of H atoms for every 1 mol of N atoms in hydrazine. Thus, in one molecule, two atoms of H occur for every atom of N; that is, the formula is NH_2. This simplest, whole-number atom ratio of atoms in a formula is called the **empirical formula**.

Percent composition data allow us to calculate the atom ratios in a compound. A *molecular formula*, however, must convey two pieces of information: (1) the relative numbers of atoms of each element in a molecule (the atom ratios) and (2) the total number of atoms in the molecule. For hydrazine there are twice as many H atoms as N atoms, so the molecular formula could be NH_2. Recognize, however, that NH_2 is only the simplest ratio of atoms in a molecule. The empirical formula of hydrazine is NH_2, but the molecular formula could be NH_2, N_2H_4, N_3H_6, N_4H_8, or any other formula having a 1 : 2 ratio of N to H.

To determine the molecular formula from the empirical formula, you need to know the molar mass. For example, experiments show that the molar mass of hydrazine is 32.0 g/mol, twice the formula mass of NH_2, which is 16.0 g/mol. Thus, the molecular formula of hydrazine is two times the empirical formula of NH_2, that is, N_2H_4.

Problem Solving Tip 2.2 Finding Empirical and Molecular Formulas

- The experimental data available to find a formula may be in the form of percent composition or the masses of elements combined in some mass of compound. No matter what the starting point, the first step is always to convert masses of elements to moles.
- Be sure to use *at least* three significant figures when calculating empirical formulas. Using fewer significant figures can give a misleading result.
- When finding atom ratios, always divide the larger number of moles by the smaller one.
- Empirical and molecular formulas can differ for molecular compounds. In contrast, there is no "molecular" formula for an ionic compound; all that can be recorded is the empirical formula.
- Determining the molecular formula of a compound after calculating the empirical formula requires knowing the molar mass.
- When *both* the percent composition and the molar mass are known for a compound, the alternative method mentioned in *Think about Your Answer* in Example 2.9 can be used.

Strategy Map 2.9

PROBLEM

Determine **empirical** and **molecular formulas** based on ***known composition*** and ***known molar mass***.

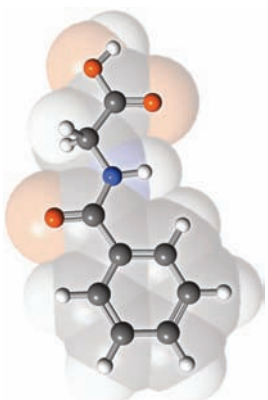
DATA/INFORMATION KNOWN

- Molar mass
- Percent composition

STEP 1. Assume each **atom %** is equivalent to **mass in grams** in **100-g** sample.

Mass of each element in a **100-g** sample of the compound

STEP 2. Use **atomic weight** of each element to calculate **amount** of each element in 100-g sample (multiply **mass** by **mol/g**).



Amount (mol) of each element in **100-g** sample

STEP 3. Divide the *amount of each element* by the *amount of the element present* ***in the least amount***.

Whole-number ratio of the *amount of each element* to the *amount of element present in the least amount* = **empirical formula**

STEP 4. Divide *known* **molar mass** by **empirical formula mass**.

Molecular formula

Hippuric Acid, $C_9H_9NO_3$ This substance, which can be isolated as white crystals, is found in the urine of humans and of herbivorous animals.

EXAMPLE 2.9

Calculating a Formula from Percent Composition

Problem Many soft drinks contain sodium benzoate as a preservative. When you consume the sodium benzoate, it reacts with the amino acid glycine in your body to form hippuric acid, which is then excreted in the urine. Hippuric acid has a molar mass of 179.17 g/mol and is 60.33% C, 5.06% H, and 7.82% N; the remainder is oxygen. What are the empirical and molecular formulas of hippuric acid?

What Do You Know? You know the mass percent of C, H, and N. The mass percent of oxygen is not known but is obtained by difference. You know the molar mass but will need atomic weights of C, H, N, and O for the calculation.

Strategy Assume the mass percent of each element is equivalent to its mass in grams, and convert each mass to moles. The ratio of moles gives the empirical formula. The mass of a mole of compound having the calculated empirical formula is compared with the actual, experimental molar mass to find the true molecular formula.

SOLUTION The mass of oxygen in a 100.0-g sample of hippuric acid is

$$100.00\ \text{g} = 60.33\ \text{g C} + 5.06\ \text{g H} + 7.82\ \text{g N} + \text{mass of O}$$

$$\text{Mass of O} = 26.79\ \text{g O}$$

The amount of each element in 100.0 g is

$$60.33\ \text{g C} \times \frac{1\ \text{mol C}}{12.011\ \text{g C}} = 5.0229\ \text{mol C}$$

$$5.06\ \text{g H} \times \frac{1\ \text{mol H}}{1.008\ \text{g H}} = 5.020\ \text{mol H}$$

$$7.82\ \text{g N} \times \frac{1\ \text{mol N}}{14.01\ \text{g N}} = 0.5582\ \text{mol N}$$

$$26.79\ \text{g O} \times \frac{1\ \text{mol O}}{15.999\ \text{g O}} = 1.6745\ \text{mol O}$$

To find the mole ratio, the best approach is to base the ratios on the smallest number of moles present—in this case, nitrogen.

$$\frac{\text{mol C}}{\text{mol N}} = \frac{5.0229\ \text{mol C}}{0.5582\ \text{mol N}} = \frac{9.00\ \text{mol C}}{1.00\ \text{mol N}} = 9\ \text{mol C}/1\ \text{mol N}$$

$$\frac{\text{mol H}}{\text{mol N}} = \frac{5.020\ \text{mol H}}{0.5582\ \text{mol N}} = \frac{8.99\ \text{mol H}}{1.00\ \text{mol N}} = 9\ \text{mol H}/1\ \text{mol N}$$

$$\frac{\text{mol O}}{\text{mol N}} = \frac{1.6745\ \text{mol O}}{0.5582\ \text{mol N}} = \frac{3.00\ \text{mol O}}{1.00\ \text{mol N}} = 3\ \text{mol O}/1\ \text{mol N}$$

Now we know there are 9 mol of C, 9 mol of H, and 3 mol of O for each mol of N. Thus, the empirical formula is $C_9H_9NO_3$. The experimentally determined molar mass of hippuric acid is 179.17 g/mol. This is the same as the empirical formula weight, so the molecular formula is $C_9H_9NO_3$.

Think about Your Answer There is another approach to finding the molecular formula. If you know both the percent composition of hippuric acid and its molar mass, you could calculate that in 179.17 g of hippuric acid there are 108.09 g of C (9.000 mol of C), 9.07 g of H (8.99 mol of H), 14.01 g N (1.000 mol N), and 48.00 g of O (3.000 mol of O). This gives us a molecular formula of $C_9H_9NO_3$. However, *this approach can only be used when you know* ***both*** *the percent composition and the molar mass.*

Check Your Understanding

1. What is the empirical formula of naphthalene, $C_{10}H_8$?
2. The empirical formula of acetic acid is CH_2O. If its molar mass is 60.05 g/mol, what is the molecular formula of acetic acid?
3. Isoprene is a liquid compound that can be polymerized to form natural rubber. It is composed of 88.17% carbon and 11.83% hydrogen. Its molar mass is 68.11 g/mol. What are its empirical and molecular formulas?
4. Camphor is found in camphor wood, much prized for its wonderful odor. It is composed of 78.90% carbon and 10.59% hydrogen. The remainder is oxygen. What is its empirical formula?

Determining a Formula from Mass Data

The composition of a compound in terms of mass percent gives us the mass of each element in a 100.0-g sample. In the laboratory we often collect information on the composition of compounds slightly differently. We can

1. Combine known masses of elements to give a sample of the compound of known mass. Element masses can be converted to amounts (moles), and the ratio of amounts gives the combining ratio of atoms—that is, the empirical formula. This approach is described in Example 2.10.
2. Decompose a known mass of an unknown compound into "pieces" of known composition. If the masses of the "pieces" can be determined, the ratio of moles of the "pieces" gives the formula. An example is a decomposition such as

$$Ni(CO)_4(\ell) \rightarrow Ni(s) + 4\ CO(g)$$

The masses of Ni and CO can be converted to moles, whose 1 : 4 ratio would reveal the formula of the compound. We will describe this approach in Example 2.11.

EXAMPLE 2.10

Formula of a Compound from Combining Masses

Problem Oxides of virtually every element are known. Bromine, for example, forms several oxides when treated with ozone (O_3). Suppose you allow 1.250 g of bromine, Br_2, to react with ozone and obtain 1.876 g of Br_xO_y. What is the empirical formula of the product?

What Do You Know? You began with a given mass of bromine and all of the bromine became part of bromine oxide of unknown formula. You also know the mass of the product, and because you know the mass of Br in this product, you can determine the mass of O in the product.

Strategy

- The mass of oxygen is determined as the difference between the product mass and the mass of bromine used.
- Calculate the amounts of Br and O from the masses of each element.
- Find the lowest whole number ratio between the moles of Br and moles of O. This defines the empirical formula.

Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

SOLUTION You already know the mass of bromine in the compound, so you can calculate the mass of oxygen in the compound.

$$1.876 \text{ g product} - 1.250 \text{ g } Br_2 = 0.626 \text{ g O}$$

Next, calculate the amount of each reactant. Notice that, although Br_2 was the reactant, we need to know the amount of Br in the product.

$$1.250 \text{ g } Br_2 \times \frac{1 \text{ mol } Br_2}{159.81 \text{ g}} = 0.0078218 \text{ mol } Br_2$$

$$0.0078218 \text{ mol } Br_2 \times \frac{2 \text{ mol Br}}{1 \text{ mol } Br_2} = 0.015644 \text{ mol Br}$$

$$0.626 \text{ g O} \times \frac{1 \text{ mol O}}{16.00 \text{ g O}} = 0.03913 \text{ mol O}$$

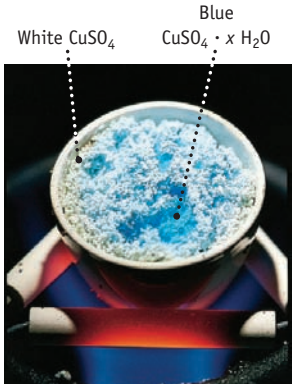
Find the ratio of moles of O to moles of Br:

$$\text{Mole ratio} = \frac{0.03913 \text{ mol O}}{0.015644 \text{ mol Br}} = \frac{2.50 \text{ mol O}}{1.00 \text{ mol Br}}$$

The atom ratio is 2.5 mol O/1.0 mol Br. However, atoms combine in the ratio of small whole numbers, so we double this to give a ratio of 5 mol O to 2 mol Br. Thus, the product is Br_2O_5 (dibromine pentaoxide).

Think about Your Answer The whole number ratio of 5 : 2 was found by realizing that 2.5 = 2 1/2 = 5/2. The calculation gave the empirical formula for this compound. To determine whether this is also the molecular formula, the molar mass of the compound would have to be determined.

Check Your Understanding



Gallium oxide, Ga_xO_y, forms when gallium is combined with oxygen. Suppose you allow 1.25 g of gallium (Ga) to react with oxygen and obtain 1.68 g of Ga_xO_y. What is the formula of the product?

EXAMPLE 2.11

Determining the Formula of a Hydrated Compound

Problem You want to know the value of x in blue, hydrated copper(II) sulfate, $CuSO_4 \cdot x\ H_2O$, that is, the number of water molecules for each unit of $CuSO_4$. In the laboratory you weigh out 1.023 g of the solid. After heating the solid thoroughly in a porcelain crucible (Figure), 0.654 g of nearly white, anhydrous copper(II) sulfate, $CuSO_4$, remains.

$$1.023 \text{ g } CuSO_4 \cdot x\ H_2O + \text{heat} \rightarrow 0.654 \text{ g } CuSO_4 + ? \text{ g } H_2O$$

© Cengage Learning/Charles D. Winters

What Do You Know? You know the mass of the copper(II) sulfate sample including water (before heating) and with no water (after heating). Therefore, you know the mass of $CuSO_4$ and can determine the mass of water in the sample.

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Strategy To find x you need to know the amount of H_2O per mole $CuSO_4$.

- First, determine the mass of water released on heating the hydrated compound.
- Next, calculate the amount (moles) of $CuSO_4$ and H_2O from their masses and molar masses.
- Finally, determine the smallest whole number ratio (amount H_2O/amount $CuSO_4$).

SOLUTION Find the mass of water.

Mass of hydrated compound	1.023 g
− Mass of anhydrous compound, $CuSO_4$	−0.654
Mass of water	0.369 g

Next convert the masses of $CuSO_4$ and H_2O to moles.

$$0.369\ \text{g}\ H_2O \times \frac{1\ \text{mol}\ H_2O}{18.02\ \text{g}\ H_2O} = 0.02048\ \text{mol}\ H_2O$$

$$0.654\ \text{g}\ CuSO_4 \times \frac{1\ \text{mol}\ CuSO_4}{159.6\ \text{g}\ CuSO_4} = 0.004098\ \text{mol}\ CuSO_4$$

The value of x is determined from the mole ratio.

$$\frac{0.02048\ \text{mol}\ H_2O}{0.004098\ \text{mol}\ CuSO_4} = \frac{5.00\ \text{mol}\ H_2O}{1.00\ \text{mol}\ CuSO_4}$$

The water-to-$CuSO_4$ ratio is 5:1, so the formula of the hydrated compound is $CuSO_4 \cdot 5\ H_2O$. Its name is copper(II) sulfate pentahydrate.

Think about Your Answer The ratio of the amount of water to the amount of $CuSO_4$ is a whole number. This is almost always the case with hydrated compounds.

Check Your Understanding

Hydrated nickel(II) chloride is a beautiful green, crystalline compound. When heated strongly, the compound is dehydrated. If 0.235 g of $NiCl_2 \cdot x\ H_2O$ gives 0.128 g of $NiCl_2$ on heating, what is the value of x?

Strategy Map 2.11

PROBLEM

Determine **formula of hydrated salt** based on ***masses of water and dehydrated salt***.

DATA/INFORMATION KNOWN

- Mass of sample before and after heating to dehydrate

STEP 1. Find *masses of salt and water* by **difference**.

Mass of salt and water in a sample of the hydrated compound

STEP 2. Use **molar mass** of salt and water to calculate **amount** of each in sample (multiply **mass** by **mol/g**).

Amount (mol) of salt and water in sample

STEP 3. Divide the *amount of water* by the *amount of the dehydrated salt*.

Formula = *ratio of the amount of water to the amount of salt* in dehydrated sample

2.8 Instrumental Analysis: Determining Compound Formulas

Goals for Section 2.8

- Determine a molecular formula from a mass spectrum.
- Identify isotopes using mass spectrometry.

Determining a Formula by Mass Spectrometry

We have described chemical methods of determining a molecular formula, but there are many instrumental methods as well. One of them is *mass spectrometry*, a technique that was introduced earlier when discussing the existence of isotopes and their relative abundance (see Figure 2.3). If a compound can be vaporized, the vapor can be passed through an electron beam in a mass spectrometer where high-energy electrons collide with the gas-phase molecules. These high-energy collisions cause molecules to lose electrons and become positive ions, which usually fragment into

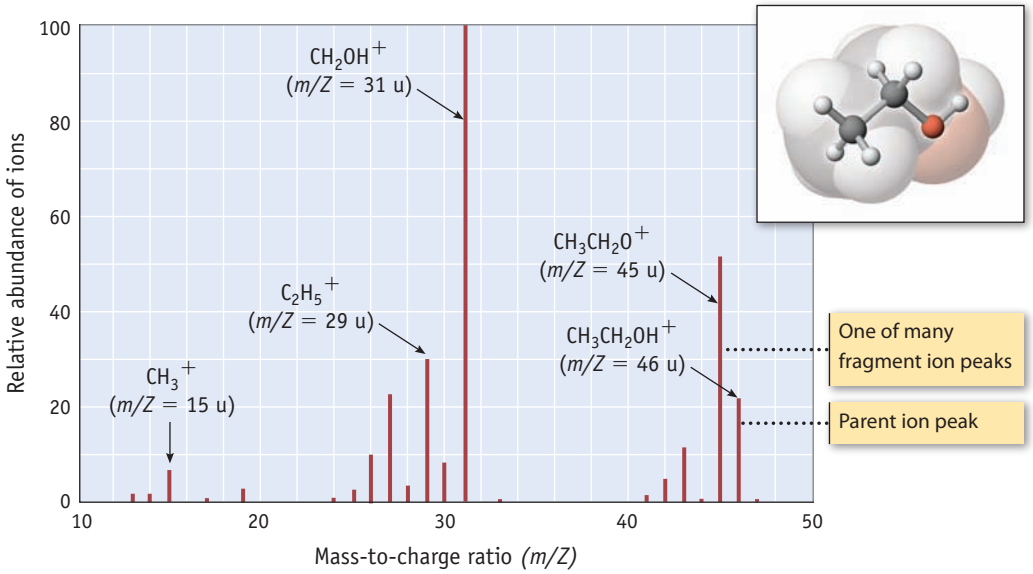

FIGURE 2.27 Mass spectrum of ethanol, CH_3CH_2OH. A prominent peak or line in the spectrum is the "parent" ion ($CH_3CH_2OH^+$) at mass 46. (The parent ion has not undergone decomposition.) The mass designated by the peak for the parent ion confirms the formula of the molecule. Other peaks are for "fragment" ions. This pattern of lines can provide further, unambiguous evidence of the formula of the compound. (The horizontal axis is the mass-to-charge ratio of a given ion. Because almost all observed ions have a charge of $Z = +1$, the value observed is the mass of the ion.)

smaller pieces. As illustrated in Figure 2.27 the cation created from ethanol ($CH_3CH_2OH^+$) fragments (losing an H atom) to give another cation ($CH_3CH_2O^+$), which further fragments. A mass spectrometer detects and records the masses of the different particles. Analysis of the spectrum can help identify a compound and can give an accurate molar mass.

Molar Mass and Isotopes in Mass Spectrometry

Bromobenzene, C_6H_5Br, has a molar mass of 157.010 g/mol. Why, then, are there two prominent lines at mass-to-charge ratios (m/Z) of 156 and 158 in the mass spectrum of the compound (Figure 2.28)? The answer shows us the influence of isotopes on molar mass.

Bromine has two naturally occurring isotopes, ^{79}Br and ^{81}Br. They are 50.7% and 49.3% abundant, respectively. What is the mass of C_6H_5Br based on each isotope? If we use the most abundant isotopes of C and H (^{12}C and ^{1}H), the mass of the molecule having the ^{79}Br isotope, $C_6H_5{}^{79}Br$, is 156. The mass of the molecule

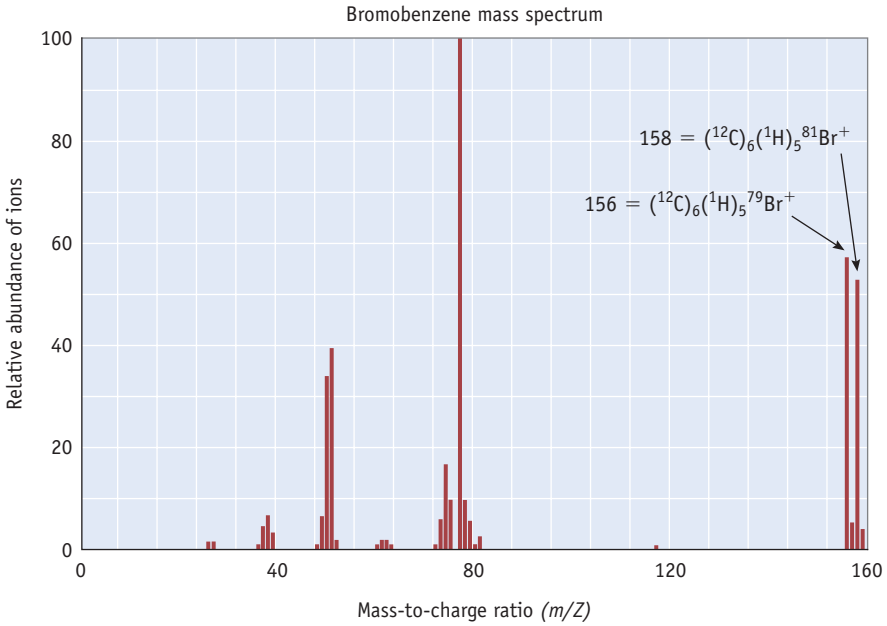

FIGURE 2.28 Mass spectrum of bromobenzene, C_6H_5Br. Two parent ion peaks are present at m/Z ratios of 156 and 158. The similar peak heights reflect the near equal abundances of the two isotopes of bromine, ^{79}Br and ^{81}Br.

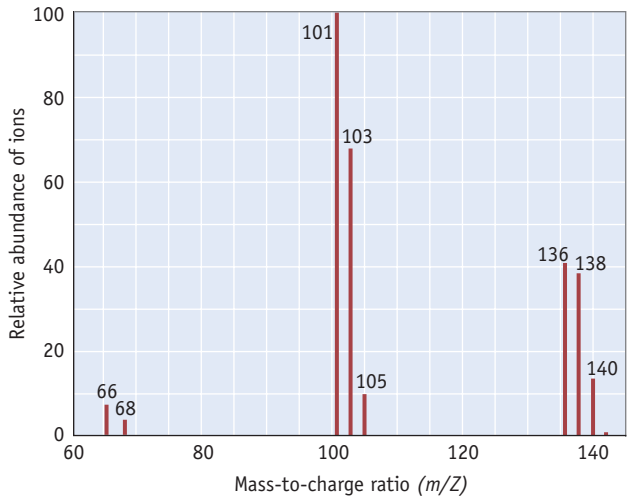
containing the ^{81}Br isotope, $C_6H_5{}^{81}Br$, is 158. The relative size of these two peaks in the spectrum reflects the relative abundances of the two bromine isotopes.

The calculated molar mass of bromobenzene (157.010 g/mol) reflects the abundances of all of the isotopes. In contrast, the mass spectrum has a line for each possible combination of isotopes. This also explains why there are also small lines at the mass-to-charge ratios of 157 and 159. They arise from various combinations of ^{1}H, ^{12}C, ^{13}C, ^{79}Br, and ^{81}Br atoms. In fact careful analysis of such patterns can identify a molecule unambiguously.

EXAMPLE 2.12

Isotopic Abundance by Mass Spectrometry

Problem The mass spectrum of phosphorus trichloride is illustrated here. Phosphorus, ^{31}P, has one stable isotope. Chlorine has two stable isotopes, ^{35}Cl and ^{37}Cl.



(a) What molecular species give rise to the parent ion peaks at *m*/Z ratios of 136, 138, and 140?

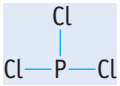
(b) What species give rise to the peaks at *m*/Z ratios of 101, 103, and 105?

(c) Predict the structural formula (see Figure 2.14) of phosphorus trichloride from the mass spectrum.

What Do You Know? You know that PCl_3 molecules ionize to form positive ions. Some of the (parent) ions fragment into smaller ions. You also know the mass numbers of each atom. The mass spectrum shows you the mass of each ion divided by its charge (*m*/Z).

Strategy Try to generate the *m*/Z ratios observed in the mass spectrum by combining the mass numbers of the elements (^{35}Cl, ^{37}Cl, and ^{31}P) in various combinations.

SOLUTION



(a) The parent ion peaks correspond to ions that have not fragmented. A parent ion formed from one ^{31}P atom and three ^{35}Cl atoms has a *m*/Z ratio of 136 (if the ion charge is +1). One ^{31}P atom combined with two ^{35}Cl atoms and one ^{37}Cl atom has a *m*/Z ratio of 138. Finally, a ^{31}P atom combined with one ^{35}Cl and two ^{37}Cl atoms has a *m*/Z ratio of 140. Thus, the molecular species are $P^{35}Cl_3$ (m/Z = 136), $P^{35}Cl_2{}^{37}Cl$ (m/Z = 138), and $P^{35}Cl^{37}Cl_2$ (m/Z = 140).

b) The ions with *m*/Z ratios of 101, 103, and 105 have the formula $PCl_2{}^{+}$. The species are $P^{35}Cl_2$ (*m*/Z = 101), $P^{35}Cl^{37}Cl$ (*m*/Z = 103), and $P^{37}Cl_2$ (*m*/Z = 105).

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

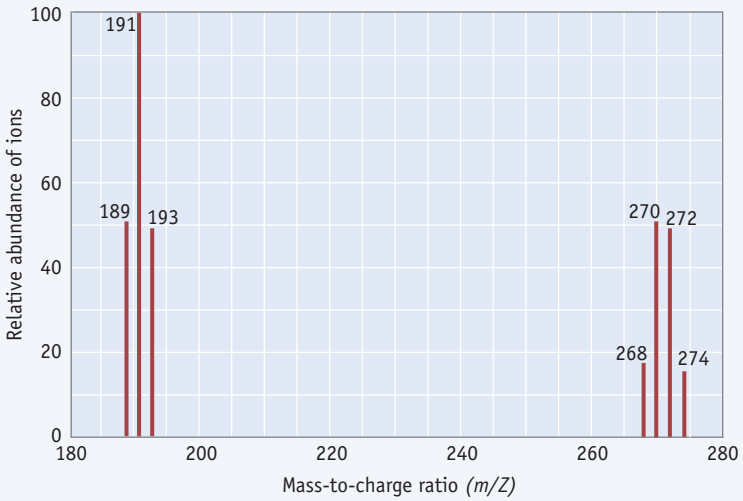
c) The probable structure is below.



The mass spectrum shows fragment ions of PCl^+ ($m/Z = 61$ and 63) and PCl_2^+, but no fragment ions of Cl_2^+ or Cl_3^+. The absence of Cl_2^+ or Cl_3^+ ions is evidence that the chlorine atoms are attached to the phosphorus atom, not each other.

Think about Your Answer When identifying ions in a mass spectrum, it is important to use the masses of each isotope of an element, rather than the average atomic mass of the element.

Check Your Understanding

The mass spectrum of phosphorus tribromide is illustrated below. Bromine has two stable isotopes, ^{79}Br and ^{81}Br with abundances of 50.7% and 49.3%, respectively.

(a) What molecular species give rise to the parent ion peaks at m/Z ratios of 270 and 272?

(b) Explain why the relative abundances of the ions at m/Z ratios of 268 and 274 are approximately one-third of those at 270 and 272.

APPLYING CHEMICAL PRINCIPLES

2.1 Using Isotopes: Ötzi, the Iceman of the Alps

In 1991 a hiker in the Alps on the Austrian-Italian border found the well-preserved remains of an approximately 46-year-old man, now nicknamed "The Iceman," who lived about 5300 years ago (Chapter 1). Studies using isotopes of oxygen, strontium, lead, and argon, among others, have helped scientists paint a detailed picture of the man and his life.

The abundance of the ^{18}O isotope of oxygen is related to the latitude and altitude at which a person was born and raised. Oxygen in biominerals such as teeth and bones comes primarily from ingested water. The lakes and rivers on the northern side of the Alps are known to have a lower ^{18}O content than those on the southern side of the mountains. The ^{18}O content

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

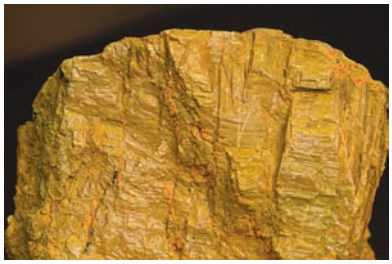
of the teeth and bones of the Iceman was found to be relatively high and characteristic of the watershed south of the Alps. He had clearly been born and raised in that area.

The relative abundance of isotopes of heavier elements also varies slightly from place to place and in their incorporation into different minerals. Strontium, a member of the same periodic group as calcium, is incorporated into teeth and bones. The ratio of strontium isotopes, $^{87}Sr/^{86}Sr$, and of lead isotopes, $^{206}Pb/^{204}Pb$, in the Iceman's teeth and bones was characteristic of soils from a narrow region of Italy south of the Alps, which established more clearly where he was born and lived most of his life.

The investigators also looked for food residues in the Iceman's intestines. Although a few grains of cereal were found, they located tiny flakes of mica believed to have broken off stones used to grind grain and that were therefore eaten when the man ate the grain. They analyzed these flakes using argon isotopes, ^{40}Ar and ^{39}Ar, and found their signature was like that of mica in an area south of the Alps, thus establishing where he lived in his later years.

The overall result of the many isotope studies showed that the Iceman lived thousands of years ago in a small area about 10–20 kilometers west of Merano in northern Italy.

For details of the isotope studies, see W. Müller, et al., *Science*, Volume 302, October 31, 2003, pages 862–866.



Questions:

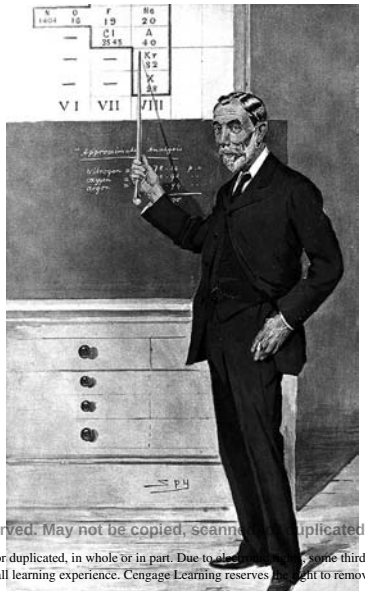
1. How many neutrons are there in atoms of ^{18}O? In each of the two isotopes of lead?
2. There are three stable isotopes of oxygen (^{16}O, mass 15.9949 u, 99.763%, ^{17}O, mass 16.9991 u, 0.0375%, and ^{18}O, 17.9991 u, 0.1995%). Use these data to calculate the atomic weight of oxygen.

2.2 Arsenic, Medicine, and the Formula of Compound 606

The practice in medicine for some centuries has been to find compounds that are toxic to certain organisms but not so toxic that the patient is harmed. In the early part of the 20th century, Paul Ehrlich set out to find just such a compound that would cure syphilis, a sexually transmitted disease that was rampant at the time. He screened hundreds of compounds, and found that his 606th compound was effective: an arsenic-containing drug now called salvarsan. It was used for some years for syphilis treatment until penicillin was discovered in the 1930s.

Salvarsan was a forerunner of the modern drug industry. Interestingly, what chemists long thought to be a single compound was in fact discovered to be a mixture of compounds. Question 2 below will lead you to the molecular formula for each of them.

John C. Kotz



A sample of orpiment, a common arsenic-containing mineral (As_2S_3). The name of the element is thought to come from the Greek word for this mineral, which was long favored by 17th century Dutch painters as a pigment.

Questions:

1. Arsenic is found widely in the environment and is a major problem in the ground water supply in Bangladesh. Orpiment is one arsenic-containing mineral and enargite is another. The latter has 19.024% As, 48.407% Cu, and 32.569% S. What is the empirical formula of the mineral?
2. Salvarsan was long thought to be a single substance. Recently, however, a mass spectrometry study of the compound shows it to be a mixture of two molecules with the same empirical formula. Each has the composition 39.37% C, 3.304% H, 8.741% O, 7.652% N, and 40.932% As. One has a molar mass of 549 g/mol and the other has a molar mass of 915 g/mol. What are the molecular formulas of the compounds?

2.3 Argon—An Amazing Discovery

The noble gas argon was discovered by Sir William Ramsay and John William Strutt (the third Lord Rayleigh) in England and reported in scientific journals in 1895. In making this discovery, Ramsay and Lord Rayleigh made highly accurate measurements of gas densities. They found that gaseous nitrogen (N_2) formed by thermal decomposition of ammonia had a density that was slightly lower than the density of the gas that remained after O_2, CO_2, and H_2O were removed from air. The reason for the difference is that the sample derived from air contained a very small amount

Wellcome Images CC/Diomedia

Sir William Ramsay (1852–1916). Ramsay was a Scottish chemist who discovered several of the noble gases (for which he received the Nobel Prize in Chemistry in 1904). Lord Rayleigh received the Nobel Prize in Physics, also in 1904, for the discovery of argon.

of other gases. After removing N_2 from the sample by reacting it with red hot magnesium (to form Mg_3N_2), a small quantity of gas remained that was more dense than air. This was identified as argon.

Lord Rayleigh's experimentally determined densities for oxygen, nitrogen, and air are given below:

Gas	Density (g/L)
Oxygen	1.42952
Nitrogen, derived from air	1.25718
Nitrogen, derived from ammonia	1.25092
Air, with water and CO_2 removed	1.29327

Questions:

1. To determine the density of atmospheric nitrogen, Lord Rayleigh removed the oxygen, water, and carbon dioxide from air, then filled an evacuated glass globe with the remaining gas. He determined that a mass of 0.20389 g of nitrogen has a density of 1.25718 g/L under standard conditions of temperature and pressure. What is the volume of the globe (in cm^3)?
2. The density of a mixture of gases may be calculated by summing the products of the density of each gas and the fractional volume of space occupied by that gas. (Note the similarity to the calculation of the molar mass of an element from the isotopic masses and fractional abundances.) Assume dry air with CO_2 removed is 20.96% (by volume) oxygen, 78.11% nitrogen, and 0.930% argon. Determine the density of argon.
3. Atmospheric argon is a mixture of three stable isotopes, ^{36}Ar, ^{38}Ar, and ^{40}Ar. Use the information in the table below to determine the atomic mass and natural abundance of ^{40}Ar.

Isotope	Atomic Mass (u)	Abundance (%)
^{36}Ar	35.967545	0.337
^{38}Ar	37.96732	0.063
^{40}Ar	?	?

4. Given that the density of argon is 1.78 g/L under standard conditions of temperature and pressure, how many argon atoms are present in a room with dimensions 4.0 m × 5.0 m × 2.4 m that is filled with pure argon under these conditions of temperature and pressure?

CHAPTER GOALS REVISITED

The goals for this chapter are keyed to specific Study Questions to help you organize your review.

2.1 Atomic Structure, Atomic Number, and Atomic Mass

- Describe electrons, protons, and neutrons, and the general structure of the atom. **1, 3.**
- Define the terms atomic number and mass number. **2, 5–7.**

2.2 Isotopes and Atomic Weight

- Define isotopes and give the mass number and number of neutrons for a specific isotope. **8, 15–17, 101.**
- Perform calculations that relate the atomic weight (atomic mass) of an element and isotopic abundances and masses. **19–24, 156b, 158.**

2.3 The Periodic Table

- Know the terminology of the periodic table (periods, groups) and know how to use the information given in the periodic table. **25, 26, 29–31, 103.**
- Recognize similarities and differences in properties of some of the common elements of a group. **28, 32.**

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

2.4 Molecules, Compounds, and Formulas

- Recognize and interpret molecular formulas, condensed formulas, and structural formulas. 33, 34.
- Remember formulas and names of common molecular compounds. 60.
- Name and write formulas for binary molecular compounds. 57–60.

2.5 Ionic Compounds: Formulas, Names, and Properties

- Recognize that metal atoms commonly lose one or more electrons to form positive ions, called cations, and nonmetal atoms often gain electrons to form negative ions, called anions. 39, 40, 116.
- Predict the charge on monatomic cations and anions based on Group number. 35–37.
- Write formulas for ionic compounds by combining ions in the proper ratio to give no overall charge. 41–48.
- Give the names of formulas of ions and ionic compounds. 49–54.
- Understand the importance of Coulomb's law in chemistry, which describes the electrostatic forces of attraction and repulsion of ions. 55, 56.

2.6 Atoms, Molecules, and the Mole

- Understand the mole concept and molar mass and their application. 61–64, 66, 67.
- Use the molar mass of an element and Avogadro's number in calculations. 65, 68, 105–106.
- Calculate the molar mass of a compound from its formula and a table of atomic weights. 69–72.
- Calculate the amount (= number of moles) of a compound represented by a given mass, and vice versa. 73–74, 116.
- Use Avogadro's number to calculate the number of atoms or ions in a compound. 75–78, 117.

2.7 Chemical Analysis: Determining Compound Formulas

- Express the composition of a compound in terms of percent composition. 79–81.
- Determine the empirical and molecular formula of a compound using percent composition or other experimental data. 87–92, 127, 133, 135.

2.8 Instrumental Analysis: Determining Compound Formulas

- Determine a molecular formula from a mass spectrum. 97–100.
- Identify isotopes using mass spectrometry. 158.

KEY EQUATIONS

Equation 2.1 (page 62) Percent abundance of an isotope.

$$\text{Percent abundance} = \frac{\text{number of atoms of a given isotope}}{\text{total number of atoms of all isotopes of that element}} \times 100\%$$

Equation 2.2 (page 63) Calculate the atomic weight from isotope abundances and the exact atomic mass of each isotope of an element.

$$\text{Atomic weight} = \left(\frac{\%\text{ abundance isotope 1}}{100}\right)(\text{mass of isotope 1}) + \left(\frac{\%\text{ abundance isotope 2}}{100}\right)(\text{mass of isotope 2}) + \ldots$$

Equation 2.3 (page 85) **Coulomb's Law**, the force of attraction between oppositely charged ions.

$$\text{Force} = -k\frac{(n^{+}\text{e})(n^{-}\text{e})}{d^2}$$

k: proportionality constant; d^2: distance between ions; $(n^{+}\text{e})$: charge on + and − ions; $(n^{-}\text{e})$: charge on electron

STUDY QUESTIONS

▲ denotes challenging questions. **Blue-numbered questions** have answers in Appendix N and fully worked solutions in the *Student Solutions Manual*.

Practicing Skills

Atoms: Their Composition and Structure

1. What are the three fundamental particles from which atoms are built? What are their electric charges? Which of these particles constitute the nucleus of an atom? Which is the least massive particle of the three?
2. Define mass number. What is the difference between mass number and atomic mass?
3. An atom has a very small nucleus surrounded by an electron "cloud." Figure 2.1 represents the nucleus with a diameter of about 2 mm and describes the electron cloud as extending over 200 m. If the diameter of an atom is 1×10^{-8} cm, what is the approximate diameter of its nucleus?
4. A gold atom has a radius of 145 pm. If you could string gold atoms like beads on a thread, how many atoms would you need to have a necklace 36 cm long?
5. Give the complete symbol ($^{A}_{Z}\text{X}$), including atomic number and mass number, for each of the following atoms: (a) magnesium with 15 neutrons, (b) titanium with 26 neutrons, and (c) zinc with 32 neutrons.
6. Give the complete symbol ($^{A}_{Z}\text{X}$), including atomic number and mass number, of (a) a nickel atom with 31 neutrons, (b) a plutonium atom with 150 neutrons, and (c) a tungsten atom with 110 neutrons.
7. How many electrons, protons, and neutrons are there in each of the following atoms?
   (a) magnesium-24, ^{24}Mg
   (b) tin-119, ^{119}Sn
   (c) thorium-232, ^{232}Th
   (d) carbon-13, ^{13}C
   (e) copper-63, ^{63}Cu
   (f) bismuth-205, ^{205}Bi

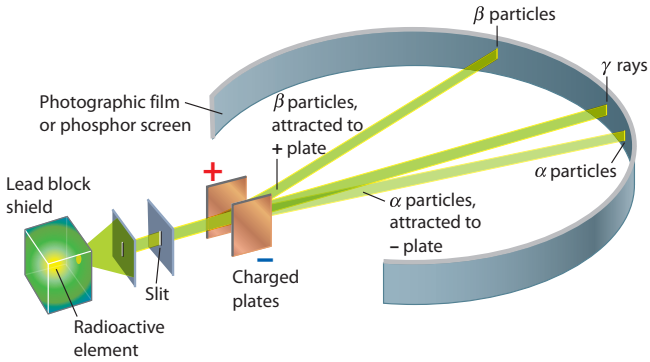
8. Atomic structure.
   (a) The synthetic radioactive element technetium is used in many medical studies. Give the number of electrons, protons, and neutrons in an atom of technetium-99.
   (b) Radioactive americium-241 is used in household smoke detectors and in bone mineral analysis. Give the number of electrons, protons, and neutrons in an atom of americium-241.

Key Experiments Developing Atomic Structure

(See pages 66–67.)



9. From cathode ray experiments, J. J. Thomson estimated that the mass of an electron was "about a thousandth" of the mass of a proton. How accurate is that estimate? Calculate the ratio of the mass of an electron to the mass of a proton.

10. In 1886 Eugene Goldstein observed positively charged particles moving in the opposite direction to electrons in a cathode ray tube (illustrated below). From their mass, he concluded that these particles were formed from residual gas in the tube. For example, if the cathode ray tube contained helium, the canal rays consisted of He^+ ions. Describe a process that could lead to these ions.

Canal rays. In 1886, Eugene Goldstein detected a stream of particles traveling in the direction opposite to that of the negatively charged cathode rays (electrons). He called this stream of positive particles "canal rays."

11. Marie Curie was born in Poland but studied and carried out her research in Paris. In 1903, she shared the Nobel Prize in Physics with H. Becquerel and her husband Pierre for their discovery of radioactivity. (In 1911 she received the Nobel Prize in Chemistry for the discovery of two new chemical elements, radium and polonium, the latter named for her homeland, Poland.) They and others observed that a radioactive substance could emit three types of radiation: alpha (α), beta (β), and gamma (γ). If the radiation from a radioactive source is passed between electrically charged plates, some particles are attached to the positive plate, some to the negative plate, and others feel no attraction. Which particles are positively charged, which are negatively charged, and which have no charge? Of the two charged particles, which has the most mass?

Radioactivity. Alpha (α), beta (β), and gamma (γ) rays from a radioactive element are separated by passing them between electrically charged plates.

12. Early in the 1800s John Dalton proposed that an atom was a "solid, massy, hard, impenetrable, moveable particle." Critique this description. How does this description misrepresent atomic structure?

Isotopes

13. The mass of an ^{16}O atom is 15.995 u. What is its mass relative to the mass of an atom of ^{12}C?

14. What is the mass of one ^{16}O atom, in grams? (The mass of an ^{16}O atom is 15.995 u.)

15. Cobalt has three radioactive isotopes used in medical studies. Atoms of these isotopes have 30, 31, and 33 neutrons, respectively. Give the complete symbol for each of these isotopes.

16. Naturally occurring silver exists as two isotopes having mass numbers 107 and 109. How many protons, neutrons, and electrons are there in each of these isotopes?

17. Name and describe the composition of the three hydrogen isotopes.

18. Which of the following are isotopes of element X, the atomic number for which is 9: $^{19}_{9}X$, $^{20}_{9}X$, $^{9}_{18}X$, and $^{21}_{9}X$?

Isotope Abundance and Atomic Weight

(See Examples 2.2 and 2.3.)

19. Thallium has two stable isotopes, ^{203}Tl and ^{205}Tl. Knowing that the atomic weight of thallium is 204.4, which isotope is the more abundant of the two?

20. Strontium has four stable isotopes. Strontium-84 has a very low natural abundance, but ^{86}Sr, ^{87}Sr, and ^{88}Sr are all reasonably abundant. Knowing that the atomic weight of strontium is 87.62, which of the more abundant isotopes predominates?

21. Verify that the atomic weight of lithium is 6.94, given the following information:

^{6}Li, mass = 6.015121 u; percent abundance = 7.50%
^{7}Li, mass = 7.016003 u; percent abundance = 92.50%

22. Verify that the atomic weight of magnesium is 24.31, given the following information:

^{24}Mg, mass = 23.985042 u; percent abundance = 78.99%
^{25}Mg, mass = 24.985837 u; percent abundance = 10.00%
^{26}Mg, mass = 25.982593 u; percent abundance = 11.01%

23. Gallium has two naturally occurring isotopes, ^{69}Ga and ^{71}Ga, with masses of 68.9257 u and 70.9249 u, respectively. Calculate the percent abundances of these isotopes of gallium.

24. Europium has two stable isotopes, ^{151}Eu and ^{153}Eu, with masses of 150.9197 u and 152.9212 u, respectively. Calculate the percent abundances of these isotopes of europium.

The Periodic Table

(See Section 2.3.)

25. Titanium and thallium have symbols that are easily confused with each other. Give the symbol, atomic number, atomic weight, and group and period number of each element. Are they metals, metalloids, or nonmetals?

26. In Groups 4A–6A, there are several elements whose symbols begin with S. Name these elements, and for each one give its symbol, atomic number, group number, and period. Describe each as a metal, metalloid, or nonmetal.

27. How many periods of the periodic table have 8 elements, how many have 18 elements, and how many have 32 elements?

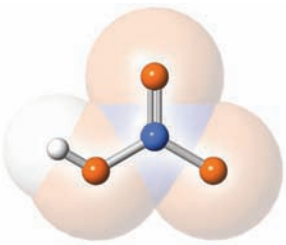
28. How many elements occur in the seventh period? What is the name given to the majority of these elements, and what well-known property characterizes them?

29. Select answers to the questions listed below from the following list of elements whose symbols start with the letter C: C, Ca, Cr, Co, Cd, Cl, Cs, Ce, Cm, Cu, and Cf. (You should expect to use some symbols more than once.)

(a) Which are nonmetals?
(b) Which are main group elements?
(c) Which are lanthanides?
(d) Which are transition elements?
(e) Which are actinides?
(f) Which are gases?

30. Give the name and chemical symbol for the following.

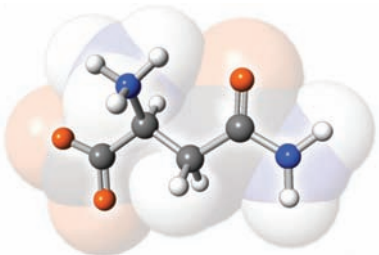
(a) a nonmetal in the second period
(b) an alkali metal in the fifth period
(c) the third-period halogen
(d) an element that is a gas at 20°C and 1 atmosphere pressure



31. Classify the following elements as metals, metalloids, or nonmetals: N, Na, Ni, Ne, and Np.

32. Here are symbols for five of the seven elements whose names begin with the letter B: B, Ba, Bk, Bi, and Br. Match each symbol with one of the descriptions below.

(a) a radioactive element
(b) a liquid at room temperature
(c) a metalloid
(d) an alkaline earth element
(e) a group 5A element



Molecular Formulas and Models

33. A model of nitric acid is illustrated here. Write the molecular formula for nitric acid, and draw the structural formula. Describe the structure of the molecule. Is it flat? That is, are all the atoms in the plane of the paper? (Color code: nitrogen atoms are blue; oxygen atoms are red; and hydrogen atoms are white.)

Nitric acid

34. A model of the amino acid asparagine is illustrated here. Write the molecular formula for the compound, and draw its structural formula.

Asparagine, an amino acid

Ions and Ion Charges

(See Figure 2.18 and Table 2.4.)

35. What is the charge on the common monatomic ions of the following elements?

(a) magnesium (c) nickel
(b) zinc (d) gallium

36. What is the charge on the common monatomic ions of the following elements?

(a) selenium (c) iron
(b) fluorine (d) nitrogen

37. Give the symbol, including the correct charge, for each of the following ions:

(a) barium ion
(b) titanium(IV) ion
(c) phosphate ion
(d) hydrogen carbonate ion
(e) sulfide ion
(f) perchlorate ion
(g) cobalt(II) ion
(h) sulfate ion

38. Give the symbol, including the correct charge, for each of the following ions:

(a) permanganate ion
(b) nitrite ion
(c) dihydrogen phosphate ion
(d) ammonium ion
(e) phosphate ion
(f) sulfite ion

39. When a potassium atom becomes a monatomic ion, how many electrons does it lose or gain? What noble gas atom has the same number of electrons as a potassium ion?

40. When oxygen and sulfur atoms become monatomic ions, how many electrons does each lose or gain? Which noble gas atom has the same number of electrons as an oxide ion? Which noble gas atom has the same number of electrons as a sulfide ion?

Ionic Compounds

(See Examples 2.4 and 2.5.)

41. What are the charges on the ions in an ionic compound containing the elements barium and bromine? Write the formula for the compound.

42. What are the charges of the ions in an ionic compound containing cobalt(III) and fluoride ions? Write the formula for the compound.

43. Give the formula and the number of each ion that makes up each of the following compounds:

(a) K_2S (d) $(NH_4)_3PO_4$
(b) $CoSO_4$ (e) $Ca(ClO)_2$
(c) $KMnO_4$ (f) $NaCH_3CO_2$

44. Give the formula and the number of each ion that makes up each of the following compounds:

(a) $Mg(CH_3CO_2)_2$ (d) $Ti(SO_4)_2$
(b) $Al(OH)_3$ (e) KH_2PO_4
(c) $CuCO_3$ (f) $CaHPO_4$

45. Cobalt forms Co^{2+} and Co^{3+} ions. Write the formulas for the two cobalt oxides formed by these transition metal ions.

46. Platinum is a transition element and forms Pt^{2+} and Pt^{4+} ions. Write the formulas for the compounds of each of these ions with (a) chloride ions and (b) sulfide ions.

47. Which of the following are correct formulas for ionic compounds? For those that are not, give the correct formula.

(a) $AlCl_2$ (c) Ga_2O_3
(b) KF_2 (d) MgS

48. Which of the following are correct formulas for ionic compounds? For those that are not, give the correct formula.

(a) Ca_2O (c) Fe_2O_5
(b) $SrBr_2$ (d) Li_2O

Naming Ionic Compounds

49. Name each of the following ionic compounds:

(a) K_2S (c) $(NH_4)_3PO_4$
(b) $CoSO_4$ (d) $Ca(ClO)_2$

50. Name each of the following ionic compounds:

(a) $Ca(CH_3CO_2)_2$ (c) $Al(OH)_3$
(b) $Ni_3(PO_4)_2$ (d) KH_2PO_4

51. Give the formula for each of the following ionic compounds:

(a) ammonium carbonate
(b) calcium iodide
(c) copper(II) bromide
(d) aluminum phosphate
(e) silver(I) acetate

52. Give the formula for each of the following ionic compounds:

(a) calcium hydrogen carbonate
(b) potassium permanganate
(c) magnesium perchlorate
(d) potassium hydrogen phosphate
(e) sodium sulfite

53. Write the formulas for the four ionic compounds that can be made by combining each of the cations Na^+ and Ba^{2+} with the anions CO_3^{2-} and I^-. Name each of the compounds.

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

54. Write the formulas for the four ionic compounds that can be made by combining the cations Mg^{2+} and Fe^{3+} with the anions PO_4^{3-} and NO_3^-. Name each compound formed.

Coulomb's Law

(See Equation 2.3 and Figure 2.22.)

55. Sodium ions, Na^+, form ionic compounds with fluoride ions, F^-, and iodide ions, I^-. The radii of these ions are as follows: $Na^+ = 116$ pm; $F^- = 119$ pm; and $I^- = 206$ pm. In which ionic compound, NaF or NaI, are the forces of attraction between cation and anion stronger? Explain your answer.

56. Consider the two ionic compounds NaCl and CaO. In which compound are the cation–anion attractive forces stronger? Explain your answer.

Naming Binary, Molecular Compounds

57. Name each of the following binary, nonionic compounds:
(a) NF_3 (c) BI_3
(b) HI (d) PF_5

58. Name each of the following binary, nonionic compounds:
(a) N_2O_5 (c) OF_2
(b) P_4S_3 (d) XeF_4

59. Give the formula for each of the following compounds:
(a) sulfur dichloride
(b) dinitrogen pentaoxide
(c) silicon tetrachloride
(d) diboron trioxide (commonly called boric oxide)

60. Give the formula for each of the following compounds:
(a) bromine trifluoride
(b) xenon difluoride
(c) hydrazine
(d) diphosphorus tetrafluoride
(e) butane

Atoms and the Mole

(See Example 2.6.)

61. Calculate the mass, in grams, of each the following:
(a) 2.5 mol of aluminum
(b) 1.25×10^{-3} mol of iron
(c) 0.015 mol of calcium
(d) 653 mol of neon

62. Calculate the mass, in grams, of each the following:
(a) 4.24 mol of gold
(b) 15.6 mol of He
(c) 0.063 mol of platinum
(d) 3.63×10^{-4} mol of Pu

63. Calculate the amount (moles) represented by each of the following:
(a) 127.08 g of Cu
(b) 0.012 g of lithium
(c) 5.0 mg of americium
(d) 6.75 g of Al

64. Calculate the amount (moles) represented by each of the following:
(a) 16.0 g of Na (c) 0.0034 g of platinum
(b) 0.876 g of tin (d) 0.983 g of Xe

65. You are given 1.0-g samples of He, Fe, Li, Si, and C. Which sample contains the largest number of atoms? Which contains the smallest?

66. You are given 0.10-g samples of K, Mo, Cr, and Al. List the samples in order of the amount (moles), from smallest to largest.

67. Analysis of a 10.0-g sample of apatite (a major component of tooth enamel) showed that it was made up of 3.99 g Ca, 1.85 g P, 4.14 g O, and 0.020 g H. List these elements based on relative amounts (moles), from smallest to largest.

68. A semiconducting material is composed of 52 g of Ga, 9.5 g of Al, and 112 g of As. Which element has the largest number of atoms in this material?

Molecules, Compounds, and the Mole

(See Example 2.7.)

69. Calculate the molar mass of each of the following compounds:
(a) Fe_2O_3, iron(III) oxide
(b) BCl_3, boron trichloride
(c) $C_6H_8O_6$, ascorbic acid (vitamin C)

70. Calculate the molar mass of each of the following compounds:
(a) $Fe(C_6H_{11}O_7)_2$, iron(II) gluconate, a dietary supplement
(b) $CH_3CH_2CH_2CH_2SH$, butanethiol, has a skunk-like odor
(c) $C_{20}H_{24}N_2O_2$, quinine, used as an antimalarial drug

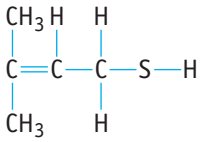
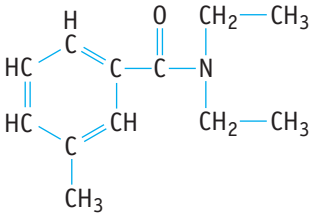
71. Calculate the molar mass of each hydrated compound. Note that the water of hydration is included in the molar mass. (See page 85.)
   (a) $Ni(NO_3)_2 \cdot 6\ H_2O$
   (b) $CuSO_4 \cdot 5\ H_2O$



72. Calculate the molar mass of each hydrated compound. Note that the water of hydration is included in the molar mass. (See page 85.)
   (a) $H_2C_2O_4 \cdot 2\ H_2O$
   (b) $MgSO_4 \cdot 7\ H_2O$, Epsom salt

73. What mass is represented by 0.0255 mol of each of the following compounds?
   (a) C_3H_7OH, 2-propanol, rubbing alcohol
   (b) $C_{11}H_{16}O_2$, an antioxidant in foods, also known as BHA (butylated hydroxyanisole)
   (c) $C_9H_8O_4$, aspirin
   (d) $(CH_3)_2CO$, acetone, an important industrial solvent



74. Assume you have 0.123 mol of each of the following compounds. What mass of each is present?
   (a) $C_{14}H_{10}O_4$, benzoyl peroxide, used in acne medications
   (b) Dimethylglyoxime, used in the laboratory to test for nickel(II) ions

   (c) The compound below, responsible for the "skunky" taste in poorly made beer.

   (d) DEET, a mosquito repellent

75. Sulfur trioxide, SO_3, is made industrially in enormous quantities by combining oxygen and sulfur dioxide, SO_2. What amount (moles) of SO_3 is represented by 1.00 kg of sulfur trioxide? How many molecules? How many sulfur atoms? How many oxygen atoms?

76. How many ammonium ions and how many sulfate ions are present in a 0.20 mol sample of $(NH_4)_2SO_4$? How many atoms of N, H, S and O are contained in this sample?

77. Acetaminophen, whose structure is drawn below, is the active ingredient in some nonprescription pain killers. The recommended dose for an adult is two 500-mg caplets. How many molecules make up one dose of this drug?

Acetaminophen

78. An Alka-Seltzer tablet contains 324 mg of aspirin ($C_9H_8O_4$), 1904 mg of $NaHCO_3$, and 1000. mg of citric acid ($H_3C_6H_5O_7$). (The last two compounds react with each other to provide the "fizz," bubbles of CO_2, when the tablet is put into water.)
   (a) Calculate the amount (moles) of each substance in the tablet.
   (b) If you take one tablet, how many molecules of aspirin are you consuming?

Percent Composition

(See Example 2.8.)

79. Calculate the mass percent of each element in the following compounds:
   (a) PbS, lead(II) sulfide, galena
   (b) C_3H_8, propane
   (c) $C_{10}H_{14}O$, carvone, found in caraway seed oil

80. Calculate the mass percent of each element in the following compounds:
   (a) $C_8H_{10}N_2O_2$, caffeine
   (b) $C_{10}H_{20}O$, menthol
   (c) $CoCl_2 \cdot 6\ H_2O$

81. Calculate the mass percent of copper in CuS, copper(II) sulfide. If you wish to obtain 10.0 g of copper metal from copper(II) sulfide, what mass of CuS (in grams) must you use?

82. Calculate the mass percent of titanium in the mineral ilmenite, $FeTiO_3$. What mass of ilmenite (in grams) is required if you wish to obtain 750 g of titanium?

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Empirical and Molecular Formulas

(See Example 2.9.)

83. Succinic acid occurs in fungi and lichens. Its empirical formula is $C_2H_3O_2$, and its molar mass is 118.1 g/mol. What is its molecular formula?

84. An organic compound has the empirical formula C_2H_4NO. If its molar mass is 116.1 g/mol, what is the molecular formula of the compound?

85. Complete the following table:

	Empirical Formula	Molar Mass (g/mol)	Molecular Formula
(a)	CH	26.0	_____
(b)	CHO	116.1	_____
(c)	_____	_____	C_8H_{16}

86. Complete the following table:

	Empirical Formula	Molar Mass (g/mol)	Molecular Formula
(a)	$C_2H_3O_3$	150.0	_____
(b)	C_3H_8	44.1	_____
(c)	_____	_____	B_4H_{10}

87. Acetylene is a colorless gas used as a fuel in welding torches, among other things. It is 92.26% C and 7.74% H. Its molar mass is 26.02 g/mol. What are the empirical and molecular formulas of acetylene?

88. A large family of boron-hydrogen compounds has the general formula B_xH_y. One member of this family contains 88.5% B; the remainder is hydrogen. What is its empirical formula?

89. Cumene, a hydrocarbon, is a compound composed only of C and H. It is 89.94% carbon, and its molar mass is 120.2 g/mol. What are the empirical and molecular formulas of cumene?

90. In 2006, a Russian team discovered an interesting molecule they called "sulflower" because of its shape and because it was based on sulfur. It is composed of 57.17% S and 42.83% C and has a molar mass of 448.70 g/mol. Determine the empirical and molecular formulas of "sulflower."

91. Mandelic acid is an organic acid composed of carbon (63.15%), hydrogen (5.30%), and oxygen (31.55%). Its molar mass is 152.14 g/mol. Determine the empirical and molecular formulas of the acid.

92. Nicotine, a poisonous compound found in tobacco leaves, is 74.0% C, 8.65% H, and 17.35% N. Its molar mass is 162 g/mol. What are the empirical and molecular formulas of nicotine?

Determining Formulas from Mass Data

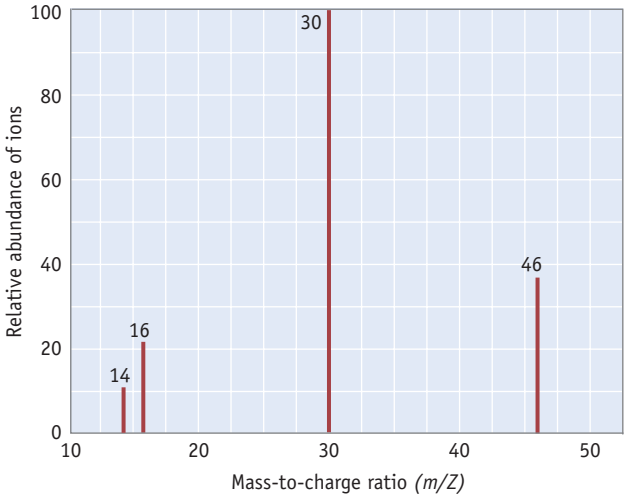
(See Examples 2.10 and 2.11.)

93. A compound containing xenon and fluorine was prepared by shining sunlight on a mixture of Xe (0.526 g) and excess F_2 gas. If you isolate 0.678 g of the new compound, what is its empirical formula?

94. Elemental sulfur (1.256 g) is combined with fluorine, F_2, to give a compound with the formula SF_x, a very stable, colorless gas. If you have isolated 5.722 g of SF_x, what is the value of x?

95. Epsom salt is used in tanning leather and in medicine. It is hydrated magnesium sulfate, $MgSO_4 \cdot 7\ H_2O$. The water of hydration is lost on heating, with the number lost depending on the temperature. Suppose you heat a 1.394-g sample at 100 °C and obtain 0.885 g of a partially hydrated sample, $MgSO_4 \cdot x\ H_2O$. What is the value of x?

96. You combine 1.25 g of germanium, Ge, with excess chlorine, Cl_2. The mass of product, Ge_xCl_y, is 3.69 g. What is the formula of the product, Ge_xCl_y?



Mass Spectrometry

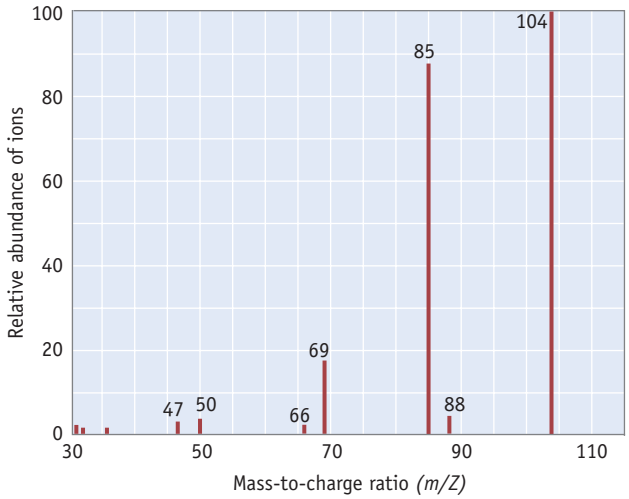
(See Section 2.8.)

97. The mass spectrum of nitrogen dioxide is illustrated here.

(a) Identify the cations present for each of the four peaks in the mass spectrum.

(b) Does the mass spectrum provide evidence that the two oxygen atoms are attached to a central nitrogen atom (ONO), or that an oxygen atom is at the center (NOO)? Explain.

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

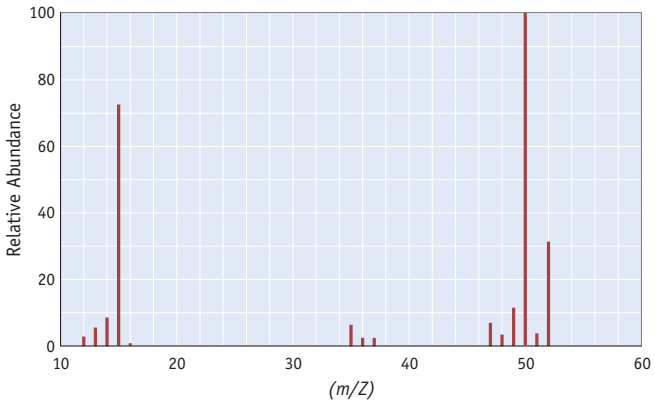


Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

98. The mass spectrum of phosphoryl chloride, POF_3, is illustrated here.

(a) Identify the cation fragment at a m/Z ratio of 85.

(b) Identify the cation fragment at a m/Z ratio of 69.



(c) Which two peaks in the mass spectrum provide evidence that the oxygen atom is connected to the phosphorus atom and is not connected to any of the three fluorine atoms?

99. The mass spectrum of CH_3Cl is illustrated here. You know that carbon has two stable isotopes, ^{12}C and ^{13}C with relative abundances of 98.9% and 1.1%, respectively, and chlorine has two isotopes, ^{35}Cl and ^{37}Cl with abundances of 75.77% and 24.23%, respectively.

(a) What molecular species gives rise to the lines at m/Z of 50 and 52? Why is the line at 52 about 1/3 the height of the line at 50?

(b) What species might be responsible for the line at $m/Z = 51$?

100. The highest mass peaks in the mass spectrum of Br_2 occur at m/Z 158, 160, and 162. The ratio of intensities of these peaks is approximately 1:2:1. Bromine has two stable isotopes, ^{79}Br (50.7% abundance) and ^{81}Br (49.3% abundance).

(a) What molecular species gives rise to each of these peaks?

(b) Explain the relative intensities of these peaks. (*Hint:* Consider the probabilities of each atom combination.)

General Questions

These questions are not designated as to type or location in the chapter. They may combine several concepts.

101. Fill in the blanks in the table (one column per element).

Symbol	^{58}Ni	^{33}S	_____	_____
Number of protons	_____	_____	10	_____
Number of neutrons	_____	_____	10	30
Number of electrons in the neutral atom	_____	_____	_____	25
Name of element	_____	_____	_____	_____

102. Potassium has three naturally occurring isotopes (^{39}K, ^{40}K, and ^{41}K), but ^{40}K has a very low natural abundance. Which of the other two isotopes is more abundant? Briefly explain your answer.

103. Crossword Puzzle: In the 2 × 2 box shown here, each answer must be correct four ways: horizontally, vertically, diagonally, and by itself. Instead of words, use symbols of elements. When the puzzle is complete, the four spaces will contain the overlapping symbols of 10 elements. There is only one correct solution.

1	2
3	4

Horizontal

1–2: two-letter symbol for a metal used in ancient times

3–4: two-letter symbol for a metal that burns in air and is found in Group 5A

Vertical

1–3: two-letter symbol for a metalloid

2–4: two-letter symbol for a metal used in U.S. coins

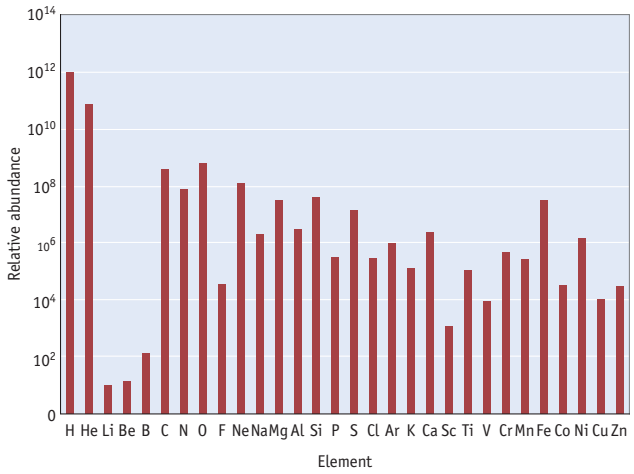
Single squares: All one-letter symbols



1: a colorful nonmetal
2: colorless, gaseous nonmetal
3: an element that makes fireworks green
4: an element that has medicinal uses

Diagonal

1–4: two-letter symbol for an element used in electronics
2–3: two-letter symbol for a metal used with Zr to make wires for superconducting magnets

This puzzle first appeared in *Chemical & Engineering News*, p. 86, December 14, 1987 (submitted by S. J. Cyvin) and in *Chem Matters*, October 1988.

104. The following chart shows a general decline in abundance with increasing mass among the first 30 elements. The decline continues beyond zinc. Notice that the scale on the vertical axis is logarithmic, that is, it progresses in powers of 10. The abundance of nitrogen, for example, is 1/10,000 ($1/10^4$) of the abundance of hydrogen. All abundances are plotted as the number of atoms per 10^{12} atoms of H. (The fact that the abundances of Li, Be, and B, as well as those of the elements near Fe, do not follow the general decline is a consequence of the way that elements are synthesized in stars.)

The abundance of the elements in the solar system from H to Zn

(a) What is the most abundant main group metal?
(b) What is the most abundant nonmetal?
(c) What is the most abundant metalloid?
(d) Which of the transition elements is most abundant?
(e) Which halogens are included on this plot, and which is the most abundant?

105. Copper atoms.
(a) What is the average mass of one copper atom?
(b) Students in a college computer science class once sued the college because they were asked to calculate the cost of one atom and could not do it. But you are in a chemistry course, and you can do this. (See E. Felsenthal, *Wall Street Journal*, May 9, 1995.) If the cost of 2.0-mm diameter copper wire (99.999% pure) is currently \$41.70 for 7.0 g, what is the cost of one copper atom?

106. Which of the following is impossible?
(a) silver foil that is 1.2×10^{-4} m thick
(b) a sample of potassium that contains 1.784×10^{24} atoms
(c) a gold coin of mass 1.23×10^{-3} kg
(d) 3.43×10^{-27} mol of S_8 molecules

107. Reviewing the periodic table.
(a) Name the element in Group 2A and the fifth period.
(b) Name the element in the fifth period and Group 4B.
(c) Which element is in the second period in Group 4A?
(d) Which element is in the fourth period in Group 5A?
(e) Which halogen is in the fifth period?
(f) Which alkaline earth element is in the third period?
(g) Which noble gas element is in the fourth period?
(h) Name the nonmetal in Group 6A and the third period.
(i) Name a metalloid in the fourth period.

108. Identify two nonmetallic elements that have allotropes and describe the allotropes of each.

109. In each case, decide which represents more mass:
(a) 0.5 mol of Na, 0.5 mol of Si, or 0.25 mol of U
(b) 9.0 g of Na, 0.50 mol of Na, or 1.2×10^{22} atoms of Na
(c) 10 atoms of Fe or 10 atoms of K

110. The recommended daily allowance (RDA) of iron for women 19–30 years old is 18 mg. How many moles is this? How many atoms?

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

111. Put the following elements in order from smallest to largest mass:

(a) 3.79×10^{24} atoms Fe
(b) 19.921 mol H_2
(c) 8.576 mol C
(d) 7.4 mol Si
(e) 9.221 mol Na
(f) 4.07×10^{24} atoms Al
(g) 9.2 mol Cl_2

112. ▲ When a sample of phosphorus burns in air, the compound P_4O_{10} forms. One experiment showed that 0.744 g of phosphorus formed 1.704 g of P_4O_{10}. Use this information to determine the ratio of the atomic weights of phosphorus and oxygen (mass P/mass O). If the atomic weight of oxygen is assumed to be 16.000, calculate the atomic weight of phosphorus.

113. ▲ Although carbon-12 is now used as the standard for atomic weights, this has not always been the case. Early attempts at classification used hydrogen as the standard, with the weight of hydrogen being set equal to 1.0000. Later attempts defined atomic weights using oxygen (with a weight of 16.0000). In each instance, the atomic weights of the other elements were defined relative to these masses. (To answer this question, you need more precise data on current atomic weights: H, 1.00794; O, 15.9994.)

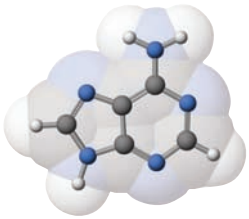
(a) If H = 1.0000 u was used as a standard for atomic weights, what would the atomic weight of oxygen be? What would be the value of Avogadro's number under these circumstances?

(b) Assuming the standard is O = 16.0000, determine the value for the atomic weight of hydrogen and the value of Avogadro's number.

114. A reagent occasionally used in chemical synthesis is sodium–potassium alloy. (Alloys are mixtures of metals, and Na-K has the interesting property that it is a liquid.) One formulation of the alloy (the one that melts at the lowest temperature) contains 68 atom percent K; that is, out of every 100 atoms, 68 are K and 32 are Na. What is the mass percent of potassium in sodium–potassium alloy?

115. Write formulas for all of the compounds that can be made by combining the cations NH_4^+ and Ni^{2+} with the anions CO_3^{2-} and SO_4^{2-}.

116. How many electrons are in a strontium atom (Sr)? Does an atom of Sr gain or lose electrons when forming an ion? How many electrons are gained or lost by the atom? When Sr forms an ion, the ion has the same number of electrons as which one of the noble gases?



117. Which of the following compounds has the highest mass percent of chlorine?

(a) BCl_3
(b) $AsCl_3$
(c) $GaCl_3$
(d) $AlCl_3$
(e) PCl_3

118. Which of the following samples has the largest number of ions?

(a) 1.0 g of $BeCl_2$
(b) 1.0 g of $MgCl_2$
(c) 1.0 g of CaS
(d) 1.0 g of $SrCO_3$
(e) 1.0 g of $BaSO_4$

119. The structure of one of the bases in DNA, adenine, is shown here. Which represents the greater mass: 40.0 g of adenine or 3.0×10^{23} molecules of the compound?

Adenine

120. Ionic and molecular compounds of the halogens.

(a) What are the names of BaF_2, $SiCl_4$, and $NiBr_2$?

(b) Which of the compounds in part (a) are ionic, and which are molecular?

(c) Which has the largest mass, 0.50 mol of BaF_2, 0.50 mol of $SiCl_4$, or 1.0 mol of $NiBr_2$?

121. A drop of water has a volume of about 0.050 mL. How many molecules of water are in a drop of water? (Assume water has a density of 1.00 g/cm^3.)

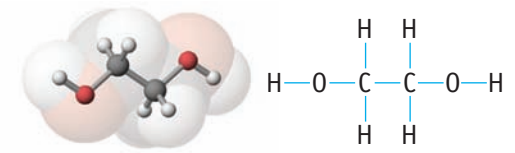
122. Capsaicin, the compound that gives the hot taste to chili peppers, has the formula $C_{18}H_{27}NO_3$.

(a) Calculate its molar mass.

(b) If you eat 55 mg of capsaicin, what amount (moles) have you consumed?

(c) Calculate the mass percent of each element in the compound.

(d) What mass of carbon (in milligrams) is there in 55 mg of capsaicin?



123. Calculate the molar mass and the mass percent of each element in the blue solid compound $Cu(NH_3)_4SO_4 \cdot H_2O$. What is the mass of copper and the mass of water in 10.5 g of the compound?

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

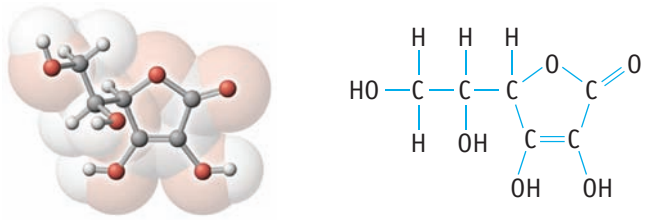
124. Write the molecular formula and calculate the molar mass for each of the molecules shown here. Which has the largest mass percent of carbon? Of oxygen?

(a) ethylene glycol (used in antifreeze)



Ethylene glycol

(b) dihydroxyacetone (used in artificial tanning lotions)

Dihydroxyacetone

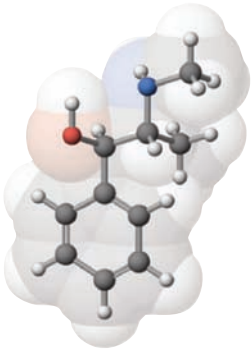
(c) ascorbic acid, commonly known as vitamin C

Ascorbic acid, vitamin C

125. Malic acid, an organic acid found in apples, contains C, H, and O in the following ratios: $C_1H_{1.50}O_{1.25}$. What is the empirical formula of malic acid?

126. Your doctor has diagnosed you as being anemic—that is, as having too little iron in your blood. At the drugstore, you find two iron-containing dietary supplements: one with iron(II) sulfate, $FeSO_4$, and the other with iron(II) gluconate, $Fe(C_6H_{11}O_7)_2$. If you take 100. mg of each compound, which will deliver more atoms of iron?

127. A compound composed of iron and carbon monoxide, $Fe_x(CO)_y$, is 30.70% iron. What is the empirical formula for the compound?



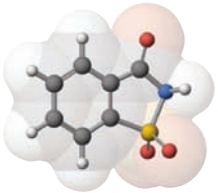
128. Ma huang, an extract from the ephedra species of plants, contains ephedrine. The Chinese have used this herb for more than 5000 years to treat asthma. More recently, ephedrine has been used in diet pills that can be purchased over the counter in herbal medicine shops. However, very serious concerns have been raised regarding these pills following reports that their use led to serious heart problems.

(a) A molecular model of ephedrine is drawn below. From this determine the molecular formula for ephedrine and calculate its molar mass.

(b) What is the weight percent of carbon in ephedrine?

(c) Calculate the amount (moles) of ephedrine in a 0.125 g sample.

(d) How many molecules of ephedrine are there in 0.125 g? How many C atoms?



Ephedrine

129. Saccharin, a molecular model of which is shown below, is more than 300 times sweeter than sugar. It was first made in 1897, when it was common practice for chemists to record the taste of any new substances they synthesized.

(a) Write the molecular formula for the compound, and draw its structural formula. (S atoms are yellow.)

(b) If you ingest 125 mg of saccharin, what amount (moles) of saccharin have you ingested?

(c) What mass of sulfur is contained in 125 mg of saccharin?

Saccharin

130. Name each of the following compounds and indicate which ones are best described as ionic:

(a) ClF_3
(b) NCl_3
(c) $SrSO_4$
(d) $Ca(NO_3)_2$
(e) XeF_4
(f) OF_2
(g) KI
(h) Al_2S_3
(i) PCl_3
(j) K_3PO_4

131. Write the formula for each of the following compounds and indicate which ones are best described as ionic:

(a) sodium hypochlorite
(b) boron triiodide
(c) aluminum perchlorate
(d) calcium acetate
(e) potassium permanganate
(f) ammonium sulfite
(g) potassium dihydrogen phosphate
(h) disulfur dichloride
(i) chlorine trifluoride
(j) phosphorus trifluoride

132. Complete the table by placing symbols, formulas, and names in the blanks.

Cation	Anion	Name	Formula
_____	_____	ammonium bromide	_____
Ba^{2+}	_____	_____	BaS
_____	Cl^-	iron(II) chloride	_____
_____	F^-	_____	PbF_2
Al^{3+}	CO_3^{2-}	_____	_____
_____	_____	iron(III) oxide	_____

133. Empirical and molecular formulas.

(a) Fluorocarbonyl hypofluorite is composed of 14.6% C, 39.0% O, and 46.3% F. The molar mass of the compound is 82 g/mol. Determine the empirical and molecular formulas of the compound.

(b) Azulene, a beautiful blue hydrocarbon, is 93.71% C and has a molar mass of 128.16 g/mol. What are the empirical and molecular formulas of azulene?

134. Cacodyl, a compound containing arsenic, was reported in 1842 by the German chemist Robert Wilhelm Bunsen. It has an almost intolerable garlic-like odor. Its molar mass is 210 g/mol, and it is 22.88% C, 5.76% H, and 71.36% As. Determine its empirical and molecular formulas.

135. The action of bacteria on meat and fish produces a compound called cadaverine. As its name and origin imply, it stinks! (It is also present in bad breath and adds to the odor of urine.) It is 58.77% C, 13.81% H, and 27.40% N. Its molar mass is 102.2 g/mol. Determine the molecular formula of cadaverine.

136. ▲ In the laboratory you combine 0.125 g of nickel with CO and isolate 0.364 g of $Ni(CO)_x$. What is the value of x?

137. ▲ A compound called MMT was once used to boost the octane rating of gasoline. What is the empirical formula of MMT if it is 49.5% C, 3.2% H, 22.0% O, and 25.2% Mn?

138. ▲ Elemental phosphorus is made by heating calcium phosphate with carbon and sand in an electric furnace. What is the mass percent of phosphorus in calcium phosphate? Use this value to calculate the mass of calcium phosphate (in kilograms) that must be used to produce 15.0 kg of phosphorus.

139. ▲ Chromium is obtained by heating chromium(III) oxide with carbon. Calculate the mass percent of chromium in the oxide, and then use this value to calculate the quantity of Cr_2O_3 required to produce 850 kg of chromium metal.

140. ▲ Stibnite, Sb_2S_3, is a dark gray mineral from which antimony metal is obtained. What is the mass percent of antimony in the sulfide? If you have 1.00 kg of an ore that contains 10.6% antimony, what mass of Sb_2S_3 (in grams) is in the ore?

141. ▲ Direct reaction of iodine (I_2) and chlorine (Cl_2) produces an iodine chloride, I_xCl_y, a bright yellow solid. If you completely consume 0.678 g of I_2 in a reaction with excess Cl_2 and produce 1.246 g of I_xCl_y, what is the empirical formula of the compound? A later experiment showed that the molar mass of I_xCl_y was 467 g/mol. What is the molecular formula of the compound?

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

142. ▲ In a reaction, 2.04 g of vanadium combined with 1.93 g of sulfur to give a pure compound. What is the empirical formula of the product?

143. ▲ Iron pyrite, often called "fool's gold," has the formula FeS_2. If you could convert 15.8 kg of iron pyrite to iron metal, what mass of the metal would you obtain?

144. Which of the following statements about 57.1 g of octane, C_8H_{18}, is (are) *not* true?

(a) 57.1 g is 0.500 mol of octane.

(b) The compound is 84.1% C by weight.

(c) The empirical formula of the compound is C_4H_9.

(d) 57.1 g of octane contains 28.0 g of hydrogen atoms.

145. The formula of barium molybdate is $BaMoO_4$. Which of the following is the formula of sodium molybdate?

(a) Na_4MoO (d) Na_2MoO_4

(b) $NaMoO$ (e) Na_4MoO_4

(c) Na_2MoO_3

146. ▲ A metal M forms a compound with the formula MCl_4. If the compound is 74.75% chlorine, what is the identity of M?

147. Pepto-Bismol, which can help provide relief for an upset stomach, contains 300. mg of bismuth subsalicylate, $C_{21}H_{15}Bi_3O_{12}$, per tablet. If you take two tablets for your stomach distress, what amount (in moles) of the "active ingredient" are you taking? What mass of Bi are you consuming in two tablets?

148. ▲ The weight percent of oxygen in an oxide that has the formula MO_2 is 15.2%. What is the molar mass of this compound? What element or elements are possible for M?

149. The mass of 2.50 mol of a compound with the formula ECl_4, in which E is a nonmetallic element, is 385 g. What is the molar mass of ECl_4? What is the identity of E?

150. ▲ The elements A and Z combine to produce two different compounds: A_2Z_3 and AZ_2. If 0.15 mol of A_2Z_3 has a mass of 15.9 g and 0.15 mol of AZ_2 has a mass of 9.3 g, what are the atomic weights of A and Z?

151. ▲ Polystyrene can be prepared by heating styrene with tribromobenzoyl peroxide in the absence of air. A sample prepared by this method has the empirical formula $Br_3C_6H_3(C_8H_8)_n$, where the value of n can vary from sample to sample. If one sample has 0.105% Br, what is the value of n?

152. A sample of hemoglobin is found to be 0.335% iron. What is the molar mass of hemoglobin if there are four iron atoms per molecule?

153. ▲ Consider an atom of ^{64}Zn.

(a) Calculate the density of the nucleus in grams per cubic centimeter, knowing that the nuclear radius is 4.8×10^{-6} nm and the mass of the ^{64}Zn atom is 1.06×10^{-22} g. (Recall that the volume of a sphere is $[4/3]\pi r^3$.)

(b) Calculate the density of the space occupied by the electrons in the zinc atom, given that the atomic radius is 0.125 nm and the electron mass is 9.11×10^{-28} g.

(c) Having calculated these densities, what statement can you make about the relative densities of the parts of the atom?

154. ▲ Estimating the radius of a lead atom.

(a) You are given a cube of lead that is 1.000 cm on each side. The density of lead is 11.35 g/cm^3. How many atoms of lead are in the sample?

(b) Atoms are spherical; therefore, the lead atoms in this sample cannot fill all the available space. As an approximation, assume that 60% of the space of the cube is filled with spherical lead atoms. Calculate the volume of one lead atom from this information. From the calculated volume (V) and the formula $(4/3)\pi r^3$ for the volume of a sphere, estimate the radius (r) of a lead atom.

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

155. A piece of nickel foil, 0.550 mm thick and 1.25 cm square, is allowed to react with fluorine, F_2, to give a nickel fluoride.

(a) How many moles of nickel foil were used? (The density of nickel is 8.902 g/cm^3.)

(b) If you isolate 1.261 g of the nickel fluoride, what is its formula?

(c) What is its complete name?

156. ▲ Uranium is used as a fuel, primarily in the form of uranium(IV) oxide, in nuclear power plants. This question considers some uranium chemistry.

(a) A small sample of uranium metal (0.169 g) is heated to between 800 and 900 °C in air to give 0.199 g of a dark green oxide, U_xO_y. How many moles of uranium metal were used? What is the empirical formula of the oxide, U_xO_y? What is the name of the oxide? How many moles of U_xO_y must have been obtained?

(b) The naturally occurring isotopes of uranium are ^{234}U, ^{235}U, and ^{238}U. Knowing that uranium's atomic weight is 238.02 g/mol, which isotope must be the most abundant?

(c) If the hydrated compound $UO_2(NO_3)_2 \cdot z\ H_2O$ is heated gently, the water of hydration is lost. If you have 0.865 g of the hydrated compound and obtain 0.679 g of $UO_2(NO_3)_2$ on heating, how many waters of hydration are in each formula unit of the original compound? (The oxide U_xO_y is obtained if the hydrate is heated to temperatures over 800 °C in the air.)

157. In an experiment, you need 0.125 mol of sodium metal. Sodium can be cut easily with a knife (Figure 2.5), so if you cut out a block of sodium, what should the volume of the block be in cubic centimeters? If you cut a perfect cube, what is the length of the edge of the cube? (The density of sodium is 0.97 g/cm^3.)

158. Mass spectrometric analysis showed that there are four isotopes of an unknown element having the following masses and abundances:

Isotope	Mass Number	Isotope Mass	Abundance (%)
1	136	135.9090	0.193
2	138	137.9057	0.250
3	140	139.9053	88.48
4	142	141.9090	11.07

Three elements in the periodic table that have atomic weights near these values are lanthanum (La), atomic number 57, atomic weight 138.9055; cerium (Ce), atomic number 58, atomic weight 140.115; and praseodymium (Pr), atomic number 59, atomic weight 140.9076. Using the data above, calculate the atomic weight, and identify the element if possible.

In the Laboratory

159. If Epsom salt, $MgSO_4 \cdot x\ H_2O$, is heated to 250 °C, all the water of hydration is lost. On heating a 1.687-g sample of the hydrate, 0.824 g of $MgSO_4$ remains. How many molecules of water occur per formula unit of $MgSO_4$?

160. The "alum" used in cooking is potassium aluminum sulfate hydrate, $KAl(SO_4)_2 \cdot x\ H_2O$. To find the value of x, you can heat a sample of the compound to drive off all of the water and leave only $KAl(SO_4)_2$. Assume you heat 4.74 g of the hydrated compound and that the sample loses 2.16 g of water. What is the value of x?

161. Tin metal (Sn) and purple iodine (I_2) combine to form orange, solid tin iodide with an unknown formula.

$$\text{Sn metal} + \text{solid } I_2 \rightarrow \text{solid } Sn_xI_y$$

Weighed quantities of Sn and I_2 are combined, where the quantity of Sn is more than is needed to react with all of the iodine. After Sn_xI_y has been formed, it is isolated by filtration. The mass of excess tin is also determined. The following data were collected:

Mass of tin (Sn) in the original mixture	1.056 g
Mass of iodine (I_2) in the original mixture	1.947 g
Mass of tin (Sn) recovered after reaction	0.601 g

What is the empirical formula of the tin iodide obtained?

162. ▲ When analyzed, an unknown compound gave these experimental results: C, 54.0%; H, 6.00%; and O, 40.0%. Four different students used these values to calculate the empirical formulas shown here. Which answer is correct? Why did some students not get the correct answer?

(a) $C_4H_5O_2$ (c) $C_7H_{10}O_4$

(b) $C_5H_7O_3$ (d) $C_9H_{12}O_5$

163. ▲ Two general chemistry students working together in the lab weigh out 0.832 g of $CaCl_2 \cdot 2\ H_2O$ into a crucible. After heating the sample for a short time and allowing the crucible to cool, the students determine that the sample has a mass of 0.739 g. They then do a quick calculation. On the basis of this calculation, what should they do next?

(a) Congratulate themselves on a job well done.

(b) Assume the bottle of $CaCl_2 \cdot 2\ H_2O$ was mislabeled; it actually contained something different.

(c) Heat the crucible again, and then reweigh it.

164. To find the empirical formula of tin oxide, you first react tin metal with nitric acid in a porcelain crucible. The metal is converted to tin nitrate, but, on heating the nitrate strongly, brown nitrogen dioxide gas is evolved and tin oxide is formed. In the laboratory you collect the following data:

Mass of crucible	13.457 g
Mass of crucible plus tin	14.710 g
Mass of crucible after heating	15.048 g

What is the empirical formula of tin oxide?

Summary and Conceptual Questions

The following questions may use concepts from this and the previous chapter.

165. ▲ Identify, from the list below, the information needed to calculate the number of atoms in 1.00 cm^3 of iron. Outline the procedure used in this calculation.

(a) the structure of solid iron

(b) the molar mass of iron

(c) Avogadro's number

(d) the density of iron

(e) the temperature

(f) iron's atomic number

(g) the number of iron isotopes

166. Consider the plot of relative element abundances on page 114. Is there a relationship between abundance and atomic number? Is there any difference between the relative abundance of an element of even atomic number and the relative abundance of an element of odd atomic number?

167. The photo here depicts what happens when a coil of magnesium ribbon and a few calcium chips are placed in water.

(a) Based on these observations, what might you expect to see when barium, another Group 2A element, is placed in water?

(b) Give the period in which each element (Mg, Ca, and Ba) is found. What correlation do you think you might find between the reactivity of these elements and their positions in the periodic table?

168. A jar contains some number of jelly beans. To find out precisely how many are in the jar, you could dump them out and count them. How could you estimate their number without counting each one? (Chemists need to do just this kind of "bean counting" when they work with atoms and molecules. Atoms and molecules are too small to count one by one, so chemists have worked out other methods to determine the number of atoms in a sample.)

CHAPTER OUTLINE

3.1 Introduction to Chemical Equations

3.2 Balancing Chemical Equations

3.3 Introduction to Chemical Equilibrium

3.4 Aqueous Solutions

3.5 Precipitation Reactions

3.6 Acids and Bases

3.7 Gas-Forming Reactions

3.8 Oxidation–Reduction Reactions

3.9 Classifying Reactions in Aqueous Solution

3.1 Introduction to Chemical Equations

Goals for Section 3.1

- Understand the information conveyed by a balanced chemical equation including the terminology used (reactants, products, stoichiometry, stoichiometric coefficients).
- Recognize that a balanced chemical equation is required by the law of conservation of matter.

When a stream of chlorine gas, Cl_2, is directed onto solid phosphorus, P_4, the mixture bursts into flame, and a chemical reaction produces liquid phosphorus trichloride, PCl_3 (Figure 3.1). We can depict this reaction using a **balanced chemical equation**.

$$\underbrace{P_4(s) + 6\ Cl_2(g)}_{\text{reactants}} \longrightarrow \underbrace{4\ PCl_3(\ell)}_{\text{product}}$$

In a chemical equation, the formulas for the **reactants** (the substances combined in the reaction) are written to the left of the arrow and the formulas of the **products** (the substances produced) are written to the right of the arrow. The physical states of reactants and products can also be indicated. The symbol (s) indicates a solid, (g) a gas, and (ℓ) a liquid. A substance dissolved in water, that is, in an *aq*ueous solution, is indicated by (aq).

States of Reactants and Products Including the states of each species (s, ℓ, g, aq) provides useful information to the reader. This practice is optional, however, and you will see equations written without this information elsewhere in this text.

◀ **Chemical reactions are at the heart of chemistry.** Here we picture four general types of reactions: **precipitation, acid-base, gas-forming,** and **redox.**

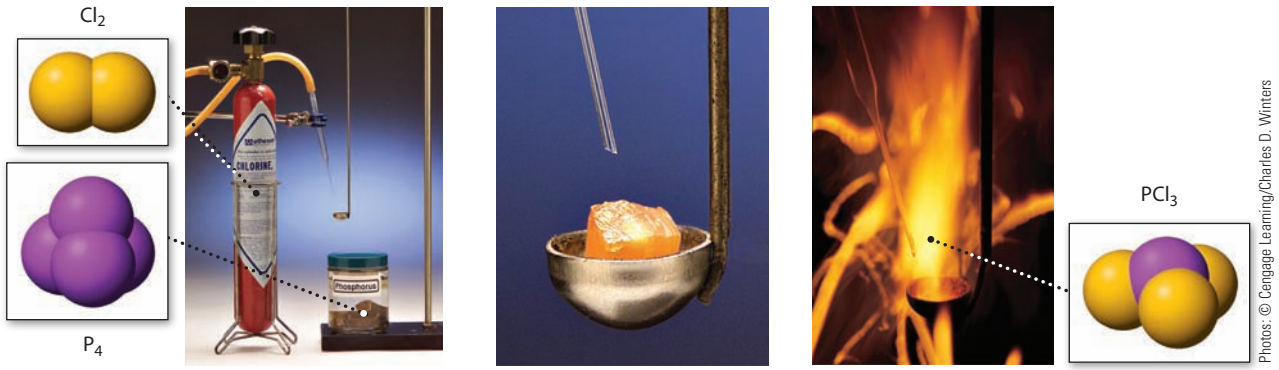

Figure 3.1 Reaction of solid white phosphorus with chlorine gas. The product is liquid phosphorus trichloride.

A CLOSER LOOK

Antoine Laurent Lavoisier, 1743–1794

On Monday, August 7, 1774, the Englishman Joseph Priestley (1733–1804) isolated oxygen. (The Swedish chemist Carl Scheele [1742–1786] also discovered the element, perhaps in 1773, but did not publish his results until later.) To obtain oxygen, Priestley heated mercury(II) oxide, HgO, causing it to decompose to mercury and oxygen.

$$2\ HgO(s) \rightarrow 2\ Hg(\ell) + O_2(g)$$

Priestley did not immediately understand the significance of the discovery, but he mentioned it to the French chemist Antoine Lavoisier in October 1774. One of Lavoisier's contributions to science was his recognition of the importance of exact scientific measurements and of carefully planned experiments, and he applied these methods to the study of oxygen. From this work, Lavoisier proposed that oxygen was an element, that it was one of the constituents of the compound water, and that burning involved a reaction with oxygen. He also mistakenly came to believe Priestley's gas was present in all acids, so he named it "oxygen" from the Greek words meaning "to form an acid."

© Cengage Learning/Charles D. Winters

The decomposition of red mercury(II) oxide. The decomposition reaction gives mercury metal and oxygen gas. The mercury is seen as a film on the surface of the test tube.

In other experiments, Lavoisier observed that the heat produced by a guinea pig when exhaling a given amount of carbon dioxide is similar to the quantity of heat produced by burning carbon to give the same amount of carbon dioxide. From these and other experiments he concluded that, "Respiration is a combustion, slow it is true, but otherwise perfectly similar to that of charcoal." Although he did not understand the details of the process, this was an important step in the development of biochemistry.

Lavoisier was a prodigious scientist, and the principles of naming chemical substances that he introduced are still in use today. Furthermore, he wrote a textbook in which he applied the principles of the conservation of matter to chemistry, and he used the idea to write early versions of chemical equations.

Because Lavoisier was an aristocrat, he came under suspicion during the Reign of Terror of the French Revolution in 1794. He was an investor in the Ferme Générale, the infamous tax-collecting organization in 18th-century France. Tobacco was a monopoly product of the Ferme Générale, and it was common to cheat the purchaser by adding water to the tobacco, a practice that Lavoisier opposed. Nonetheless, because of his involvement with the Ferme, his career was cut short by the guillotine on May 8, 1794, on the charge of "adding water to the people's tobacco."

In the 18th century, the French scientist Antoine Lavoisier (1743–1794) introduced the **law of conservation of matter**, which states that *matter can neither be created nor destroyed*. This means that if the total mass of reactants is 10 g, and if the reaction completely converts reactants to products, you must end up with 10 g of products. This also means that if 1000 atoms of a particular element are contained in the reactants, then those 1000 atoms must appear in the products in some fashion. *Atoms, and thus mass, are conserved in chemical reactions.*

When applied to the reaction of phosphorus and chlorine, the law of conservation of matter tells us that 1 molecule of phosphorus, P_4 (with 4 phosphorus atoms), and 6 molecules of Cl_2 (with 12 atoms of Cl) will produce 4 molecules of PCl_3. Because each PCl_3 molecule contains 1 P atom and 3 Cl atoms, 4 PCl_3 molecules are needed to account for 4 P atoms and 12 Cl atoms in the product. The equation is *balanced*; the same number of P and Cl atoms appear on each side of the equation.

In a chemical reaction, the relationship between the amounts of chemical reactants and products is called **stoichiometry** (pronounced "stoy-key-AHM-uh-tree"). The coefficients in a balanced equation are called **stoichiometric coefficients**. (In the P_4 and Cl_2 equation, these are 1, 6, and 4.) They can be interpreted as a number of atoms or molecules: 1 molecule of P_4 and 6 molecules of Cl_2. They can refer equally well to amounts of reactants and products: 1 mole of P_4 combines with 6 moles of Cl_2 to produce 4 moles of PCl_3.

3.2 Balancing Chemical Equations

Goal for Section 3.2

- Balance simple chemical equations.

A balanced equation is one in which the same number of atoms of each element appears on each side of the equation. The process of balancing equations involves assigning the correct stoichiometric coefficients. Many chemical equations can be balanced by trial and error, and this is the method that will often be used. However, more systematic methods exist and are especially useful if reactions are complicated.

One general class of chemical reactions is the reaction of metals or nonmetals with oxygen to give oxides of the general formula M_xO_y. For example, iron reacts with oxygen to give iron(III) oxide (Figure 3.2a).

$$4\ Fe(s) + 3\ O_2(g) \rightarrow 2\ Fe_2O_3(s)$$

The nonmetals sulfur and oxygen react to form sulfur dioxide (Figure 3.2b),

$$S(s) + O_2(g) \rightarrow SO_2(g)$$

and phosphorus, P_4, reacts vigorously with oxygen to give tetraphosphorus decaoxide, P_4O_{10} (Figure 3.2c).

$$P_4(s) + 5\ O_2(g) \rightarrow P_4O_{10}(s)$$

The equations written above are balanced. The same number of iron, sulfur, or phosphorus atoms and oxygen atoms occurs on each side of these equations.

Figure 3.3 **A combustion reaction.** Here, propane, C_3H_8, burns to give CO_2 and H_2O. These simple oxides are always the products of the complete combustion of a hydrocarbon.

When balancing chemical equations, there are two important things to remember:

- Formulas for reactants and products must be correct. Once the correct formulas for the reactants and products have been determined, the subscripts in their formulas cannot be changed to balance an equation. Changing the subscripts changes the identity of the substance. For example, you cannot change CO_2 to CO to balance an equation; carbon monoxide, CO, and carbon dioxide, CO_2, are different compounds.
- Chemical equations are balanced using stoichiometric coefficients. The entire chemical formula of a substance is multiplied by the stoichiometric coefficient.

Every day, you encounter **combustion** reactions, the burning of a fuel in oxygen accompanied by the evolution of energy as heat (Figure 3.3). The combustion of octane, C_8H_{18}, a component of gasoline is an example.

$$2\ C_8H_{18}(\ell) + 25\ O_2(g) \rightarrow 16\ CO_2(g) + 18\ H_2O(g)$$

In all combustion reactions, some or all of the elements in the reactants end up as oxides, compounds containing oxygen. When the reactant is a hydrocarbon (a compound that contains only C and H, such as octane), the products of complete combustion are carbon dioxide and water.

To illustrate equation balancing, let us write the balanced equation for the complete combustion of propane, C_3H_8, a common fuel.

Step 1 *Write correct formulas for the reactants and products.* Here propane and oxygen are the reactants, and carbon dioxide and water are the products.

$$C_3H_8(g) + O_2(g) \xrightarrow{\text{unbalanced equation}} CO_2(g) + H_2O(g)$$

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Step 2 *Balance the C atoms.* In combustion reactions such as this it is usually best to balance the carbon atoms first and leave the oxygen atoms until the end (because oxygen atoms are often found in more than one product). In this case three carbon atoms are in the reactants, so three must occur in the products. Three CO_2 molecules are therefore required on the right side.

$$C_3H_8(g) + O_2(g) \xrightarrow{\text{unbalanced equation}} 3\ CO_2(g) + H_2O(g)$$

Step 3 *Balance the H atoms.* A molecule of propane contains 8 H atoms. Each molecule of water has two hydrogen atoms, so four molecules of water account for the required eight hydrogen atoms on the right side.

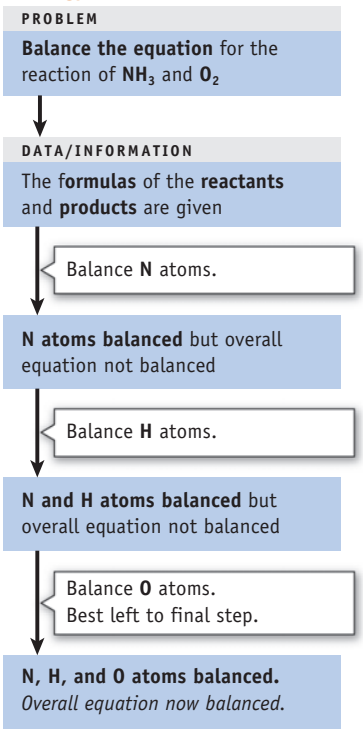
$$C_3H_8(g) + O_2(g) \xrightarrow{\text{unbalanced equation}} 3\ CO_2(g) + 4\ H_2O(g)$$

Step 4 *Balance the O atoms.* Ten oxygen atoms are on the right side ($3 \times 2 = 6$ in CO_2 plus $4 \times 1 = 4$ in H_2O). Five O_2 molecules are needed to supply the required ten oxygen atoms.

$$C_3H_8(g) + 5\ O_2(g) \xrightarrow{\text{balanced equation}} 3\ CO_2(g) + 4\ H_2O(g)$$

Step 5 *Verify that the number of atoms of each element is balanced.* There are three carbon atoms, eight hydrogen atoms, and ten oxygen atoms on each side of the equation.

EXAMPLE 3.1



Balancing an Equation for a Combustion Reaction

Problem Write the balanced equation for the combustion of ammonia gas (NH_3) to give water vapor and nitrogen monoxide gas (NO).

What Do You Know? You know the correct formulas and/or names for the reactants (NH_3 and oxygen, O_2) and the products (H_2O and nitrogen monoxide, NO). You also know their states.

Strategy First write the unbalanced equation. Next balance the N atoms, then the H atoms, and finally the O atoms.

Strategy Map 3.1

SOLUTION

Step 1. *Write out the equation using correct formulas for the reactants and products. The reactants are $NH_3(g)$ and $O_2(g)$, and the products are $NO(g)$ and $H_2O(g)$.*

$$NH_3(g) + O_2(g) \xrightarrow{\text{unbalanced equation}} NO(g) + H_2O(g)$$

Step 2. *Balance the N atoms. There is one N atom on each side of the equation. The N atoms are in balance, at least for the moment.*

$$NH_3(g) + O_2(g) \xrightarrow{\text{unbalanced equation}} NO(g) + H_2O(g)$$

Step 3. *Balance the H atoms. There are three H atoms on the left and two on the right. To have the same number on each side (6), use two molecules of NH_3 on the left and three molecules of H_2O on the right (which gives us six H atoms on each side).*

$$2\ NH_3(g) + O_2(g) \xrightarrow{\text{unbalanced equation}} NO(g) + 3\ H_2O(g)$$

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Notice that when we balance the H atoms, the N atoms are no longer balanced. To bring them into balance, use 2 NO molecules on the right.

$$2\ NH_3(g) + O_2(g) \xrightarrow{\text{unbalanced equation}} 2\ NO(g) + 3\ H_2O(g)$$

Step 4. *Balance the O atoms. After Step 3, there is an even number of O atoms (two) on the left and an odd number (five) on the right. Because there cannot be an odd number of O atoms on the left (O atoms are paired in O_2 molecules), multiply each coefficient on both sides of the equation by 2 so that an even number of oxygen atoms (10) now occurs on the right side:*

$$4\ NH_3(g) + O_2(g) \xrightarrow{\text{unbalanced equation}} 4\ NO(g) + 6\ H_2O(g)$$

Now the oxygen atoms can be balanced by having five O_2 molecules on the left side of the equation:

$$4\ NH_3(g) + 5\ O_2(g) \xrightarrow{\text{balanced equation}} 4\ NO(g) + 6\ H_2O(g)$$

Step 5. *Verify the result. Four N atoms, 12 H atoms, and 10 O atoms occur on each side of the equation.*

Think about Your Answer An alternative way to write this equation is

$$2\ NH_3(g) + {}^5/_2\ O_2(g) \rightarrow 2\ NO(g) + 3\ H_2O(g)$$

where a fractional coefficient has been used. This equation is correctly balanced. In general, however, we balance equations with whole-number coefficients.

Check Your Understanding

(a) Butane gas, C_4H_{10}, can burn completely in air [use $O_2(g)$ as the other reactant] to give carbon dioxide gas and water vapor. Write a balanced equation for this combustion reaction.

(b) Write a balanced chemical equation for the complete combustion of $C_3H_7BO_3$, a gasoline additive. The products of combustion are $CO_2(g)$, $H_2O(g)$, and $B_2O_3(s)$.

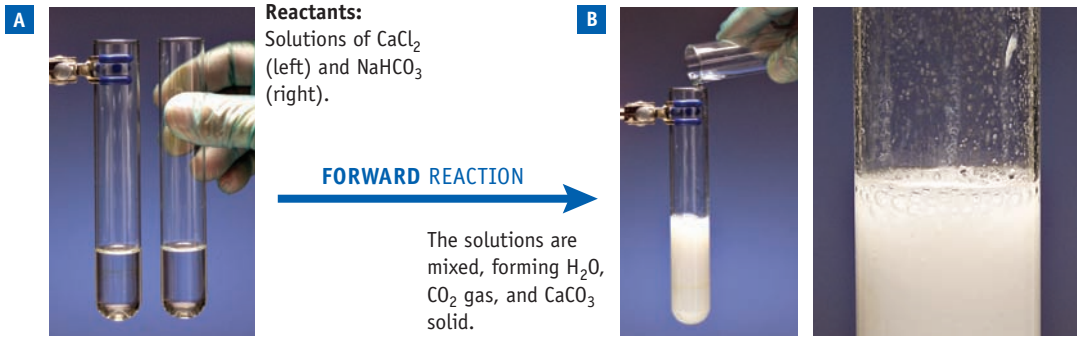
Art Palmer

Figure 3.4 Cave chemistry. Calcium carbonate stalactites cling to the roof of a cave, and stalagmites grow up from the cave floor. The chemistry producing these formations is a good example of the reversibility of chemical reactions.

3.3 Introduction to Chemical Equilibrium

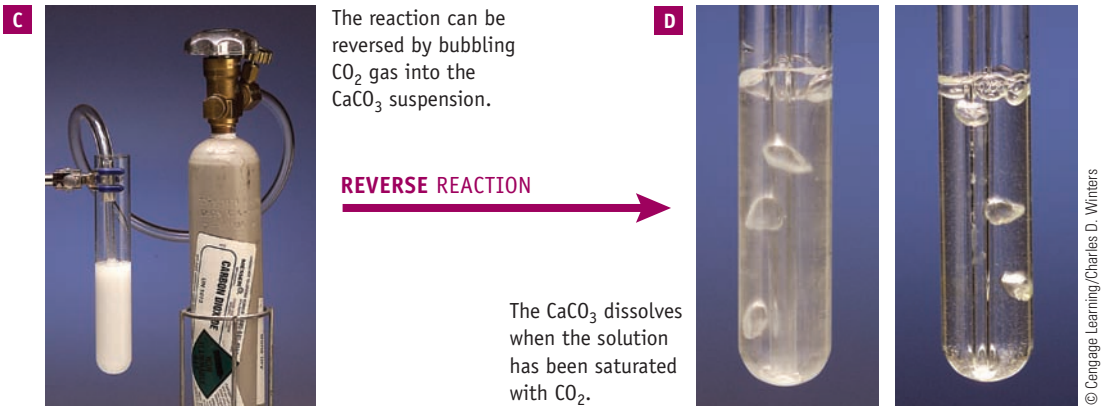
Goals for Section 3.3

- Recognize that all chemical reactions are reversible and that reactions eventually reach a dynamic equilibrium.
- Recognize the difference between reactant-favored and product-favored reactions at equilibrium.



To this point, we have treated chemical reactions as proceeding in one direction only, with reactants being converted *completely* to products. Nature, however, is more complex than this. All chemical reactions are reversible, in principle, and many reactions lead to incomplete conversion of reactants to products.

The formation of stalactites and stalagmites in a limestone cave is an example of a system that depends on the reversibility of a chemical reaction (Figure 3.4). Stalactites and stalagmites are made chiefly of calcium carbonate, a mineral found in underground deposits in the form of limestone, a leftover from ancient oceans. If water seeping through the limestone contains dissolved CO_2, a reaction occurs in which the mineral dissolves, giving an aqueous solution of $Ca(HCO_3)_2$.



$$CaCO_3(s) + CO_2(aq) + H_2O(\ell) \rightarrow Ca(HCO_3)_2(aq)$$

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Solutions of $CaCl_2$ (a source of Ca^{2+} ions) and $NaHCO_3$ (a source of HCO_3^- ions) are mixed and produce a precipitate of $CaCO_3$ and CO_2 gas.

© Cengage Learning/Charles D. Winters

If CO_2 gas is bubbled into a suspension of $CaCO_3$, solid $CaCO_3$ and gaseous CO_2 react to produce Ca^{2+} and HCO_3^- ions in solution.

Figure 3.5 The reversibility of chemical reactions. The experiments here demonstrate the reversibility of chemical reactions. The system is described by the following balanced chemical equation:

$$Ca^{2+}(aq) + 2\ HCO_3^-(aq) \rightleftharpoons CaCO_3(s) + CO_2(g) + H_2O(\ell)$$

When the mineral-laden water reaches a cave, the reverse reaction occurs, with CO_2 being evolved into the cave and solid $CaCO_3$ being deposited.

$$Ca(HCO_3)_2(aq) \rightarrow CaCO_3(s) + CO_2(g) + H_2O(\ell)$$

As illustrated in Figure 3.5, these reactions can be done in a laboratory.

Another example of a reversible reaction is the reaction of nitrogen with hydrogen to form ammonia gas, a compound made industrially in enormous quantities and used directly as a fertilizer and in the production of other chemicals.

$$N_2(g) + 3\ H_2(g) \rightarrow 2\ NH_3(g)$$

Nitrogen and hydrogen react to form ammonia, but, under the conditions of the reaction, ammonia also breaks down into nitrogen and hydrogen in the reverse reaction.

$$2\ NH_3(g) \rightarrow N_2(g) + 3\ H_2(g)$$

Let us consider what would happen if we mixed nitrogen and hydrogen in a closed container under the proper conditions for the reaction to occur. At first, N_2 and H_2 react to produce some ammonia. As the ammonia is produced, however,

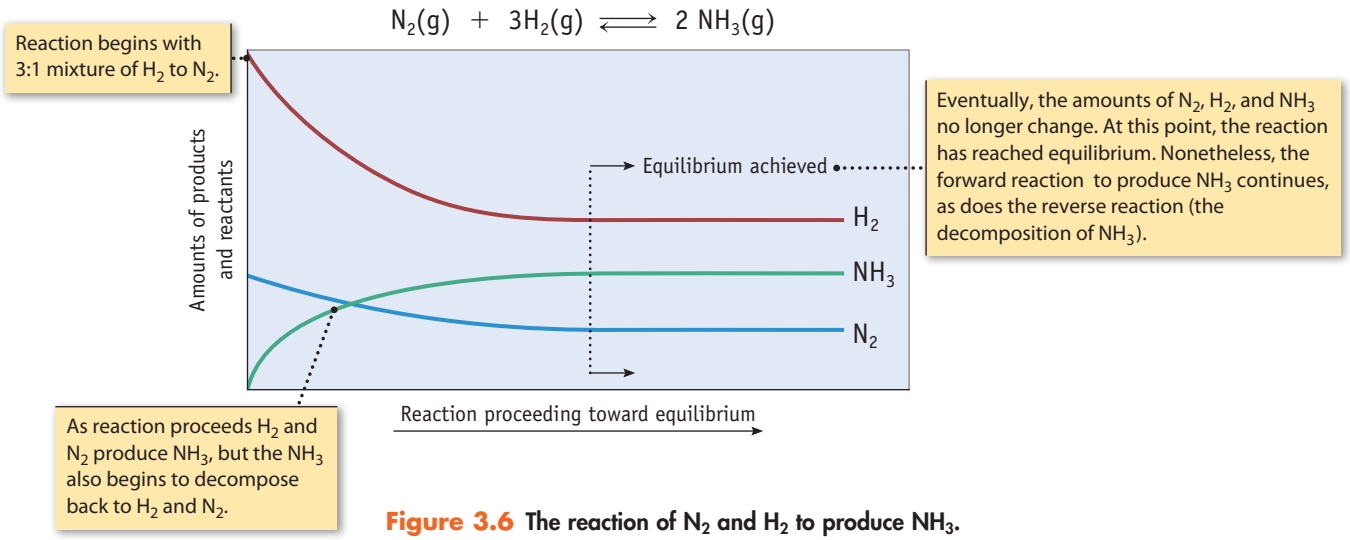

Figure 3.6 **The reaction of N_2 and H_2 to produce NH_3.**

some NH_3 molecules decompose to re-form nitrogen and hydrogen in the reverse reaction (Figure 3.6). At the beginning of the process, the forward reaction to give NH_3 predominates, but, as the reactants are consumed, the rate (or speed) of the forward reaction progressively slows. At the same time, the reverse reaction speeds up as the amount of ammonia increases. Eventually, the rate of the forward reaction will equal the rate of the reverse reaction. At this point, no further *macroscopic* change is observed; the amounts of nitrogen, hydrogen, and ammonia in the container stop changing (although the forward and reverse reactions continue). We say the system has reached **chemical equilibrium**. The reaction vessel will contain all three substances—nitrogen, hydrogen, and ammonia. Because the forward and reverse processes are still occurring we refer to this state as a **dynamic equilibrium**. Systems in dynamic equilibrium are represented by writing a double arrow symbol ($\rightleftharpoons$) connecting the reactants and products.

$$N_2(g) + 3\,H_2(g) \rightleftharpoons 2\,NH_3(g)$$

An important principle in chemistry is that chemical reactions always proceed spontaneously toward equilibrium. A reaction will never proceed spontaneously in a direction that takes a system further from equilibrium.

Quantitative Description of Chemical Equilibrium As you shall see in Chapters 15–17, the extent to which a reaction is product-favored can be described by a mathematical expression called the *equilibrium constant expression*. Each chemical reaction has a numerical value for the equilibrium constant, symbolized by *K*. Product-favored reactions have large values of *K*; small *K* values indicate reactant-favored reactions.

A key question is "When a reaction reaches equilibrium, will the reactants be converted largely to products or will most of the reactants still be present?" For the present it is useful to define **product-favored reactions** as *reactions in which reactants are completely or largely converted to products when equilibrium is reached*. The combustion reactions we have been studying are examples of reactions that are product-favored at equilibrium. In fact, most of the reactions you will study in the rest of this chapter are product-favored reactions at equilibrium. We usually write the equations for reactions that are very product-favored using a single arrow ($\rightarrow$) connecting reactants and products.

The opposite of a product-favored reaction is one that is **reactant-favored** at equilibrium. Such reactions lead to the conversion of only a small amount of the reactants to products. An example of a reactant-favored reaction is the ionization of acetic acid in water where only a tiny fraction of the acid produces ions.

$$CH_3CO_2H(aq) + H_2O(\ell) \rightleftharpoons CH_3CO_2^-(aq) + H_3O^+(aq)$$

Acetic acid is an example of a large number of acids called "weak acids" because the reaction with water is reactant-favored at equilibrium and only a few percent of the molecules react with water to form ionic products.

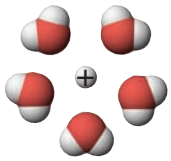
3.4 Aqueous Solutions

Goals for Section 3.4

- Explain the difference between electrolytes and nonelectrolytes and recognize examples of each.
- Predict the solubility of ionic compounds in water.

Many of the reactions you will study in your chemistry course and almost all of the reactions that occur in living things are carried out in solutions in which the reacting substances are dissolved in water. In Chapter 1, we defined a **solution** as a homogeneous mixture of two or more substances. One substance is generally considered the **solvent**, the medium in which another substance—the **solute**—is dissolved. The remainder of this chapter is an introduction to some of the types of reactions that occur in **aqueous solutions**, solutions in which *water* is the solvent. First, it is important to understand something about the behavior of compounds dissolved in water.

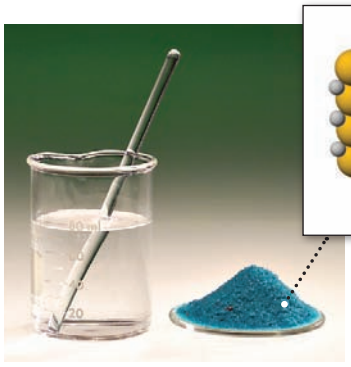
Ions and Molecules in Aqueous Solutions



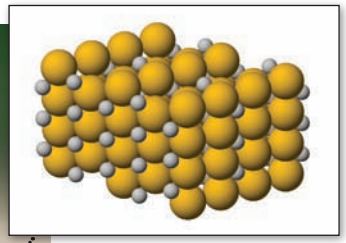
Dissolving an ionic solid requires separating each ion from the oppositely charged ions that surround it in the solid state (Figure 3.7). Water is especially good at dissolving ionic compounds because each water molecule has a positively charged end and a negatively charged end. When an ionic compound dissolves in water, each negative ion becomes surrounded by water molecules with the positive ends of water molecules pointing toward it, and each positive ion becomes surrounded by the negative ends of several water molecules. The forces involved are described by Coulomb's law (Equation 2.3, page 85).

The water-encased ions produced by dissolving an ionic compound are free to move about in solution. Under normal conditions, the movement of ions is random, and the cations and anions from a dissolved ionic compound are dispersed uniformly throughout the solution. However, if two **electrodes** (conductors of electricity such as copper wire) are placed in the solution and connected to a battery, positive cations are drawn toward the negative electrode and negative anions are

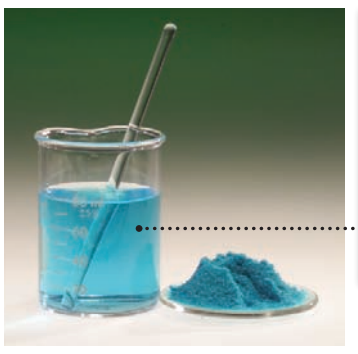
A water molecule is electrically positive on one side (the H atoms) and electrically negative on the other (the O atom). These charges enable water to interact with negative and positive ions in aqueous solution.



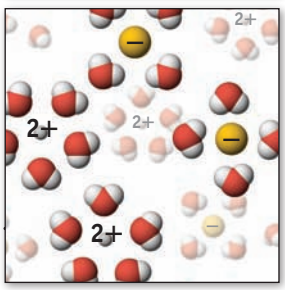
Water molecules are attracted to both positive cations and negative anions in aqueous solution.



Water surrounding a cation



Water surrounding an anion



When an ionic substance dissolves in water, each ion is surrounded by up to six water molecules.

Copper(II) chloride is added to water. Interactions between water and the Cu^{2+} and Cl^- ions allow the solid to dissolve.

The ions are now sheathed in water molecules.

drawn toward the positive electrode (Figure 3.8). Conduction of electricity in the solution is a consequence of the movement of charged particles in solution.

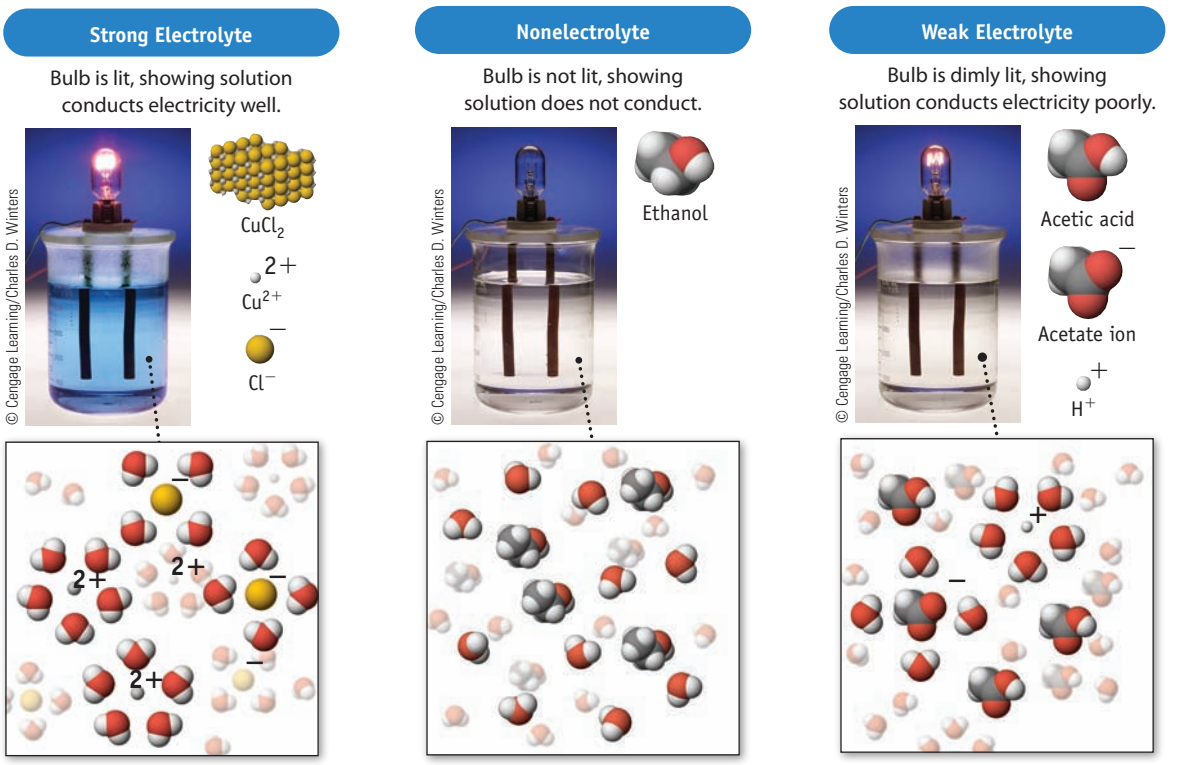
Compounds whose aqueous solutions conduct electricity are called **electrolytes**. *All ionic compounds that are soluble in water are electrolytes.* The extent to which a solution conducts electricity, its conductivity, depends on the ion concentration. You can test the conductivity of a solution by inserting a lightbulb in the circuit. The greater the ion concentration, the greater the conductivity, and the brighter the bulb will glow.

For every mole of NaCl that dissolves, 1 mol of Na^+ and 1 mol of Cl^- ions enter the solution.

$$NaCl(s) \rightarrow Na^+(aq) + Cl^-(aq)$$

$$100\%\ \text{Dissociation} \rightarrow \text{strong electrolyte}$$

There will be a significant concentration of ions in the solution, and the solution will be a good conductor of electricity. Substances whose solutions are good electrical conductors are called **strong electrolytes** (Figure 3.8a). The ions into which an ionic compound will dissociate are given by the compound's name, and the relative amounts of these ions are given by its formula. For example, sodium chloride yields sodium ions (Na^+) and chloride ions (Cl^-) in solution in a 1:1 ratio. The ionic compound barium chloride, $BaCl_2$, is also a strong electrolyte. In this case there are two chloride ions for each barium ion in solution.



$$BaCl_2(s) \rightarrow Ba^{2+}(aq) + 2\ Cl^-(aq)$$

Notice that the two chloride ions per formula unit are present as two separate particles in solution. In yet another example, the ionic compound barium nitrate yields barium ions and nitrate ions in solution. For each Ba^{2+} ion in solution, there are two NO_3^- ions.

$$Ba(NO_3)_2(s) \rightarrow Ba^{2+}(aq) + 2\ NO_3^-(aq)$$

Notice also that NO_3^-, a polyatomic ion, does not dissociate further; the ion exists as one unit in aqueous solution.

FIGURE 3.8

(a) A **strong electrolyte** conducts electricity. $CuCl_2$ is completely dissociated into Cu^{2+} and Cl^- ions.

(b) A **nonelectrolyte** does not conduct electricity because no ions are present in solution.

(c) A **weak electrolyte** conducts electricity poorly because only a few ions are present in solution.

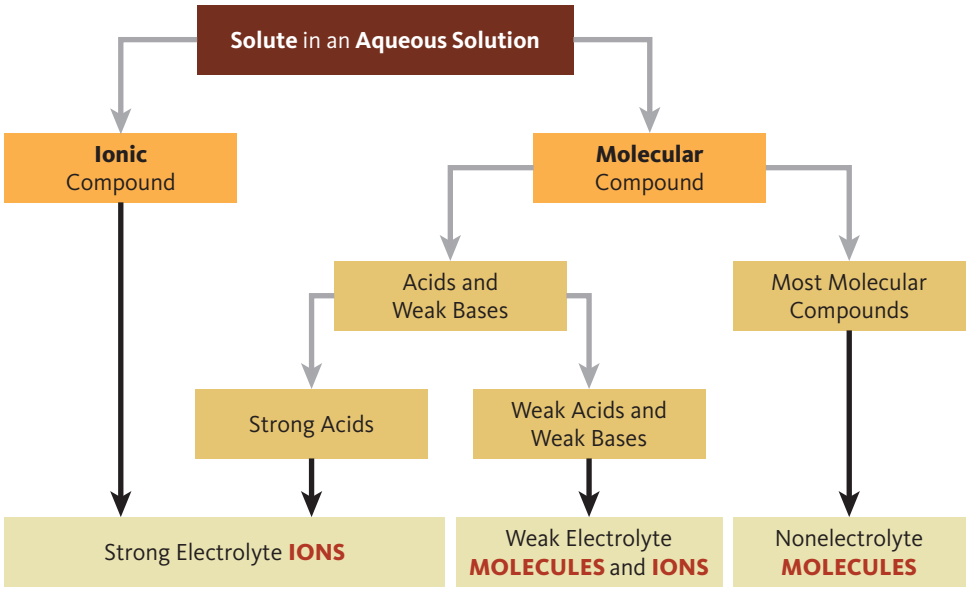

FIGURE 3.9 Predicting the species present in aqueous solution. When compounds dissolve, ions may result from ionic or molecular compounds. Some molecular compounds may remain intact as molecules in solution. (Note that hydroxide-containing strong bases are ionic compounds.)

Compounds whose aqueous solutions do not conduct electricity are called **nonelectrolytes** (Figure 3.8b). The solute particles present in these aqueous solutions are molecules, not ions. For example, when the molecular compound ethanol (C_2H_5OH) dissolves in water, each molecule of ethanol stays together as a single unit. We do not get ions in the solution. Other examples of nonelectrolytes are sucrose ($C_{12}H_{22}O_{11}$) and antifreeze (ethylene glycol, $HOCH_2CH_2OH$).

Some molecular compounds (strong acids, weak acids, and weak bases) can react with water to produce ions in aqueous solutions and are thus electrolytes. One example is gaseous hydrogen chloride, a molecular compound, which reacts with water to form ions. The aqueous solution is referred to as hydrochloric acid.

$$HCl(g) + H_2O(\ell) \rightarrow H_3O^+(aq) + Cl^-(aq)$$

This reaction is very product-favored. Each molecule of HCl ionizes completely in solution, so hydrochloric acid is a strong electrolyte.

Some molecular compounds are **weak electrolytes** (Figure 3.8c). When these compounds dissolve in water only a small fraction of the molecules ionize to form ions; the majority remain intact. These aqueous solutions are poor conductors of electricity. Acetic acid is a weak electrolyte. In vinegar, an aqueous solution of acetic acid, only about 0.5% of the molecules of acetic acid are ionized to form acetate ($CH_3CO_2^-$) and hydronium (H_3O^+) ions.

$$CH_3CO_2H(aq) + H_2O(\ell) \rightleftharpoons CH_3CO_2^-(aq) + H_3O^+(aq)$$

Figure 3.9 summarizes whether a given type of solute will be present in aqueous solution as ions, molecules, or a combination of ions and molecules.

Solubility of Ionic Compounds in Water

Solubilities of ionic compounds vary widely. Many ionic compounds are soluble in water, but some dissolve only to a small extent; still others are essentially insoluble. However, we can make some general statements about which ionic compounds are water-soluble. In this classification, we consider solubility as an "either-or" question, referring to those materials that are soluble beyond a certain extent as "soluble" and to those that do not dissolve to that extent as "insoluble."

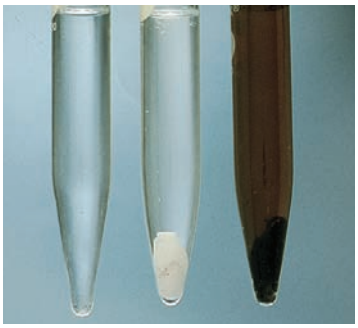

Figure 3.10 gives broad guidelines that can help you to predict whether an ionic compound is soluble in water based on the ions that make up the compound. For example, sodium nitrate, $NaNO_3$, contains an alkali metal cation, Na^+, and the nitrate anion, NO_3^-. The presence of *either* of these ions ensures that the compound is soluble in water; at 20 °C, over 90 g of $NaNO_3$ will dissolve in 100 mL of water.

FIGURE 3.10 Guidelines to predict the solubility of ionic compounds. If a compound contains one of the ions in the columns on the left side of the chart above, it is predicted to be at least moderately soluble in water. Exceptions to the guidelines are noted.

In contrast, calcium hydroxide is poorly soluble in water. If a spoonful of solid $Ca(OH)_2$ is added to 100 mL of water, less than 1 g will dissolve at 20 °C. Nearly all of the $Ca(OH)_2$ remains as a solid (Figure 3.10c).

Solubility Guidelines Observations such as those shown in Figure 3.10 were used to create the solubility guidelines. Note, however, that these are general guidelines. There are exceptions. See B. Blake, *Journal of Chemical Education*, Vol. 80, pp. 1348–1350, 2003.

EXAMPLE 3.2

Solubility Guidelines

Problem Predict whether the following ionic compounds are likely to be water-soluble. For soluble compounds, list the ions present in solution.

(a) KCl (b) $MgCO_3$ (c) $Fe(OH)_3$ (d) $Cu(NO_3)_2$

What Do You Know? You know the formulas of the compounds but need to be able to identify the ions that make up each of them in order to use the solubility guidelines in Figure 3.10.

Strategy Use the solubility guidelines given in Figure 3.10. Soluble compounds will dissociate into their respective ions in solution.

SOLUTION

(a) KCl is composed of K^+ and Cl^- ions. The presence of *either* of these ions means that the compound is likely to be soluble in water. The solution contains K^+ and Cl^- ions dissolved in water.

$$KCl(s) \rightarrow K^+(aq) + Cl^-(aq)$$

(The solubility of KCl is about 35 g in 100 mL of water at 20 °C.)

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

(b) Magnesium carbonate is composed of Mg^{2+} and CO_3^{2-} ions. Salts containing the carbonate ion usually are insoluble, unless combined with an ion like Na^+ or NH_4^+. Therefore, $MgCO_3$ is predicted to be insoluble in water. (The solubility of $MgCO_3$ is less than 0.2 g/100 mL of water.)

(c) Iron(III) hydroxide is composed of Fe^{3+} and OH^- ions. Hydroxides are soluble only when OH^- is combined with ions of the alkali metals, strontium or barium; Fe^{3+} is a transition metal ion, so $Fe(OH)_3$ is insoluble.

(d) Copper(II) nitrate is composed of Cu^{2+} and NO_3^- ions. Nitrate salts are soluble, so this compound dissolves in water, giving ions in solution as shown in the equation below.

$$Cu(NO_3)_2(s) \longrightarrow Cu^{2+}(aq) + 2\ NO_3^-(aq)$$

Think about Your Answer For chemists, a set of guidelines like those in Figure 3.10 is useful. If needed, accurate solubility information is available for many compounds in chemical resource books or online databases.

Check Your Understanding

Predict whether each of the following ionic compounds is likely to be soluble in water. If it is soluble, write the formulas of the ions present in aqueous solution.

(a) $LiNO_3$ (b) $CaCl_2$ (c) $Cu(OH)_2$ (d) $NaCH_3CO_2$

3.5 Precipitation Reactions

Goals for Section 3.5

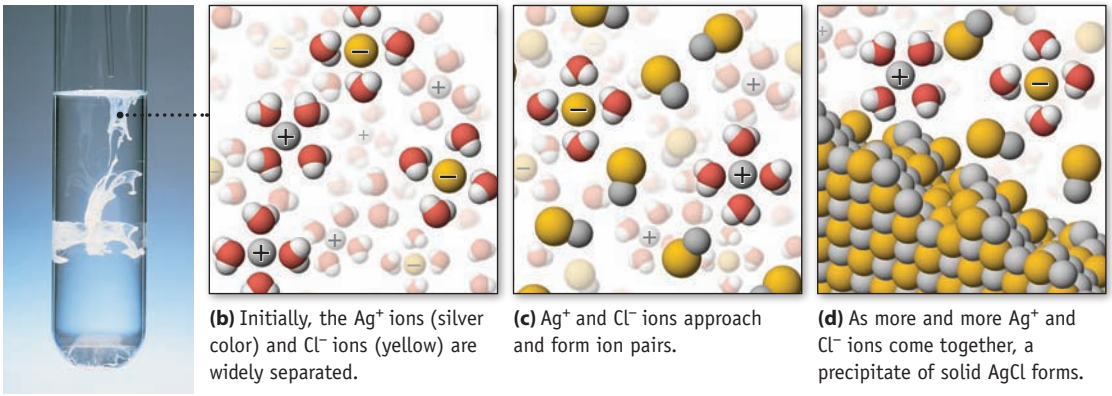
- Recognize what ions are formed when an ionic compound or acid or base dissolves in water.
- Recognize exchange reactions in which there is an exchange of anions between the cations of reactants in solution.
- Predict the products of precipitation reactions.
- Write net ionic equations for reactions in aqueous solution.

With a background on whether compounds will yield ions or molecules when dissolved in water and whether ionic compounds are soluble or insoluble in water, we can begin to discuss types of chemical reactions that occur in aqueous solutions. It will be useful to look for patterns that can help you predict the reaction products.

Many reactions you will encounter are **exchange reactions** (sometimes called double displacement, double replacement, or metathesis reactions). In these reactions *the ions of the reactants exchange partners.*

$$A^+B^- + C^+D^- \longrightarrow A^+D^- + C^+B^-$$

Reactions in which a precipitate forms (**precipitation reactions**) are exchange reactions. For example, aqueous solutions of silver nitrate and potassium chloride react to produce solid silver chloride and aqueous potassium nitrate (Figure 3.11).



$$AgNO_3(aq) + KCl(aq) \longrightarrow AgCl(s) + KNO_3(aq)$$

Reactants	**Products**
$Ag^+(aq) + NO_3^-(aq)$	Insoluble $AgCl(s)$
$K^+(aq) + Cl^-(aq)$	$K^+(aq) + NO_3^-(aq)$

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. PbS from $Pb(NO_3)_2$ and $(NH_4)_2S$

Photos: © Cengage Learning/Charles D. Winters

$Fe(OH)_3$ from $FeCl_3$ and NaOH

The solubility guidelines (Figure 3.10) predict that almost all metal sulfides are insoluble in water. If a solution of a soluble metal compound comes in contact with a source of sulfide ions, the metal sulfide precipitates.

$$Pb(NO_3)_2(aq) + (NH_4)_2S(aq) \rightarrow PbS(s) + 2\ NH_4NO_3(aq)$$

Reactants	Products
$Pb^{2+}(aq) + 2\ NO_3^-(aq)$	Insoluble PbS(s)
$2\ NH_4^+(aq) + S^{2-}(aq)$	$2\ NH_4^+(aq) + 2\ NO_3^-(aq)$

In yet another example, the solubility guidelines indicate that with the exception of the alkali metal cations (and Sr^{2+} and Ba^{2+}), metal cations form insoluble hydroxides. Thus, water-soluble iron(III) chloride and sodium hydroxide react to give insoluble iron(III) hydroxide.

$$FeCl_3(aq) + 3\ NaOH(aq) \rightarrow Fe(OH)_3(s) + 3\ NaCl(aq)$$

Reactants	Products
$Fe^{3+}(aq) + 3\ Cl^-(aq)$	Insoluble $Fe(OH)_3(s)$
$3\ Na^+(aq) + 3\ OH^-(aq)$	$3\ Na^+(aq) + 3\ Cl^-(aq)$

EXAMPLE 3.3

Writing the Equation for a Precipitation Reaction

Problem Is an insoluble product formed when aqueous solutions of potassium chromate and silver nitrate are mixed? If so, write the balanced equation.

What Do You Know? Names of the two reactants are given. You should recognize that this can be an exchange reaction, and you will need the information on solubilities in Figure 3.10.

Strategy

- Determine the formulas from the names of the reactants and identify the ions that make up these compounds.
- Write formulas for the products in this reaction by exchanging cations and anions and determine whether either product is insoluble using information in Figure 3.10.
- Write and balance the equation.

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

SOLUTION The reactants are $AgNO_3$ and K_2CrO_4. The possible products of the exchange reaction are silver chromate (Ag_2CrO_4) and potassium nitrate (KNO_3). Based on the solubility guidelines, we know that silver chromate is an insoluble compound (chromates are insoluble except for those with Group 1A cations or NH_4^+), and potassium nitrate is soluble in water. A precipitate of silver chromate is predicted to form if these reactants are mixed.

$$2\ AgNO_3(aq) + K_2CrO_4(aq) \rightarrow Ag_2CrO_4(s) + 2\ KNO_3(aq)$$

Think about Your Answer You can figure out that chromate ion (CrO_4^{2-}) has a charge of 2^- because potassium chromate consists two potassium ions (K^+) for each chromate ion. Likewise, the silver ion must have a 1+ charge because it was initially paired with nitrate ion (NO_3^-).

Check Your Understanding

In each of the following cases, does a precipitation reaction occur when solutions of the two water-soluble reactants are mixed? Give the formula of any precipitate that forms, and write a balanced chemical equation for the precipitation reactions that occur.

(a) sodium carbonate and copper(II) chloride

(b) potassium carbonate and sodium nitrate

(c) nickel(II) chloride and potassium hydroxide

Photos: © Cengage Learning/Charles D. Winters

Ag_2CrO_4 from $AgNO_3$ and K_2CrO_4

Net Ionic Equations

When aqueous solutions of silver nitrate and potassium chloride are mixed, insoluble silver chloride forms, leaving potassium nitrate in solution (see Figure 3.11). The balanced chemical equation for this process is

$$AgNO_3(aq) + KCl(aq) \rightarrow AgCl(s) + KNO_3(aq)$$

We can represent this reaction in another way by writing an equation in which we show that the *soluble* ionic compounds are present in solution as dissociated ions. An aqueous solution of silver nitrate contains Ag^+ and NO_3^- ions, and an aqueous solution of potassium chloride contains K^+ and Cl^- ions. In the products, potassium nitrate is present in solution as K^+ and NO_3^- ions. However, silver chloride is insoluble and thus is not present in the solution as dissociated ions. It is shown in the equation as AgCl(s).

$$\underset{\text{before reaction}}{Ag^+(aq) + NO_3^-(aq) + K^+(aq) + Cl^-(aq)} \longrightarrow \underset{\text{after reaction}}{AgCl(s) + K^+(aq) + NO_3^-(aq)}$$

This type of equation is called a **complete ionic equation**.

The K^+ and NO_3^- ions are present in solution both before and after reaction, so they appear on both the reactant and product sides of the complete ionic equation. Such ions are often called **spectator ions** because they do not participate in the net reaction; they only "look on" from the sidelines. Little chemical information is lost if the equation is written without them, so we can simplify the equation to

$$Ag^+(aq) + Cl^-(aq) \rightarrow AgCl(s)$$

The balanced equation that results from leaving out spectator ions is the **net ionic equation** for the reaction. The significance of net ionic equations, and the reason that net ionic equations are commonly used, is that they *more accurately describe the reaction that takes place.*

Leaving out spectator ions does not mean that K^+ and NO_3^- ions are unimportant in the $AgNO_3$ + KCl reaction. Indeed, Ag^+ ions cannot exist alone in solution; a negative ion, in this case NO_3^-, must be present to balance the positive charge of Ag^+. Any anion will do, however, as long as it forms a water-soluble compound with Ag^+. Thus, we could have used $AgClO_4$ instead of $AgNO_3$. Similarly, there must be a

Net Ionic Equations All chemical equations, including net ionic equations, must be balanced. The same number of atoms of each kind must appear on both the product and reactant sides. In addition, *the sum of positive and negative charges must be the same on both sides of the equation.*

Problem Solving Tip 3.1 Writing Net Ionic Equations

Net ionic equations are commonly written for chemical reactions in aqueous solution because they describe the actual chemical species involved in a reaction. To write net ionic equations you must know which compounds exist as ions in solution.

1. Strong acids, strong bases, and soluble salts exist as ions in solution. Examples include the acids HCl and HNO_3, a base such as NaOH, and salts such as NaCl and $CuCl_2$.
2. All other species should be represented by their complete formulas. Weak acids such as acetic acid (CH_3CO_2H) exist in aqueous solutions primarily as molecules. (See Section 3.6.) Insoluble salts such as $CaCO_3(s)$ or insoluble bases such as $Mg(OH)_2(s)$ should not be written in ionic form, even though they are ionic compounds.

The best way to approach writing net ionic equations is to follow precisely a set of steps.

1. Write a complete, balanced equation. Indicate the state of each substance (aq, s, ℓ, g).
2. Next rewrite the whole equation, writing all strong acids, strong bases, and soluble salts as ions. (Consider only species labeled "(aq)" in this step.)
3. Some ions may remain unchanged in the reaction (the ions that appear in the equation both as reactants and products). These "spectator ions" are not part of the chemistry that is going on, and you can eliminate them from each side of the equation.
4. Net ionic equations must be balanced. The same number of atoms appears on each side of the arrow, and the sum of the ion charges on the two sides must also be equal.

positive ion present to balance the negative charge of Cl^-. In this case, the positive ion present is K^+ in KCl, but we could have used NaCl instead of KCl. The net ionic equation would have been the same.

Finally, notice that there must always be a *charge balance* as well as a mass balance in a balanced equation. In the $Ag^+ + Cl^-$ net ionic equation, the cation and anion charges on the left add together to give a net charge of zero, the same as the zero charge on AgCl(s) on the right.

© Cengage Learning/Charles D. Winters

Precipitation reaction. The reaction of barium chloride and sodium sulfate produces insoluble barium sulfate and water-soluble sodium chloride.

EXAMPLE 3.4

Writing and Balancing Net Ionic Equations

Problem Write a balanced, net ionic equation for the reaction of aqueous solutions of $BaCl_2$ and Na_2SO_4.

What Do You Know? The formulas for the reactants are given. You should recognize that this is an exchange reaction, and that you will need the information on solubilities in Figure 3.10.

Strategy Follow the strategy outlined in Problem Solving Tip 3.1.

SOLUTION

Step 1. *In this exchange reaction, the Ba^{2+} and Na^+ cations exchange anions (Cl^- and SO_4^{2-}) to give $BaSO_4$ and NaCl.* Now that the reactants and products are known, we can write an equation for the reaction. To balance the equation, we place a 2 in front of the NaCl.

$$BaCl_2 + Na_2SO_4 \rightarrow BaSO_4 + 2\ NaCl$$

Step 2. *Decide on the solubility of each compound (see Figure 3.10). Compounds containing sodium ions are always water-soluble, as are those containing chloride ions (with some important exceptions).* Sulfate salts are also usually soluble, one important exception being $BaSO_4$. We can therefore write

$$BaCl_2(aq) + Na_2SO_4(aq) \rightarrow BaSO_4(s) + 2\ NaCl(aq)$$

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Step 3. *Identify the ions in solution.* All soluble ionic compounds dissociate to form ions in aqueous solution. Writing the soluble substances as ions in solution results in the following complete ionic equation:

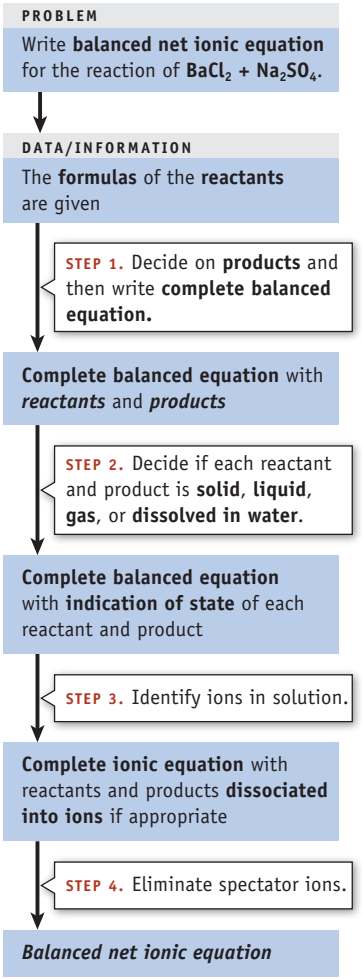
$$Ba^{2+}(aq) + 2\ Cl^{-}(aq) + 2\ Na^{+}(aq) + SO_4^{2-}(aq) \longrightarrow BaSO_4(s) + 2\ Na^{+}(aq) + 2\ Cl^{-}(aq)$$

Step 4. *Identify and eliminate the spectator ions (Na^+ and Cl^-) to give the net ionic equation.*

$$Ba^{2+}(aq) + SO_4^{2-}(aq) \longrightarrow BaSO_4(s)$$

Think about Your Answer Notice that the sum of ion charges is the same on both sides of the equation. On the left, 2+ and 2− sum to zero; on the right the charge on $BaSO_4$ is also zero.

Check Your Understanding



In each of the following cases, aqueous solutions containing the compounds indicated are mixed. Write balanced net ionic equations for the reactions that occur.

(a) $CaCl_2 + Na_3PO_4$

(b) iron(III) chloride and potassium hydroxide

(c) lead(II) nitrate and potassium chloride

Strategy Map 3.4

3.6 Acids and Bases

Goals for Section 3.6

- Know the names and formulas of common acids and bases and categorize them as strong or weak.
- Define the Arrhenius and Brønsted-Lowry concepts of acids and bases.
- Identify the Brønsted acid and base in a reaction and write equations for Brønsted–Lowry acid-base reactions.
- Recognize substances that are amphiprotic and oxides that dissolve in water to give acidic solutions and basic solutions.

Acids and bases are two important classes of compounds. You may already be familiar with some common properties of acids. They produce bubbles of CO_2 gas when added to a metal carbonate such as $CaCO_3$ (Figure 3.12a), and they react with many metals to produce hydrogen gas (H_2) (Figure 3.12b). Although tasting substances is *never* done in a chemistry laboratory, you have probably experienced the sour taste of acids such as acetic acid in vinegar and citric acid (commonly found in fruits and added to candies and soft drinks).

Acids and bases have some related properties. Solutions of acids or bases, for example, can change the colors of natural pigments (Figure 3.12c). You may have seen acids change the color of litmus, a dye derived from certain lichens, from blue to red. Adding a base reverses the effect, making the litmus blue again. Thus, acids and bases seem to be opposites. A base can neutralize the effect of an acid, and an acid can neutralize the effect of a base. Table 3.1 lists common acids and bases.

Over the years, chemists have examined the properties, chemical structures, and reactions of acids and bases and have proposed different definitions of the terms *acid* and *base*. We shall examine the two most commonly used definitions, one proposed by Svante Arrhenius (1859–1927) and another proposed by Johannes N. Brønsted (1879–1947) and Thomas M. Lowry (1874–1936).

$H_2C_2O_4$	Oxalic acid		
$H_2C_4H_4O_6$	Tartaric acid		
$H_3C_6H_5O_7$	Citric acid		
$HC_9H_7O_4$	Aspirin		

*The electrolytic behavior refers to aqueous solutions of these acids and bases.

**$Ca(OH)_2$ is often listed as a strong base, although it is poorly soluble.

Acids and Bases: The Arrhenius Definition

In the late 1800s, the Swedish chemist Svante Arrhenius proposed that acids and bases dissolve in water and ultimately form ions. This theory predated any knowledge of the composition and structure of atoms and was not well accepted initially. With a knowledge of atomic structure, however, we now take it for granted.

A CLOSER LOOK

Naming Common Acids

As we outlined in Section 2.4, the simple covalent compound HCl is called *hydrogen chloride* when it is in the pure, gaseous state. However, in this section we see that an aqueous solution of HCl is acidic, and this solution is given the name *hydrochloric acid.* The same pattern, adding *hydro–* at the beginning and an *–ic* ending, applies to other acids where the anion has an *–ide* ending. For example, HF(aq) is hydrofluoric acid and H_2S(aq) is hydrosulfuric acid.

Notice that other common acids, such as sulfuric acid (H_2SO_4) and nitric acid (HNO_3), also have names ending in *–ic.* If you begin with the common anions with names ending in *–ate* (such as nitrate, sulfate, chlorate, perchlorate, and acetate), the acid associated with that anion has a name ending in *–ic.* Thus, we have nitric, sulfuric, chloric, perchloric, and acetic acids.

You learned in Chapter 2 that there are series of anions based on chlorine, sulfur, and nitrogen. Among them are the hypochlorite (ClO^-) and chlorite (ClO_2^-) ions and the sulfite (SO_3^{2-}) and nitrite (NO_2^-) ions. Acids based on ions ending in *–ite* have names ending in *–ous.* Thus, we have hypochlorous, chlorous, sulfurous, and nitrous acids.

These naming conventions are summarized in the table below.

Common Anion Names	Name of Corresponding Acid
Cl^-, chloride ion	HCl, hydrochloric acid
ClO^-, hypochlorite ion	HClO, hypochlorous acid
ClO_2^-, chlorite ion	$HClO_2$, chlorous acid
ClO_4^-, perchlorate ion	$HClO_4$, perchloric acid
S^{2-}, sulfide ion	H_2S, hydrosulfuric acid
SO_3^{2-}, sulfite ion	H_2SO_3, sulfurous acid
SO_4^{2-}, sulfate ion	H_2SO_4, sulfuric acid
NO_2^-, nitrite ion	HNO_2, nitrous acid
NO_3^-, nitrate ion	HNO_3, nitric acid

The Arrhenius definition for acids and bases focuses on formation of H^+ and OH^- ions in aqueous solutions.

- An acid is a substance that, when dissolved in water, increases the concentration of hydrogen ions, H^+, in solution.

$$HCl(g) \rightarrow H^+(aq) + Cl^-(aq)$$

- A base is a substance that, when dissolved in water, increases the concentration of hydroxide ions, OH^-, in the solution.

$$NaOH(s) \rightarrow Na^+(aq) + OH^-(aq)$$

- The reaction of an acid and a base produces a salt and water. Because the characteristic properties of an acid are lost when a base is added, and vice versa, acid–base reactions were logically described as resulting from the combination of H^+ and OH^- to form water.

$$HCl(aq) + NaOH(aq) \rightarrow NaCl(aq) + H_2O(\ell)$$

Arrhenius further proposed that acid strength was related to the extent to which the acid ionized. Some acids such as hydrochloric acid (HCl) and nitric acid (HNO_3) ionize completely in water; they are strong electrolytes, and we now call them **strong acids**. Other acids such as acetic acid and hydrofluoric acid are incompletely ionized; they are weak electrolytes and are **weak acids**. Weak acids exist in solution primarily as molecules, and only a fraction of these molecules ionize to produce H^+(aq) ions along with the appropriate anion.

Water-soluble compounds that contain hydroxide ions, such as sodium hydroxide (NaOH) and potassium hydroxide (KOH), are strong electrolytes and **strong bases**.

Aqueous ammonia, NH_3(aq), is a weak electrolyte. Even though OH^- ions are not part of its formula, it does produce ammonium ions and hydroxide ions from its reaction with water and so is a base (Figure 3.13). The fact that this is a weak electrolyte indicates that this reaction with water to form ions is reactant-favored at equilibrium. Most of the ammonia remains in solution in molecular form.

$$NH_3(aq) + H_2O(\ell) \rightleftharpoons NH_4^+(aq) + OH^-(aq)$$

Although the Arrhenius theory is still used to some extent and is interesting in a historical context, modern concepts of acid–base chemistry such as the Brønsted–Lowry theory have gained preference among chemists.

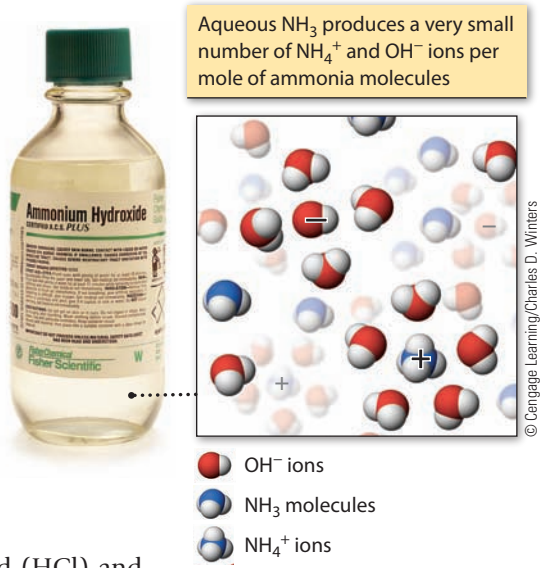

Figure 3.13 Ammonia, a weak electrolyte. The name on the bottle, ammonium hydroxide, is misleading. The solution consists almost entirely of NH_3 molecules dissolved in water. It is better referred to as "aqueous ammonia."

Acids and Bases: The Brønsted–Lowry Definition

H_3O^+ versus H^+ The formula for the hydronium ion, H_3O^+ is a fairly accurate description and will usually be used to represent the hydrogen ion in solution. However, there will be instances when, for simplicity, we will represent the hydrogen ion as $H^+(aq)$.

Experiments show that other forms of the ion also exist in water, one example being $[H_3O(H_2O)_3]^+$.

In 1923, Johannes Brønsted (1879–1947) in Copenhagen, Denmark, and Thomas Lowry (1874–1936) in Cambridge, England, independently suggested a new concept of acid and base behavior. They viewed acids and bases in terms of the transfer of a proton (H^+) from one species to another, and they described all acid–base reactions in terms of equilibria. The Brønsted–Lowry theory expanded the scope of the definition of acids and bases and helped chemists make predictions of product- or reactant-favorability based on acid and base strength. We will describe this theory here qualitatively; a more complete discussion will be given in Chapter 16.

The main concepts of the Brønsted–Lowry theory are the following:

- *An acid is a proton donor.*
- *A base is a proton acceptor.* This definition includes the OH^- ion but it also broadens the number and type of bases to include anions derived from acids as well as neutral compounds such as ammonia and water.
- *An acid–base reaction involves the transfer of a proton from an acid to a base to form a new acid and a new base.*

According to Brønsted–Lowry theory, the behavior of acids such as HCl or CH_3CO_2H in water is written as an acid–base reaction. Both species (both Brønsted acids) donate a proton to water (a Brønsted base) forming $H_3O^+(aq)$, the hydronium ion.

Hydrochloric acid, HCl(aq), a strong electrolyte and a strong acid, ionizes completely in aqueous solution; it is classified as a strong acid.

Hydrochloric acid, a strong acid. 100% ionized. Equilibrium strongly favors products.

$$HCl(aq) + H_2O(\ell) \longrightarrow H_3O^+(aq) + Cl^-(aq)$$

hydrochloric acid strong electrolyte = 100% ionized | water | hydronium ion | chloride ion

In contrast, CH_3CO_2H, a weak electrolyte and weak acid, ionizes only to a small extent.

Acetic acid, a weak acid, << 100% ionized. Equilibrium favors reactants.

$$CH_3CO_2H(aq) + H_2O(\ell) \rightleftharpoons CH_3CO_2^-(aq) + H_3O^+(aq)$$

acetic acid | water | acetate ion | hydronium ion

Sulfuric acid, a *diprotic acid* (an acid capable of transferring two H^+ ions), reacts with water in two steps. The first step strongly favors products, whereas the second step is reactant-favored.

Strong acid: $H_2SO_4(aq) + H_2O(\ell) \longrightarrow H_3O^+(aq) + HSO_4^-(aq)$

sulfuric acid 100% ionized | hydronium ion | hydrogen sulfate ion

Weak acid: $HSO_4^-(aq) + H_2O(\ell) \rightleftharpoons H_3O^+(aq) + SO_4^{2-}(aq)$

hydrogen sulfate ion <100% ionized | hydronium ion | sulfate ion

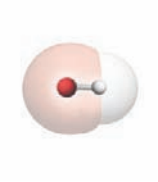
Ammonia, a weak base, reacts with water to produce $OH^-(aq)$ ions. The reaction is reactant-favored at equilibrium.

Ammonia, a weak base, << 100% ionized. Equilibrium favors reactants.

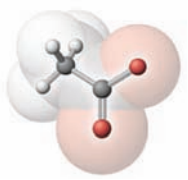
$$NH_3(aq) + H_2O(\ell) \rightleftharpoons NH_4^+(aq) + OH^-(aq)$$



ammonia, base
weak electrolyte
< 100% ionized

water

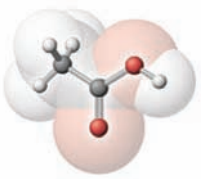
ammonium
ion



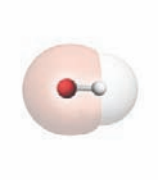
hydroxide ion

According to the Brønsted-Lowry theory, anions can add a proton and are thus classified as bases. In particular, anions of weak acids typically behave as weak bases, and basic solutions result from dissolving a salt containing the anion of a weak acid in water. For example, an aqueous solution of sodium acetate is basic because of the following reaction:

Acetate ion, weak base; equilibrium favors reactants.



$$CH_3CO_2^-(aq) + H_2O(\ell) \rightleftharpoons CH_3CO_2H(aq) + OH^-(aq)$$



acetate ion, a weak base

water

acetic acid molecules

hydroxide ion

Some species are described as **amphiprotic**, that is, they can function either as acids or as bases depending on the reaction. In the examples above, water functions as a base in reactions with acids (it accepts a proton) and as an acid in its reaction with ammonia (where it donates a proton to ammonia, forming the ammonium ion).

EXAMPLE 3.5

Brønsted Acids and Bases

Problem Write a balanced net ionic equation for the reaction that occurs when the cyanide ion, CN^-, accepts a proton (H^+) from water to form HCN. Is CN^- a Brønsted acid or base?

What Do You Know? You know the formulas of the reactants (CN^- and H_2O) and of one of the products, (HCN). You also know a proton transfer occurs from water to CN^-.

Strategy As it is a proton transfer, you should move an H^+ ion from H_2O to CN^- to give the products.

SOLUTION

$$H_2O(\ell) + CN^-(aq) \rightleftharpoons OH^-(aq) + HCN(aq)$$

In this reaction water is the Brønsted acid and the CN^- ion is the Brønsted base.

Think about Your Answer The CN^- ion interacts with water to produce OH^- ion. In general, anions derived from weak acids produce basic solutions in water.

Check Your Understanding

(a) Write a balanced equation for the reaction that occurs when H_3PO_4, phosphoric acid, donates a proton to water to form the dihydrogen phosphate ion.

(b) Write a net ionic equation showing the dihydrogen phosphate ion acting as a Brønsted acid in a reaction with water. Write another net ionic equation showing the dihydrogen phosphate ion acting as a Brønsted base in a reaction with water. What term is used to describe a species such as the dihydrogen phosphate ion that can act both as an acid or as a base?

Reactions of Acids and Bases

Acids and bases in aqueous solution usually react to produce a salt and water. Note that these reactions are also exchange reactions, with cations and anions changing partners. For example (Figure 3.14),

$$\underset{\text{hydrochloric acid}}{HCl(aq)} + \underset{\text{sodium hydroxide}}{NaOH(aq)} \longrightarrow \underset{\text{water}}{H_2O(\ell)} + \underset{\text{sodium chloride}}{NaCl(aq)}$$

The word "salt" has come into the language of chemistry to describe any ionic compound whose cation comes from a base (here Na^+ from NaOH) and whose anion comes from an acid (here Cl^- from HCl). The reaction of any of the acids listed in Table 3.1 with any of the listed hydroxide-containing bases produces a salt and water.

Hydrochloric acid and sodium hydroxide are strong electrolytes in water (see Figure 3.14 and Table 3.1), so the complete ionic equation for the reaction of HCl(aq) and NaOH(aq) is written as

$$\underbrace{H_3O^+(aq) + Cl^-(aq)}_{\text{from HCl(aq)}} + \underbrace{Na^+(aq) + OH^-(aq)}_{\text{from NaOH(aq)}} \longrightarrow \underset{\text{water}}{2\,H_2O(\ell)} + \underbrace{Na^+(aq) + Cl^-(aq)}_{\text{from salt}}$$

Because Na^+ and Cl^- ions appear on both sides of the equation they can be cancelled out, and the *net ionic equation* is just the combination of the ions H_3O^+ and OH^- to give water.

$$H_3O^+(aq) + OH^-(aq) \longrightarrow 2\,H_2O(\ell)$$

This is always the net ionic equation when a strong acid reacts with a strong base.

Reactions between strong acids *and* strong bases are called **neutralization reactions** because, on completion of the reaction, the solution is neither acidic nor basic if exactly the same amounts (number of moles) of the acid and base are mixed. The other ions (the cation of the base and the anion of the acid) remain unchanged.

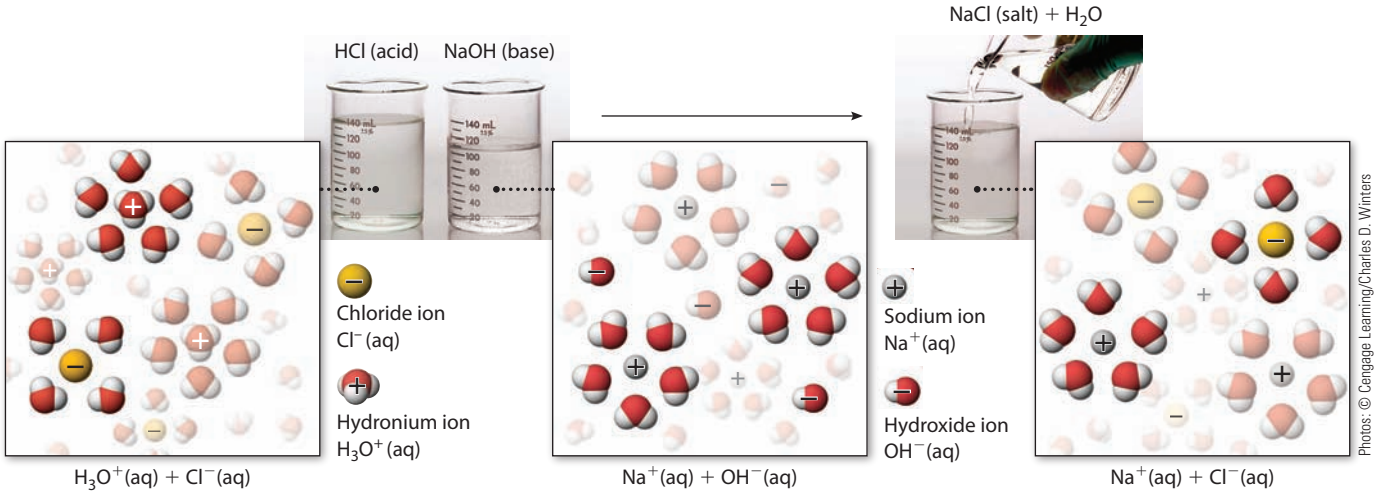

FIGURE 3.14 An acid–base reaction, HCl and NaOH. On mixing, the H_3O^+ and OH^- ions combine to produce H_2O, whereas the ions Na^+ and Cl^- remain in solution.

A CLOSER LOOK

Sulfuric Acid

For many years sulfuric acid has been the chemical produced in the largest quantity in the United States (as well as in many other industrialized countries). About 40–50 billion kilograms (40–50 million metric tons) is made annually in the United States. The acid is so important to the economy of industrialized nations that some economists have said sulfuric acid production is a measure of a nation's industrial strength.

Sulfuric acid is a colorless, syrupy liquid with a density of 1.84 g/mL and a boiling point of 337 °C. It has several desirable properties that have led to its widespread use: it is generally less expensive to produce than other acids, is a strong acid, and can be handled in steel containers. It reacts readily with many organic compounds to produce useful products and reacts readily with lime (CaO), the least expensive and most readily available base, to give calcium sulfate, a compound used to make wall board for the construction industry.

The first step in the industrial preparation of sulfuric acid is the production of sulfur dioxide from the combustion of sulfur in air,

$$S(s) + O_2(g) \rightarrow SO_2(g)$$

or using the SO_2 produced in smelting sulfur-containing copper, nickel, or other metal ores. The SO_2 is then combined with more oxygen, in the presence of a catalyst (a substance that speeds up the reaction), to give sulfur trioxide,

$$2\ SO_2(g) + O_2(g) \rightarrow 2\ SO_3(g)$$

which then gives sulfuric acid when dissolved in water.

$$SO_3(g) + H_2O(\ell) \rightarrow H_2SO_4(aq)$$

Currently, over two thirds of the production is used in the fertilizer industry. The remainder is used to make pigments, explosives, pulp and paper, detergents, and as a component in storage batteries.

"The Acid Touch," *Chemical and Engineering News,* April 14, 2008, p. 27.

SIAATH/Shutterstock.com

Sulfur. Much of the sulfur used in the United States used to be mined, but it is now largely a by-product from natural gas and oil-refining processes. It takes about 1 ton of sulfur to make 3 tons of sulfuric acid.

If acetic acid and sodium hydroxide are mixed, the following reaction will take place.

$$CH_3CO_2H(aq) + NaOH(aq) \rightarrow NaCH_3CO_2(aq) + H_2O(\ell)$$

Because acetic acid is a weak acid (Figure 3.8c), the molecular species is the predominant form in aqueous solutions. In ionic equations, therefore, acetic acid is shown as molecular $CH_3CO_2H(aq)$. The *complete ionic equation* for this reaction is

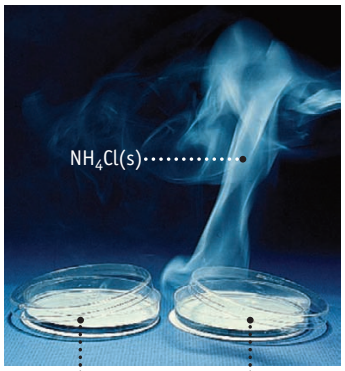
$$CH_3CO_2H(aq) + Na^+(aq) + OH^-(aq) \rightarrow Na^+(aq) + CH_3CO_2^-(aq) + H_2O(\ell)$$

The only spectator ions in this equation are the sodium ions, so the *net ionic equation* is

$$CH_3CO_2H(aq) + OH^-(aq) \rightarrow CH_3CO_2^-(aq) + H_2O(\ell)$$

EXAMPLE 3.6

Net Ionic Equation for an Acid–Base Reaction



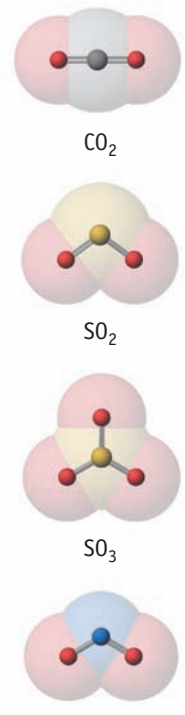
Problem Ammonia, NH_3, is one of the most important chemicals in industrial economies. Not only is it used directly as a fertilizer but it is the raw material for the manufacture of nitric acid, another commercially important chemical. As a base, ammonia reacts with acids such as hydrochloric acid. Write a balanced, net ionic equation for this reaction.

What Do You Know? The reactants are $NH_3(aq)$ and HCl(aq). A proton will transfer from the acid to the base.

Strategy Follow the general strategy for writing net ionic equations as outlined in Problem Solving Tip 3.1.

SOLUTION A proton transfers from HCl to NH_3, a weak Brønsted base, to form the ammonium ion, NH_4^+. This positive ion must have a negative counterion from the acid, Cl^-, so the reaction product is NH_4Cl, and the overall balanced equation is

$$\underset{\text{ammonia}}{NH_3(aq)} + \underset{\text{hydrochloric acid}}{HCl(aq)} \rightarrow \underset{\text{ammonium chloride}}{NH_4Cl(aq)}$$



© Cengage Learning/Charles D. Winters

Reaction of gaseous HCl and NH_3. Open dishes of aqueous ammonia and hydrochloric acid were placed side by side. When molecules of NH_3 and HCl escape from solution to the atmosphere and encounter one another, a cloud of solid ammonium chloride, NH_4Cl, is observed.

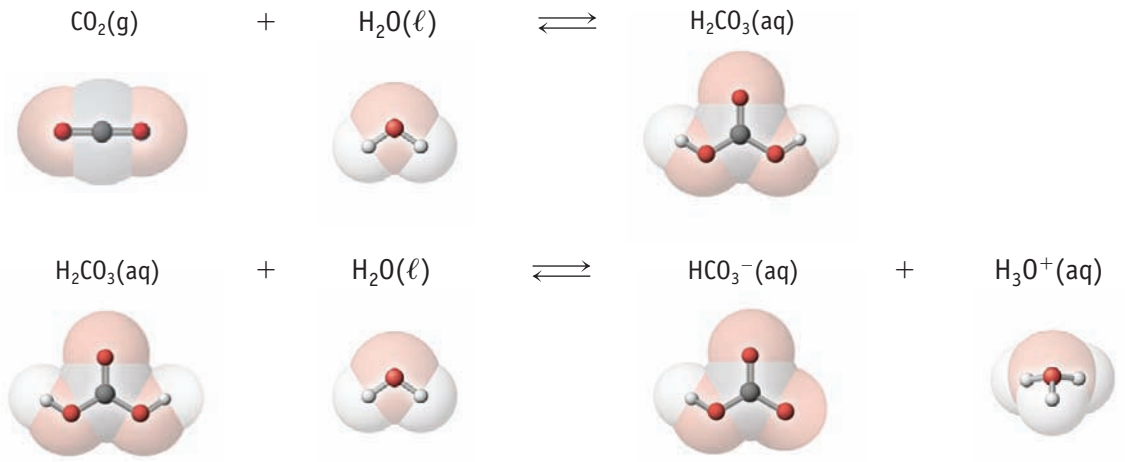
Some common nonmetal oxides that form acids in water.

Hydrochloric acid is a strong acid and produces H_3O^+ and Cl^- ions in water. NH_4Cl is quite soluble and exists as NH_4^+ and Cl^- ions in solution. On the other hand, ammonia is a weak base and so is predominantly present in the solution as the molecular species, NH_3. The complete ionic equation for this reaction is

$$NH_3(aq) + H_3O^+(aq) + Cl^-(aq) \rightarrow NH_4^+(aq) + Cl^-(aq) + H_2O(\ell)$$

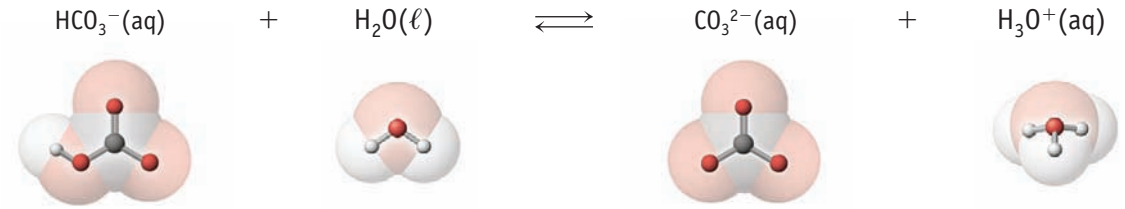
Eliminating the spectator ion, Cl^-, we have

$$NH_3(aq) + H_3O^+(aq) \rightarrow NH_4^+(aq) + H_2O(\ell)$$



Think about Your Answer The net ionic equation shows that the important aspect of the reaction between the weak base ammonia and the strong acid HCl is the transfer of an H^+ ion from the acid to the NH_3. Any strong acid could be used here (HBr, HNO_3, $HClO_4$, H_2SO_4) and the net ionic equation would be the same. Also notice that, even though H_2O is not in the overall balanced equation, it is present in the net ionic equation.

Check Your Understanding



Write the balanced, overall equation and the net ionic equation for the reaction of magnesium hydroxide with hydrochloric acid. (*Hint:* Think about the solubility guidelines.)

Oxides of Nonmetals and Metals

Each acid shown in Table 3.1 has one or more H atoms that ionize in water to form H_3O^+ ions. There are, however, less obvious compounds that form acidic solutions. Carbon dioxide and sulfur trioxide, oxides of nonmetals, have no H atoms, but both react with water to produce H_3O^+ ions. Carbon dioxide, for example, dissolves in water to a small extent, and a few of the dissolved molecules react with water to form the weak acid, carbonic acid. This acid then ionizes to a small extent to form the hydronium ion, H_3O^+, and the hydrogen carbonate (bicarbonate) ion, HCO_3^-.

The HCO_3^- ion can also function as an acid, ionizing to produce H_3O^+ and the carbonate ion, CO_3^{2-}.

These reactions are important in our environment and in the human body. Carbon dioxide is found in small amounts in the atmosphere, so rainwater is always slightly acidic. In the human body, carbon dioxide is dissolved in body fluids where the HCO_3^- and CO_3^{2-} ions perform an important "buffering" action that keeps our bodies stable (Chapter 17).

Oxides of nonmetals such as CO_2, SO_2, SO_3, and NO_2 that react with water to produce an acidic solution are called **acidic oxides**. In contrast, oxides of metals are called **basic oxides** because they produce basic solutions if they dissolve appreciably in water. Perhaps the best example of a basic oxide is calcium oxide, CaO, often called *lime*, or *quicklime*. Almost 20 billion kg of lime are produced annually in the United States for use in the metals and construction industries, in sewage and pollution control, in water treatment, and in agriculture. Calcium oxide reacts with water to give calcium hydroxide, commonly called *slaked lime*. Although only slightly soluble in water (about 0.2 g/100 g H_2O at 10 °C), $Ca(OH)_2$ is widely used in industry as a base because it is inexpensive.

$$\underset{\text{lime}}{CaO(s)} + H_2O(\ell) \rightarrow \underset{\text{slaked lime}}{Ca(OH)_2(s)}$$

3.7 Gas-Forming Reactions

Goal for Section 3.7

- Identify common reactions in which a gas is formed and write equations for these reactions.

Reactions that produce a gas represent another type of exchange reaction, and there are several commonly encountered examples in a chemical laboratory. The odor of rotten eggs will be very noticeable when you produce hydrogen sulfide, $H_2S(g)$, from a metal sulfide and an acid. Probably the most commonly encountered examples of gas-forming reactions, however, involve the formation of $CO_2(g)$ when either metal carbonates or metal hydrogen carbonates are treated with acid (Figure 3.15). Equations for several types of gas-forming reactions are given in Table 3.2.

Although we usually write a single equation for the formation of $CO_2(g)$ in the reaction between a metal carbonate (or hydrogen carbonate), the formation of $CO_2(g)$ actually occurs in two distinct steps. Consider the reaction of $CaCO_3$ and hydrochloric acid. The first step is an exchange reaction in which hydrogen ions are exchanged for the cation(s) in the metal carbonate.

$$CaCO_3(s) + 2\ HCl(aq) \rightarrow CaCl_2(aq) + H_2CO_3(aq)$$

© Cengage Learning/Charles D. Winters

Figure 3.15 Dissolving limestone (calcium carbonate, $CaCO_3$) in vinegar. Notice the bubbles of CO_2 rising from the surface of the limestone. This reaction shows why vinegar can be used as a household cleaning agent. It can be used, for example, to clean the calcium carbonate deposited from hard water.

TABLE 3.2 Gas-Forming Reactions

Metal carbonate or hydrogen carbonate + acid → metal salt + $CO_2(g)$ + $H_2O(\ell)$
$Na_2CO_3(aq) + 2\ HCl(aq) \rightarrow 2\ NaCl(aq) + CO_2(g) + H_2O(\ell)$
$NaHCO_3(aq) + HCl(aq) \rightarrow NaCl(aq) + CO_2(g) + H_2O(\ell)$
Metal sulfide + acid → metal salt + $H_2S(g)$
$Na_2S(aq) + 2\ HCl(aq) \rightarrow 2\ NaCl(aq) + H_2S(g)$
Metal sulfite + acid → metal salt + $SO_2(g)$ + $H_2O(\ell)$
$Na_2SO_3(aq) + 2\ HCl(aq) \rightarrow 2\ NaCl(aq) + SO_2(g) + H_2O(\ell)$
Ammonium salt + strong base → metal salt + $NH_3(g)$ + $H_2O(\ell)$
$NH_4Cl(aq) + NaOH(aq) \rightarrow NaCl(aq) + NH_3(g) + H_2O(\ell)$

Problem Solving Tip 3.2 Recognizing Gas-Forming Reactions

How can you recognize that a particular reaction will lead to gas formation? After you predict the products of the exchange reaction, be alert for certain products:

(a) H_2CO_3: This will decompose into carbon dioxide gas and water.

(b) H_2SO_3: This will decompose into sulfur dioxide gas and water.

(c) H_2S: This is already a gaseous product.

(d) If NH_4^+ and OH^- ions are produced, they will form NH_3 and water.

The product formed in this reaction is carbonic acid, H_2CO_3. This compound is unstable, however, and decomposes to CO_2 and H_2O.

$$H_2CO_3(aq) \rightarrow H_2O(\ell) + CO_2(g)$$

Carbon dioxide bubbles then escape the solution because CO_2 is not very soluble in water. The overall equation is obtained by adding the two equations.

$$\text{Overall reaction:} \quad CaCO_3(s) + 2\ HCl(aq) \rightarrow CaCl_2(aq) + H_2O(\ell) + CO_2(g)$$

Calcium carbonate is a common residue from hard water in home heating systems and cooking utensils. Washing with vinegar is a good way to clean the system or utensils because insoluble calcium carbonate is turned into water-soluble calcium acetate in the following gas-forming reaction (see Figure 3.15).

$$2\ CH_3CO_2H(aq) + CaCO_3(s) \rightarrow Ca(CH_3CO_2)_2(aq) + H_2O(\ell) + CO_2(g)$$

What is the net ionic equation for this reaction? Acetic acid is a weak acid, and calcium carbonate is insoluble in water. Therefore, the reactants are simply $CH_3CO_2H(aq)$ and $CaCO_3(s)$. On the products side, calcium acetate is water-soluble and so is present in solution as aqueous calcium and acetate ions. Water and carbon dioxide are molecular compounds, so the net ionic equation is

$$2\ CH_3CO_2H(aq) + CaCO_3(s) \rightarrow Ca^{2+}(aq) + 2\ CH_3CO_2^-(aq) + H_2O(\ell) + CO_2(g)$$

There are no spectator ions in this reaction.

Have you ever made biscuits or muffins? As you bake the dough, it rises in the oven because a gas-forming reaction occurs between an acid and baking soda, sodium hydrogen carbonate (bicarbonate of soda, $NaHCO_3$). One acid used for this purpose is tartaric acid, a weak acid found in many foods. The net ionic equation for a typical reaction is

$$\underset{\text{tartaric acid}}{H_2C_4H_4O_6(aq)} + \underset{\text{hydrogen carbonate ion}}{HCO_3^-(aq)} \longrightarrow \underset{\text{hydrogen tartrate ion}}{HC_4H_4O_6^-(aq)} + H_2O(\ell) + CO_2(g)$$

EXAMPLE 3.7

Gas-Forming Reactions

Problem Write a balanced equation for the reaction that occurs when nickel(II) carbonate is treated with sulfuric acid.

What Do You Know? You know the names of the reactants and therefore their formulas. You should recognize that the reaction of a metal carbonate with an acid is a gas-forming reaction (CO_2 is formed in these reactions).

Strategy

- Write the formulas for the reactants.
- Determine the products of the reaction and their formulas.
- Write and balance the equation.

SOLUTION The reactants are $NiCO_3$ and H_2SO_4, and the products of the reaction are $NiSO_4$, CO_2, and H_2O. The complete, balanced equation is

$$NiCO_3(s) + H_2SO_4(aq) \rightarrow NiSO_4(aq) + H_2O(\ell) + CO_2(g)$$

Think about Your Answer The products in this reaction were determined by first exchanging cations (Ni^{2+} and 2 H^+) and anions (CO_3^{2-} and SO_4^{2-}). This exchange reaction is then followed by a second reaction in which one product, H_2CO_3, decomposes to give CO_2 and H_2O.

Check Your Understanding

Barium carbonate, $BaCO_3$, is used in the brick, ceramic, glass, and chemical manufacturing industries. Write a balanced equation that shows what happens when barium carbonate is treated with nitric acid. Give the name of each of the reaction products.

3.8 Oxidation–Reduction Reactions

Goals for Section 3.8

- Determine oxidation numbers of elements in a compound and understand that these numbers represent the charge an atom has, or appears to have, when the electrons of the compound are counted according to a set of guidelines.
- Recognize common oxidizing and reducing agents.
- Identify oxidation–reduction reactions (redox reactions), identify the oxidizing and reducing agents and substances oxidized and reduced in the reaction, and write and balance equations for redox reactions.

The terms *oxidation* and *reduction* come from reactions that have been known for centuries. Ancient civilizations learned how to change metal oxides and sulfides into the metal, that is, how to "reduce" ore to the metal. A modern example is the reduction of iron(III) oxide with carbon monoxide to give iron metal.

Fe_2O_3 loses oxygen and is reduced.

$$Fe_2O_3(s) + 3\ CO(g) \longrightarrow 2\ Fe(s) + 3\ CO_2(g)$$

CO is the reducing agent. It gains oxygen and is oxidized.

Jan Halaska/Science Source

Iron ore, which is largely Fe_2O_3, is reduced to metallic iron with carbon (C) or carbon monoxide (CO) in a blast furnace. The C or CO is oxidized to CO_2.

In this reaction carbon monoxide is the agent that brings about the reduction of iron ore to iron metal, so carbon monoxide is called the **reducing agent**.

When Fe_2O_3 is reduced by carbon monoxide, oxygen is removed from the iron ore and added to the carbon monoxide. The carbon monoxide, therefore, is "oxidized" by the addition of oxygen. *Any process in which oxygen is added to another substance is an oxidation.*

Burning magnesium metal in air produces magnesium oxide. The magnesium is oxidized by the oxidizing agent O_2. Oxygen is reduced by the reducing agent Mg.

© Cengage Learning/Charles D. Winters

Magnesium metal and oxygen produce magnesium oxide. In such oxidations, oxygen is called the **oxidizing agent** because it is the substance responsible for the oxidation of the metal.

Mg combines with oxygen and is oxidized.

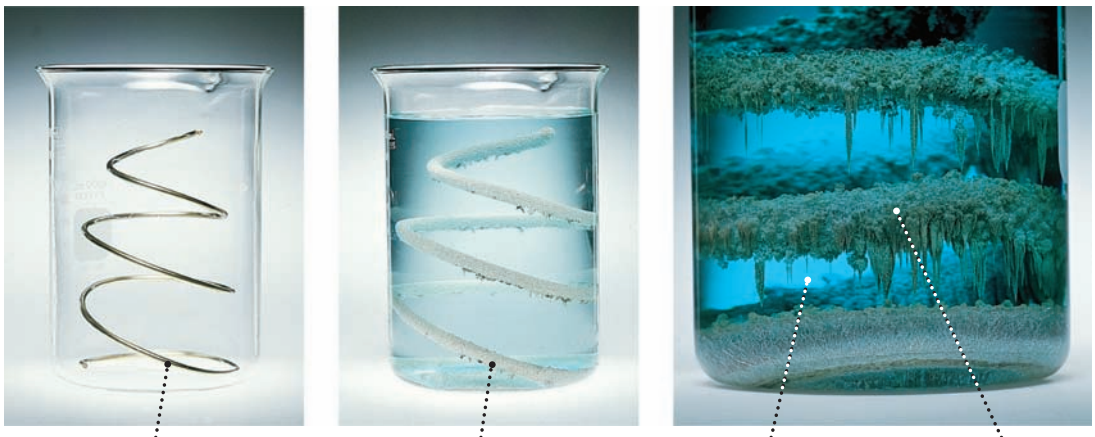
$$2\ Mg(s) + O_2(g) \longrightarrow 2\ MgO(s)$$

O_2 is the oxidizing agent.

Oxidation–Reduction Reactions and Electron Transfer

The concept of oxidation–reduction reactions can be extended to a vast number of other reactions that do not involve oxygen. Rather than concentrate on whether oxygen is gained or lost, let us look at what is going on with electrons during the course of the reaction. All oxidation and reduction reactions can be accounted for by considering them to occur by a transfer of electrons between substances. When a substance accepts electrons, it is said to be reduced because there is a reduction in the numerical value of the charge on an atom of the substance. In the reaction of a silver salt with copper metal, positively charged Ag^+ ions accept electrons from copper metal and are reduced to uncharged silver atoms (Figure 3.16).

Ag^+ ions accept electrons from Cu and are reduced to Ag. Ag^+ is the oxidizing agent.



$$Ag^+(aq) + e^- \longrightarrow Ag(s)$$

$$2\ Ag^+(aq) + Cu(s) \longrightarrow 2\ Ag(s) + Cu^{2+}(aq)$$

Cu donates electrons to Ag^+ and is oxidized to Cu^{2+}. Cu is the reducing agent.

$$Cu(s) \longrightarrow Cu^{2+}(aq) + 2\ e^-$$

Because copper metal supplies the electrons that cause Ag^+ ions to be reduced, Cu is the *reducing agent*.

Pure copper wire

Copper wire in dilute $AgNO_3$ solution after several hours

Blue color due to Cu^{2+} ions formed in redox reaction

Silver crystals formed after several weeks

Photos: © Cengage Learning/Charles D. Winters

Figure 3.16 The oxidation of copper metal by silver ions. A clean piece of copper wire is placed in a solution of silver nitrate, $AgNO_3$. Over time, the copper reduces Ag^+ ions, forming silver crystals, and the copper metal is oxidized to copper ions, Cu^{2+}. The blue color of the solution is due to the presence of aqueous copper(II) ions formed in the reaction.

When a substance *loses electrons*, the numerical value of the charge on an atom of the substance increases. The substance is said to have been **oxidized**. In our example, copper metal releases electrons on going to Cu^{2+}, so the metal is oxidized. For this to happen, something must be available to accept the electrons from copper. In this case, Ag^+ is the electron acceptor; its charge is reduced to zero in silver metal, so we say the metal ion has been **reduced**. Furthermore, because Ag^+ is the "agent" that causes Cu metal to be oxidized, we say Ag^+ is the *oxidizing agent*.

In every oxidation–reduction reaction, one reactant is reduced (and therefore is the oxidizing agent) and one reactant is oxidized (and therefore is the reducing agent). We can show this by dividing the general redox reaction $X + Y \rightarrow X^{n+} + Y^{n-}$ into two parts or *half-reactions*:

Half-Reaction	Electron Transfer	Result
$X \rightarrow X^{n+} + n\,e^-$	X transfers electrons to Y	X is oxidized to X^{n+}. X is the reducing agent.
$Y + n\,e^- \rightarrow Y^{n-}$	Y accepts electrons from X	Y is reduced to Y^{n-}. Y is the oxidizing agent.

In the reaction of magnesium and oxygen, the oxidizing agent, O_2, is reduced because it gains electrons (four electrons per molecule) on going to two oxide ions.

In the same reaction, magnesium is the reducing agent because it releases two electrons per atom on being oxidized to the Mg^{2+} ion (and so two Mg atoms are required to supply the four electrons required by one O_2 molecule). All oxidation–reduction reactions can be analyzed in a similar manner.

An important principle to remember concerning oxidation–reduction reactions is that in a balanced equation the extents of oxidation and reduction must be the same. This is easy to see in the Mg/O_2 equation. Here, four electrons are released when two magnesium atoms are oxidized, so four electrons must be taken up by the oxidizing agent, in this example one molecule of O_2.

The observations outlined so far lead to several important conclusions:

- If one substance is oxidized, another substance in the same reaction must be reduced. For this reason, such reactions are called *oxidation–reduction reactions*, or **redox reactions** for short.
- The reducing agent is itself oxidized, and the oxidizing agent is reduced.
- Reduction involves the gain of electrons, oxidation involves the loss of electrons.
- The extents of oxidation and reduction in a reaction must be the same. This means that the number of electrons released when a substance is oxidized must equal the number of electrons gained by the substance being reduced.

Balancing Equations for Redox Reactions The notion that a redox reaction can be divided into a reduction portion and an oxidation portion will lead us to a method of balancing more complex equations for redox reactions described in Chapter 19.

Oxidation Numbers

How can you tell an oxidation–reduction reaction when you see one? Sometimes it is obvious. For example, if an uncombined element becomes part of a compound (Mg becomes part of MgO, for example), the reaction is definitely a redox process. If it's not obvious, then the answer is to *look for a change in the oxidation number of an element in the course of the reaction*. The **oxidation number** of an atom in a

Writing Charges and Oxidation Numbers on Ions Conventionally, charges on ions are written as (number, sign), whereas oxidation numbers are written as (sign, number). For example, the oxidation number of the Cu^{2+} ion is +2 and its charge is 2+.

molecule or ion is defined as the charge an atom has, *or appears to have*, as determined by the following guidelines for assigning oxidation numbers.

1. **Each atom in a pure element has an oxidation number of zero.** The oxidation number of Cu in metallic copper is 0, and it is 0 for each atom in I_2 and S_8.
2. **For monatomic ions, the oxidation number is equal to the charge on the ion.** Magnesium forms ions with a 2+ charge (Mg^{2+}); the oxidation number of magnesium in this ion is therefore +2.
3. **When combined with another element, fluorine always has an oxidation number of −1**.
4. **The oxidation number of O is −2 in most compounds.** Exceptions to this rule occur
   (a) when oxygen is combined with fluorine (where oxygen takes on a positive oxidation number),
   (b) in compounds called *peroxides* (such as Na_2O_2) and *superoxides* (such as KO_2) in which oxygen has an oxidation number of −1 and −1/2, respectively.
5. **Cl, Br, and I have oxidation numbers of −1 in compounds, except when combined with oxygen and fluorine.** This means that Cl has an oxidation number of −1 in NaCl (in which Na's oxidation number is +1, as predicted by the fact that it is an element of Group 1A). In the ion ClO^-, however, the Cl atom has an oxidation number of +1 (and O has an oxidation number of −2; see Guideline 4).
6. **The oxidation number of H is +1 in most compounds.** The main exception to this guideline occurs when H forms a binary compound with a metal. In such cases, the metal forms a positive ion and H becomes a hydride ion, H^-. Thus, in CaH_2 the oxidation number of Ca is +2 (equal to the group number) and that of H is −1.
7. **The algebraic sum of the oxidation numbers for the atoms in a neutral compound must be zero; in a polyatomic ion, the sum must equal the ion charge.** For example, in $HClO_4$ the H atom is assigned +1 and each O atom is assigned −2. This means the Cl atom must be +7. In ClO_4^-, the sum of the oxidation states of O ($-2 \times 4 = -8$) and Cl (+7) is the charge on the ion, −1.

Peroxides In hydrogen peroxide (H_2O_2), each hydrogen atom has an oxidation number of +1. To balance this, each oxygen must have an oxidation number of −1. A 3% aqueous solution of H_2O_2 is sometimes used as an antiseptic.

EXAMPLE 3.8

Determining Oxidation Numbers

Problem Determine the oxidation number of the indicated element in each of the following compounds or ions:

(a) aluminum in aluminum oxide, Al_2O_3

(b) phosphorus in phosphoric acid, H_3PO_4

(c) sulfur in the sulfate ion, SO_4^{2-}

(d) each Cr atom in the dichromate ion, $Cr_2O_7^{2-}$

What Do You Know? Correct formulas for each species are given.

Strategy Follow the guidelines in the text, paying particular attention to Guidelines 4, 6, and 7.

SOLUTION

(a) Al_2O_3 is a neutral compound. Assuming that oxygen has its usual oxidation number of −2, we can solve the following algebraic equation for the oxidation number of aluminum.

Net charge on Al_2O_3 = sum of oxidation numbers for two Al atoms + three O atoms

$$0 = 2(x) + 3(-2) \text{ and so } x = +3$$

The oxidation number of Al must be +3, in agreement with its position in the periodic table.

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

(b) H_3PO_4 has an overall charge of 0. If each of the oxygen atoms has an oxidation number of −2 and each of the H atoms is +1, then the oxidation number of phosphorus is +5.

Net charge on H_3PO_4 = sum of oxidation numbers for three H atoms + one P atom + four O atoms

$$0 = 3(+1) + (x) + 4(-2) \text{ and so } x = +5$$

(c) The sulfate ion, SO_4^{2-}, has an overall charge of 2−. Oxygen is assigned its usual oxidation number of −2, and so sulfur in this ion has an oxidation number of +6.

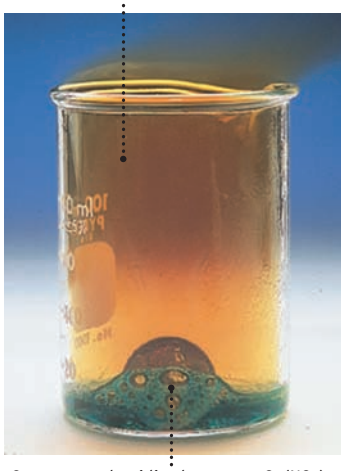
Net charge on SO_4^{2-} = sum of oxidation number of one S atom + four O atoms

$$-2 = (x) + 4(-2) \text{ and so } x = +6$$

(d) The net charge on the $Cr_2O_7^{2-}$ ion is 2−. Oxygen is assigned its usual oxidation number of −2.

Net charge on $Cr_2O_7^{2-}$ = sum of oxidation numbers for two Cr atoms + seven O atoms

$$-2 = 2(x) + 7(-2) \text{ and so } x = +6$$



The oxidation number of each chromium in this polyatomic ion is +6.

Think about Your Answer In each of these examples, the oxidation number of Al, S, P, and Cr matched the number of the periodic group in which the element is found. This is often (but not always) the case. For example, S, P, and Cr have a range of oxidation numbers, depending on the compound.

Check Your Understanding

Assign an oxidation number to the underlined atom in each ion or molecule.

(a) $\underline{Fe}_2O_3$ (b) $H_2\underline{S}O_4$ (c) $\underline{C}O_3^{2-}$ (d) $\underline{N}O_2^+$

Figure 3.17 Oxidizing and reducing agents. The reaction of copper with nitric acid. Copper (a reducing agent) reacts vigorously with concentrated nitric acid (an oxidizing agent) to give the brown gas NO_2 and a deep blue-green solution of copper(II) nitrate.

Recognizing Oxidation–Reduction Reactions

You can always tell whether a reaction involves oxidation and reduction by assessing the oxidation number of each element and noting whether any of these numbers change in the course of the reaction. In many cases, however, this will not be necessary. For example, it will be obvious that a redox reaction has occurred if an uncombined element is converted to a compound or if a well-known oxidizing or reducing agent is involved.

The halogens and oxygen (see Figures 3.1 and 3.2) are oxidizing agents, and another common oxidizing agent is nitric acid, HNO_3. In Figure 3.17 copper metal

A CLOSER LOOK

Are Oxidation Numbers "Real"?

Do oxidation numbers reflect the actual electric charge on an atom in a molecule or ion? With the exception of monatomic ions such as Cl^- or Na^+, the answer is generally no.

Oxidation numbers assume that all atoms in a molecule are positive or negative ions, which is not true. For example, in H_2O, the H atoms are not H^+ ions and the O atoms are not O^{2-} ions. This is not to say, however, that atoms in molecules do not bear an electric charge of any kind. Advanced calculations indicate the O atom in water actually has a charge of about 0.4− (or 40% of the electron charge) and the H atoms are each about 0.2+.

So why use oxidation numbers? Oxidation numbers provide a convenient way of dividing up the electrons among the atoms in a molecule or polyatomic ion. Because the distribution of electrons changes in a redox reaction, we use oxidation numbers to decide whether a redox reaction has occurred and to distinguish the oxidizing and reducing agents.

TABLE 3.3 Common Oxidizing and Reducing Agents

Oxidizing Agent	Reaction Product	Reducing Agent	Reaction Product
O_2, oxygen	O^{2-}, oxide ion or O combined in H_2O or other molecule	H_2, hydrogen	$H^+(aq)$, hydrogen ion or H combined in H_2O or other molecule
Halogen, F_2, Cl_2, Br_2, or I_2	Halide ion, F^-, Cl^-, Br^-, or I^-	M, metals such as Na, K, Fe, and Al	M^{n+}, metal ions such as Na^+, K^+, Fe^{2+} or Fe^{3+}, and Al^{3+}
HNO_3, nitric acid	Nitrogen oxides* such as NO and NO_2	C, carbon (used to reduce metal oxides)	CO and CO_2
$Cr_2O_7^{2-}$, dichromate ion	Cr^{3+}, chromium(III) ion (in acid solution)		
MnO_4^-, permanganate ion	Mn^{2+}, manganese(II) ion (in acid solution)		

*NO is produced with dilute HNO_3, whereas NO_2 is a product of concentrated acid.

is oxidized by the acid to give copper(II) nitrate, and the nitrate ion is reduced to the brown gas NO_2. The net ionic equation for the reaction is

Oxidation number of Cu changes from 0 to +2. Cu is oxidized to Cu^{2+} and is the reducing agent.

$$Cu(s) + 2\ NO_3^-(aq) + 4\ H_3O^+(aq) \longrightarrow Cu^{2+}(aq) + 2\ NO_2(g) + 6\ H_2O(\ell)$$

N in NO_3^- changes from +5 to +4 in NO_2. NO_3^- is reduced to NO_2 and is the oxidizing agent.

Nitrogen has been reduced from +5 (in the NO_3^- ion) to +4 (in NO_2); therefore, the nitrate ion in acid solution is the oxidizing agent. Copper metal is the reducing agent; each metal atom has given up two electrons to produce the Cu^{2+} ion.

Tables 3.3 and 3.4 may help you organize your thinking as you look for oxidation–reduction reactions and use their terminology.

TABLE 3.4 Recognizing Oxidation–Reduction Reactions

	Oxidation	Reduction
In terms of oxidation number	Increase in oxidation number of an atom	Decrease in oxidation number of an atom
In terms of electrons	Loss of electrons by an atom	Gain of electrons by an atom
In terms of oxygen	Gain of one or more O atoms	Loss of one or more O atoms

EXAMPLE 3.9

Oxidation–Reduction Reaction

Problem For the reaction of the iron(II) ion with permanganate ion in aqueous acid,

$$5\ Fe^{2+}(aq) + MnO_4^-(aq) + 8\ H_3O^+(aq) \rightarrow 5\ Fe^{3+}(aq) + Mn^{2+}(aq) + 12\ H_2O(\ell)$$

decide which atoms are undergoing a change in oxidation number and identify the oxidizing and reducing agents.

What Do You Know? The equation given here is balanced (but, for practice, you might verify this). Based on the reactants and products you can quickly decide this is an oxidation–reduction reaction. Here you know MnO_4^- is a common oxidizing agent (see Table 3.3), and you see that iron changes from Fe^{2+} to Fe^{3+}.

Strategy Determine the oxidation number of the atoms in each molecule or ion in the equation and identify which atoms change oxidation number.

SOLUTION The Mn oxidation number in MnO_4^- is +7, and it decreases to +2 in the product, the Mn^{2+} ion. Thus, the MnO_4^- ion has been reduced and is the oxidizing agent (see Table 3.3).

$$\underset{+2}{5\ Fe^{2+}(aq)} + \underset{+7,\ -2}{MnO_4^-(aq)} + \underset{+1,\ -2}{8\ H_3O^+(aq)} \rightarrow \underset{+3}{5\ Fe^{3+}(aq)} + \underset{+2}{Mn^{2+}(aq)} + \underset{+1,\ -2}{12\ H_2O(\ell)}$$

The oxidation number of iron has increased from +2 to +3, so each Fe^{2+} ion has lost one electron upon being oxidized to Fe^{3+} (see Table 3.4). This means the Fe^{2+} ion is the reducing agent.

Think about Your Answer If one of the reactants in a redox reaction is a simple substance such as an element or a monoatomic ion (here Fe^{2+}), it usually is obvious whether its oxidation number has increased or decreased. Once a species has been established as having been reduced (or oxidized), you know another species has undergone the opposite process.

Check Your Understanding

The following reaction is used in a device for testing the breath of a person for the presence of ethanol. Identify the oxidizing and reducing agents, the substance oxidized, and the substance reduced.

$$\underset{\text{ethanol}}{3\ CH_3CH_2OH(aq)} + \underset{\substack{\text{dichromate ion;}\\ \text{orange-red}}}{2\ Cr_2O_7^{2-}(aq)} + 16\ H_3O^+(aq) \rightarrow \underset{\text{acetic acid}}{3\ CH_3CO_2H(aq)} + \underset{\substack{\text{chromium(III)}\\ \text{ion; green}}}{4\ Cr^{3+}(aq)} + 27\ H_2O(\ell)$$

© Cengage Learning/Charles D. Winters

Oxidizing and reducing agents. The reaction of iron(II) ion and permanganate ion. The reaction of purple permanganate ion (MnO_4^-) with the iron(II) ion (Fe^{2+}) in acidified aqueous solution gives the nearly colorless manganese(II) ion (Mn^{2+}) and the iron(III) ion (Fe^{3+}).

3.9 Classifying Reactions in Aqueous Solution

Goals for Section 3.9

- Recognize the key characteristics of four types of reactions in aqueous solution and identify reactions based on these characteristics.
- Predict products for precipitation, acid-base, and gas-forming reactions and write balanced chemical equations and net ionic equations for these reactions.

One goal of this chapter has been to explore common types of reactions that can occur in aqueous solution. This helps you decide, for example, that a gas-forming

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Figure 3.18 A gas-forming reaction. An Alka-Seltzer tablet contains an acid (citric acid) and sodium hydrogen carbonate ($NaHCO_3$), the reactants in a gas-forming reaction.

reaction occurs when an Alka-Seltzer tablet (containing citric acid and $NaHCO_3$) is dropped into water (Figure 3.18).

$$\underset{\text{citric acid}}{H_3C_6H_5O_7(aq)} + \underset{\text{hydrogen carbonate ion}}{HCO_3^-(aq)} \longrightarrow \underset{\text{dihydrogen citrate ion}}{H_2C_6H_5O_7^-(aq)} + H_2O(\ell) + CO_2(g)$$

We have examined four types of reactions in aqueous solution: precipitation, acid–base, gas-forming, and oxidation–reduction. Three of these four (precipitation, acid–base, and gas-forming) fall into the category of exchange reactions.

Precipitation Reactions: Ions combine in solution to form an insoluble reaction product.

Overall Equation

$$Pb(NO_3)_2(aq) + 2\ KI(aq) \rightarrow PbI_2(s) + 2\ KNO_3(aq)$$

Net Ionic Equation

$$Pb^{2+}(aq) + 2\ I^-(aq) \rightarrow PbI_2(s)$$

Acid–Base Reactions: Water is a product of many acid–base reactions, and the cation of the base and the anion of the acid form a salt.

Overall Equation for the Reaction of a Strong Acid and a Strong Base

$$HNO_3(aq) + KOH(aq) \rightarrow HOH(\ell) + KNO_3(aq)$$

Net Ionic Equation for the Reaction of a Strong Acid and a Strong Base

$$H_3O^+(aq) + OH^-(aq) \rightarrow 2\ H_2O(\ell)$$

A CLOSER LOOK

Alternative Organizations of Reaction Types

As we said in Chapter 1, chemistry is about the transformation of one or more substances into other substances. This is done by chemical reactions, and thousands upon thousands of reactions have been carried out by chemists. Although students beginning their study of chemistry can be bewildered by the apparent infinite variety of these reactions, there are some common reaction types. We have classified them as oxidation–reduction reactions and exchange reactions. The latter include precipitation, acid–base, and gas-forming reactions. Classifying reactions is useful because it helps to see their common features and to predict what might happen if you see a new set of reactants.

There are two other terms that are commonly used when describing chemical reactions: synthesis and decomposition. These terms are widely used in chemistry because they describe the possible outcome of a reaction.

Synthesis describes the preparation of a compound from elements or other compounds. You have already seen synthesis reactions such as the preparation of ammonium chloride, which is widely used in fertilizers, in medicines, in consumer products such as shampoo, and in explosives. The synthesis of ammonium chloride can be carried out using an acid–base reaction.

$$NH_3(aq) + HCl(aq) \rightarrow NH_4Cl(aq)$$

Decomposition describes a reaction in which a compound is broken apart into smaller constituents. One such reaction is the decomposition of hydrogen peroxide to water and oxygen, an oxidation-reduction reaction seen in the Figure.

$$2\ H_2O_2(aq) \rightarrow 2\ H_2O(\ell) + O_2(g)$$

© Cengage Learning/Charles D. Winters

The decomposition of hydrogen peroxide, H_2O_2. This can also be classified as an oxidation–reduction reaction.

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Overall Equation for the Reaction of a Weak Acid and a Strong Base

$$CH_3CO_2H(aq) + NaOH(aq) \rightarrow NaCH_3CO_2(aq) + HOH(\ell)$$

Net Ionic Equation for the Reaction of a Weak Acid and a Strong Base

$$CH_3CO_2H(aq) + OH^-(aq) \rightarrow CH_3CO_2^-(aq) + H_2O(\ell)$$

Gas-Forming Reactions: The most common examples involve metal carbonates and acids but others exist. The reaction of a metal carbonate and acid produces carbonic acid, H_2CO_3, which decomposes to H_2O and CO_2. Carbon dioxide is the gas in the bubbles you see during these reactions.

Overall Equation: $CuCO_3(s) + 2\ HNO_3(aq) \rightarrow Cu(NO_3)_2(aq) + CO_2(g) + H_2O(\ell)$

Net Ionic Equation: $CuCO_3(s) + 2\ H_3O^+(aq) \rightarrow Cu^{2+}(aq) + CO_2(g) + 3\ H_2O(\ell)$

Oxidation–Reduction Reactions: These reactions are *not* ion exchange reactions. Rather, electrons are transferred from one material to another.

Overall Equation: $Cu(s) + 2\ AgNO_3(aq) \rightarrow Cu(NO_3)_2(aq) + 2\ Ag(s)$

Net Ionic Equation: $Cu(s) + 2\ Ag^+(aq) \rightarrow Cu^{2+}(aq) + 2\ Ag(s)$

The four types of reactions usually are easy to recognize, but keep in mind that a reaction can fall into more than one category. For example, barium hydroxide reacts readily with sulfuric acid to give barium sulfate and water, a reaction that is both a precipitation and an acid–base reaction.

$$Ba(OH)_2(aq) + H_2SO_4(aq) \rightarrow BaSO_4(s) + 2\ H_2O(\ell)$$

EXAMPLE 3.10

Types of Reactions

Problem Complete and balance each of the following equations for these exchange reactions and classify each as a precipitation, acid–base, or gas-forming reaction.

(a) $Na_2S(aq) + Cu(NO_3)_2(aq) \rightarrow$

(b) $Na_2SO_3(aq) + HCl(aq) \rightarrow$

(c) $HClO_4(aq) + NaOH(aq) \rightarrow$

What Do You Know? You know the formulas for the reactants and that these are all exchange reactions.

Strategy

- Recognize that these are exchange reactions. The products of each reaction can be found by exchanging cations and anions between the two reactants.
- Write and balance each equation.
- To determine the kind of reaction examine the reactants and products. Look specifically for common acids and bases, for a product that is insoluble, and for anions that react with acid to give a gas (CO_3^{2-}, S^{2-}, SO_3^{2-}).

SOLUTION

(a) The products of the exchange reaction are predicted to be $NaNO_3$ and CuS. The first of these is water-soluble, but the second is an insoluble salt. Thus, this is a precipitation reaction. The balanced chemical equation is

$$Na_2S(aq) + Cu(NO_3)_2(aq) \rightarrow 2\ NaNO_3(aq) + CuS(s)$$

Strategy Map 3.10a

PROBLEM

Write equation for the reaction of **Na_2S** and **$Cu(NO_3)_2$** and decide on ***reaction type***

DATA/INFORMATION

The **formulas** of the **reactants** are given

STEP 1. Decide on **products** and then write **complete balanced equation.**

Complete balanced equation with ***reactants*** and ***products***

STEP 2. Decide if each reactant and product is **solid**, **liquid**, **gas**, or **dissolved in water.**

Complete balanced equation with **indication of state** of each reactant and product

STEP 3. Decide on **reaction type.**

One product is ***insoluble in water***, so this is a **precipitation reaction.**

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

(b) The products of the exchange reaction are predicted to be NaCl and H_2SO_3. The H_2SO_3 should immediately alert us to the fact that this is a gas-forming reaction because it will decompose into $SO_2(g)$ and $H_2O(\ell)$ (see Table 3.2). The balanced equation is

$$Na_2SO_3(aq) + 2\ HCl\ (aq) \longrightarrow 2\ NaCl(aq) + SO_2\ (g) + H_2O(\ell)$$

(c) The products of the exchange reaction are predicted to be $NaClO_4$ and H_2O, a salt and water; this is an acid–base reaction. The balanced equation is

$$HClO_4(aq) + NaOH(aq) \longrightarrow NaClO_4(aq) + H_2O(\ell)$$

Think about Your Answer As practice, try writing the net ionic equations for each of the preceding reactions. The answers are:

(a) $S^{2-}(aq) + Cu^{2+}(aq) \longrightarrow CuS(s)$

(b) $SO_3^{2-}(aq) + 2\ H_3O^+(aq) \longrightarrow 3\ H_2O(\ell) + SO_2(g)$

(c) $H_3O^+(aq) + OH^-(aq) \longrightarrow 2\ H_2O(\ell)$

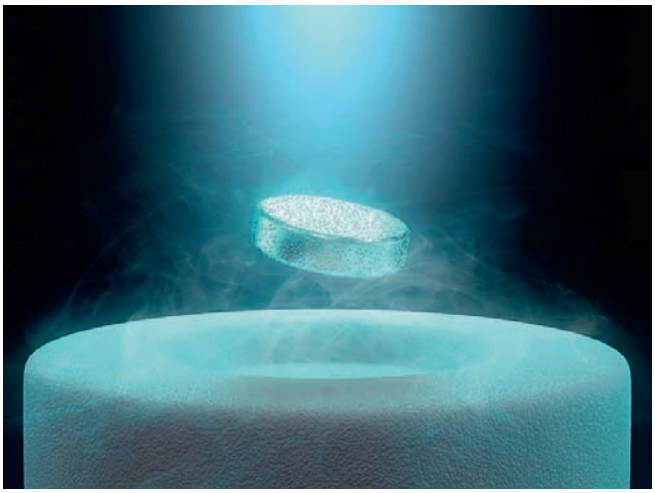
Check Your Understanding

Classify each of the following reactions as a precipitation, acid–base, gas-forming, or oxidation–reduction reaction. Predict the products of the reaction, and then balance the completed equation. Write the net ionic equation for each.

(a) $CuCO_3(s) + H_2SO_4(aq) \longrightarrow$

(b) $Ga(s) + O_2(g) \longrightarrow$

(c) $Ba(OH)_2(s) + HNO_3(aq) \longrightarrow$



(d) $CuCl_2(aq) + (NH_4)_2S(aq) \longrightarrow$

APPLYING CHEMICAL PRINCIPLES

3.1 Superconductors

In 1987, the Nobel Prize in Physics was awarded to Georg Benorz and Karl Müller (IBM Labs, Zurich, Switzerland) for their pioneering work in superconductivity, including their discovery of a new class of superconductors based on a lanthanum, barium, copper, and oxygen compound. The superconductor was identified as $La_{2-x}Ba_xCuO_4$, where the value of x varied from 0.10 to 0.20. In the same year, researchers at the University of Alabama at Huntsville synthesized $YBa_2Cu_3O_{7-x}$ (or YBCO), where x varies from 0 to 0.50. YBCO was the first material discovered to superconduct at temperatures above the boiling point of liquefied nitrogen (77 K). Further research determined that the critical temperature for superconductivity of YBCO varies with changes to the ratios of its components. The highest superconducting temperature, 95 K, is found for $YBa_2Cu_3O_{6.93}$.

Superconductors are important because these materials have no resistance to the flow of electric current. Once a current (that is, a flow of electrons) is induced in a superconductor, it will continue indefinitely with no energy loss. A potential application for superconductors is electricity storage. Currently, electricity produced at power plants must be used as it is produced. If unused electricity could be fed into a superconducting storage ring, the current could be stored indefinitely.

David Parker/IMI/Science Source

Superconductivity. When a superconducting material is cooled to a low temperature, say in liquid nitrogen (boiling point 77 K), and is placed in a magnetic field, the field does not penetrate the superconductor but rather is rejected from the superconductor. The effect is seen here where a magnet floats above cooled superconductors.

Unfortunately, no superconductor has been discovered that can carry large currents at temperatures greater than 77 K.

Compound formulas containing subscripts that are not whole numbers are common for a variety of compounds, including high-temperature superconductors. Answer the following questions concerning a couple of these superconductors.

Questions:

1. Use the following mass percentages to determine the value of x in a sample of $La_{2-x}Ba_xCuO_4$: %La = 63.43, %Ba = 5.085, %Cu = 15.69, and %O = 15.80.
2. What is the percent by mass of each element in YBCO when $x = 0.07$?
3. Assuming the charges on the yttrium and barium ions are 3+ and 2+, respectively, what charges are present on the copper ions in $YBa_2Cu_3O_7$? (Note: Although most copper compounds are based on Cu^{2+}, charges of 1+ and 3+ are also possible. Assume at least one copper ion in this substance is Cu^{2+}.)
4. The reaction of Y_2O_3, $BaCO_3$, and CuO produces $YBa_2Cu_3O_{7-x}$ with $CO_2(g)$ as the only by-product. Write a balanced chemical equation of this reaction and determine the value of x.
5. The percentage of oxygen in YBCO is adjusted by heating it in the presence of elemental oxygen. What mass of oxygen is required to convert 1.00 g $YBa_2Cu_3O_{6.50}$ to $YBa_2Cu_3O_{6.93}$?

3.2 Sequestering Carbon Dioxide

Scientific evidence strongly indicates that the rising concentration of CO_2 in the atmosphere contributes to warming of our planet. These concerns have led to a variety of studies that attempt to limit the CO_2 entering the atmosphere. The best known of these involves pumping CO_2 into deep wells underground. However, there are concerns about how well CO_2 can be stored this way; in particular, there is concern that this gas will escape containment and leak to the surface.

There is an interesting pilot study underway in Iceland to address the problem of leakage. Here CO_2 was dissolved in water. Then a chemical to serve as an indicator was added, and the solution was pumped 2000 meters underground into the basalt rock strata that underlies most of Iceland. Basalt is an igneous aluminosilicate rock, widely distributed on Earth. It consists of a matrix of aluminum and silicon oxides in which metal ions including Ca^{2+} are dispersed. It is somewhat porous so that water under high pressure can be forced into and through the rock itself.

Surrounding the injection well were eight monitoring holes 500 meters deep. The injected water-CO_2-indicator mixture slowly diffused through the basalt and after about 60 days reached the monitoring wells. The researchers then followed changes in dissolved carbon (CO_2) and the acidity in the mixture over time, observing an initial significant increase in CO_2 and acidity, both of which quickly diminished as the flow continued. Tests of the material from the monitoring hole showed that most of the CO_2 was not being released to the atmosphere but instead was being converted to calcite, $CaCO_3$, within the rock formation. The hydrogen ions, presumably, remained in the basalt lattice.

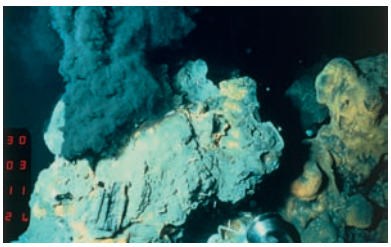
Basalt, an igneous rock found in volcanic regions. A project in Iceland has found that the mineral is effective in sequestering CO_2.

The significance of this is that the CO_2 now was bound up in a stable solid material and no longer free to escape confinement. Will this idea catch on and be used on a large scale? This has yet to be determined.

Questions:

1. Write a balanced net ionic equation for the reaction of Ca^{2+} ion with H_2CO_3.
2. One of the indicators used was CO_2 labeled with the radioactive carbon isotope carbon-14. The researchers detected that H_2CO_3 was moving through the rock matrix by measuring the radioactivity of the water at the detection well. Give the number of protons, electrons, and neutrons in a carbon-14 atom.

3.3 Black Smokers and Volcanoes



In 1977, scientists were exploring the junction of two of the tectonic plates that form the floor of the Pacific Ocean. There they found thermal springs gushing a hot, black soup of minerals. Seawater seeps into cracks in the ocean floor and, as it sinks deeper into Earth's crust, the water is superheated to between 300 °C and 400 °C by the hot magma just below Earth's crust. This superhot water dissolves minerals in the crust and is pushed back to the surface. When this hot water, now laden with dissolved metal cations and rich in anions such as sulfide and sulfate, gushes through the surface, it cools,

and metal sulfates—such as calcium sulfate—and metal sulfides—such as those of copper, manganese, iron, zinc, and nickel—precipitate. Many metal sulfides are black, and the plume of material coming from the sea bottom looks like black "smoke;" thus, the vents have been called "black smokers." The solid sulfides and other minerals settle around the edges of the vent on the sea floor and eventually form a "chimney" of precipitated minerals. You can see the same deposits of metal sulfides around steam vents from volcanoes on Earth's surface and in the water flowing away from a volcano or steam vent.

Scientists were amazed to discover that the deep sea vents were surrounded by peculiar animals living in the hot, sulfide-rich environment. Because black smokers are under hundreds of feet of water and sunlight does not penetrate to these depths, the animals have developed a way to live without the energy from sunlight. In a terrestrial environment, plants use the energy of the Sun to synthesize organic molecules by the process of photosynthesis. In the lightless ecosystem deep in the ocean, energy is derived from the oxidation of sulfides. With this source of energy, microbes are able to make the organic molecules that are the basis of life.

B. Murton/Southampton Oceanography Centre/Science Source

Metal sulfides from a black smoker. A "black smoker" photographed deep in the Pacific Ocean along the East Pacific Rise. The "smoke" is a cloud of insoluble metal sulfides formed when the molten material is forced from the Earth's interior.

Questions:

1. When the superheated water that gushes from vents in the sea floor cools, compounds such as $CaSO_4$, MnS, FeS, and NiS precipitate from solution. What are the formulas and names for the ions making up these compounds?
2. The oxidation of sulfide ion to sulfate ion by oxygen can be carried out in the lab. What are the oxidation numbers of sulfur in these two ions?

CHAPTER GOALS REVISITED

The goals for this chapter are keyed to specific Study Questions to help you organize your review.

3.1 Introduction to Chemical Equations

- Understand the information conveyed by a balanced chemical equation including the terminology used (reactants, products, stoichiometry, stoichiometric coefficients). **1, 2.**
- Recognize that a balanced chemical equation is required by the law of conservation of matter. **3–6.**

3.2 Balancing Chemical Equations

- Balance simple chemical equations. **7–12, 67, 68.**

3.3 Introduction to Chemical Equilibrium

- Recognize that all chemical reactions are reversible and that reactions eventually reach a dynamic equilibrium. **13, 14, 88.**
- Recognize the difference between reactant-favored and product-favored reactions at equilibrium. **15, 16.**

3.4 Aqueous Solutions

- Explain the difference between electrolytes and nonelectrolytes and recognize examples of each. **17, 18 , 84, 85.**
- Predict the solubility of ionic compounds in water (Figure 3.10). **19, 20, 23, 24, 69, 70.**

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

3.5 Precipitation Reactions

- Recognize what ions are formed when an ionic compound or acid or base dissolves in water. **21, 22.**
- Recognize exchange reactions in which there is an exchange of anions between the cations of reactants in solution. **27, 28, 59, 60.**
- Predict the products of precipitation reactions. **27, 28, 82.**
- Write net ionic equations for reactions in aqueous solution. **43–46.**

3.6 Acids and Bases

- Know the names and formulas of common acids and bases and categorize them as strong or weak. **29, 30.**
- Define the Arrhenius and Brønsted-Lowry concepts of acids and bases. **35–38.**
- Identify the Brønsted acid and base in a reaction and write equations for Brønsted–Lowry acid-base reactions. **39, 40.**
- Recognize substances that are amphiprotic and oxides that dissolve in water to give acidic solutions and basic solutions. **33, 34, 41, 42.**

3.7 Gas-Forming Reactions

- Identify common reactions in which a gas is formed and write equations for these reactions (Table 3.2). **49–52.**

3.8 Oxidation-Reduction Reactions

- Determine oxidation numbers of elements in a compound and understand that these numbers represent the charge an atom has, or appears to have, when the electrons of the compound are counted according to a set of guidelines. **53, 54.**
- Recognize common oxidizing and reducing agents. **57, 58.**
- Identify oxidation–reduction reactions (redox reactions), identify the oxidizing and reducing agents and substances oxidized and reduced in the reaction (Tables 3.3 and 3.4), and write and balance equations for redox reactions. **55–58, 75, 89.**

3.9 Classifying Reactions in Aqueous Solution

- Recognize the key characteristics of four types of reactions in aqueous solution and identify reactions based on these characteristics. **59–66.**

Reaction Type	Key Characteristic
Precipitation	Formation of an insoluble compound
Acid–base	Formation of a salt and water
Gas-forming	Evolution of a water-insoluble gas such as CO_2
Oxidation–reduction	Transfer of electrons (with changes in oxidation numbers)

- Predict products for precipitation, acid-base, and gas-forming reactions and write balanced chemical equations and net ionic equations for these reactions. **61–64.**

STUDY QUESTIONS

▲ denotes challenging questions. **Blue-numbered questions** have answers in Appendix N and fully worked solutions in the *Student Solutions Manual*.

Practicing Skills

Introduction to Chemical Equations

(See Section 3.1.)

1. The equation for the oxidation of phosphorus in air is $P_4(s) + 5\ O_2(g) \rightarrow P_4O_{10}(s)$. Identify the reactants and products and the stoichiometric coefficients. To what do the designations s and g refer?
2. Write an equation from the following description: reactants are gaseous NH_3 and O_2, products are gaseous NO_2 and liquid H_2O, and the stoichiometric coefficients are 4, 7, 4, and 6, respectively.
3. The equation for the reaction of phosphorus and chlorine is $P_4(s) + 6\ Cl_2(g) \rightarrow 4\ PCl_3(\ell)$. If you use 8000 molecules of P_4 in this reaction how many molecules of Cl_2 are required to consume the P_4 completely?
4. The equation for the reaction of aluminum and bromine is $2\ Al(s) + 3\ Br_2(\ell) \rightarrow Al_2Br_6(s)$. If you use 6.0×10^{23} molecules of Br_2 in a reaction how many atoms of Al will be consumed?
5. Oxidation of 1.00 g of carbon monoxide, CO, produces 1.57 g of carbon dioxide, CO_2. How many grams of oxygen were required in this reaction?
6. A 0.20 mol sample of magnesium burns in air to form 0.20 mol of solid MgO. What amount (moles) of oxygen (O_2) is required for a complete reaction?

Balancing Equations

(See Example 3.1.)

7. Write balanced chemical equations for the following reactions.
   (a) The reaction of aluminum and iron(III) oxide to form iron and aluminum oxide (known as the thermite reaction).
   (b) The reaction of carbon and water at high temperature to form a mixture of gaseous CO and H_2 (known as water gas and once used as a fuel).
   (c) The reaction of liquid silicon tetrachloride and magnesium forming silicon and magnesium chloride. This is one step in the preparation of ultrapure silicon used in the semiconductor industry.

© Cengage Learning/Charles D. Winters

Thermite reaction

8. Write balanced chemical equations for the following reactions:
   (a) production of ammonia, $NH_3(g)$, by combining $N_2(g)$ and $H_2(g)$
   (b) production of methanol, $CH_3OH(\ell)$ by combining $H_2(g)$ and $CO(g)$
   (c) production of sulfuric acid by combining sulfur, oxygen, and water
9. Balance the following equations:
   (a) $Cr(s) + O_2(g) \rightarrow Cr_2O_3(s)$
   (b) $Cu_2S(s) + O_2(g) \rightarrow Cu(s) + SO_2(g)$
   (c) $C_6H_5CH_3(\ell) + O_2(g) \rightarrow H_2O(\ell) + CO_2(g)$
10. Balance the following equations:
   (a) $Cr(s) + Cl_2(g) \rightarrow CrCl_3(s)$
   (b) $SiO_2(s) + C(s) \rightarrow Si(s) + CO(g)$
   (c) $Fe(s) + H_2O(g) \rightarrow Fe_3O_4(s) + H_2(g)$
11. Balance the following equations, and name each reactant and product:
   (a) $Fe_2O_3(s) + Mg(s) \rightarrow MgO(s) + Fe(s)$
   (b) $AlCl_3(s) + NaOH(aq) \rightarrow Al(OH)_3(s) + NaCl(aq)$
   (c) $NaNO_3(s) + H_2SO_4(aq) \rightarrow Na_2SO_4(s) + HNO_3(aq)$
   (d) $NiCO_3(s) + HNO_3(aq) \rightarrow Ni(NO_3)_2(aq) + CO_2(g) + H_2O(\ell)$

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

12. Balance the following equations, and name each reactant and product:

(a) $SF_4(g) + H_2O(\ell) \rightarrow SO_2(g) + HF(\ell)$

(b) $NH_3(aq) + O_2(aq) \rightarrow NO(g) + H_2O(\ell)$

(c) $BF_3(g) + H_2O(\ell) \rightarrow HF(aq) + H_3BO_3(aq)$

Chemical Equilibrium

(See Section 3.3.)

13. Identify each of the following statements as either true or false.

(a) At equilibrium the rates of the forward and reverse reactions are equal.

(b) When a reaction reaches equilibrium the forward and reverse reactions cease to occur.

(c) Chemical reactions always proceed toward equilibrium.

14. Identify each of the following statements as either true or false.

(a) All chemical reactions are product-favored at equilibrium.

(b) There is no observable change in a chemical system at equilibrium.

(c) An equilibrium involving a weak acid in water is product favored.

15. Equal amounts of two acids—HCl and HCO_2H (formic acid)—are placed in aqueous solution. When equilibrium has been achieved, the HCl solution has a much greater electrical conductivity than the HCO_2H solution. Which reaction is more product-favored at equilibrium?

$$HCl(aq) + H_2O(\ell) \rightleftharpoons H_3O^+(aq) + Cl^-(aq)$$

$$HCO_2H(aq) + H_2O(\ell) \rightleftharpoons H_3O^+(aq) + HCO_2^-(aq)$$

16. Two aqueous solutions were prepared, one containing 0.10 mol of boric acid (H_3BO_3) in 200 mL and the second containing 0.10 mol phosphoric acid (H_3PO_4) in 200 mL. Both were weak conductors of electricity, but the H_3PO_4 solution was a noticeably stronger conductor. Write equations to describe the equilibrium in each solution, and explain the observed difference in conductivity.

Ions and Molecules in Aqueous Solution

(See Section 3.4 and Example 3.2.)

17. What is an electrolyte? How can you differentiate experimentally between a weak electrolyte and a strong electrolyte? Give an example of each.

18. Name and give the formulas of two acids that are strong electrolytes and one acid that is a weak electrolyte. Name and give formulas of two bases that are strong electrolytes and one base that is a weak electrolyte.

19. Which compound or compounds in each of the following groups is (are) soluble in water?

(a) CuO, $CuCl_2$, $FeCO_3$

(b) AgI, Ag_3PO_4, $AgNO_3$

(c) K_2CO_3, KI, $KMnO_4$

20. Which compound or compounds in each of the following groups is (are) soluble in water?

(a) $BaSO_4$, $Ba(NO_3)_2$, $BaCO_3$

(b) Na_2SO_4, $NaClO_4$, $NaCH_3CO_2$

(c) AgBr, KBr, Al_2Br_6

21. The following compounds are water-soluble. What ions are produced by each compound in aqueous solution?

(a) KOH (c) $LiNO_3$

(b) K_2SO_4 (d) $(NH_4)_2SO_4$

22. The following compounds are water-soluble. What ions are produced by each compound in aqueous solution?

(a) KI (c) K_2HPO_4

(b) $Mg(CH_3CO_2)_2$ (d) NaCN

23. Decide whether each of the following is water-soluble. If soluble, tell what ions are produced when the compound dissolves in water.

(a) Na_2CO_3 (c) NiS

(b) $CuSO_4$ (d) $BaBr_2$

24. Decide whether each of the following is water-soluble. If soluble, tell what ions are produced when the compound dissolves in water.

(a) $NiCl_2$ (c) $Pb(NO_3)_2$

(b) $Cr(NO_3)_3$ (d) $BaSO_4$

Precipitation Reactions and Net Ionic Equations

(See Section 3.5 and Examples 3.3 and 3.4.)

25. Balance the equation for the following precipitation reaction, and then write the net ionic equation. Indicate the state of each species (s, ℓ, aq, or g).

$$CdCl_2 + NaOH \rightarrow Cd(OH)_2 + NaCl$$

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

26. Balance the equation for the following precipitation reaction, and then write the net ionic equation. Indicate the state of each species (s, ℓ, aq, or g).

$$Ni(NO_3)_2 + Na_2CO_3 \rightarrow NiCO_3 + NaNO_3$$

27. Predict the products of each precipitation reaction. Balance the equation, and then write the net ionic equation.

(a) $NiCl_2(aq) + (NH_4)_2S(aq) \rightarrow$

(b) $Mn(NO_3)_2(aq) + Na_3PO_4(aq) \rightarrow$

28. Predict the products of each precipitation reaction. Balance the equation, and then write the net ionic equation.

(a) $Pb(NO_3)_2(aq) + KBr(aq) \rightarrow$

(b) $Ca(NO_3)_2(aq) + KF(aq) \rightarrow$

(c) $Ca(NO_3)_2(aq) + Na_2C_2O_4(aq) \rightarrow$

Acids and Bases and Their Reactions

(See Section 3.6 and Example 3.5.)

29. Write a balanced equation for the ionization of nitric acid in water.

30. Write a balanced equation for the ionization of perchloric acid in water.

31. Oxalic acid, $H_2C_2O_4$, which is found in certain plants, can provide two hydronium ions in water. Write balanced equations (like those for sulfuric acid on page 142) to show how oxalic acid can supply one and then a second H_3O^+ ion.

32. Phosphoric acid can supply one, two, or three H_3O^+ ions in aqueous solution. Write balanced equations (like those for sulfuric acid on page 142) to show this successive loss of hydrogen ions.

33. Write a balanced equation for reaction of the basic oxide, magnesium oxide, with water.

34. Write a balanced equation for the reaction of sulfur trioxide gas with water.

35. Complete and balance the equations for the following acid–base reactions. Name the reactants and products.

(a) $CH_3CO_2H(aq) + Mg(OH)_2(s) \rightarrow$

(b) $HClO_4(aq) + NH_3(aq) \rightarrow$

36. Complete and balance the equations for the following acid–base reactions. Name the reactants and products.

(a) $H_3PO_4(aq) + KOH(aq) \rightarrow$

(b) $H_2C_2O_4(aq) + Ca(OH)_2(s) \rightarrow$
($H_2C_2O_4$ is oxalic acid, an acid capable of donating two H^+ ions. See Study Question 31.)

37. Write a balanced equation for the reaction of barium hydroxide with nitric acid.

38. Write a balanced equation for the reaction of aluminum hydroxide with sulfuric acid.

39. Write an equation that describes the equilibrium that exists when nitric acid dissolves in water. Identify each of the four species in solution as either Brønsted acids or Brønsted bases. Does the equilibrium favor the products or the reactants?

40. Write an equation that describes the equilibrium that exists when the weak acid benzoic acid ($C_6H_5CO_2H$) dissolves in water. Identify each of the four species in solution as either Brønsted acids or Brønsted bases. Does the equilibrium favor the products or the reactants? (In acting as an acid, the —CO_2H group supplies H^+ to form H_3O^+.)

41. Write two chemical equations, one that shows H_2O reacting (with HBr) as a Brønsted base and a second that shows H_2O reacting (with NH_3) as a Brønsted acid.

42. Write two chemical equations, one in which $H_2PO_4^-$ is a Brønsted acid (in reaction with the carbonate ion, CO_3^{2-}), and a second in which HPO_4^{2-} is a Brønsted base (in reaction with acetic acid, CH_3CO_2H).

Writing Net Ionic Equations

(See Examples 3.4 and 3.6.)

43. Balance the following equations, and then write the net ionic equation.

(a) $(NH_4)_2CO_3(aq) + Cu(NO_3)_2(aq) \rightarrow CuCO_3(s) + NH_4NO_3(aq)$

(b) $Pb(OH)_2(s) + HCl(aq) \rightarrow PbCl_2(s) + H_2O(\ell)$

(c) $BaCO_3(s) + HCl(aq) \rightarrow BaCl_2(aq) + H_2O(\ell) + CO_2(g)$

(d) $CH_3CO_2H(aq) + Ni(OH)_2(s) \rightarrow Ni(CH_3CO_2)_2(aq) + H_2O(\ell)$

44. Balance the following equations, and then write the net ionic equation:

(a) $Zn(s) + HCl(aq) \rightarrow H_2(g) + ZnCl_2(aq)$

(b) $Mg(OH)_2(s) + HCl(aq) \rightarrow MgCl_2(aq) + H_2O(\ell)$

(c) $HNO_3(aq) + CaCO_3(s) \rightarrow Ca(NO_3)_2(aq) + H_2O(\ell) + CO_2(g)$

(d) $(NH_4)_2S(aq) + FeCl_2(aq) \rightarrow NH_4Cl(aq) + FeS(s)$

45. Balance the following equations, and then write the net ionic equation. Show states for all reactants and products (s, ℓ, g, aq).

(a) the reaction of silver nitrate and potassium iodide to give silver iodide and potassium nitrate

(b) the reaction of barium hydroxide and nitric acid to give barium nitrate and water

(c) the reaction of sodium phosphate and nickel(II) nitrate to give nickel(II) phosphate and sodium nitrate

46. Balance each of the following equations, and then write the net ionic equation. Show states for all reactants and products (s, ℓ, g, aq).

(a) the reaction of sodium hydroxide and iron(II) chloride to give iron(II) hydroxide and sodium chloride

(b) the reaction of barium chloride with sodium carbonate to give barium carbonate and sodium chloride

(c) the reaction of ammonia with phosphoric acid

47. Write balanced net ionic equations for the following reactions:

(a) the reaction of nitrous acid (a weak acid) and sodium hydroxide in aqueous solution

(b) the reaction of calcium hydroxide and hydrochloric acid

48. Write balanced net ionic equations for the following reactions:

(a) the reaction of aqueous solutions of silver nitrate and sodium iodide

(b) the reaction of aqueous solutions of barium chloride and potassium carbonate

Gas-Forming Reactions

(See Section 3.7 and Example 3.7.)

49. Siderite is a mineral consisting largely of iron(II) carbonate. Write an overall, balanced equation for its reaction with nitric acid, and name the products.

50. The mineral rhodochrosite is manganese(II) carbonate. Write an overall, balanced equation for the reaction of the mineral with hydrochloric acid, and name the products.

© Cengage Learning/Charles D. Winters

Rhodochrosite, a mineral consisting largely of $MnCO_3$

51. Write an overall, balanced equation for the reaction of $(NH_4)_2S$ with HBr, and name the reactants and products.

52. Write an overall, balanced equation for the reaction of Na_2SO_3 with CH_3CO_2H, and name the reactants and products.

Oxidation Numbers

(See Section 3.8 and Example 3.8.)

53. Determine the oxidation number of each element in the following ions or compounds.

(a) BrO_3^- (d) CaH_2

(b) $C_2O_4^{2-}$ (e) H_4SiO_4

(c) F^- (f) HSO_4^-

54. Determine the oxidation number of each element in the following ions or compounds.

(a) PF_6^- (d) N_2O_5

(b) $H_2AsO_4^-$ (e) $POCl_3$

(c) UO^{2+} (f) XeO_4^{2-}

Oxidation–Reduction Reactions

(See Section 3.8 and Example 3.9.)

55. Which two of the following reactions are oxidation–reduction reactions? Explain your answer in each case. Classify the remaining reaction.

(a) $Zn(s) + 2\ NO_3^-(aq) + 4\ H_3O^+(aq) \rightarrow Zn^{2+}(aq) + 2\ NO_2(g) + 6\ H_2O(\ell)$

(b) $Zn(OH)_2(s) + H_2SO_4(aq) \rightarrow ZnSO_4(aq) + 2\ H_2O(\ell)$

(c) $Ca(s) + 2\ H_2O(\ell) \rightarrow Ca(OH)_2(s) + H_2(g)$

56. Which two of the following reactions are oxidation–reduction reactions? Explain your answer briefly. Classify the remaining reaction.

(a) $CdCl_2(aq) + Na_2S(aq) \rightarrow CdS(s) + 2\ NaCl(aq)$

(b) $2\ Ca(s) + O_2(g) \rightarrow 2\ CaO(s)$

(c) $4\ Fe(OH)_2(s) + 2\ H_2O(\ell) + O_2(g) \rightarrow 4\ Fe(OH)_3(s)$

57. In the following reactions, decide which reactant is oxidized and which is reduced. Designate the oxidizing agent and the reducing agent.

(a) $C_2H_4(g) + 3\ O_2(g) \rightarrow 2\ CO_2(g) + 2\ H_2O(\ell)$

(b) $Si(s) + 2\ Cl_2(g) \rightarrow SiCl_4(\ell)$

58. In the following reactions, decide which reactant is oxidized and which is reduced. Designate the oxidizing agent and the reducing agent.

(a) $Cr_2O_7^{2-}(aq) + 3\ Sn^{2+}(aq) + 14\ H_3O^+(aq) \rightarrow 2\ Cr^{3+}(aq) + 3\ Sn^{4+}(aq) + 21\ H_2O(\ell)$

(b) $FeS(s) + 3\ NO_3^-(aq) + 4\ H_3O^+(aq) \rightarrow 3\ NO(g) + SO_4^{2-}(aq) + Fe^{3+}(aq) + 6\ H_2O(\ell)$

Types of Reactions in Aqueous Solution

(See Section 3.9 and Example 3.10.)

59. Balance the following equations, and then classify each as a precipitation, acid–base, or gas-forming reaction.

(a) $Ba(OH)_2(aq) + HCl(aq) \rightarrow BaCl_2(aq) + H_2O(\ell)$

(b) $HNO_3(aq) + CoCO_3(s) \rightarrow Co(NO_3)_2(aq) + H_2O(\ell) + CO_2(g)$

(c) $Na_3PO_4(aq) + Cu(NO_3)_2(aq) \rightarrow Cu_3(PO_4)_2(s) + NaNO_3(aq)$

60. Balance the following equations, and then classify each as a precipitation, acid–base, or gas-forming reaction.

(a) $K_2CO_3(aq) + Cu(NO_3)_2(aq) \rightarrow CuCO_3(s) + KNO_3(aq)$

(b) $Pb(NO_3)_2(aq) + HCl(aq) \rightarrow PbCl_2(s) + HNO_3(aq)$

(c) $MgCO_3(s) + HCl(aq) \rightarrow MgCl_2(aq) + H_2O(\ell) + CO_2(g)$

61. Classify each of the following reactions as a precipitation, acid–base, or gas-forming reaction. Show states for the products (s, ℓ, g, aq), and then balance the completed equation. Write the net ionic equation.

(a) $MnCl_2(aq) + Na_2S(aq) \rightarrow MnS + NaCl$

(b) $K_2CO_3(aq) + ZnCl_2(aq) \rightarrow ZnCO_3 + KCl$

62. Classify each of the following reactions as a precipitation, acid–base, or gas-forming reaction. Show states for the products (s, ℓ, g, aq), and then balance the completed equation. Write the net ionic equation.

(a) $Fe(OH)_3(s) + HNO_3(aq) \rightarrow Fe(NO_3)_3 + H_2O$

(b) $FeCO_3(s) + HNO_3(aq) \rightarrow Fe(NO_3)_2 + CO_2 + H_2O$

63. Balance each of the following equations, and classify them as precipitation, acid–base, gas-forming, or oxidation–reduction reactions. Show states for reactants and products (s, ℓ, g, aq).

(a) $CuCl_2 + H_2S \rightarrow CuS + HCl$

(b) $H_3PO_4 + KOH \rightarrow H_2O + K_3PO_4$

(c) $Ca + HBr \rightarrow H_2 + CaBr_2$

(d) $MgCl_2 + NaOH \rightarrow Mg(OH)_2 + NaCl$

64. ▲ Complete and balance the equations below, and classify them as precipitation, acid–base, gas-forming, or oxidation–reduction reactions. Show states for reactants and products (s, ℓ, g, aq).

(a) $NiCO_3 + H_2SO_4 \rightarrow$

(b) $Co(OH)_2 + HBr \rightarrow$

(c) $AgCH_3CO_2 + NaCl \rightarrow$

(d) $NiO + CO \rightarrow$

65. The products formed in several reactions are given below. Identify the reactants (labeled x and y) and write the complete balanced equation for each reaction.

(a) $x + y \rightarrow H_2O(\ell) + CaBr_2(aq)$

(b) $x + y \rightarrow Mg(NO_3)_2(aq) + CO_2(g) + H_2O(\ell)$

(c) $x + y \rightarrow BaSO_4(s) + NaCl(aq)$

(d) $x + y \rightarrow NH_4^+(aq) + OH^-(aq)$

66. The products formed in several reactions are given below. Identify the reactants (labeled x and y) and write the complete balanced equation for each reaction.

(a) $x + y \rightarrow (NH_4)_2SO_4(aq)$

(b) $x + y \rightarrow CaCl_2(aq) + CO_2(g) + H_2O(\ell)$

(c) $x + y \rightarrow Ba(NO_3)_2(aq) + AgCl(s)$

(d) $x + y \rightarrow H_3O^+(aq) + ClO_4^-(aq)$

General Questions

These questions are not designated as to type or location in the chapter. They may combine concepts.

67. Balance the following equations:

(a) for the synthesis of urea, a common fertilizer

$$CO_2(g) + NH_3(g) \rightarrow NH_2CONH_2(s) + H_2O(\ell)$$

(b) for the reactions used to make uranium(VI) fluoride for the enrichment of natural uranium

$$UO_2(s) + HF(aq) \rightarrow UF_4(s) + H_2O(\ell)$$

$$UF_4(s) + F_2(g) \rightarrow UF_6(s)$$

(c) for the reaction to make titanium(IV) chloride, which is then converted to titanium metal

$$TiO_2(s) + Cl_2(g) + C(s) \rightarrow TiCl_4(\ell) + CO(g)$$

$$TiCl_4(\ell) + Mg(s) \rightarrow Ti(s) + MgCl_2(s)$$

68. Balance the following equations:

(a) for the reaction to produce "superphosphate" fertilizer

$$Ca_3(PO_4)_2(s) + H_2SO_4(aq) \rightarrow Ca(H_2PO_4)_2(aq) + CaSO_4(s)$$

(b) for the reaction to produce diborane, B_2H_6

$$NaBH_4(s) + H_2SO_4(aq) \rightarrow B_2H_6(g) + H_2(g) + Na_2SO_4(aq)$$

(c) for the reaction to produce tungsten metal from tungsten(VI) oxide

$$WO_3(s) + H_2(g) \rightarrow W(s) + H_2O(\ell)$$

(d) for the decomposition of ammonium dichromate

$$(NH_4)_2Cr_2O_7(s) \rightarrow N_2(g) + H_2O(\ell) + Cr_2O_3(s)$$

69. Give a formula for each of the following compounds:

(a) a soluble compound containing the bromide ion

(b) an insoluble hydroxide

(c) an insoluble carbonate

(d) a soluble nitrate-containing compound

(e) a weak Brønsted acid

70. Give the formula for each of the following compounds:

(a) a soluble compound containing the acetate ion

(b) an insoluble sulfide

(c) a soluble hydroxide

(d) an insoluble chloride

(e) a strong Brønsted base

71. Indicate which of the following copper(II) salts are soluble in water and which are insoluble: $Cu(NO_3)_2$, $CuCO_3$, $Cu_3(PO_4)_2$, $CuCl_2$.

72. Name two anions that combine with Al^{3+} ion to produce water-soluble compounds.

73. Write the net ionic equation and identify the spectator ion or ions in the reaction of nitric acid and magnesium hydroxide. What type of reaction is this?

$$2\ H_3O^+(aq) + 2\ NO_3^-(aq) + Mg(OH)_2(s) \rightarrow 4\ H_2O(\ell) + Mg^{2+}(aq) + 2\ NO_3^-(aq)$$

74. Identify and name the water-insoluble product in each reaction and write the net ionic equation:

(a) $CuCl_2(aq) + H_2S(aq) \rightarrow CuS + 2\ HCl$

(b) $CaCl_2(aq) + K_2CO_3(aq) \rightarrow 2\ KCl + CaCO_3$

(c) $AgNO_3(aq) + NaI(aq) \rightarrow AgI + NaNO_3$

75. Bromine is obtained from sea water by the following redox reaction:

$$Cl_2(g) + 2\ NaBr(aq) \rightarrow 2\ NaCl(aq) + Br_2(\ell)$$

(a) What has been oxidized? What has been reduced?

(b) Identify the oxidizing and reducing agents.

76. Identify each of the following substances as a likely oxidizing or reducing agent: HNO_3, Na, Cl_2, O_2, $KMnO_4$.

77. The mineral dolomite contains magnesium carbonate. This reacts with hydrochloric acid.

$$MgCO_3(s) + 2\ HCl(aq) \rightarrow CO_2(g) + MgCl_2(aq) + H_2O(\ell)$$

(a) Write the net ionic equation for this reaction and identify the spectator ions.

(b) What type of reaction is this?

Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

78. Aqueous solutions of ammonium sulfide, $(NH_4)_2S$, and $Hg(NO_3)_2$ react to produce HgS and NH_4NO_3.
   (a) Write the overall, balanced equation for the reaction. Indicate the state (s, aq) for each compound.
   (b) Name each compound.
   (c) What type of reaction is this?

79. Identify the primary species (atoms, molecules, or ions) present in an aqueous solution of each of the following compounds. Decide which species are Brønsted acids or bases and whether they are strong or weak.
   (a) NH_3
   (b) CH_3CO_2H
   (c) NaOH
   (d) HBr

80. (a) Name and give formulas for two water-soluble compounds containing the Cu^{2+} ion. Name two water-insoluble compounds containing the Cu^{2+} ion.
   (b) Name and give formulas for two water-soluble compounds containing the Ba^{2+} ion. Name two water-insoluble compounds containing the Ba^{2+} ion.

81. Balance equations for these reactions that occur in aqueous solution, and then classify each as a precipitation, acid–base, or gas-forming reaction. Show states for the products (s, ℓ, g, aq), give their names, and write the net ionic equation.
   (a) $K_2CO_3 + HClO_4 \rightarrow KClO_4 + CO_2 + H_2O$
   (b) $FeCl_2 + (NH_4)_2S \rightarrow FeS + NH_4Cl$
   (c) $Fe(NO_3)_2 + Na_2CO_3(aq) \rightarrow FeCO_3 + NaNO_3$
   (d) $NaOH + FeCl_3 \rightarrow NaCl + Fe(OH)_3$

82. For each reaction, write an overall, balanced equation and the net ionic equation.
   (a) the reaction of aqueous lead(II) nitrate and aqueous potassium hydroxide
   (b) the reaction of aqueous copper(II) nitrate and aqueous sodium carbonate

83. You are given mixtures containing the following compounds. Which compound in each pair could be separated by stirring the solid mixture with water?
   (a) NaOH and $Ca(OH)_2$
   (b) $MgCl_2$ and MgF_2
   (c) AgI and KI
   (d) NH_4Cl and $PbCl_2$

84. Identify, from each list below, the compound or compounds that will dissolve in water to give a solution that strongly conducts electricity.
   (a) $CuCO_3$, $Cu(OH)_2$, $CuCl_2$, CuO
   (b) HCl, $H_2C_2O_4$, H_3PO_4, H_2SO_4

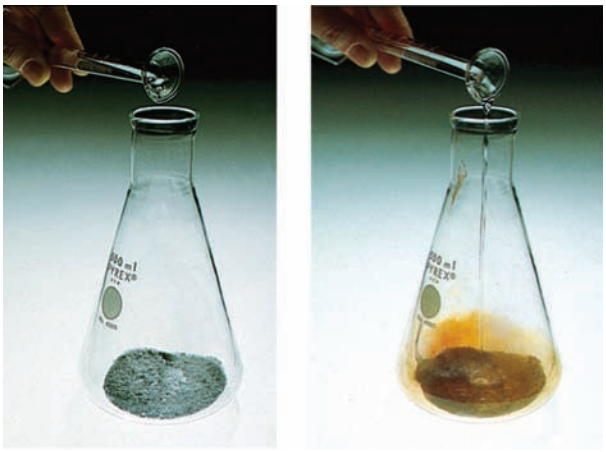
85. Identify, from each list below, the compound or compounds that will dissolve in water to give a solution that is only a very weak conductor of electricity.
   (a) NH_3, NaOH, $Ba(OH)_2$, $Fe(OH)_3$
   (b) CH_3CO_2H, Na_3PO_4, HF, HNO_3

86. Write net ionic equations for the following reactions:
   (a) The reaction of acetic acid, a weak acid, and $Sr(OH)_2(aq)$.
   (b) The reaction of zinc and hydrochloric acid to form zinc(II) chloride and hydrogen gas.

87. Gas evolution was observed when a solution of Na_2S was treated with acid. The gas was bubbled into a solution containing $Pb(NO_3)_2$, and a black precipitate formed. Write net ionic equations for the two reactions.

88. Heating HI(g) at 425 °C causes some of this compound to decompose, forming $H_2(g)$ and $I_2(g)$. Eventually, the amounts of the three species do not change further; the system has reached equilibrium. (At this point, approximately 22% of the HI has decomposed.) Describe what is happening in this system at the molecular level.

In the Laboratory



89. The following reaction can be used to prepare iodine in the laboratory.

$$2\ NaI(s) + 2\ H_2SO_4(aq) + MnO_2(s) \rightarrow Na_2SO_4(aq) + MnSO_4(aq) + I_2(g) + 2\ H_2O(\ell)$$

   (a) Determine the oxidation number of each atom in the equation.
   (b) What is the oxidizing agent, and what has been oxidized? What is the reducing agent, and what has been reduced?
   (c) Is the reaction product-favored or reactant-favored?
   (d) Name the reactants and products.

Preparation of iodine. A mixture of NaI and MnO_2 was placed in a flask *(left)*. On adding concentrated H_2SO_4 *(right)*, brown gaseous I_2 evolved.

90. ▲ If you have "silverware" in your home, you know it tarnishes easily. Tarnish is from the oxidation of silver in the presence of sulfur-containing compounds (in the atmosphere or in your food) to give black Ag_2S. To remove the tarnish, you can warm the tarnished object with some aluminum foil in water with a small amount of baking soda. Silver sulfide reacts with aluminum to produce silver as well as aluminum oxide and hydrogen sulfide.

$$3\ Ag_2S(s) + 2\ Al(s) + 3\ H_2O(\ell) \rightarrow 6\ Ag(s) + Al_2O_3(s) + 3\ H_2S(aq)$$

Hydrogen sulfide is foul smelling, but it is removed by reaction with the baking soda.

$$NaHCO_3(aq) + H_2S(aq) \rightarrow NaHS(aq) + H_2O(\ell) + CO_2(g)$$

Classify the two reactions, and identify any acids, bases, oxidizing agents, or reducing agents.

Photos: © Cengage Learning/Charles D. Winters

(a) **(b)**

Removing silver tarnish. **(a)** A badly tarnished piece of silver is placed in a dish with aluminum foil and aqueous sodium hydrogen carbonate. **(b)** The portion of the silver in contact with the solution is now free of tarnish.

91. ▲ Suppose you wish to prepare a sample of magnesium chloride. One way to do this is to use an acid–base reaction, the reaction of magnesium hydroxide with hydrochloric acid.

$$Mg(OH)_2(s) + 2\ HCl(aq) \rightarrow MgCl_2(aq) + 2\ H_2O(\ell)$$

When the reaction is complete, evaporating the water will give solid magnesium chloride. Suggest another way to prepare $MgCl_2$.

92. ▲ Suggest a laboratory method for preparing barium phosphate. (See Study Question 97 for a way to approach this question.)

93. The Tollen's test for the presence of reducing sugars (say, in a urine sample) involves treating the sample with silver ions in aqueous ammonia. The result is the formation of a silver mirror within the reaction vessel if a reducing sugar is present. Using glucose, $C_6H_{12}O_6$, to illustrate this test, the oxidation–reduction reaction occurring is

$$C_6H_{12}O_6\ (aq) + 2\ Ag^+(aq) + 2\ OH^-(aq) \rightarrow C_6H_{12}O_7(aq) + 2\ Ag(s) + H_2O(\ell)$$

What has been oxidized, and what has been reduced? What is the oxidizing agent, and what is the reducing agent?

Photos: © Cengage Learning/Charles D. Winters

(a) **(b)**

Tollen's test. The reaction of silver ions with a sugar such as glucose produces metallic silver. **(a)** The set-up for the reaction. **(b)** The silvered test tube.

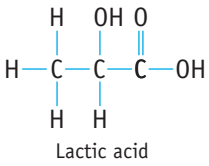
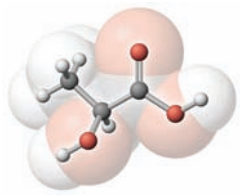
Summary and Conceptual Questions

The following questions may use concepts from this and previous chapters.



94. There are many ionic compounds that dissolve in water to a very small extent. One example is lead(II) chloride. When it dissolves an equilibrium is established between the solid salt and its component ions. Suppose you stir some solid $PbCl_2$ into water. Explain how you would prove that the compound dissolves but to a small extent? Is the dissolving process product-favored or reactant-favored?

$$PbCl_2(s) \rightleftharpoons Pb^{2+}(aq) + 2\ Cl^-(aq)$$



95. ▲ Most naturally occurring acids are weak acids. Lactic acid is one example.

$$CH_3CH(OH)CO_2H(s) + H_2O(\ell) \rightleftharpoons H_3O^+(aq) + CH_3CH(OH)CO_2^-(aq)$$

If you place some lactic acid in water, it will ionize to a small extent, and an equilibrium will be established. Suggest some experiments to prove that this is a weak acid and that the establishment of equilibrium is a reversible process.

Lactic acid

96. ▲ You want to prepare barium chloride, $BaCl_2$, using an exchange reaction of some type. To do so, you have the following reagents from which to select the reactants: $BaSO_4$, $BaBr_2$, $BaCO_3$, $Ba(OH)_2$, HCl, $HgSO_4$, $AgNO_3$, and HNO_3. Write a complete, balanced equation for the reaction chosen. (*Note:* There are several possibilities.)

97. ▲ Describe how to prepare $BaSO_4$, barium sulfate, by (a) a precipitation reaction and (b) a gas-forming reaction. The available starting materials are $BaCl_2$, $BaCO_3$, $Ba(OH)_2$, H_2SO_4, and Na_2SO_4. Write complete, balanced equations for the reactions chosen. (See page 138 for an illustration of the preparation of the compound.)

98. ▲ Describe how to prepare zinc chloride by (a) an acid–base reaction, (b) a gas-forming reaction, and (c) an oxidation–reduction reaction. The available starting materials are $ZnCO_3$, HCl, Cl_2, HNO_3, $Zn(OH)_2$, NaCl, $Zn(NO_3)_2$, and Zn. Write complete, balanced equations for the reactions chosen.

99. A common method for analyzing for the nickel content of a sample is to use a precipitation reaction. Adding the organic compound dimethylglyoxime to a solution containing Ni^{2+} ions precipitates a red solid.

© Cengage Learning/Charles D. Winters

Derive the empirical formula for the red solid based on the following composition: Ni, 20.315%; C, 33.258%; H, 4.884%; O, 22.151%; and N, 19.392%.

100. The lanthanide elements react with oxygen to give, generally, compounds of the type Ln_2O_3 (where Ln stands for a lanthanide element). However, there are interesting exceptions, such as a common oxide of terbium, Tb_xO_y. Given that the compound is 73.945% Tb, what is its formula? What is the oxidation number of terbium in this compound? Write a balanced equation for the reaction of terbium and oxygen to give this oxide.

101. The presence of arsenic in a sample that may also contain another Group 5A element, antimony, can be confirmed by first precipitating the As^{3+} and Sb^{3+} ions as yellow solid As_2S_3 and orange solid Sb_2S_3. If aqueous HCl is then added, only Sb_2S_3 dissolves, leaving behind solid As_2S_3. The As_2S_3 can then be dissolved using aqueous HNO_3.

$$3\ As_2S_3(s) + 10\ HNO_3(aq) + 4\ H_2O(\ell) \rightarrow 6\ H_3AsO_4(aq) + 10\ NO(g) + 9\ S(s)$$

Finally, the presence of arsenic is confirmed by adding $AgNO_3$ to the solution of H_3AsO_4 to precipitate a reddish brown solid Ag_xAsO_y. The composition of this solid is As, 16.199% and Ag, 69.964%.

(a) What are the oxidation numbers of As, S, and N in the reaction of As_2S_3 with nitric acid?

(b) What is the formula of the reddish brown solid Ag_xAsO_y?

Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

102. You have a bottle of solid barium hydroxide and some dilute sulfuric acid. You place some of the barium hydroxide in water and slowly add sulfuric acid to the mixture. While adding the sulfuric acid, you measure the conductivity of the mixture.

(a) Write the complete, balanced equation for the reaction occurring when barium hydroxide and sulfuric acid are mixed.

(b) Write the net ionic equation for the barium hydroxide and sulfuric acid reaction.

(c) Which diagram represents the change in conductivity as the acid is added to the aqueous barium hydroxide? Explain briefly.

4.1 Mass Relationships in Chemical Reactions: Stoichiometry

Goals for Section 4.1

- Understand the principle of conservation of matter, which forms the basis of chemical stoichiometry.
- Calculate the mass of one reactant or product in a reaction knowing the balanced equation and the mass of another reactant or product in that reaction.
- Use amounts tables to organize chemical information.

The reaction of elemental phosphorus and chlorine produces the compound PCl_3 (Figure 3.1), and the balanced equation below shows the quantitative relationship between reactants and products in this reaction.

$$\begin{array}{ccccc} P_4(s) & + & 6\ Cl_2(g) & \longrightarrow & 4\ PCl_3(\ell) \\ 1\ \text{mol} & & 6\ \text{mol} & & 4\ \text{mol} \\ 124\ \text{g} & & 425\ \text{g} & & 549\ \text{g} \end{array}$$

At the molecular level the balanced equation tells you that one molecule of phosphorus reacts with six molecules of chlorine to produce four molecules of phosphorus trichloride. Or, at the macroscopic level where we work in the laboratory, the coefficients refer to the number of moles of each reactant and product. For example, the equation tells us that 1 mol (124 g) of solid phosphorus (P_4) can react with 6 mol (425 g) of chlorine gas (Cl_2) to form 4 mol (549 g) of liquid phosphorus trichloride (PCl_3).

◀ **Thermite reaction.** When ignited, iron(III) oxide is reduced by aluminum to produce iron and aluminum oxide. The reaction generates an enormous amount of energy, sufficient to produce iron in the molten state. Although the thermite reaction was originally developed as a way of producing metals from their oxides (copper, chromium, and others also work well), it was quickly realized that it can be used for welding. For some years the reaction was used to weld the rails of railroad train tracks.

Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Now, suppose you want to use less P_4 in the reaction, only 1.45 g. What mass of Cl_2 gas is required and what mass of PCl_3 could be produced? This is an example of a situation common in chemistry, so we want to work carefully through the steps you should follow when solving a stoichiometry problem.

Part (a): Calculate the mass of Cl_2 required by 1.45 g of P_4

Step 1. *Write the balanced equation* (using correct formulas for reactants and products). This is *always* the first step when dealing with chemical reactions.

$$P_4(s) + 6\ Cl_2(g) \rightarrow 4\ PCl_3(\ell)$$

Step 2. *Calculate amount (moles) from mass (grams).* Recall that chemical equations reflect the *relative amounts* of reactants and products, not their masses. Therefore, calculate the amount (moles) of P_4 available.

$$1.45\ \text{g } P_4 \times \frac{1\ \text{mol } P_4}{123.9\ \text{g } P_4} = 0.01170\ \text{mol } P_4$$

↑

1/molar mass of P_4

Step 3a. *Use a stoichiometric factor.* Use the balanced equation to relate the amount of P_4 available to the amount of Cl_2 required to completely consume the P_4. This relationship is a **stoichiometric factor**, a mole ratio based on the stoichiometric coefficients in the balanced equation. Here the balanced equation specifies that 6 mol of Cl_2 is required for each mole of P_4, so the stoichiometric factor is (6 mol Cl_2/1 mol P_4).

$$0.01170\ \text{mol } P_4 \times \frac{6\ \text{mol } Cl_2\ \text{required}}{1\ \text{mol } P_4\ \text{available}} = 0.07022\ \text{mol } Cl_2\ \text{required}$$

↑

stoichiometric factor from balanced equation

Step 4a. *Calculate mass from amount.* Convert the amount (moles) of Cl_2 calculated in Step 3 to the mass of Cl_2 required.

$$0.07022\ \text{mol } Cl_2 \times \frac{70.91\ \text{g } Cl_2}{1\ \text{mol } Cl_2} = 4.98\ \text{g } Cl_2$$

↑

molar mass of Cl_2

Part (b): Calculate mass of PCl_3 produced from 1.45 g of P_4 and 4.98 g of Cl_2

From part (a), we know that 1.45 g of P_4 and 4.98 g of Cl_2 are the correct quantities needed for complete reaction. Because mass is conserved, the answer can be obtained by adding the masses of P_4 and Cl_2 used (giving 1.45 g + 4.98 g = 6.43 g of PCl_3 produced). Alternatively, Steps 3 and 4 can be repeated, but with the appropriate stoichiometric factor and molar mass.

Step 3b. *Use a stoichiometric factor.* Convert the amount of available P_4 to the amount of PCl_3 produced. Here the balanced equation specifies that 4 mol of PCl_3 is produced for each mole of P_4 used, so the stoichiometric factor is (4 mol PCl_3/1 mol P_4).

$$0.01170\ \text{mol } P_4 \times \frac{4\ \text{mol } PCl_3\ \text{produced}}{1\ \text{mol } P_4\ \text{available}} = 0.04681\ \text{mol } PCl_3\ \text{produced}$$

↑

stoichiometric factor from balanced equation

Step 4b. *Calculate the mass of product from its amount.* Convert the amount of PCl_3 produced to its mass in grams.

$$0.04681\ \text{mol } PCl_3 \times \frac{137.3\ \text{g } PCl_3}{1\ \text{mol } PCl_3} = 6.43\ \text{g } PCl_3$$

Problem Solving Tip 4.1 Stoichiometry Calculations

You are asked to determine what mass of product can be formed from a given mass of reactant. It is not possible to calculate the mass of product in a single step. Instead, you must follow a route such as that illustrated in the strategy map here for the reaction of reactant A to give the product B according to an equation such as x A $\rightarrow$ y B.

- The mass (g) of reactant A is converted to the amount (moles) of A using the molar mass of A.
- Next, using the stoichiometric factor, you find the amount (moles) of B.
- Finally, the mass (g) of B is obtained by multiplying the amount of B by its molar mass.

When solving a stoichiometry problem, remember that you will always use a stoichiometric factor at some point.

We find it useful to summarize the mole relationships of reactants and products for a reaction in an **amounts table**.

Equation	$P_4(s)$	+	6 $Cl_2(g)$	→	4 $PCl_3(\ell)$
Initial amount (mol)	0.01170		0.07022		0
Change in amount upon reaction (mol)	−0.01170		−0.07022		+0.04681
Amount after complete reaction (mol)	0		0		0.04681

Amounts Tables The mole (and mass) relationships of reactants and products in a reaction can be summarized in an *amounts table*. Such tables will be used extensively when studying chemical equilibria in Chapters 15–17.

The balanced chemical equation is written across the top of the table. The next three lines contain the following information:

- *Initial* amount (moles) of each reactant and product present.
- *Change* in amount that occurs during the reaction.
- *Final* amount of each reactant and product present after the reaction.

The completed amounts table indicates that the reactants P_4 and Cl_2 were initially present in the correct stoichiometric ratio but no PCl_3 was present. During the course of the reaction, all of the reactants were consumed as product formed. The total mass of reactants consumed (1.45 g of P_4 and 4.98 g of Cl_2) is always the same as the total mass of products formed (6.43 g of PCl_3).

EXAMPLE 4.1

Mass Relations in Chemical Reactions

Problem Glucose, $C_6H_{12}O_6$, reacts with oxygen to give CO_2 and H_2O. What mass of oxygen (in grams) is required to completely react with 25.0 g of glucose? What masses of carbon dioxide and water (in grams) are formed?

What Do You Know? You are given the mass of one of the reactants (glucose) and are asked to determine the masses of the other substances in the reaction. You know formulas for the reactants and products and need to calculate their molar masses.

Strategy Write the balanced chemical equation for this reaction. Then, follow the scheme outlined in Problem Solving Tip 4.1 and in the Strategy Map 4.1.

Strategy Map 4.1

PROBLEM

Calculate mass of O_2 required for combustion of **25.0 g of glucose.**

↓

DATA/INFORMATION

Formulas for reactants and products and the **mass** of one reactant (glucose)

↓ STEP 1. Write the **balanced equation.**

Balanced equation to give the required ***stoichiometric factor***

↓ STEP 2. Amount glucose = mass × (1/molar mass).

Amount of **reactant** (glucose)

↓ STEP 3. Use stoichiometric factor = [6 mol O_2/1 mol glucose].

Amount of **O_2**

↓ STEP 4. Mass of O_2 = mol O_2 × mass/1 mol.

Mass of O_2

Significant Figures As outlined in "Let's Review," we show one more than the number of required significant figures in each step until the final step when the answer is rounded to the correct number of significant figures.

SOLUTION

Step 1. *Write a balanced equation.*

$$C_6H_{12}O_6(s) + 6\ O_2(g) \rightarrow 6\ CO_2(g) + 6\ H_2O(\ell)$$

Step 2. *Find the amount (moles) of glucose available.*

$$25.0\ \text{g glucose} \times \frac{1\ \text{mol glucose}}{180.2\ \text{g glucose}} = 0.1387\ \text{mol glucose}$$

Step 3. *Use the stoichiometric factor to calculate the amount of O_2 required based on the amount of glucose.*

$$0.1387\ \text{mol glucose} \times \frac{6\ \text{mol } O_2}{1\ \text{mol glucose}} = 0.8324\ \text{mol } O_2$$

Step 4. *Calculate the mass of O_2 required.*

$$0.8324\ \text{mol } O_2 \times \frac{32.00\ \text{g } O_2}{1\ \text{mol } O_2} = 26.6\ \text{g } O_2$$

Repeat Steps 3 and 4 to find the mass of CO_2 produced in the combustion. First, relate the amount (moles) of glucose available to the amount of CO_2 produced using a stoichiometric factor. Then convert the amount of CO_2 to its mass in grams.

$$0.1387\ \text{mol glucose} \times \frac{6\ \text{mol } CO_2}{1\ \text{mol glucose}} \times \frac{44.01\ \text{g } CO_2}{1\ \text{mol } CO_2} = 36.6\ \text{g } CO_2$$

Now, how can you find the mass of H_2O produced? You could go through Steps 3 and 4 again. However, recognize that the total mass of reactants

$$25.0\ \text{g } C_6H_{12}O_6 + 26.6\ \text{g } O_2 = 51.6\ \text{g reactants}$$

must be the same as the total mass of products. The mass of water that can be produced is therefore

$$\text{Total mass of products} = 51.6\ \text{g} = 36.6\ \text{g } CO_2 \text{ produced} + ?\ \text{g } H_2O$$

$$\text{Mass of } H_2O \text{ produced} = 15.0\ \text{g}$$

Think about Your Answer The results of this calculation can be summarized in an amounts table.

Equation	$C_6H_{12}O_6(s)$	+	$6\ O_2(g)$	→	$6\ CO_2(g)$	+	$6\ H_2O(\ell)$
Initial amount (mol)	0.1387		6(0.1387) = 0.8324		0		0
Change in amount upon reaction (mol)	−0.1387		−0.8324		+0.8324		+0.8324
Amount after complete reaction (mol)	0		0		0.8324		0.8324

When you know the mass of all but one of the chemicals in a reaction, you can find the unknown mass using the principle of mass conservation (the total mass of reactants must equal the total mass of products; page 125).

Check Your Understanding

What mass of oxygen, O_2, is required to completely combust 454 g of propane, C_3H_8? What masses of CO_2 and H_2O are produced?

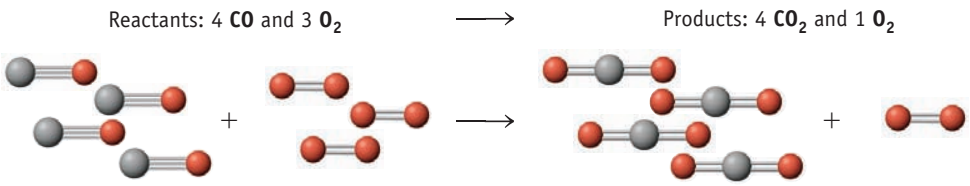
4.2 Reactions in Which One Reactant Is Present in Limited Supply

Goals for Section 4.2

- Determine which reactant is in limited supply in a reaction involving several reactants.
- Determine the yield of a product based on the limiting reactant.

Reactions are often carried out with an excess of one reactant over that required by stoichiometry. This is usually done to make sure that one of the reactants is consumed completely, even though some of another reactant remains unused.

Suppose you burn a toy sparkler, a wire coated with a mixture of aluminum or iron powder and potassium chlorate (Figure 4.1). The aluminum or iron burns, consuming oxygen from the air or from the potassium salt and producing a metal oxide.



$$4\ Al(s) + 3\ O_2(g) \rightarrow 2\ Al_2O_3(s)$$

The sparkler burns until the metal powder is consumed completely. What about the oxygen? Four moles of aluminum require three moles of oxygen, but there is much, much more O_2 available in the air than is needed to consume the metal in a sparkler. How much metal oxide is produced? That depends on the quantity of metal powder in the sparkler, not on the quantity of O_2 in the atmosphere. The metal powder in this example is called the **limiting reactant** because its amount determines, or limits, the amount of product formed.

Now let us see how this principle applies to another example. The balanced equation for the reaction of oxygen and carbon monoxide to give carbon dioxide is

$$2\ CO(g) + O_2(g) \rightarrow 2\ CO_2(g)$$

Suppose you have a mixture of four CO molecules and three O_2 molecules. The four CO molecules require only two O_2 molecules (and produce four CO_2 molecules). This means that one O_2 molecule remains after reaction is complete.

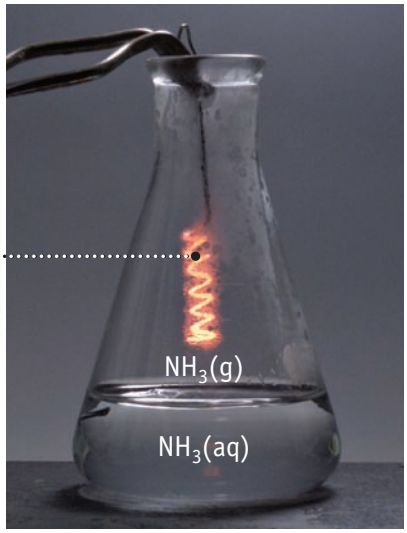
Because more O_2 molecules are available than are required, the number of CO_2 molecules produced is determined by the number of CO molecules available. Carbon monoxide, CO, is therefore the limiting reactant in this case.

A Stoichiometry Calculation with a Limiting Reactant

The first step in the manufacture of nitric acid is the oxidation of ammonia to NO over a platinum-wire gauze (Figure 4.2).

$$4\ NH_3(g) + 5\ O_2(g) \rightarrow 4\ NO(g) + 6\ H_2O(\ell)$$

Suppose equal masses of NH_3 and O_2 are mixed (750. g of each). Are these reactants mixed in the correct stoichiometric ratio or is one of them in short supply? That is, will one of them limit the quantity of NO that can be produced? How much NO can be formed if the reaction using this reactant mixture goes to completion? And how much of the excess reactant is left over when the maximum amount of NO has been formed?



© Cengage Learning/Charles D. Winters

Figure 4.1 Burning aluminum and iron powder. A toy sparkler contains a metal powder such as Al or Fe and other chemicals such as $KClO_3$. When ignited, the metal burns with a brilliant white light.

© Cengage Learning/Charles D. Winters

JAMES L. AMOS/National Geographic Creative

Figure 4.2 Oxidation of ammonia. Billions of kilograms of HNO_3 are made annually starting with the oxidation of ammonia over a wire gauze containing platinum.

Step 1. *Calculate the amount of each reactant.* That is, convert the mass of each reactant to moles.

$$750.\ \text{g NH}_3 \times \frac{1\ \text{mol NH}_3}{17.03\ \text{g NH}_3} = 44.04\ \text{mol NH}_3\ \text{available}$$

$$750.\ \text{g O}_2 \times \frac{1\ \text{mol O}_2}{32.00\ \text{g O}_2} = 23.44\ \text{mol O}_2\ \text{available}$$

Step 2. *Calculate the mass of product.* Calculate the expected mass of product, NO, based on the amount of each reactant, NH_3 and O_2.

$$44.04\ \text{mol NH}_3 \times \frac{4\ \text{mol NO}}{4\ \text{mol NH}_3} \times \frac{30.01\ \text{g NO}}{1\ \text{mol NO}} = 1320.\ \text{g NO}$$

$$23.44\ \text{mol O}_2 \times \frac{4\ \text{mol NO}}{5\ \text{mol O}_2} \times \frac{30.01\ \text{g NO}}{1\ \text{mol NO}} = 563\ \text{g NO}$$

Step 3. *Decide which is the limiting reactant and what is the maximum mass of product that can be obtained.*

Here O_2 is the limiting reactant because the amount of O_2 available limits the amount of product (NO) formed to 563 g.

Step 4. *Calculate the mass of excess reactant.* Ammonia is the "excess reactant" because more than enough NH_3 is available to react with 23.4 mol of O_2. To calculate the mass of NH_3 remaining after all the O_2 has been used, we first need to know the amount of NH_3 required to consume all the limiting reactant, O_2.

$$23.44\ \text{mol O}_2\ \text{available} \times \frac{4\ \text{mol NH}_3\ \text{required}}{5\ \text{mol O}_2} = 18.75\ \text{mol NH}_3\ \text{required}$$

Because 44.04 mol of NH_3 is available, the amount of excess NH_3 can be calculated.

$$\begin{aligned}\text{Excess NH}_3 &= 44.04\ \text{mol NH}_3\ \text{available} - 18.75\ \text{mol NH}_3\ \text{required} \\ &= 25.29\ \text{mol NH}_3\ \text{remaining}\end{aligned}$$

Finally, the amount of excess NH_3 can be converted to a mass. Because 431 g of NH_3 is left over, this means that 319 g of the initial 750. g of NH_3 has been consumed.

$$25.29\ \text{mol NH}_3 \times \frac{17.03\ \text{g NH}_3}{1\ \text{mol NH}_3} = 431\ \text{g NH}_3\ \text{in excess}$$

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

The information from the scheme above can be organized in an amounts table.

Equation	$4\ NH_3(g)$	+	$5\ O_2(g)$	→	$4\ NO(g)$	+	$6\ H_2O(g)$
Initial amount (mol)	44.04		23.44		0		0
Change in amount upon reaction (mol)	−(4/5)(23.44) = −18.75		−23.44		+(4/5)(23.44) = +18.75		+(6/5)(23.44) = +28.13
Amount after complete reaction (mol)	44.04 − 18.75 = 25.29		0		18.75		28.13

All of the limiting reactant, O_2, is consumed. Of the original 44.04 mol of NH_3, 18.75 mol is consumed and 25.29 mol remains. The balanced equation indicates that the amount of NO produced is equal to the amount of NH_3 consumed, so 18.75 mol of NO is produced from 18.75 mol of NH_3. In addition, 28.13 mol of H_2O is produced.

EXAMPLE 4.2

A Reaction with a Limiting Reactant

Problem Methanol, CH_3OH, which can be used as a fuel in racing cars and in fuel cells, can be made by the reaction of carbon monoxide and hydrogen.

$$CO(g) + 2\ H_2(g) \rightarrow \underset{\text{methanol}}{CH_3OH(\ell)}$$

Suppose 356 g of CO and 65.0 g of H_2 are mixed and allowed to react.

(a) What mass of methanol can be produced?

(b) What mass of the excess reactant remains after the limiting reactant has been consumed?

What Do You Know? Any problem in which masses of two or more reactants are given is likely a limiting reactant problem so we will proceed on that assumption. Here the equation for the reaction is also given, and you know the masses of CO and H_2 available. You will need the molar masses of the two reactants and the product to solve the problem.

Strategy See Strategy Map, 4.2. After calculating the amount of each reactant, calculate the mass of product expected based on the amount of each reactant (Problem Solving Tip 4.1). From that, decide which reactant is limiting. Knowing that, you now know the maximum possible mass of product. The mass of excess reactant is the difference between its starting mass and what was required by the limiting reactant.

SOLUTION

(a) *What is the maximum mass of product expected?* We begin by calculating the amount of each reactant.

$$\text{Amount of CO} = 356\ \text{g CO} \times \frac{1\ \text{mol CO}}{28.01\ \text{g CO}} = 12.71\ \text{mol CO}$$

$$\text{Amount of } H_2 = 65.0\ \text{g } H_2 \times \frac{1\ \text{mol } H_2}{2.016\ \text{g } H_2} = 32.24\ \text{mol } H_2$$

AP Images/RICK BOWMER

Strategy Map 4.2

PROBLEM

Calculate **mass** of **product** from a reaction.

↓

DATA/INFORMATION

- **Masses** of the reactants
- Balanced equation

↓

STEP 1. Calculate **amount** of each **reactant** = mass × (1 mol/molar mass).

↓

Amount of each reactant

↓

STEP 2. Calculate **mass** of each **product** based on amount of each reactant = mol product × (molar mass/1 mol).

↓

Mass of product from amount of each reactant

↓

STEP 3. Decide which reactant is **limiting**. LR = reactant producing smallest mass of product.

↓

Mass of product now known

The mass of product expected based on each reactant is

$$12.71 \text{ mol CO} \times \frac{1 \text{ mol } CH_3OH \text{ formed}}{1 \text{ mol CO available}} \times \frac{32.04 \text{ g } CH_3OH}{1 \text{ mol } CH_3OH} = 407 \text{ g } CH_3OH$$

$$32.24 \text{ mol } H_2 \times \frac{1 \text{ mol } CH_3OH \text{ formed}}{2 \text{ mol } H_2 \text{ available}} \times \frac{32.04 \text{ g } CH_3OH}{1 \text{ mol } CH_3OH} = 517 \text{ g } CH_3OH$$

The amount of CO available produces less product than the amount of H_2 available. Carbon monoxide, CO, is the limiting reactant, and we now know that the maximum mass of CH_3OH that can be produced is 407 g.

(b) *What mass of H_2 remains when all the CO has been converted to product?* First, you must find the mass of H_2 required to react with all the CO.

$$12.71 \text{ mol CO} \times \frac{2 \text{ mol } H_2}{1 \text{ mol CO}} \times \frac{2.016 \text{ g } H_2}{1 \text{ mol } H_2} = 51.25 \text{ g } H_2 \text{ required}$$

You began with 65.0 g of H_2, but only 51.25 g is required by the limiting reactant; thus, the mass that is present in excess is

$$65.0 \text{ g } H_2 \text{ present} - 51.25 \text{ g } H_2 \text{ required} = 13.8 \text{ g } H_2 \text{ left}$$

Think about Your Answer The amounts table for this reaction is as follows.

Equation	CO(g)	+	2 H_2(g)	→	$CH_3OH(\ell)$
Initial amount (mol)	12.71		32.24		0
Change in amount upon reaction (mol)	−12.71		−2(12.71)		+12.71
Amount after complete reaction (mol)	0		6.82		12.71

The mass of product formed plus the mass of H_2 remaining after reaction (407.2 g CH_3OH produced + 13.8 g H_2 remaining = 421 g) is equal to the mass of reactants present before reaction (356 g CO + 65.0 g H_2 = 421 g).

Check Your Understanding

The thermite reaction produces iron metal and aluminum oxide from a mixture of powdered aluminum metal and iron(III) oxide (page 172).

$$Fe_2O_3(s) + 2\ Al(s) \rightarrow 2\ Fe(\ell) + Al_2O_3(s)$$

A mixture of 50.0 g each of Fe_2O_3 and Al is used. Which is the limiting reactant? What mass of iron metal can be produced?

4.3 Percent Yield

Goal for Section 4.3

- Explain the differences among actual yield, theoretical yield, and percent yield, and calculate percent yield for a reaction.

The maximum mass of product that can be obtained from a chemical reaction is the **theoretical yield**. The theoretical yield is obtained from a stoichiometry calculation. The **actual yield** of the product—the mass of material that is actually obtained in the

Problem Solving Tip 4.2 Moles of Reaction and Limiting Reactants

There is another method for solving stoichiometry problems that applies especially well to limiting reactant problems. This involves the useful concept of "moles of reaction."

One "mole of reaction" is said to have occurred when the reaction has taken place according to the number of moles given by the coefficients in the equation. For example, for the reaction of CO and O_2,

$$2\ CO(g) + O_2(g) \rightarrow 2\ CO_2(g)$$

1 mole of reaction occurs when 2 mol of CO and 1 mol of O_2 produce 2 mol of CO_2.

Now, suppose 9.5 g of CO and excess O_2 are combined. What amount of CO_2 (moles) can be produced?

$$9.5\ g\ CO \times \frac{1\ mol\ CO}{28.0\ g\ CO} \times \frac{1\ mol\text{-}rxn}{2\ mol\ CO} = 0.170\ mol\text{-}rxn$$

$$0.17\ mol\text{-}rxn \times \frac{2\ mol\ CO_2}{1\ mol\text{-}rxn} = 0.340\ mol\ CO_2$$

All reactants and products involved in a chemical reaction undergo the same number of moles of reaction because the reaction can only occur a certain number of times before one or more of the reactants are consumed and the reaction reaches completion.

If one of the reactants is in short supply the actual number of times a reaction can be carried out—the number of "moles of reaction"—will be determined by the limiting reactant. Using an approach similar to Example 4.2, you first calculate the amount of each reactant initially present and then calculate the moles of reaction that could occur with each amount of reactant. [This is equivalent to dividing the amount (moles) of each reactant by its stoichiometric coefficient.] The reactant producing the smaller number of moles of reaction is the limiting reactant. Once the limiting reactant is known, you proceed as before.

As an example, consider again the NH_3/O_2 reaction on page 177:

$$4\ NH_3(g) + 5\ O_2(g) \rightarrow 4\ NO(g) + 6\ H_2O(\ell)$$

1. *Calculate the moles of reaction predicted for each reactant and decide on the limiting reactant.*

In the case of the NH_3/O_2 reaction, 1 "mole of reaction" uses 4 mol of NH_3 and 5 mol of O_2 and produces 4 mol of NO and 6 mol of H_2O. In the example on page 178, we started with 44.04 mol of NH_3, so 11.01 mol of reaction could result.

$$44.04\ mol\ NH_3 \times \frac{1\ mol\text{-}rxn}{4\ mol\ NH_3} = 11.01\ mol\text{-}rxn$$

Based on the amount of O_2 available, 4.688 mol of reaction could occur.

$$23.44\ mol\ O_2 \times \frac{1\ mol\text{-}rxn}{5\ mol\ O_2} = 4.688\ mol\text{-}rxn$$

Fewer moles of reaction can occur with the amount of O_2 available, so O_2 is the limiting reactant.

2. *Calculate the change in amount and the amount upon completion of the reaction for each reactant and product.*

The number of moles of reaction predicted by the limiting reactant corresponds to the number of moles of reaction that can *actually* occur. Each reactant and product will undergo this number of moles of reaction, 4.688 mol-rxn in this case. To calculate the *change* in amount for a given reactant or product, multiply this number of moles of reaction by the stoichiometric coefficient of the reactant or product. To illustrate, for NH_3 this corresponds to the following calculation:

$$4.688\ mol\text{-}rxn \times \left(\frac{4\ mole\ NH_3}{1\ mol\text{-}rxn}\right) = 18.75\ mol\ NH_3$$

The amount of each reactant and product after reaction is calculated as usual.

Note: The concept of "moles of reaction" will be applied in this text in the discussion of thermochemistry in Chapters 5 and 18.

Amounts Table

Equation	$4\ NH_3(g)$	+	$5\ O_2(g)$	→	$4\ NO(g)$	+	$6\ H_2O(g)$
Initial amount (mol)	44.04		23.44		0		0
Moles of reaction based on limiting reactant (mol)	4.688		4.688		4.688		4.688
Change in amount (mol)*	−4.688(4) = −18.75		−4.688(5) = −23.44		+4.688(4) = +18.75		+4.688(6) = +28.13
Amount after complete reaction (mol)	25.29		0		18.75		28.13

*Moles of reaction are multiplied by the stoichiometric coefficient for each reactant and product.

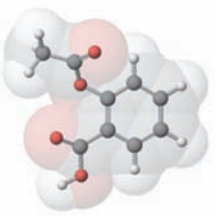

Figure 4.3 Percent yield. Although not a chemical reaction, popping corn is a good analogy to the difference between a theoretical yield and an actual yield. Here, we began with 16 popcorn kernels and found that only 12 of them popped. The percent yield from our "reaction" was (12/16) × 100%, or 75%.

laboratory or a chemical plant—is almost always less than the theoretical yield. Product loss almost always occurs when you are trying to isolate and purify the compound. In addition, some reactions do not go completely to products, and other reactions are sometimes complicated by giving more than one set of products.

To provide information to other chemists who might want to carry out a reaction, it is customary to report a percent yield (Figure 4.3). **Percent yield**, which specifies how much of the theoretical yield was obtained, is defined as

$$\text{Percent yield} = \frac{\text{actual yield}}{\text{theoretical yield}} \times 100\% \qquad (4.1)$$

$C_9H_8O_4(s)$
aspirin

Suppose you made aspirin in the laboratory by the following reaction:

$$\underset{\text{acetic anhydride}}{C_4H_6O_3(\ell)} + \underset{\text{salicylic acid}}{C_7H_6O_3(s)} \rightarrow \underset{\text{acetic acid}}{CH_3CO_2H(\ell)} + \underset{\text{aspirin}}{C_9H_8O_4(s)}$$

and that you began with 14.4 g of salicylic acid ($C_7H_6O_3$) and an excess of acetic anhydride. That is, salicylic acid is the limiting reactant. If you obtain 6.26 g of aspirin, what is the percent yield of this product? The first step is to find the amount of the limiting reactant, salicylic acid.

$$14.4 \text{ g } C_7H_6O_3 \times \frac{1 \text{ mol } C_7H_6O_3}{138.1 \text{ g } C_7H_6O_3} = 0.1043 \text{ mol } C_7H_6O_3$$

Next, use the stoichiometric factor from the balanced equation to find the amount of aspirin expected based on the limiting reactant, $C_7H_6O_3$.

$$0.1043 \text{ mol } C_7H_6O_3 \times \frac{1 \text{ mol aspirin}}{1 \text{ mol } C_7H_6O_3} = 0.1043 \text{ mol aspirin}$$

The maximum amount of aspirin that can be produced—the theoretical yield—is 0.104 mol or 18.8 g.

$$0.1043 \text{ mol aspirin} \times \frac{180.2 \text{ g aspirin}}{1 \text{ mol aspirin}} = 18.79 \text{ g aspirin}$$

Finally, with the actual yield known to be only 6.26 g, the percent yield of aspirin can be calculated.

$$\text{Percent yield} = \frac{6.26 \text{ g aspirin obtained (actual yield)}}{18.79 \text{ g aspirin expected (theoretical yield)}} \times 100\% = 33.3\% \text{ yield}$$

4.4 Chemical Equations and Chemical Analysis

Goals for Section 4.4

- Use stoichiometry principles to analyze a mixture of compounds.
- Find the empirical formula of an unknown compound using chemical stoichiometry.

Quantitative Analysis of a Mixture

Quantitative chemical analysis generally depends on one of the following basic ideas:

- A substance (A), present in an unknown amount, can be allowed to react with a known amount of another substance (B). If the stoichiometric ratio for their reaction is known (A/B), the unknown amount (of A) can be determined.
- A material of unknown composition can be converted to one or more substances of known composition. Those substances can be identified, their amounts determined, and these amounts related to the amount of the original, unknown substance.

An example of the first type of analysis is the determination of the amount of acetic acid in vinegar. (Acetic acid is the ingredient that makes vinegar acidic.) The acid reacts readily and completely with sodium hydroxide.

$$\underset{\text{acetic acid}}{CH_3CO_2H(aq)} + NaOH(aq) \rightarrow CH_3CO_2Na(aq) + H_2O(\ell)$$

If the exact amount of sodium hydroxide used in the reaction can be measured, the amount of acetic acid present can be calculated. This type of analysis is discussed in Section 4.8.

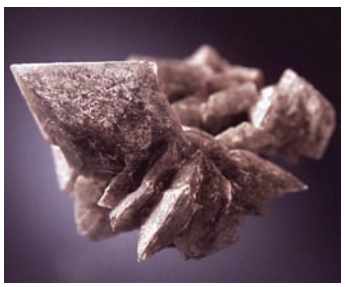
An example of the second type of analysis is the analysis of a sample of a mineral, thenardite, which is described in the following example.

EXAMPLE 4.3

Analysis of a Mineral

Problem Sodium sulfate, Na_2SO_4, occurs naturally as the mineral thenardite. To analyze an impure mineral sample for the quantity of Na_2SO_4, the sample is crushed, then dissolved in water to form a solution of Na_2SO_4. Next, the aqueous solution is treated with aqueous barium chloride, $BaCl_2$, to give solid $BaSO_4$ (Figure 4.4).

$$Na_2SO_4(aq) + BaCl_2(aq) \rightarrow BaSO_4(s) + 2\ NaCl(aq)$$



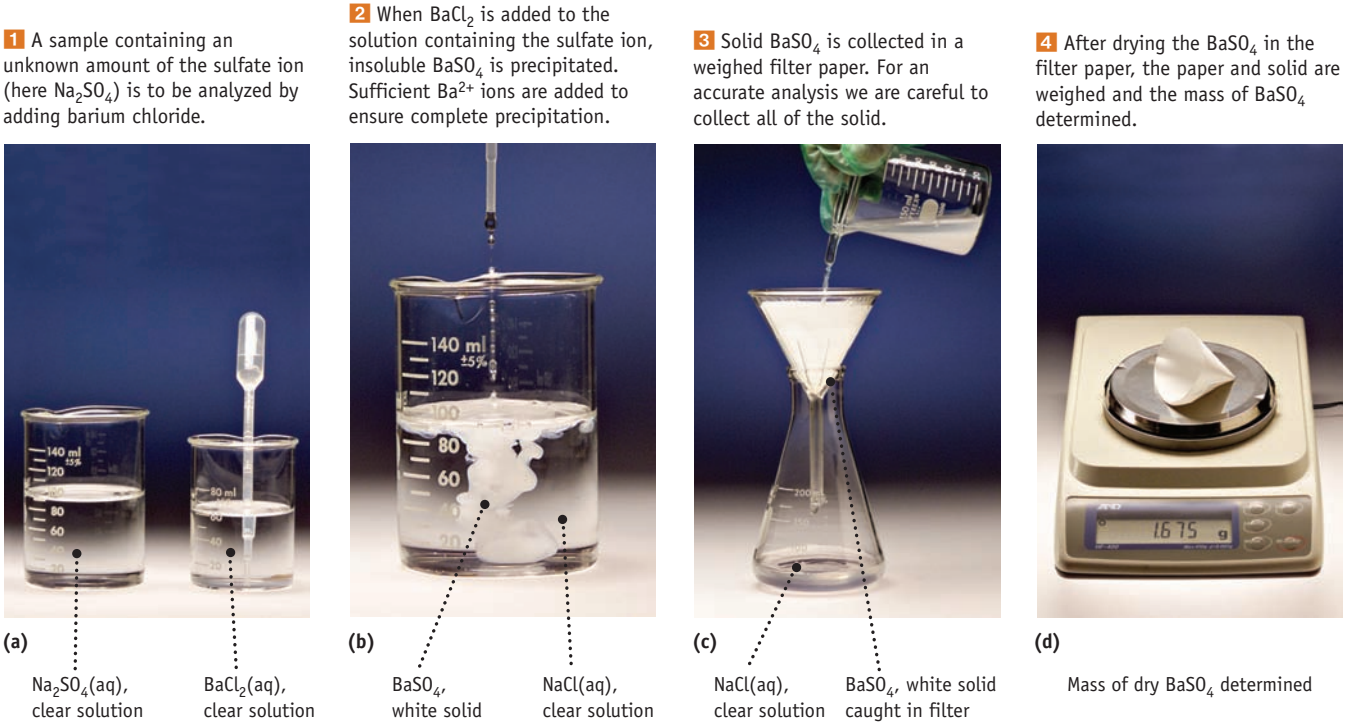
Suppose a 0.498-g sample containing thenardite produces 0.541 g of solid $BaSO_4$. What is the mass percent of Na_2SO_4 in the sample?

What Do You Know? You know the mass of thenardite and the mass of $BaSO_4$ produced in the reaction. You also know the balanced equation for the reaction leading to the formation of $BaSO_4$. You will need molar masses of Na_2SO_4 and $BaSO_4$.

Strategy First calculate the amount of $BaSO_4$ from its mass. Because 1 mol of Na_2SO_4 was present in the sample for each mole of $BaSO_4$ isolated, you therefore know the amount of Na_2SO_4 and can then calculate its mass and mass percent in the sample.

SOLUTION The molar mass of $BaSO_4$ is 233.4 g/mol. The amount of this solid is

$$0.541\ \text{g } BaSO_4 \times \frac{1\ \text{mol } BaSO_4}{233.4\ \text{g } BaSO_4} = 2.318 \times 10^{-3}\ \text{mol } BaSO_4$$



© Cengage Learning/Charles D. Winters

Thenardite. The mineral thenardite is sodium sulfate, Na_2SO_4. It is named after the French chemist Louis Thenard (1777–1857). Sodium sulfate is used in making detergents, glass, and paper.

Figure 4.4 The procedure for analyzing a solution for the sulfate ion content by precipitation. Using the mass of a precipitate to determine the composition of an unknown sample is often called "gravimetric analysis."

Because 1 mol of $BaSO_4$ is produced from 1 mol of Na_2SO_4, the amount of Na_2SO_4 in the sample must also have been 2.318×10^{-3} mol.

$$2.318 \times 10^{-3} \text{ mol } BaSO_4 \times \frac{1 \text{ mol } Na_2SO_4}{1 \text{ mol } BaSO_4} = 2.318 \times 10^{-3} \text{ mol } Na_2SO_4$$

With the amount of Na_2SO_4 known, the mass of Na_2SO_4 can be calculated.

$$2.318 \times 10^{-3} \text{ mol } Na_2SO_4 \times \frac{142.0 \text{ g } Na_2SO_4}{1 \text{ mol } Na_2SO_4} = 0.3291 \text{ g } Na_2SO_4$$

Finally, the mass percent of Na_2SO_4 in the 0.498-g sample is

$$\text{Mass percent } Na_2SO_4 = \frac{0.3291 \text{ g } Na_2SO_4}{0.498 \text{ g sample}} \times 100\% = 66.1\% \text{ } Na_2SO_4$$

Think about Your Answer For an analytical procedure to be used, the reactants must be *completely* converted to product and the product being measured must be isolated without losses in handling. Very careful experimental techniques are needed.

Check Your Understanding

One method for determining the purity of a sample of titanium(IV) oxide, TiO_2, an important industrial chemical, is to react the sample with bromine trifluoride.

$$3 \text{ } TiO_2(s) + 4 \text{ } BrF_3(\ell) \rightarrow 3 \text{ } TiF_4(s) + 2 \text{ } Br_2(\ell) + 3 \text{ } O_2(g)$$

This reaction is known to occur completely and quantitatively. That is, all of the oxygen in TiO_2 is evolved as O_2. Suppose 2.367 g of a TiO_2-containing sample evolves 0.143 g of O_2. What is the mass percent of TiO_2 in the sample?

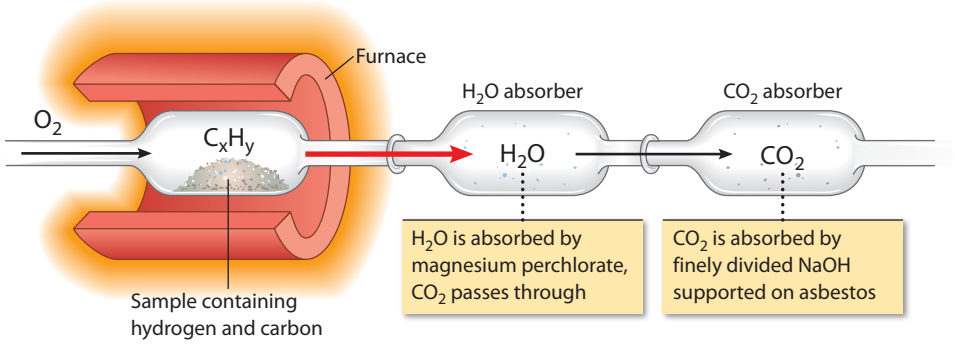

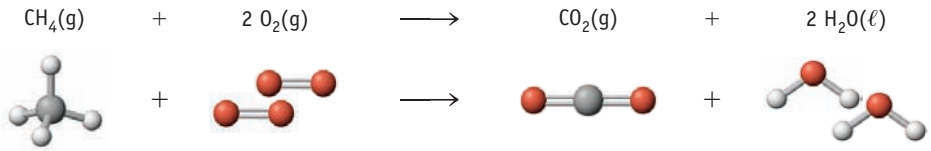

Figure 4.5 Combustion analysis of a hydrocarbon. If a compound containing C and H is burned in oxygen, CO_2 and H_2O are formed, and the mass of each can be determined. The mass of each absorbent before and after combustion gives the masses of CO_2 and H_2O. Only a few milligrams of a combustible compound are needed for analysis.

Determining the Formula of a Compound by Combustion

The empirical formula of a compound can be determined if the percent composition of the compound is known (see Section 2.7). But where do the percent composition data come from? One chemical method that works well for compounds that burn in oxygen is combustion analysis. In this technique, each element in the compound combines with oxygen to produce the appropriate oxide.

Take methane, CH_4, as an example. A balanced equation for its combustion shows that every carbon atom in the original compound appears as CO_2 and every hydrogen atom appears in the form of water. In other words, for every mole of CO_2 observed, there must have been one mole of carbon in the unknown compound. Similarly, for every mole of H_2O observed from combustion, there must have been *two* moles of H atoms in the unknown compound.

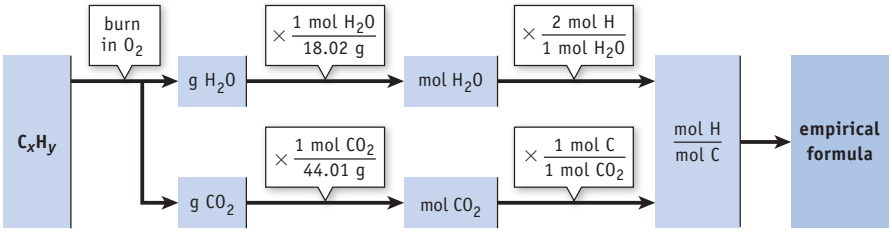
In the combustion experiment gaseous carbon dioxide and water are separated (as illustrated in Figure 4.5) and their masses determined. From these masses it is possible to calculate the amounts of C and H in CO_2 and H_2O, respectively, and the ratio of amounts of C and H in a sample of the original compound can then be found. This ratio gives the empirical formula. If the molar mass is known from a separate experiment, the molecular formula can also be determined.

General Approach to Finding an Empirical Formula by Chemical Analysis

1. The unknown but pure compound is converted in a chemical reaction into known products.
2. The reaction products are isolated, and the amount of each is determined.
3. The amount of each product is related to the amount of each element in the original compound.
4. The empirical formula is determined from the relative amounts of elements in the original compound.

EXAMPLE 4.4

Using Combustion Analysis to Determine the Empirical Formula of a Hydrocarbon



Problem When 1.125 g of a liquid hydrocarbon, C_xH_y, was burned (Figure 4.5), 3.447 g of CO_2 and 1.647 g of H_2O were produced. In a separate experiment the molar mass of the compound was found to be 86.2 g/mol. Determine the empirical and molecular formulas for the unknown hydrocarbon, C_xH_y.

What Do You Know? You know the mass of the hydrocarbon, the fact that it contains only C and H, and the molar mass of this compound. You are also given the masses of H_2O and CO_2 formed when the hydrocarbon is burned.

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Strategy The strategy to solve this problem is outlined in the diagram below.

The steps in sequence are as follows:

- Calculate the amounts of CO_2 and H_2O from the given masses.
- Calculate the amounts of C and H from the amounts of CO_2 and H_2O, respectively.
- Determine the lowest whole-number ratio of amounts of C and H. This gives the subscripts for C and H in the empirical formula.
- Compare the experimental molar mass of the hydrocarbon with that of the empirical formula to determine the molecular formula.

SOLUTION The amounts of CO_2 and H_2O isolated from the combustion are

$$3.447 \text{ g } CO_2 \times \frac{1 \text{ mol } CO_2}{44.010 \text{ g } CO_2} = 0.078323 \text{ mol } CO_2$$

$$1.647 \text{ g } H_2O \times \frac{1 \text{ mol } H_2O}{18.015 \text{ g } H_2O} = 0.091424 \text{ mol } H_2O$$

For every mole of CO_2 isolated, 1 mol of C must have been present in the unknown compound.

$$0.078323 \text{ mol } CO_2 \times \frac{1 \text{ mol C in unknown}}{1 \text{ mol } CO_2} = 0.078323 \text{ mol C}$$

For every mole of H_2O isolated, 2 mol of H must have been present in the unknown.

$$0.091424 \text{ mol } H_2O \times \frac{2 \text{ mol H in unknown}}{1 \text{ mol } H_2O} = 0.18285 \text{ mol H}$$

The original 1.125-g sample of compound therefore contained 0.078323 mol of C and 0.18285 mol of H. To determine the empirical formula of the unknown, we find the ratio of moles of H to moles of C (Section 2.7).

$$\frac{0.18285 \text{ mol H}}{0.078323 \text{ mol C}} = \frac{2.3345 \text{ mol H}}{1.0000 \text{ mol C}}$$

The empirical formula gives the simplest *whole-number* ratio. The translation of this ratio (2.335/1) to a whole-number ratio can usually be done quickly by trial and error. Multiplying the numerator and denominator by 3 gives 7/3. So, we know the ratio is 7 mol H to 3 mol C, which means the empirical formula of the hydrocarbon is C_3H_7.

Comparing the experimental molar mass with the molar mass calculated for the empirical formula,

$$\frac{\text{Experimental molar mass}}{\text{Molar mass of } C_3H_7} = \frac{86.2 \text{ g/mol}}{43.1 \text{ g/mol}} = \frac{2}{1}$$

we find that the molecular formula is twice the empirical formula, that is, $(C_3H_7)_2$ or C_6H_{14}.

Think about Your Answer As noted in Problem Solving Tip 2.2 (page 95), for problems of this type be sure to use data with enough significant figures to give accurate atom ratios.

Check Your Understanding

A 0.523-g sample of the unknown compound C_xH_y was burned in air to give 1.612 g of CO_2 and 0.7425 g of H_2O. A separate experiment gave a molar mass for C_xH_y of 114 g/mol. Determine the empirical and molecular formulas for the hydrocarbon.

You can also determine the empirical formula of an oxygenated hydrocarbon, such as ethanol (C_2H_6O), by combustion analysis. You first find the amount of carbon and hydrogen from the masses of collected carbon dioxide and water. Then, by calculating the mass of carbon and hydrogen from the amounts of those elements and subtracting these masses from the mass of the combusted compound, the mass of oxygen, and ultimately the amount of oxygen, may be determined (Example 4.5).

EXAMPLE 4.5

Using Combustion Analysis to Determine the Empirical Formula of a Compound Containing C, H, and O

Problem You have isolated an acid from clover leaves and know it contains only the elements C, H, and O. Burning 0.513 g of the acid in oxygen produces 0.501 g of CO_2 and 0.103 g of H_2O. What is the empirical formula of the acid, $C_xH_yO_z$?

What Do You Know? You know the mass of the compound and that it contains only C, H, and O. You also know the masses of H_2O and CO_2 formed when the compound is burned.

Strategy In order to determine the empirical formula, you need to determine the amounts (moles) of C, H, and O in the unknown compound. Follow the steps outlined below.

- Determine the amounts of C and H following the procedure in Example 4.4.
- Determine the masses of C and H from the amounts of C and H.
- The mass of O is the mass of the sample minus the masses of C and H.
- From the mass of O determine the amount of O.
- Finally, determine the smallest whole number ratio between the amounts of the three elements. This determines the subscripts for the elements in the empirical formula.

SOLUTION The first step is to determine the amounts of C and H in the sample.

$$0.501\ \text{g}\ CO_2 \times \frac{1\ \text{mol}\ CO_2}{44.01\ \text{g}\ CO_2} \times \frac{1\ \text{mol C}}{1\ \text{mol}\ CO_2} = 0.01138\ \text{mol C}$$

$$0.103\ \text{g}\ H_2O \times \frac{1\ \text{mol}\ H_2O}{18.02\ \text{g}\ H_2O} \times \frac{2\ \text{mol H}}{1\ \text{mol}\ H_2O} = 0.01143\ \text{mol H}$$

From these amounts, you can determine the mass of C and the mass of H in the sample.

$$0.01138\ \text{mol C} \times \frac{12.01\ \text{g C}}{1\ \text{mol C}} = 0.1367\ \text{g C}$$

$$0.01143\ \text{mol H} \times \frac{1.008\ \text{g H}}{1\ \text{mol H}} = 0.01152\ \text{g H}$$

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Using the mass of the original sample and the masses of C and H in the sample, you can now determine the mass of O in the sample. From this, you can find the amount of O in the sample.

$$\text{Mass of sample} = 0.513\ \text{g} = 0.1367\ \text{g C} + 0.01152\ \text{g H} + x\ \text{g O}$$

$$\text{Mass of O} = 0.3648\ \text{g O}$$

$$0.3648\ \text{g O} \times \frac{1\ \text{mol O}}{16.00\ \text{g O}} = 0.02280\ \text{mol O}$$

To find the mole ratios of elements, *divide the number of moles of each element by the smallest amount present*. Because both C and H are present in very nearly the same amount in the sample, you know their ratio is 1 C : 1 H. What about O?

$$\frac{0.02280\ \text{mol O}}{0.01143\ \text{mol C}} = \frac{2\ \text{mol O}}{1\ \text{mol C}}$$

The mole ratios show that, for every C atom in the molecule, there is one H atom and two O atoms. The empirical formula of the acid is therefore CHO_2.

Think about Your Answer If the molar mass of the unknown compound were known, you would then be able to derive the molecular formula of the compound.

Check Your Understanding

A 0.1342-g sample of a compound composed of C, H, and O was burned in oxygen and 0.240 g of CO_2 and 0.0982 g of H_2O was isolated. What is the empirical formula of the compound? If the experimentally determined molar mass is 74.1 g/mol, what is the molecular formula of the compound?

4.5 Measuring Concentrations of Compounds in Solution

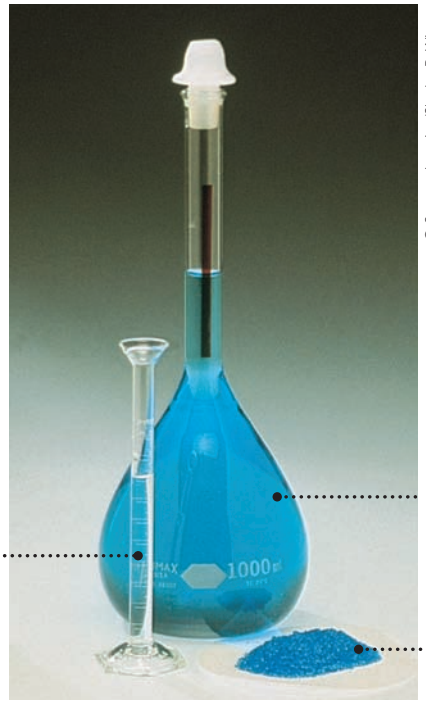
Goals for Section 4.5

- Calculate the concentration of a solute in a solution in units of moles per liter (molarity) and use solution concentrations in calculations.
- Describe how to prepare a solution of a given concentration from the solute and solvent or by dilution of a more concentrated solution.

Solution Concentration: Molarity

Most chemical studies require quantitative measurements, including experiments involving solutions. When doing these experiments, we continue to use balanced equations and moles, but we measure volumes of solutions rather than masses of solids, liquids, or gases.

Molarity, c, is defined as the amount of solute per liter of solution.



$$\text{Molarity of } x\ (c_x) = \frac{\text{amount of solute } x\ \text{(mol)}}{\text{volume of solution (L)}} \tag{4.2}$$

For example, if 58.4 g (1.00 mol) of NaCl is dissolved in enough water to give a total solution volume of 1.00 L, the molarity, c, is 1.00 mol/L. This is often abbreviated as 1.00 M, where the capital "M" stands for "moles per liter." Another common notation is to place the formula of the compound in square brackets (for example, [NaCl]); this notation indicates that the concentration of the solute in moles per liter of solution is being specified.

$$c_{\text{NaCl}} = [\text{NaCl}] = 1.00\ \text{mol/L} = 1.00\ \text{M}$$

For this photo, we measured out exactly 1.00 L of water, which was slowly added to the volumetric flask containing 25.0 g of $CuSO_4 \cdot 5\ H_2O$. When enough water had been added so that the *solution volume* was exactly 1.00 L, approximately 8 mL was left over from the original 1.00 L of water.

1.00 L of 0.100 M $CuSO_4$

To make a 0.100 M solution of $CuSO_4$, 25.0 g (0.100 mol) of $CuSO_4 \cdot 5\ H_2O$ (the blue crystalline solid) was placed in a 1.00-L volumetric flask.

Figure 4.6 Volume of solution versus volume of solvent. This figure emphasizes that molar concentrations are defined as moles of solute per liter of solution and not per liter of water or other solvent.

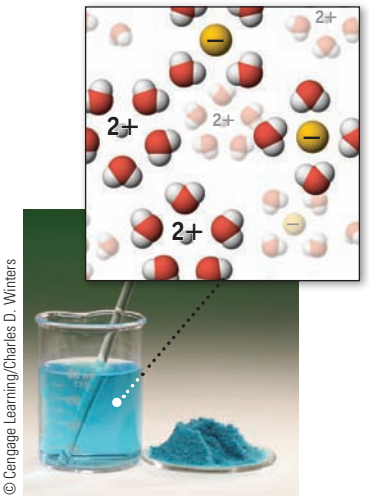
It is important to notice that molarity refers to the amount of solute *per liter of solution* and not per liter of solvent. If one liter of water is added to one mole of a solid compound, the final volume will not be exactly one liter, and the final concentration will not be exactly one mol/L (Figure 4.6). When making solutions of a given concentration, it is always the case that we dissolve the solute in a volume of solvent smaller than the desired volume of solution, then add solvent until the final solution volume is reached.

Potassium permanganate, $KMnO_4$, which was used at one time as a germicide when treating burns, is a shiny, purple-black solid that dissolves readily in water to give a deep purple solution. Suppose you dissolve 0.435 g of $KMnO_4$ in enough water to give 250. mL of solution (Figure 4.7). What is the concentration of $KMnO_4$? First, convert the mass of $KMnO_4$ to an amount.

$$0.435\ \text{g KMnO}_4 \times \frac{1\ \text{mol KMnO}_4}{158.0\ \text{g KMnO}_4} = 0.002753\ \text{mol KMnO}_4$$

Next, combine the volume of solution—which must be in liters—with the amount of $KMnO_4$ to give the concentration. Because 250. mL is equivalent to 0.250 L,

$$\text{Concentration of KMnO}_4 = c_{\text{KMnO}_4} = [\text{KMnO}_4] = \frac{0.002753\ \text{mol KMnO}_4}{0.250\ \text{L}} = 0.0110\ \text{M}$$



The $KMnO_4$ concentration is 0.0110 mol/L, or 0.0110 M. This is useful information, but it is often useful to know the concentration of each type of ion in a solution. Like all soluble ionic compounds, $KMnO_4$ dissociates completely into its ions, K^+ and MnO_4^-, when dissolved in water.

$$\underset{\text{100\% dissociation}}{\text{KMnO}_4(aq) \longrightarrow \text{K}^+(aq) + \text{MnO}_4^-(aq)}$$

One mole of $KMnO_4$ provides 1 mol of K^+ ions and 1 mol of MnO_4^- ions. Accordingly, 0.0110 M $KMnO_4$ gives a concentration of K^+ in the solution of 0.0110 M; similarly, the concentration of MnO_4^- is also 0.0110 M.

Finally, consider an aqueous solution of $CuCl_2$.

$$\underset{\text{100\% dissociation}}{\text{CuCl}_2(aq) \longrightarrow \text{Cu}^{2+}(aq) + 2\ \text{Cl}^-(aq)}$$

© Cengage Learning/Charles D. Winters

Ion concentrations for a soluble ionic compound. Here, 1 mol of $CuCl_2$ dissociates to 1 mol of Cu^{2+} ions and 2 mol of Cl^- ions. Therefore, the Cl^- concentration is twice the concentration calculated for $CuCl_2$.

Figure 4.7 Making a solution. A 0.0110 M solution of $KMnO_4$ is made by adding enough water to 0.435 g of $KMnO_4$ to make 0.250 L of solution.

If 0.10 mol of $CuCl_2$ is dissolved in enough water to make 1.0 L of solution, the concentration of the copper(II) ion, $[Cu^{2+}]$, is 0.10 M. However, the concentration of chloride ions, $[Cl^-]$, is 0.20 M because the compound dissociates in water to provide 2 mol of Cl^- ions for each mole of $CuCl_2$.

EXAMPLE 4.6

Concentration

Problem If 25.3 g of sodium carbonate, Na_2CO_3, is dissolved in enough water to make 250. mL of solution, what is the concentration of Na_2CO_3? What are the concentrations of the Na^+ and CO_3^{2-} ions?

What Do You Know? You know the mass of the solute, Na_2CO_3, and the volume of the solution. You will need the molar mass of Na_2CO_3 to calculate the amount of this compound.

Strategy The concentration (moles/L) of Na_2CO_3 is the amount of Na_2CO_3 (moles) divided by the volume (in liters). To determine the concentrations of the ions, recognize that one mole of this ionic compound contains two moles of Na^+ and one mole of CO_3^{2-} ions.

$$Na_2CO_3(s) \longrightarrow 2\ Na^+(aq) + CO_3^{2-}(aq)$$

SOLUTION First find the amount of Na_2CO_3.

$$25.3\ \text{g}\ Na_2CO_3 \times \frac{1\ \text{mol}\ Na_2CO_3}{106.0\ \text{g}\ Na_2CO_3} = 0.2387\ \text{mol}\ Na_2CO_3$$

and then the concentration of Na_2CO_3,

$$\text{Concentration of } Na_2CO_3 = \frac{0.2387\ \text{mol}\ Na_2CO_3}{0.250\ \text{L}} = 0.9548\ \text{M} = 0.955\ \text{mol/L}$$

The ion concentrations follow from knowing that each mole of Na_2CO_3 produces 2 mol of Na^+ ions and 1 mol of CO_3^{2-} ions.

$$[Na^+] = 2 \times 0.9548\ \text{M}\ Na^+(aq) = 1.91\ \text{M}$$

$$[CO_3^{2-}] = 0.955\ \text{M}$$

Think about Your Answer While we refer to this solution as 0.955 M Na_2CO_3, there are no actual particles of Na_2CO_3 present. This soluble ionic compound is present in solution as dissociated sodium and carbonate ions.

Check Your Understanding

Sodium bicarbonate, $NaHCO_3$, is used in baking powder formulations and in the manufacture of plastics and ceramics, among other things. If 26.3 g of the compound is dissolved in enough water to make 200. mL of solution, what is the concentration of $NaHCO_3$? What are the concentrations of the ions in solution?

Preparing Solutions of Known Concentration

Chemists often have to prepare a given volume of solution of known concentration. There are two commonly used methods to do this.

Combining a Weighed Solute with the Solvent

Suppose you need to prepare 2.00 L of a 1.50 M solution of aqueous Na_2CO_3. You have some solid Na_2CO_3, distilled water, and a 2.00-L volumetric flask. To make the solution, you must weigh the required quantity of Na_2CO_3 as accurately as possible considering the number of significant figures desired for the concentration, carefully place all the solid in the volumetric flask, and then add some water to dissolve the solid. After the solid has dissolved completely, more water is added to bring the solution volume to 2.00 L. After thorough mixing, the solution then has the desired concentration and volume.

Volumetric Flask A volumetric flask is a special flask with a line marked on its neck (see page 40 and Figures 4.6–4.8). If the flask is filled with a solution to this line (at a given temperature), it contains precisely the volume of solution specified.

But what mass of Na_2CO_3 is required to make 2.00 L of 1.50 M Na_2CO_3? First, calculate the amount of Na_2CO_3 required,

$$2.00\ \cancel{L} \times \frac{1.50\ \text{mol}\ Na_2CO_3}{1.00\ \cancel{L}\ \text{solution}} = 3.000\ \text{mol}\ Na_2CO_3\ \text{required}$$

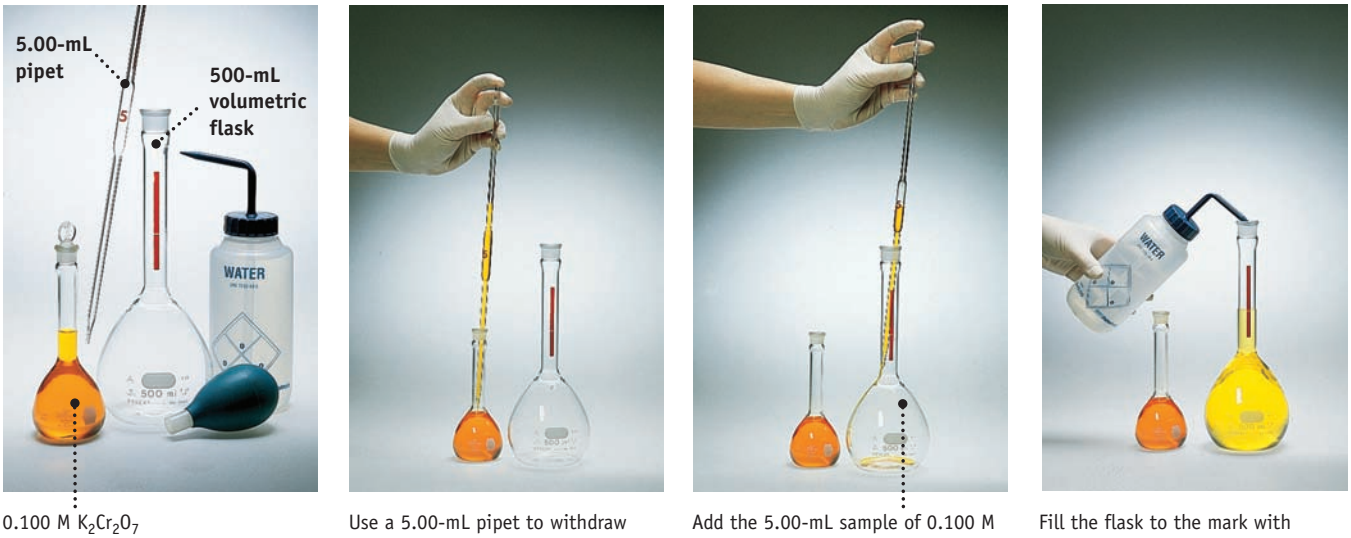
and then the mass in grams.

$$3.000\ \cancel{\text{mol}\ Na_2CO_3} \times \frac{106.0\ \text{g}\ Na_2CO_3}{1\ \cancel{\text{mol}\ Na_2CO_3}} = 318\ \text{g}\ Na_2CO_3$$

Thus, to prepare the desired solution, you should dissolve 318 g of Na_2CO_3 in enough water to make 2.00 L of solution.

Diluting a More Concentrated Solution

Another method of making a solution of a given concentration is to begin with a concentrated solution of known concentration and add more solvent (usually water) until the desired, lower concentration is reached (Figure 4.8). Many of the solutions prepared for your laboratory course are probably made by this dilution method. It is more efficient to store a small volume of a concentrated solution and then, when needed, add water to make a much larger volume of a dilute solution.



Suppose you need 500. mL of aqueous 0.00100 M potassium dichromate, $K_2Cr_2O_7$, for use in chemical analysis. You have some 0.100 M $K_2Cr_2O_7$ solution available. To make the required 0.00100 M solution, place a measured volume of the more concentrated $K_2Cr_2O_7$ solution in a flask and then add water until the $K_2Cr_2O_7$ is contained in the appropriate, larger volume of water (Figure 4.8).

What volume of a 0.100 M $K_2Cr_2O_7$ solution must be diluted to make 500. mL of 0.00100 M solution? The amount of solute in the dilute solution can be calculated from its volume and concentration.

$$\text{Amount of } K_2Cr_2O_7 \text{ in dilute solution} = c_{K_2Cr_2O_7} \times V_{K_2Cr_2O_7} = \left(\frac{0.00100\ \text{mol}}{\cancel{L}}\right) \times (0.500\ \cancel{L})$$
$$= 0.0005000\ \text{mol}\ K_2Cr_2O_7$$

© Cengage Learning/Charles D. Winters

Figure 4.8 Making a solution by dilution. Here, 5.00 mL of a 0.100 M $K_2Cr_2O_7$ solution is diluted to 500. mL. This means the solution is diluted by a factor of 100, from 0.100 M to 0.00100 M.

The more concentrated solution containing this amount of $K_2Cr_2O_7$ is placed in a 500.-mL flask and then diluted to the final volume. The volume of 0.100 M $K_2Cr_2O_7$ required is 5.00 mL.

$$0.0005000 \text{ mol } K_2Cr_2O_7 \times \frac{1.00 \text{ L}}{0.100 \text{ mol } K_2Cr_2O_7} = 0.00500 \text{ L or } 5.00 \text{ mL}$$

Thus, to prepare 500. mL of 0.0010 M $K_2Cr_2O_7$, place 5.00 mL of 0.100 M $K_2Cr_2O_7$ in a 500.-mL flask and add water until a volume of 500. mL is reached (Figure 4.8).

EXAMPLE 4.7

Preparing a Solution by Dilution

Problem What is the concentration of iron(III) ions in a solution prepared by diluting 1.00 mL of a 0.236 M solution of iron(III) nitrate to a volume of 100.0 mL?

What Do You Know? You know the initial concentration and volume of the iron-containing solution and the final volume required after dilution.

Strategy First calculate the amount of iron(III) ions in the 1.00-mL sample (amount = concentration × volume). The concentration of the iron(III) ions in the final, dilute solution is equal to this amount of iron(III) ions divided by the new volume.

SOLUTION The amount of iron(III) ion in the 1.00 mL sample is

$$\text{Amount of } Fe^{3+} = c_{Fe^{3+}} \times V_{Fe^{3+}} = \frac{0.236 \text{ mol } Fe^{3+}}{\text{L}} \times 1.00 \times 10^{-3} \text{ L} = 2.360 \times 10^{-4} \text{ mol } Fe^{3+}$$

This amount of iron(III) ion is contained in the new volume of 100.0 mL, so the final concentration of the diluted solution is

$$c_{Fe^{3+}} = [Fe^{3+}] = \frac{2.360 \times 10^{-4} \text{ mol } Fe^{3+}}{0.1000 \text{ L}} = 2.36 \times 10^{-3} \text{ M}$$

Think about Your Answer The sample has been diluted 100-fold, so we would expect the final concentration to be 1/100th of the initial value. See also Problem Solving Tip 4.3, which gives a quick and easy-to-use method for this calculation.

Check Your Understanding

An experiment calls for you to use 250. mL of 1.00 M NaOH, but you are given a large bottle of 2.00 M NaOH. Describe how to make the desired volume of 1.00 M NaOH.

Problem Solving Tip 4.3 Preparing a Solution by Dilution

There is a straightforward method to use for problems involving dilution. The central idea is that the amount of solute in the final, dilute solution has to be equal to the amount of solute taken from the more concentrated solution. If c is the concentration (molarity) and V is the volume (and the subscripts d and c identify the dilute and concentrated solutions, respectively), then the amount of solute in either solution (in the case of the $K_2Cr_2O_7$ example in the text) can be calculated as follows:

(a) Amount of $K_2Cr_2O_7$ in the final dilute solution is

$$c_d \times V_d = 0.000500 \text{ mol}$$

(b) Amount of $K_2Cr_2O_7$ taken from the more concentrated solution is

$$c_c \times V_c = 0.000500 \text{ mol}$$

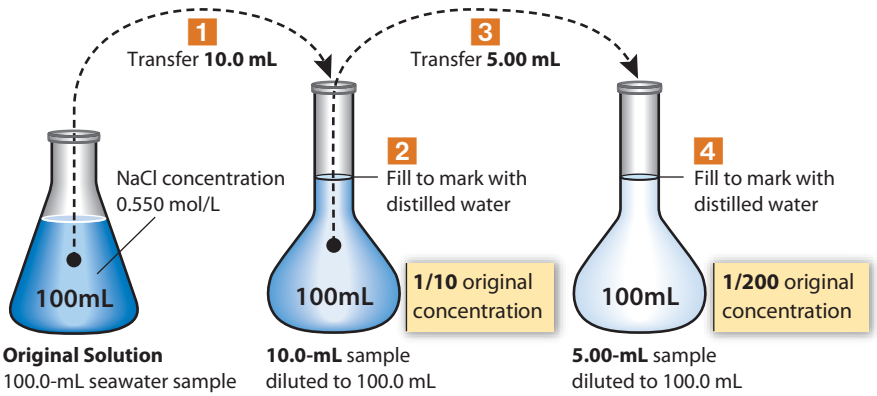
Both the concentrated and dilute solutions contain the same amount of solute. Therefore, we can use the following equation:

$$\text{Amount in concentrated solution} = \text{Amount in dilute solution}$$

$$c_c \times V_c = c_d \times V_d$$

One of the parameters can be calculated if the other three are known.

A CLOSER LOOK



Serial Dilutions

We often find in the laboratory that a solution is too concentrated for the analytical technique we want to use. You might want to analyze a seawater sample for its chloride ion content, for instance. To obtain a solution with a chloride concentration of the proper magnitude for analysis by the Mohr method (Applying Chemical Principles 4.3, page 209), for example, you might want to dilute the sample, not once but several times.

Suppose you have 100.0 mL of a seawater sample that has an NaCl concentration of 0.550 mol/L. You transfer 10.00 mL of that sample to a 100.0-mL volumetric flask and fill to the mark with distilled water. After thoroughly mixing the diluted sample, you then transfer 5.00 mL of that sample to another 100.0-mL flask and fill to the mark with distilled water. What is the NaCl concentration in the final 100.0-mL sample?

The original solution contains 0.550 mol/L of NaCl. If you remove 10.00 mL, you have removed

$$0.01000 \text{ L} \times 0.550 \text{ mol/L} = 5.500 \times 10^{-3} \text{ mol NaCl}$$

and the concentration in 100.0 mL of the diluted solution is

$$c_{NaCl} = 5.500 \times 10^{-3} \text{ mol}/0.1000 \text{ L} = 5.500 \times 10^{-2} \text{ M}$$

or 1/10 of the concentration of the original solution (because we diluted the sample by a factor of 10).

Now we take 5.00 mL of the diluted solution and dilute that once again to 100.0 mL. The final concentration is

$$0.00500 \text{ L} \times 5.500 \times 10^{-2} \text{ mol/L} = 2.750 \times 10^{-4} \text{ mol NaCl}$$

$$c_{NaCl} = 2.750 \times 10^{-4} \text{ mol}/0.1000 \text{ L} = 2.75 \times 10^{-3} \text{ M}$$

This is 1/200 of the concentration of the original solution.

A fair question at this point is why we did not just take 1 mL of the original solution and dilute to 200 mL. The answer is that there is less error in using larger pipets such as 5.00- or 10.00-mL pipets rather than a 1.00-mL pipet. And then there is a limitation in available glassware. A 200.00-mL volumetric flask is unlikely to be available.

4.6 pH, a Concentration Scale for Acids and Bases

Goals for Section 4.6

- Understand the pH scale.
- Calculate the pH of a solution from the concentration of hydronium ions in the solution. Calculate the hydronium ion concentration in a solution from its pH.

A sample of vinegar, which contains the weak acid acetic acid, has a hydronium ion concentration of 1.6×10^{-3} M and "pure" rainwater has $[H_3O^+] = 2.5 \times 10^{-6}$ M. These small values can be expressed using scientific notation, but a more convenient way to express such numbers is the logarithmic pH scale.

The pH of a solution is the negative of the base-10 logarithm of the hydronium ion concentration.

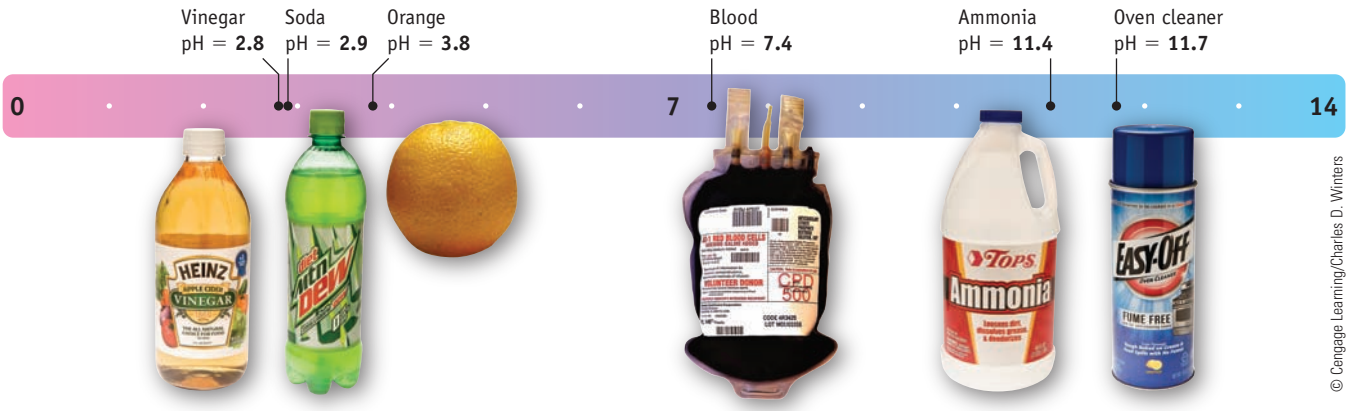
$$pH = -\log[H_3O^+] \tag{4.3}$$

Logarithms Numbers less than 1 have negative logs. Defining pH as $-\log[H_3O^+]$ produces a positive number if the H_3O^+ concentration is less than 1 molar. See Appendix A for a discussion of logs.

Taking vinegar, pure water, blood, and ammonia as examples,

pH of vinegar	$= -\log(1.6 \times 10^{-3}\ M) = -(-2.80) = 2.80$		acidic
pH of pure water (at 25 °C)	$= -\log(1.0 \times 10^{-7}\ M) = -(-7.00) = 7.00$		neutral
pH of blood	$= -\log(4.0 \times 10^{-8}\ M) = -(-7.40) = 7.40$		basic
pH of household ammonia	$= -\log(4.3 \times 10^{-12}\ M) = -(-11.37) = 11.37$		basic

You see that something you recognize as acidic has a relatively low pH, whereas ammonia, a common base, has a very low hydronium ion concentration and a high pH. *For aqueous solutions at 25 °C, acids have pH values less than 7, bases have values greater than 7, and a pH of 7 represents a neutral solution* (Figure 4.9). Blood, which your common sense tells you is likely to be neither acidic nor basic, has a pH slightly greater than 7.



Logs and Your Calculator All scientific calculators have a key marked "log." To find an antilog, use the key marked "10^x" or the inverse log. In determining $[H_3O^+]$ from a pH, when you enter the value of x for 10^x, make sure it has a negative sign.

To find the hydronium ion concentration of a solution you take the antilog of the pH. That is,

$$[H_3O^+] = 10^{-pH} \tag{4.4}$$

For example, the pH of a diet soda is 2.92, and the hydronium ion concentration of the solution is

$$[H_3O^+] = 10^{-2.92} = 1.2 \times 10^{-3}\ M$$

© Cengage Learning/Charles D. Winters

Figure 4.9 pH values of some common substances. Here, the "bar" is colored red at one end and blue at the other. These are the colors of litmus paper, commonly used in the laboratory to decide whether a solution is acidic (litmus is red) or basic (litmus is blue).

(a) Some household products. Each solution contains a few drops of an acid–base indicator. A color of yellow or red indicates a pH less than 7. A green to purple color indicates a pH greater than 7.

(b) The pH of a soda is measured with a modern pH meter. Soft drinks are often quite acidic, owing to dissolved CO_2 and other ingredients.

Photos: © Cengage Learning/Charles D. Winters

Figure 4.10 Determining pH.

The approximate pH of a solution can also be determined using a variety of dyes. Litmus paper, for example, contains a dye extracted from a type of lichen, but many other dyes are also available (Figure 4.10a). A more accurate measurement of pH is done with a pH meter (such as the one in Figure 4.10b). Here, a pH electrode is immersed in the solution to be tested, and the pH is read from the instrument.

EXAMPLE 4.8

pH of Solutions

Problem

(a) Lemon juice has $[H_3O^+] = 0.0032$ M. What is its pH?

(b) Seawater has a pH of 8.07. What is the hydronium ion concentration of this solution?

(c) A solution of nitric acid has a concentration of 0.0056 mol/L. What is the pH of this solution?

What Do You Know? In part (a) you are given a concentration and asked to calculate the pH, whereas the opposite is true in (b). For part (c), however, you first must recognize that HNO_3 is a strong acid and is 100% ionized in water.

Strategy Use Equation 4.3 to calculate pH from the H_3O^+ concentration and Equation 4.4 to find $[H_3O^+]$ from the pH.

Solution

(a) Lemon juice: When the hydronium ion concentration is known, the pH is found using Equation 4.3.

$$pH = -\log [H_3O^+] = -\log (3.2 \times 10^{-3}) = -(-2.49) = 2.49$$

(b) Seawater: Here pH = 8.07. Therefore,

$$[H_3O^+] = 10^{-pH} = 10^{-8.07} = 8.5 \times 10^{-9}\ M$$

(c) Nitric acid: Nitric acid, a strong acid (Table 3.1, page 140), is completely ionized in aqueous solution. Because the concentration of HNO_3 is 0.0056 mol/L, the ion concentrations are also 0.0056 mol/L.

$$[H_3O^+] = [NO_3^-] = 0.0056\ M$$

$$pH = -\log [H_3O^+] = -\log (0.0056\ M) = 2.25$$

Weak and Strong Acids and Hydronium Ion Concentration Because a weak acid (e.g., acetic acid) does not ionize completely in water, the hydronium ion concentration in an aqueous solution of a weak monoprotic acid is less than the concentration of the acid. In contrast, the hydronium ion concentration in strong acid solutions is the same as the acid concentration.

Think about Your Answer A comment on logarithms and significant figures (Appendix A) is useful. The number to the left of the decimal point in a logarithm is called the *characteristic*, and the number to the right is the *mantissa*. The mantissa has as many significant figures as the number whose log was found. For example, the logarithm of 3.2×10^{-3} (two significant figures) is –2.49. (The significant figures are the two numbers to the right of the decimal point.)

Check Your Understanding

(a) What is the pH of a solution of HCl in which $[HCl] = 2.6 \times 10^{-2}$ M?

(b) What is the hydronium ion concentration in orange juice with a pH of 3.80?

4.7 Stoichiometry of Reactions in Aqueous Solution—Fundamentals

Goal for Section 4.7

- Use stoichiometry principles for reactions occurring in solution.

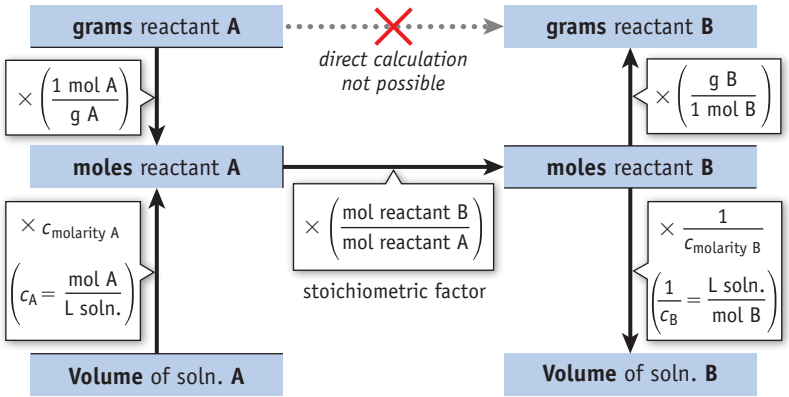
The majority of chemical reactions are done in solutions, usually in water. Certainly the reactions occurring in our bodies are in aqueous solution.

One example of a reaction occurring with at least one reactant in solution is a gas-forming exchange reaction involving a metal carbonate and an aqueous acid (Figure 4.11)

$$\underset{\text{metal carbonate}}{CaCO_3(s)} + 2\ \underset{\text{acid}}{HCl(aq)} \rightarrow \underset{\text{salt}}{CaCl_2(aq)} + \underset{\text{water}}{H_2O(\ell)} + \underset{\text{carbon dioxide}}{CO_2(g)}$$

In this case we could ask what mass of $CaCO_3$ is required to react completely with 25 mL of 0.750 M HCl. This problem differs from the previous stoichiometry problems in that the quantity of one reactant (HCl) is given as a volume of a solution of known concentration instead of as a mass in grams. Because our balanced equation is written in terms of amounts (moles), our first step will be to determine the amount of HCl present so we can relate the amount of HCl available to the amount of $CaCO_3$ required.

$$\text{Amount of HCl} = c_{HCl} \times V_{HCl} = \frac{0.750 \text{ mol HCl}}{1 \text{ L HCl}} \times 0.025 \text{ L HCl} = 0.0188 \text{ mol HCl}$$



© Cengage Learning/Charles D. Winters

Figure 4.11 A commercial remedy for excess stomach acid. The tablet contains calcium carbonate, which reacts with hydrochloric acid, the acid present in the digestive system. The most obvious product is CO_2 gas, but $CaCl_2(aq)$ is also produced.

Problem Solving Tip 4.4 Stoichiometry Calculations Involving Solutions

In Problem Solving Tip 4.1, you learned about a general approach to stoichiometry problems. We can now modify that scheme for a reaction involving solutions such as $x\ A(aq) + y\ B(aq) \rightarrow$ products.

This is then related to the amount of $CaCO_3$ required using the stoichiometric factor from the balanced equation.

$$0.0188 \text{ mol HCl} \times \frac{1 \text{ mol } CaCO_3}{2 \text{ mol HCl}} = 0.00938 \text{ mol } CaCO_3$$

Finally, the amount of $CaCO_3$ is converted to a mass in grams using the molar mass of $CaCO_3$ as the conversion factor.

$$0.00938 \text{ mol } CaCO_3 \times \frac{100. \text{ g } CaCO_3}{1 \text{ mol } CaCO_3} = 0.94 \text{ g } CaCO_3$$

If you follow the general scheme outlined in Problem-Solving Tip 4.4 and pay attention to the units on the numbers, you can successfully carry out any kind of stoichiometry calculations involving concentrations.

EXAMPLE 4.9

Stoichiometry of a Reaction in Solution

Problem Metallic zinc reacts with aqueous HCl (Figure 3.12).

$$Zn(s) + 2\ HCl(aq) \longrightarrow ZnCl_2(aq) + H_2(g)$$

What volume of 2.50 M HCl, in milliliters, is required to completely consume 11.8 g of Zn?

What Do You Know? You have the balanced equation for the reaction of Zn and HCl(aq) and know the mass of zinc and the concentration of HCl(aq).

Strategy

- Calculate the amount of zinc.
- Use a stoichiometric factor (= 2 mol HCl/1 mol Zn) to relate amount of HCl required to amount of Zn available.
- Calculate the volume of HCl solution from the amount of HCl and its concentration.

Solution Begin by calculating the amount of Zn.

$$11.8 \text{ g Zn} \times \frac{1 \text{ mol Zn}}{65.38 \text{ g Zn}} = 0.1805 \text{ mol Zn}$$

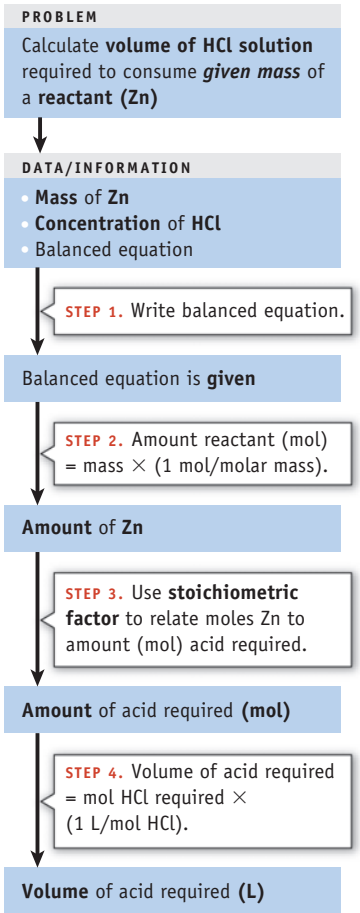
Use the stoichiometric factor to calculate the amount of HCl required.

$$0.1805 \text{ mol Zn} \times \frac{2 \text{ mol HCl}}{1 \text{ mol Zn}} = 0.3610 \text{ mol HCl}$$

Use the amount of HCl and the solution concentration to calculate the volume.

$$0.3610 \text{ mol HCl} \times \frac{1.00 \text{ L solution}}{2.50 \text{ mol HCl}} = 0.144 \text{ L of 2.50 M HCl}$$

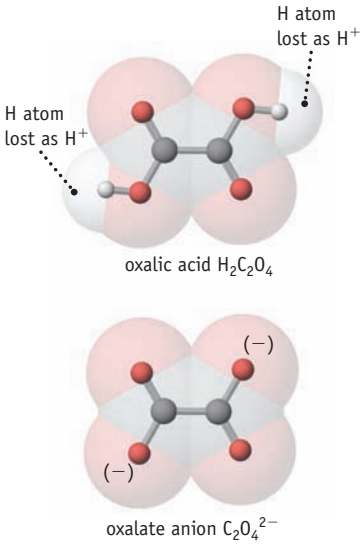
The answer is requested in units of milliliters, so the calculated volume is converted to milliliters. That is, 144 mL of 2.50 M HCl is required to convert 11.8 g of Zn completely to products.



Think about Your Answer You began with 0.180 mol of zinc. Because the concentration of the HCl solution is 2.50 mol/L, it makes sense that significantly less than 1 L of HCl solution is needed. Notice also that this is a redox reaction in which zinc is oxidized (oxidation number changes from 0 to +2) and hydrogen, in HCl(aq), is reduced (its oxidation number changes from +1 to 0).

Check Your Understanding

If you combine 75.0 mL of 0.350 M HCl and an excess of Na_2CO_3, what mass of CO_2, in grams, is produced?



$$Na_2CO_3(s) + 2\ HCl(aq) \longrightarrow 2\ NaCl(aq) + H_2O(\ell) + CO_2(g)$$

Strategy Map 4.9

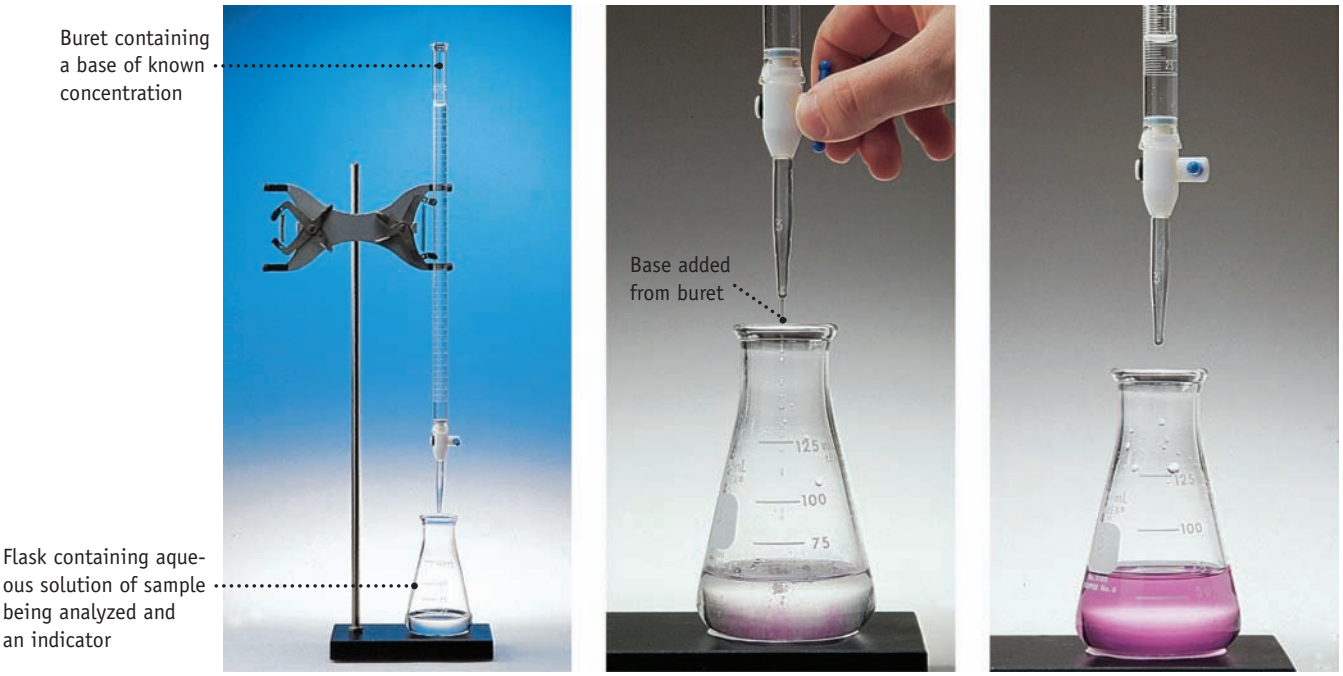
Oxalic acid. Oxalic acid has two groups that can supply an H^+ ion to solution. Hence, 1 mol of the acid requires 2 mol of NaOH for complete reaction.

4.8 Stoichiometry of Reactions in Aqueous Solution—Titrations

Goal for Section 4.8

- Explain how a titration is carried out, explain the procedure for standardization of a solution, and calculate concentrations or amounts of reactants from titration data.

Titration: A Method of Chemical Analysis



Suppose you are asked to determine the mass of naturally occurring oxalic acid, $H_2C_2O_4$, in an impure sample. Because the compound is an acid, it reacts with a base such as sodium hydroxide.

$$H_2C_2O_4(aq) + 2\ NaOH(aq) \rightarrow Na_2C_2O_4(aq) + 2\ H_2O(\ell)$$

You can use this reaction to determine the quantity of oxalic acid present in a given mass of sample if the following conditions are met:

- You can determine when the amount of sodium hydroxide added is exactly enough to react with all the oxalic acid present in solution.
- You know the concentration of the sodium hydroxide solution and volume that has been added at exactly the point of complete reaction.

These conditions are fulfilled in a titration, a procedure illustrated in Figure 4.12. The solution containing oxalic acid is placed in a flask along with an acid–base indicator, a dye that changes color when the pH of the reaction solution reaches a certain value. Aqueous sodium hydroxide of accurately known concentration is placed in a buret. The sodium hydroxide in the buret is added slowly to the acid solution in the flask. As long as some acid is present in solution, all the base supplied from the buret is consumed, the solution remains acidic, and the indicator color is unchanged. At

Photos: © Cengage Learning/Charles D. Winters

1 A buret, a volumetric measuring device calibrated in divisions of 0.1 mL (and consequently read to the nearest 0.01 mL), is filled with an aqueous solution of a base of known concentration.

2 Base is added slowly from the buret to the solution containing the acid being analyzed and an indicator.

3 When the amount of NaOH added from the buret equals the amount of H_3O^+ supplied by the acid (the equivalence point), the dye (the indicator) changes color. (The indicator used here is phenolphthalein.)

Figure 4.12 Titration of an acid in aqueous solution with a base.

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

some point—the **equivalence point**—the amount of OH^- added exactly equals the amount of H_3O^+ that can be supplied by the acid. However, as soon as the slightest excess of base has been added beyond the equivalence point, the solution becomes basic, and the indicator changes color (see Figure 4.12). Example 4.10 shows how to use the equivalence point and the other information to determine the percentage of oxalic acid in a mixture.

EXAMPLE 4.10

Acid–Base Titration

Problem A 1.034-g sample of impure oxalic acid is dissolved in water and an acid–base indicator added. The sample requires 34.47 mL of 0.485 M NaOH to reach the equivalence point. What is the mass of oxalic acid in the sample, and what is its mass percent?

What Do You Know? You know the mass of impure oxalic acid and the volume and concentration of NaOH solution used in the titration.

Strategy See also the Strategy Map for Example 4.10.

Step 1. *Write a balanced chemical equation for this acid–base reaction.*

Step 2. *Calculate the amount of NaOH used in the titration from its volume and concentration.*

Step 3. *Use the stoichiometric factor defined by the balanced equation to determine the amount of $H_2C_2O_4$.*

Step 4. *Calculate the mass of $H_2C_2O_4$ from the amount and its molar mass.*

Step 5. *Determine the percent by mass of $H_2C_2O_4$ in the sample.*

Solution The balanced equation for the reaction of NaOH and $H_2C_2O_4$ is

$$H_2C_2O_4(aq) + 2\ NaOH(aq) \rightarrow Na_2C_2O_4(aq) + 2\ H_2O(\ell)$$

and the amount of NaOH is given by

$$\text{Amount of NaOH} = c_{NaOH} \times V_{NaOH} = \frac{0.485\ \text{mol NaOH}}{\text{L}} \times 0.03447\ \text{L} = 0.01672\ \text{mol NaOH}$$

The balanced equation for the reaction shows that 1 mol of oxalic acid requires 2 mol of sodium hydroxide. This is the required stoichiometric factor to obtain the amount of oxalic acid present.

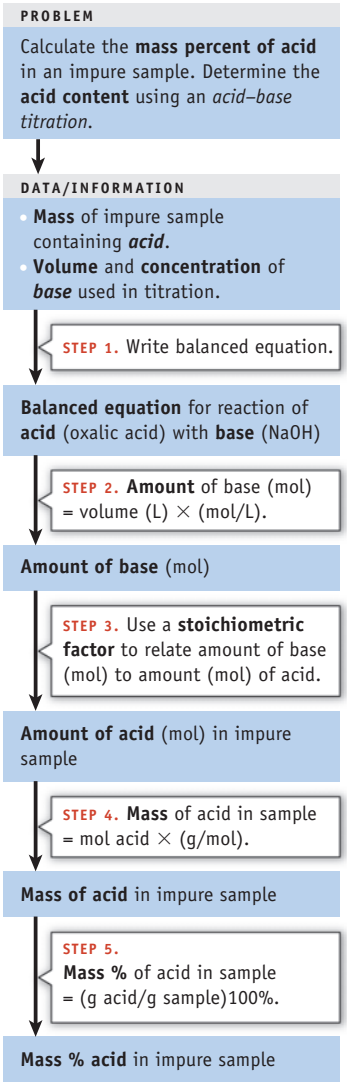
$$0.01672\ \text{mol NaOH} \times \frac{1\ \text{mol } H_2C_2O_4}{2\ \text{mol NaOH}} = 0.008359\ \text{mol } H_2C_2O_4$$

The mass of oxalic acid is found from the amount of the acid and its molar mass.

$$0.008359\ \text{mol } H_2C_2O_4 \times \frac{90.04\ \text{g } H_2C_2O_4}{1\ \text{mol } H_2C_2O_4} = 0.753\ \text{g } H_2C_2O_4$$

This mass of oxalic acid represents 72.8% of the total sample mass.

$$\frac{0.7526\ \text{g } H_2C_2O_4}{1.034\ \text{g sample}} \times 100\% = 72.8\%\ H_2C_2O_4$$



Think about Your Answer Problem Solving Tip 4.4 outlines the procedure used to solve this problem.

Check Your Understanding

A 25.0-mL sample of vinegar (which contains the weak acid acetic acid, CH_3CO_2H) requires 28.33 mL of a 0.953 M solution of NaOH for titration to the equivalence point. What is the mass of acetic acid (molar mass = 60.05 g/mol), in grams, in the vinegar sample, and what is the concentration of acetic acid in the vinegar?

$$CH_3CO_2H(aq) + NaOH(aq) \rightarrow NaCH_3CO_2(aq) + H_2O(\ell)$$

Strategy Map 4.10

Standardizing an Acid or Base

In Example 4.10 the concentration of the base used in the titration was given. In actual practice this usually has to be found in a prior experiment. The procedure by which the concentration of an analytical reagent is determined accurately is called **standardization**, and there are two general approaches.

One approach is to weigh accurately a sample of a pure, solid acid or base (known as a *primary standard*) and then titrate this sample with a solution of the base or acid to be standardized (Example 4.11). An alternative approach to standardizing a solution is to titrate it with another solution that is already standardized (see "Check Your Understanding" in Example 4.11). This is often done using standard solutions purchased from chemical supply companies.

EXAMPLE 4.11

Standardizing an Acid by Titration

Problem Sodium carbonate, Na_2CO_3, is a base, and an accurately weighed sample can be used to standardize an acid. A sample of sodium carbonate (0.263 g) requires 28.35 mL of aqueous HCl for titration to the equivalence point. What is the concentration of the HCl?

What Do You Know? The concentration of the HCl(aq) solution is the unknown in this problem. You know the mass of Na_2CO_3 and the volume of HCl(aq) solution needed to react completely with the Na_2CO_3. You need the molar mass of Na_2CO_3 and a balanced equation for the reaction.

Strategy

- Write a balanced equation for this acid–base and gas-forming reaction.
- Calculate the amount of Na_2CO_3 from its mass and molar mass.
- Use the stoichiometric factor (from the balanced equation) to find the amount of HCl(aq).
- The amount of HCl divided by the volume of solution (in liters) gives its concentration (mol/L).

Solution The balanced equation for the reaction is written first.

$$Na_2CO_3(aq) + 2\ HCl(aq) \longrightarrow 2\ NaCl(aq) + H_2O(\ell) + CO_2(g)$$

Calculate the amount of the base, Na_2CO_3, from its mass and molar mass.

$$0.263\ \text{g}\ Na_2CO_3 \times \frac{1\ \text{mol}\ Na_2CO_3}{106.0\ \text{g}\ Na_2CO_3} = 0.002481\ \text{mol}\ Na_2CO_3$$

Next, use the stoichiometric factor to calculate the amount of HCl in 28.35 mL.

$$0.002481\ \text{mol}\ Na_2CO_3 \times \frac{2\ \text{mol HCl required}}{1\ \text{mol}\ Na_2CO_3\ \text{available}} = 0.004962\ \text{mol HCl}$$

Calculate the concentration of HCl solution by dividing the amount of HCl by the volume of HCl used in the titration.

$$[HCl] = \frac{0.004962\ \text{mol HCl}}{0.02835\ \text{L}} = 0.175\ \text{M HCl}$$

Think about Your Answer Sodium carbonate is commonly used as a primary standard. It can be obtained in pure form, can be weighed accurately, and it reacts completely with strong acids.

Check Your Understanding

Hydrochloric acid, HCl, with a concentration of 0.100 M can be purchased from chemical supply houses, and this solution can be used to standardize the solution of a base. If titrating 25.00 mL of a sodium hydroxide solution to the equivalence point requires 29.67 mL of 0.100 M HCl, what is the concentration of the base?

Determining Molar Mass by Titration

In Chapter 2 and in this chapter we used analytical data to determine the empirical formula of a compound. The molecular formula could then be derived if the molar mass were known. If the unknown substance is an acid or a base, it is possible to determine the molar mass by titration.

EXAMPLE 4.12

Determining the Molar Mass of an Acid by Titration

Problem A 1.056-g sample of an unknown organic acid, HA, is titrated with standardized NaOH (that is, with a NaOH solution whose concentration is accurately known). Calculate the molar mass of HA knowing the acid sample reacts with 33.78 mL of 0.256 M NaOH according to the equation

$$HA(aq) + NaOH(aq) \longrightarrow NaA(aq) + H_2O(\ell)$$

What Do You Know? You know the mass of the sample of unknown acid, and the volume and concentration of NaOH(aq). From the balanced chemical equation given, you know that the acid and base react in a 1 : 1 ratio.

Strategy The key to this problem is to recognize that the molar mass of a substance is the ratio of the mass of the sample (g) to its amount (mol). You know the mass, but you need to determine the amount equivalent to that mass. The balanced chemical equation informs you that 1 mol of HA reacts with 1 mol of NaOH, so the amount of HA equals the amount of NaOH used in the titration. The latter can be calculated from its concentration and volume.

Solution First calculate the amount of NaOH used in the titration.

$$\text{Amount of NaOH} = c_{NaOH} \times V_{NaOH} = \frac{0.256 \text{ mol}}{\cancel{L}} \times 0.03378 \cancel{L} = 8.648 \times 10^{-3} \text{ mol NaOH}$$

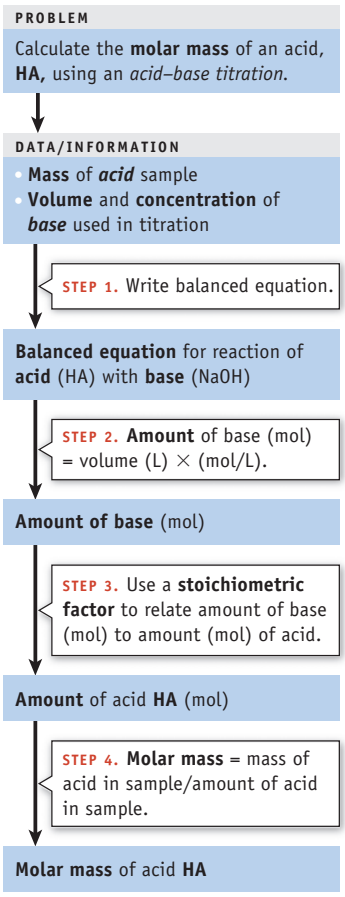
The amount of NaOH used in the titration is the same as the amount of acid titrated. That is,

$$8.648 \times 10^{-3} \cancel{\text{ mol NaOH}} \times \frac{1 \text{ mol HA}}{1 \cancel{\text{ mol NaOH}}} = 8.648 \times 10^{-3} \text{ mol HA}$$

The ratio of the mass of HA to its amount is the molar mass.

$$\text{Molar mass of acid} = \frac{1.056 \text{ g HA}}{8.648 \times 10^{-3} \text{ mol HA}} = 122 \text{ g/mol}$$

Think about Your Answer The molar masses of common water-soluble acids range from 20 g/mol (for HF) to a few hundred grams per mole.



Check Your Understanding

An unknown monoprotic acid reacts with NaOH according to the net ionic equation

$$HA(aq) + OH^-(aq) \longrightarrow A^-(aq) + H_2O(\ell)$$

Calculate the molar mass of HA if 0.856 g of the acid requires 30.08 mL of 0.323 M NaOH.

Titrations Using Oxidation–Reduction Reactions

Many oxidation–reduction reactions can be used in chemical analysis because the reactions go rapidly to completion in aqueous solution, and methods exist to determine their equivalence points.

© Cengage Learning/Charles D. Winters

Using an oxidation–reduction reaction for analysis by titration. Purple, aqueous $KMnO_4$ is added to a solution containing Fe^{2+}. As $KMnO_4$ drops into the solution, colorless Mn^{2+} and pale yellow Fe^{3+} form.

EXAMPLE 4.13

Using an Oxidation–Reduction Reaction in a Titration

Problem The iron in a sample of an iron ore can be converted quantitatively to the iron(II) ion, Fe^{2+}, in aqueous solution, and this solution can then be titrated with aqueous potassium permanganate, $KMnO_4$. The balanced, net ionic equation for the reaction occurring in this titration is

$$\underset{\text{purple}}{MnO_4^-(aq)} + 5\ \underset{\text{colorless}}{Fe^{2+}(aq)} + 8\ H_3O^+(aq) \rightarrow \underset{\text{colorless}}{Mn^{2+}(aq)} + 5\ \underset{\text{pale yellow}}{Fe^{3+}(aq)} + 12\ H_2O(\ell)$$

A 1.026-g sample of iron-containing ore requires 24.35 mL of 0.0195 M $KMnO_4$ to reach the equivalence point. What is the mass percent of iron in the ore?

What Do You Know? You know the concentration and volume of the $KMnO_4$ solution used to titrate $Fe^{2+}(aq)$ to the equivalence point. The stoichiometric factor relating amounts of $KMnO_4$ and $Fe^{2+}(aq)$ is derived from the balanced equation.

Strategy

- Use the volume and concentration of the $KMnO_4$ solution to calculate the amount of $KMnO_4$ used in the titration.
- Use the stoichiometric factor to determine the amount of Fe^{2+} from the amount of $KMnO_4$.
- Convert the amount of Fe^{2+} to mass of iron using the molar mass of iron.
- Calculate the mass percent of iron in the sample.

Solution First, calculate the amount of $KMnO_4$.

$$\text{Amount of } KMnO_4 = c_{KMnO_4} \times V_{KMnO_4} = \frac{0.0195 \text{ mol } KMnO_4}{\cancel{L}} \times 0.02435 \cancel{L} = 0.0004748 \text{ mol}$$

Use the stoichiometric factor to calculate the amount of iron(II) ion.

$$0.0004748 \cancel{\text{ mol } KMnO_4} \times \frac{5 \text{ mol } Fe^{2+}}{1 \cancel{\text{ mol } KMnO_4}} = 0.002374 \text{ mol } Fe^{2+}$$

Next, calculate the mass of iron.

$$0.002374 \cancel{\text{ mol } Fe^{2+}} \times \frac{55.85 \text{ g } Fe^{2+}}{1 \cancel{\text{ mol } Fe^{2+}}} = 0.1326 \text{ g } Fe^{2+}$$

Finally, determine the mass percent.

$$\frac{0.1326 \text{ g } Fe^{2+}}{1.026 \text{ g sample}} \times 100\% = 12.9\% \text{ iron}$$

Think about Your Answer The reaction of iron(II) ions with $KMnO_4$ is well-suited for use in a titration because it is easy to detect when all the iron(II) ion has reacted. The MnO_4^- ion is deep purple, but the reaction product, Mn^{2+}, is colorless. Therefore, $KMnO_4$ solution is added from a buret until the initially colorless, Fe^{2+}-containing solution just turns a faint purple color (due to a trace of unreacted $KMnO_4$), the signal that the equivalence point has been reached.

Check Your Understanding

Vitamin C, ascorbic acid ($C_6H_8O_6$) (molar mass = 176.1 g/mol), is a reducing agent. One way to determine the ascorbic acid content of a sample is to mix the acid with an excess of iodine,

$$C_6H_8O_6(aq) + I_2(aq) + 2\ H_2O(\ell) \rightarrow C_6H_6O_6(aq) + 2\ H_3O^+(aq) + 2\ I^-(aq)$$

and then titrate the iodine that did not react with the ascorbic acid with sodium thiosulfate. The balanced, net ionic equation for the reaction occurring in this titration is

$$I_2(aq) + 2\ S_2O_3^{2-}(aq) \rightarrow 2\ I^-(aq) + S_4O_6^{2-}(aq)$$

Suppose 50.00 mL of 0.0520 M I_2 was added to the sample containing ascorbic acid. After the ascorbic acid/I_2 reaction was complete, the I_2 not used in this reaction required 20.30 mL of 0.196 M $Na_2S_2O_3$ for titration to the equivalence point. Calculate the mass of ascorbic acid in the unknown sample.

4.9 Spectrophotometry

Goal for Section 4.9

- Understand and use the principles of spectrophotometry to determine the concentration of a colored compound or ion in solution.

Solutions of many compounds are colored, a consequence of the absorption of light (Figure 4.13). It is possible to measure, quantitatively, the extent of light absorption and to relate this to the concentration of the dissolved solute. This is an example of the use of **spectrophotometry**, an important analytical method and one you may use in your laboratory course. Spectrophotometry is one of the most frequently used methods of quantitative analysis. It is applicable to many industrial, clinical, and forensic problems involving the quantitative determination of compounds that are colored or that react to form a colored product.

Every substance absorbs or transmits certain wavelengths of radiant energy but not others (Figures 4.13 and 4.14). For example, nickel(II) ions (and chlorophyll) absorb red and blue/violet light while they transmit green light. Your eyes "see" the transmitted or reflected light as the color green. Furthermore, the specific wavelengths of light absorbed and transmitted are characteristic for a substance and serve as a "fingerprint" of the substance that can help identify an unknown.

© Cengage Learning/Charles D. Winters

Figure 4.13 Light absorption and color.

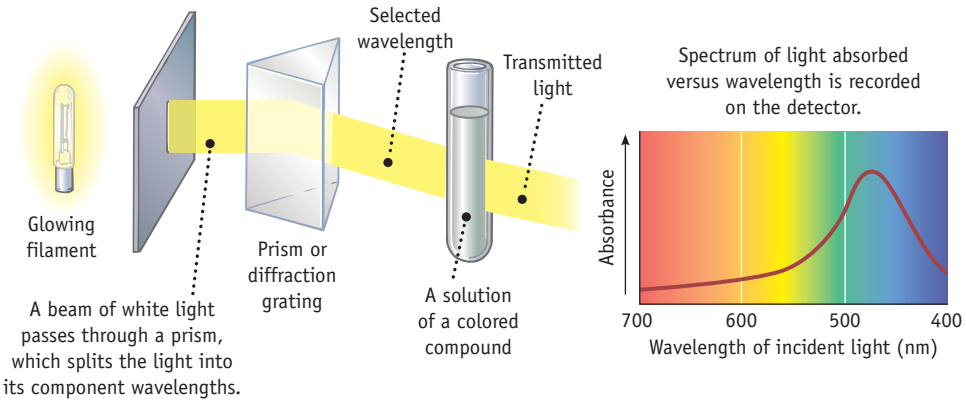
Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.



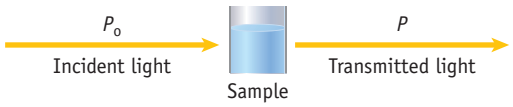


Figure 4.14 An absorption spectrophotometer. The detector in the spectrophotometer "scans" all wavelengths of light and determines the absorbance at each wavelength. The output is a *spectrum*, a plot of absorbance as a function of the wavelength or frequency of the incoming or incident light. Here, the sample absorbs light in the green-blue part of the spectrum and transmits light in the remaining wavelengths. The sample would appear red to orange to your eye.

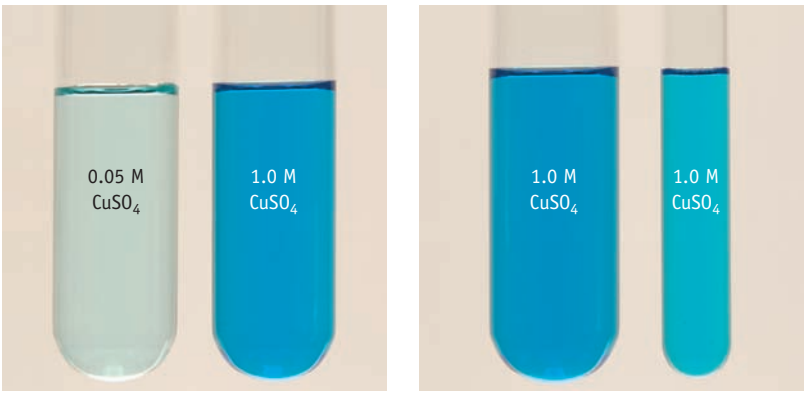
Now look at two solutions containing copper(II) ions, one a deeper color than the other. Your common sense tells you that the intensely colored one is the more concentrated (Figure 4.15a). This is true: the intensity of the color is a measure of the concentration of the color-producing material in the solution.



Transmittance, Absorbance, and the Beer–Lambert Law

To understand the exact relationship of light absorption and solution concentration, we need to define several terms. **Transmittance** (T) is the ratio of the amount of light transmitted by or passing through the sample (P) relative to the amount of light that initially fell on the sample (the incident light, P_0).

$$\text{Transmittance } (T) = \frac{P}{P_0} = \frac{\text{intensity of transmitted light}}{\text{intensity of incident light}}$$

Figure 4.15 Light absorption, concentration, and path length.

© Cengage Learning/Charles D. Winters

(a) Test tubes of the same diameter contain copper(II) sulfate solutions of different concentrations. More light is absorbed by the more concentrated solution, and it appears darker blue.

(b) Here the test tubes have copper(II) sulfate solutions of the same concentration. However, the distance the light travels is longer in one than in the other.

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

The **absorbance** of a sample is defined as the negative logarithm of its transmittance. That is, absorbance and transmittance have an inverse relationship. As the transmittance of a solution increases, the absorbance decreases

$$\text{Absorbance} = -\log T = -\log P/P_o$$

The solutions in Figure 4.15 illustrate transmittance and absorbance. In Figure 4.15a we have solutions with different concentrations of copper(II) sulfate in test tubes of the same diameter. Here you may deduce that the bluer solution appears more blue because this solution has a greater concentration of copper(II) sulfate. That is, the *absorbance, A, of a sample increases as the concentration increases.*

Next, suppose that there are two test tubes of different diameter, both containing the same solution at the same concentration (Figure 4.15b). We shine light of the same intensity (P_0) on both test tubes. In the narrower-diameter tube, the light has to travel only a short distance through the sample before its strikes your eyes, whereas in the other tube it has to pass through more of the sample. In the wider-diameter tube more of the light will be absorbed because the path length is longer. In other words, *absorbance increases as path length increases.*

The two observations described above constitute the **Beer–Lambert law:**

$$\text{Absorbance } (A) \propto \text{path length } (\ell) \times \text{concentration } (c)$$
$$A = \varepsilon \times \ell \times c \qquad (4.5)$$

Beer–Lambert Law The Beer–Lambert law applies strictly to relatively dilute solutions. At higher solute concentrations, the dependence of absorbance on concentration may not be linear.

where

- A, the absorbance of the sample, is a dimensionless number.
- ε, a proportionality constant, is called the *molar absorptivity* (L/mol · cm). For a given substance the molar absorptivity varies with wavelength and temperature, so when doing spectrophotometric experiments these parameters must be kept constant.
- ℓ and c have the units of length (cm) and concentration (mol/L), respectively.

The Beer–Lambert law shows *there is a linear relationship between a sample's absorbance and its concentration for a given path length.*

Spectrophotometric Analysis

There are usually four steps in carrying out a spectrophotometric analysis.

1. **Record the absorption spectrum of the substance to be analyzed.** In introductory chemistry laboratories, this is often done using instruments such as the one shown in Figure 4.16. The result is a spectrum such as that for aqueous permanganate ions (MnO_4^-) in Figure 4.17. The spectrum is a plot of the absorbance of the sample as a function of the wavelength of the incident light. Here, the maximum absorbance is at about 525 nm.
2. **Choose the wavelength for the measurement.** The absorbance at each wavelength is proportional to concentration. Therefore, in theory you could choose any wavelength for quantitative estimations of concentration. However, the magnitude of the absorbance is important, especially when you are trying to detect very small amounts of material. In the spectra of permanganate ions in Figure 4.17, note that the difference in absorbance between curves 1 and 2 is largest at about 525 nm, and at this wavelength the change in absorbance is greatest for a given change in concentration. That is, the measurement of concentration as a function of concentration is most sensitive at this wavelength. For this reason, *the wavelength of maximum absorbance is selected for our measurements.*

© Cengage Learning/Charles D. Winters

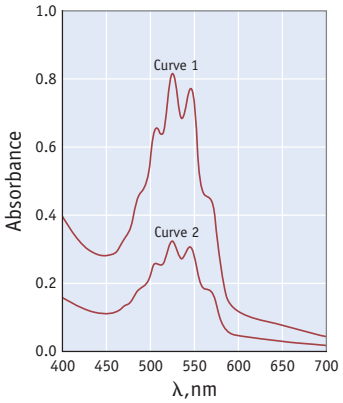

Figure 4.17 The absorption spectrum of solutions of potassium permanganate ($KMnO_4$) at different concentrations. The solution for curve 1 has a higher concentration than that for curve 2.

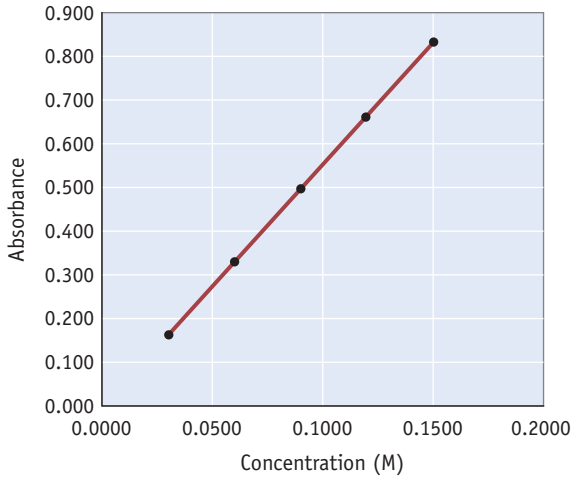
3. **Prepare a calibration plot.** Once you have chosen the wavelength, the next step is to construct a **calibration curve** or **calibration plot** at this wavelength. This consists of a plot of absorbance as a function of concentration for a series of standard solutions whose concentrations are accurately known. Because of the linear relation between concentration and absorbance (at a given wavelength and path length), this plot is a straight line with a positive slope. (You will prepare a calibration plot in Example 4.14.)
4. **Determine the concentration of the species of interest in other solutions.** Once the calibration plot has been made, and the equation for the line is known, you can find the concentration of an unknown sample from its absorbance.

EXAMPLE 4.14

Using Spectrophotometry in Chemical Analysis



Problem A solution of $KMnO_4$ has an absorbance of 0.539 when measured at 540 nm in a 1.0-cm cell. What is the concentration of the $KMnO_4$? Prior to determining the absorbance for the unknown solution, the following calibration data were collected.

Concentration of $KMnO_4$ (M)	Absorbance
0.0300	0.162
0.0600	0.330
0.0900	0.499
0.120	0.670
0.150	0.840

What Do You Know? The table relates concentration and absorbance (at 540 nm in a 1.0-cm cell) for aqueous solutions of $KMnO_4$. The absorbance of the unknown sample under the same conditions is given.

Strategy Prepare a calibration plot from the data given above, and then use this plot to estimate the concentration of the unknown from its absorbance. A more accurate value of the concentration can be obtained if you find the equation for the straight line in the calibration plot and calculate the unknown concentration using this equation.

SOLUTION Using Microsoft Excel (or equivalent software) or a calculator, prepare a calibration plot from the experimental data.

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

The equation for the straight line (as determined using Excel) is

$$y = 5.653x - 0.009$$

$$\text{Absorbance} = 5.653\ c - 0.009$$

If we put in the absorbance for the unknown solution,

$$0.539 = 5.653\ c - 0.009$$

$$\text{Unknown concentration } (c) = 0.0969\ \text{M}$$

Think about Your Answer The absorbance of the unknown was 0.539. Looking back at our calibration data, we can see that this absorbance falls between the data points for absorbances of 0.499 and 0.670. Our answer determined for the concentration of $KMnO_4$ in the unknown (0.0969 M) falls between the concentrations for these two data points of 0.0900 M and 0.120 M, as it should. (See pages 44-45 for information on graphing.)

Check Your Understanding

A solution of copper(II) ions has an absorbance of 0.418 when measured at 645 nm in a 1.0-cm cell. Using the following data, calculate the concentration of copper(II) ions in the unknown solution.

Calibration Data	
Concentration of Cu^{2+} (M)	Absorbance
0.0562	0.720
0.0337	0.434
0.0281	0.332
0.0169	0.219

APPLYING CHEMICAL PRINCIPLES

4.1 Green Chemistry and Atom Economy

Chemists and chemical industries are increasingly following the principles of "green chemistry." One of these principles is to try to convert all of the atoms of the reactants into the product as efficiently as possible, and one way to evaluate the efficiency of a reaction is to calculate the "atom economy."

$$\%\ \text{atom economy} = \frac{\text{molar mass of atoms utilized}}{\text{molar mass of reactants}} \times 100\%$$

A simple example of the concept is the reaction of methanol and carbon monoxide to produce acetic acid. The atom economy is 100% because all of the atoms of the reactants appear in the product.

$$CH_3OH + CO \rightarrow CH_3CO_2H$$

Ibuprofen is a widely used nonsteroidal anti-inflammatory drug, which is used in the United States in products under tradenames such as Motrin and Advil. A recently developed synthesis of ibuprofen involves the collection of compounds

below (which combine in three reaction steps to give ibuprofen and, as a by-product, acetic acid).

What is the atom economy for this reaction? The reactants, collectively, have 15 C atoms, 22 H atoms, and 4 O atoms. The "molar mass" of this collection is 266 g/mol. In contrast, ibuprofen has a molar mass of 206 g/mol (13 C atoms, 18 H atoms, and 2 O atoms). Therefore, the atom economy is 77% [= (206/266) x 100%]. This is far superior to a competing commercial process for the synthesis of ibuprofen that has an atom economy of only 40%.

Question:

1. Methyl methacrylate is used to prepare plastics you may know as Lucite or some other tradename. The substance was introduced in 1933, but chemists have long sought better (and less costly) ways to make the compound. In a newly developed process, ethylene (C_2H_4), methanol (CH_3OH), CO, and formaldehyde (CH_2O) combine in two steps to give methyl methacrylate and water. What is the atom economy of this new process?

4.2 Forensic Chemistry—Food Tampering

The U.S. Food and Drug Administration (FDA) discovered cases of product tampering involving the addition of bleach to products such as soup, infant formula, and soft drinks. Household bleach is a dilute solution of sodium hypochlorite (NaClO), a compound that is an oxidizing agent and is dangerous if swallowed.

Starch-iodine. A distinctive blue color is generated when iodine reacts with water-soluble starch.

© Cengage Learning/Charles D. Winters

One method of detecting bleach uses starch-iodide paper. The bleach oxidizes the iodide ion to iodine in an acid solution,

$$2\ I^-(aq) + HClO(aq) + H_3O^+(aq) \rightarrow I_2(aq) + 2\ H_2O(\ell) + Cl^-(aq)$$

and the presence of I_2 is detected by a deep blue color in the presence of starch.

This reaction is also used in the quantitative analysis of solutions containing bleach. Excess iodide ion (in the form of KI) is added to the sample. The bleach in the sample (which forms HClO in acid solution) oxidizes iodide ions to iodine, I_2. The iodine formed in the reaction is then titrated with sodium thiosulfate, $Na_2S_2O_3$ in another oxidation-reduction reaction (as in "Check Your Understanding" in Example 4.13).

$$I_2(aq) + 2\ S_2O_3^{2-}(aq) \rightarrow 2\ I^-(aq) + S_4O_6^{2-}(aq)$$

The amount of $Na_2S_2O_3$ used in the titration can then be used to determine the amount of NaClO in the original sample.

Question:

1. Excess KI is added to a 100.0-mL sample of a soft drink that had been contaminated with bleach, NaClO. The iodine (I_2) generated in the solution is then titrated with 0.0425 M $Na_2S_2O_3$ and requires 25.3 mL to reach the equivalence point. What mass of NaClO was contained in the 100.0-mL sample of adulterated soft drink?

4.3 How Much Salt is There in Seawater?

Saltiness is one of the basic taste sensations, and a taste of seawater quickly reveals it is salty. How did the oceans become salty?

Dissolved CO_2 reacts with water to produce H_2CO_3, a weak acid that partially dissociates to form hydronium and bicarbonate ions.

$$CO_2(g) + H_2O(\ell) \rightarrow H_2CO_3(aq)$$

$$H_2CO_3(aq) + H_2O(\ell) \rightleftharpoons H_3O^+(aq) + HCO_3^-(aq)$$

Indeed, this is the reason rain is normally acidic, and this slightly acidic rainwater can then cause substances such as limestone or corals to dissolve, producing calcium ions and more bicarbonate ions.

$$CaCO_3(s) + H_3O^+(aq) \rightarrow Ca^{2+}(aq) + HCO_3^-(aq) + H_2O(\ell)$$

Sodium ions arrive in the oceans by a similar reaction with sodium-bearing minerals such as albite, $NaAlSi_3O_6$. Acidic rain falling on the land extracts sodium ions that are then carried by rivers to the ocean.

The average chloride content of rocks in Earth's crust is only 0.01%, so only a minute proportion of the chloride ion in the oceans can come from the weathering of rocks and minerals. What then is the origin of the chloride ions in seawater? The answer is volcanoes: hydrogen chloride gas, HCl, is a constituent of volcanic gases. Early in Earth's history, the planet was much hotter, and volcanoes were much more widespread. The HCl gas emitted from these volcanoes is very soluble in water and quickly dissolves to give a dilute solution of hydrochloric acid. The chloride ions from dissolved HCl gas and sodium ions from weathered rocks are the source of the salt in the sea.

Suppose you are an oceanographer, and you want to determine the concentration of chloride ions in a sample of seawater. How can you do this? And what results might you find?

There are several ways to analyze a solution for its chloride ion content; among them is the classic "Mohr method" in which a solution containing chloride ions is titrated with standardized silver nitrate. The following reaction will occur:

$$Ag^+(aq) + Cl^-(aq) \rightarrow AgCl(s)$$

Courtesy of John C. Kotz

Salt in seawater. Every kilogram of seawater contains about 35 g of dissolved salts, predominantly NaCl.

The reaction will continue until the chloride ions have been precipitated completely. To detect the equivalence point of the titration of Cl^- with Ag^+, the Mohr method involves the addition of a few drops of a solution of potassium chromate. This "indicator" works because silver chromate is slightly more soluble than AgCl, so the red Ag_2CrO_4 precipitates only after all of the AgCl is precipitated.

$$2\ Ag^+(aq) + CrO_4^{2-}(aq) \rightarrow Ag_2CrO_4(s)$$

The appearance of the red color of Ag_2CrO_4 (page 137) signals the equivalence point.

Question:

1. Calculate the chloride ion concentration in a sample of seawater given the following experimental information: The volume of original seawater sample was 100.0 mL. A 10.00-mL sample of the seawater was diluted to 100.0 mL with distilled water, and 10.00 mL of the diluted sample was again diluted to 100.0 mL. A Mohr titration was performed on 50.00 mL from the second dilution. and this sample required 26.25 mL of 0.100 M $AgNO_3$ to reach the equivalence point.

4.4 The Martian

In the book and movie, *The Martian* (Andy Weir, Crown Publishers, 2011), Astronaut Mark Watney is faced with the problem of surviving on the bleak surface of Mars. One of his first and greatest needs is water, and he proposes to synthesize it by reacting hydrogen and oxygen. He has a suitable oxygen source: deriving it from atmospheric CO_2. Decomposition of hydrazine, N_2H_4, leftover rocket fuel from the Mars Descent Vehicle (MDV), would produce N_2 and H_2.

In developing plans he guesses that from 50 liters of liquid oxygen he could make 100 liters of water ("50 liters of O_2

Photos 12/Alamy Stock Photo

The Martian. This was recently a popular book and movie that involved chemistry.

make 100 liters of molecules that have one oxygen each."). He uses the same thinking to estimate that one liter of hydrazine, N_2H_4, should yield two liters of water ("Each molecule of hydrazine has 4 hydrogen atoms in it. So each liter of hydrazine has enough hydrogen for 2 liters of water."). Before answering the questions below, make a guess: How good do you think these predictions about liquid volumes based on numbers of atoms will be (excellent, good, fair, or poor)?

With appropriate data, we can calculate the volume of water that could be obtained by reacting 1.00 L of liquid oxygen with hydrogen. An outline of the approach for this calculation is shown below. Labels 1 through 5 are the factors used in each step of the calculation, and A is the mass of O_2 and B is the amount of H_2O.

$$\text{vol } O_2 \xrightarrow{1} \text{A} \xrightarrow{2} \text{mol } O_2 \xrightarrow{3} \text{B} \xrightarrow{4} \text{mass } H_2O \xrightarrow{5} \text{vol } H_2O$$

Questions:

1. Identify the factor labeled 4 in the strategy map
   (a) Density $H_2O(\ell)$, 1.00 g/mL
   (b) Density of $O_2(\ell)$, 1.14 g/mL
   (c) molar mass of O_2, 32.0 g/mol
   (d) molar mass of H_2O, 18.0 g/mol
2. Identify the factor labeled 3 in this strategy map.
   (a) 1 mol O_2/1 mol H_2O
   (b) 1 mol O_2/2 mol H_2O
   (c) 1 mol H_2O/1 mol O_2
   (d) 2 mol H_2O/1 mol O_2
3. Calculate the volume of water obtained from 1.00 liter of liquid oxygen.
   (a) 2.0 L
   (b) 1.28 L
   (c) 0.64 L
   (d) 1.0 L
4. *For Further Thought:* The density of hydrazine, N_2H_4, is 1.02 g/mL and its molar mass is 32.05 g/mol. If all of the hydrogen in 1.0 L of hydrazine is converted to water, what volume of water will be formed? Look back at your earlier prediction. The analogy between liquid volume and atom count is quite poor. Speculate on why this estimate was not very good.

CHAPTER GOALS REVISITED

The Goals for this chapter are keyed to specific Study Questions to help you organize your review.

4.1 Mass Relationships in Chemical Reactions: Stoichiometry

- Understand the principle of conservation of matter, which forms the basis of chemical stoichiometry. 5.
- Calculate the mass of one reactant or product in a reaction knowing the balanced equation and the mass of another reactant or product in that reaction. 2–6, 79, 81, 83, 97, 99.
- Use amounts tables to organize chemical information. 7–10.

4.2 Reactions in Which One Reactant is Present in Limited Supply

- Determine which reactant is in limited supply in a reaction involving several reactants. 11–14, 98.
- Determine the yield of a product based on the limiting reactant. 11–18, 85.

4.3 Percent Yield

- Explain the differences among actual yield, theoretical yield, and percent yield, and calculate percent yield for a reaction. 21, 23.

4.4 Chemical Equations and Chemical Analysis

- Use stoichiometry principles to analyze a mixture of compounds. 25–28, 129, 130.
- Find the empirical formula of an unknown compound using chemical stoichiometry. 31–36, 90, 91.

Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

4.5 Measuring Concentrations of Compounds in Solution

- Calculate the concentration of a solute in a solution in units of moles per liter (molarity) and use solution concentrations in calculations. 39, 41, 43.
- Describe how to prepare a solution of a given concentration from the solute and solvent or by dilution of a more concentrated solution. 47–52, 53, 121.

4.6 pH, A Concentration Scale for Acids and Bases

- Understand the pH scale. 55, 56.
- Calculate the pH of a solution from the concentration of hydronium ions in the solution. Calculate the hydronium ion concentration in a solution from its pH. 57–60.

4.7 Stoichiometry of Reactions in Aqueous Solution—Fundamentals

- Use stoichiometry principles for reactions occurring in solution. 61–64, 106, 107.

4.8 Stoichiometry of Reactions in Aqueous Solution—Titrations

- Explain how a titration is carried out, explain the procedure for standardization of a solution, and calculate concentrations or amounts of reactants from titration data. 69–72, 125.

4.9 Spectrophotometry

- Understand and use the principles of spectrophotometry to determine the concentration of a colored compound or ion in solution. 77, 133.

KEY EQUATIONS

Equation 4.1 (page 182) Percent yield.

$$\text{Percent yield} = \frac{\text{actual yield}}{\text{theoretical yield}} \times 100\%$$

Equation 4.2 (page 188) Definition of molarity, a measure of the concentration of a solute in a solution.

$$\text{Molarity of } x \ (c_x) = \frac{\text{amount of solute } x \text{ (mol)}}{\text{volume of solution (L)}}$$

A useful form of this equation is

$$\text{Amount of solute } x \text{ (mol)} = c_x \text{ (mol/L)} \times \text{volume of solution (L)}$$

Dilution Equation (page 192) This is a shortcut to find, for example, the concentration of a solution (c_d) after diluting some volume (V_c) of a more concentrated solution (c_c) to a new volume (V_d).

$$c_c \times V_c = c_d \times V_d$$

Equation 4.3 (page 194) pH. The pH of a solution is the negative logarithm of the hydronium ion concentration.

$$\text{pH} = -\log[H_3O^+]$$

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Equation 4.4 (page 194) Calculating $[H_3O^+]$ from pH. The equation for calculating the hydronium ion concentration of a solution from the pH of the solution.

$$[H_3O^+] = 10^{-pH}$$

Equation 4.5 (page 205) Beer–Lambert law. The absorbance of light (A) by a substance in solution is equal to the product of the molar absorptivity of the substance (A), the path length of the cell (ℓ), and the concentration of the solute (c).

$$\text{Absorbance } (A) \propto \text{path length } (\ell) \times \text{concentration } (c)$$

$$A = \varepsilon \times \ell \times c$$

STUDY QUESTIONS

▲ denotes challenging questions. **Blue-numbered questions** have answers in Appendix N and fully worked solutions in the *Student Solutions Manual*.

Practicing Skills

Mass Relationships in Chemical Reactions: Basic Stoichiometry

(See Example 4.1.)

1. The reaction of iron(III) oxide with aluminum to give molten iron is known as the thermite reaction (page 172).

$$Fe_2O_3(s) + 2\ Al(s) \rightarrow 2\ Fe(\ell) + Al_2O_3(s)$$

What amount of Al, in moles, is needed for complete reaction with 3.0 mol of Fe_2O_3? What mass of Fe, in grams, can be produced?

2. What mass of HCl, in grams, is required to react with 0.750 g of $Al(OH)_3$? What mass of water, in grams, is produced?

$$Al(OH)_3(s) + 3\ HCl(aq) \rightarrow AlCl_3(aq) + 3\ H_2O(\ell)$$

3. Like many metals, aluminum reacts with a halogen (here the orange-brown liquid Br_2) to give a metal halide, aluminum bromide. (The white solid on the lip of the beaker at the end of the reaction is Al_2Br_6.)

Before reaction

After reaction

Photos: © Cengage Learning/Charles D. Winters

$$2\ Al(s) + 3\ Br_2(\ell) \rightarrow Al_2Br_6(s)$$

What mass of Br_2, in grams, is required for complete reaction with 2.56 g of Al? What mass of white, solid Al_2Br_6 is expected?

4. The balanced equation for the reduction of iron ore to the metal using CO is

$$Fe_2O_3(s) + 3\ CO(g) \rightarrow 2\ Fe(s) + 3\ CO_2(g)$$

(a) What is the maximum mass of iron, in grams, that can be obtained from 454 g (1.00 lb) of iron(III) oxide?

(b) What mass of CO is required to react with 454 g of Fe_2O_3?

5. Methane, CH_4, burns in oxygen.

(a) What are the products of the reaction?

(b) Write the balanced equation for the reaction.

(c) What mass of O_2, in grams, is required for complete combustion of 25.5 g of methane?

(d) What is the total mass of products expected from the combustion of 25.5 g of methane?

6. The formation of water-insoluble silver chloride is useful in the analysis of chloride-containing substances. Consider the following *unbalanced* equation:

$$BaCl_2(aq) + AgNO_3(aq) \rightarrow AgCl(s) + Ba(NO_3)_2(aq)$$

(a) Write the balanced equation.

(b) What mass of $AgNO_3$, in grams, is required for complete reaction with 0.156 g of $BaCl_2$? What mass of AgCl is produced?

Amounts Tables and Chemical Stoichiometry

For each question below, set up an amounts table that lists the initial amount or amounts of reactants, the changes in amounts of reactants and products, and the amounts of reactants and products after reaction (see page 175 and Example 4.1).

7. The metals industry was a major source of air pollution years ago. One common process involved "roasting" metal sulfides in the air:

$$2\ PbS(s) + 3\ O_2(g) \rightarrow 2\ PbO(s) + 2\ SO_2(g)$$

If 2.50 mol of PbS is heated in air, what amount of O_2 is required for complete reaction? What amounts of PbO and SO_2 are expected?

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

8. Iron ore is converted to iron metal in a reaction with carbon.

$$2\ Fe_2O_3(s) + 3\ C(s) \rightarrow 4\ Fe(s) + 3\ CO_2(g)$$

If 6.2 mol of $Fe_2O_3(s)$ is used, what amount of C(s) is needed, and what amounts of Fe and CO_2 are produced?

9. Chromium metal reacts with oxygen to give chromium(III) oxide, Cr_2O_3.
   (a) Write a balanced equation for the reaction.
   (b) What mass (in grams) of Cr_2O_3 is produced if 0.175 g of chromium metal is converted completely to the oxide?
   (c) What mass of O_2 (in grams) is required for the reaction?

10. Ethane, C_2H_6, burns in oxygen.
   (a) What are the products of the reaction?
   (b) Write the balanced equation for the reaction.
   (c) What mass of O_2, in grams, is required for complete combustion of 13.6 of ethane?
   (d) What is the total mass of products expected from the combustion of 13.6 g of ethane?

Limiting Reactants

(See Example 4.2.)

11. Sodium sulfide, Na_2S, is used in the leather industry to remove hair from hides. The Na_2S is made by the reaction

$$Na_2SO_4(s) + 4\ C(s) \rightarrow Na_2S(s) + 4\ CO(g)$$

Suppose you mix 15 g of Na_2SO_4 and 7.5 g of C. Which is the limiting reactant? What mass of Na_2S is produced?

12. Ammonia gas can be prepared by the reaction of a metal oxide such as calcium oxide with ammonium chloride.

$$CaO(s) + 2\ NH_4Cl(s) \rightarrow 2\ NH_3(g) + H_2O(g) + CaCl_2(s)$$

If 112 g of CaO and 224 g of NH_4Cl are mixed, what is the limiting reactant, and what mass of NH_3 can be produced?

13. The compound SF_6 is made by burning sulfur in an atmosphere of fluorine. The balanced equation is

$$S_8(s) + 24\ F_2(g) \rightarrow 8\ SF_6(g)$$

Starting with a mixture of 1.6 mol of sulfur, S_8, and 35 mol of F_2,
   (a) Which is the limiting reagent?
   (b) What amount of SF_6 is produced?

14. Disulfur dichloride, S_2Cl_2, is used to vulcanize rubber. It can be made by treating molten sulfur with gaseous chlorine:

$$S_8(\ell) + 4\ Cl_2(g) \rightarrow 4\ S_2Cl_2(\ell)$$

Starting with a mixture of 32.0 g of sulfur and 71.0 g of Cl_2,
   (a) Which is the limiting reactant?
   (b) What is the theoretical yield of S_2Cl_2?
   (c) What mass of the excess reactant remains when the reaction is completed?

15. The reaction of methane and water is one way to prepare hydrogen for use as a fuel:

$$CH_4(g) + H_2O(g) \rightarrow CO(g) + 3\ H_2(g)$$

If you begin with 995 g of CH_4 and 2510 g of water,
   (a) Which reactant is the limiting reactant?
   (b) What is the maximum mass of H_2 that can be prepared?
   (c) What mass of the excess reactant remains when the reaction is completed?

16. Aluminum chloride, $AlCl_3$, is made by treating scrap aluminum with chlorine.

$$2\ Al(s) + 3\ Cl_2(g) \rightarrow 2\ AlCl_3(s)$$

If you begin with 2.70 g of Al and 4.05 g of Cl_2,
   (a) Which reactant is limiting?
   (b) What mass of $AlCl_3$ can be produced?
   (c) What mass of the excess reactant remains when the reaction is completed?
   (d) Set up an amounts table for this problem.

17. In the thermite reaction, iron(III) oxide is reduced by aluminum to give molten iron.

$$Fe_2O_3(s) + 2\ Al(s) \rightarrow 2\ Fe(\ell) + Al_2O_3(s)$$

If you begin with 10.0 g of Fe_2O_3 and 20.0 g of Al,
   (a) Which reactant is limiting?
   (b) What mass of Fe can be produced?
   (c) What mass of the excess reactant remains after the limiting reactant is consumed?
   (d) Set up an amounts table for this problem.

18. Aspirin, $C_6H_4(OCOCH_3)CO_2H$, is produced by the reaction of salicylic acid, $C_6H_4(OH)CO_2H$, and acetic anhydride, $(CH_3CO)_2O$ (page 182).

$$C_6H_4(OH)CO_2H(s) + (CH_3CO)_2O(\ell) \rightarrow C_6H_4(OCOCH_3)CO_2H(s) + CH_3CO_2H(\ell)$$

If you mix 100. g of each of the reactants, what is the maximum mass of aspirin that can be obtained?

Percent Yield

(See Section 4.3.)

19. In Example 4.2, you found that a particular mixture of CO and H_2 could produce 407 g CH_3OH.

$$CO(g) + 2\ H_2(g) \rightarrow CH_3OH(\ell)$$

If only 332 g of CH_3OH is actually produced, what is the percent yield of the compound?

20. Ammonia gas can be prepared by the following reaction:

$$CaO(s) + 2\ NH_4Cl(s) \rightarrow 2\ NH_3(g) + H_2O(g) + CaCl_2(s)$$

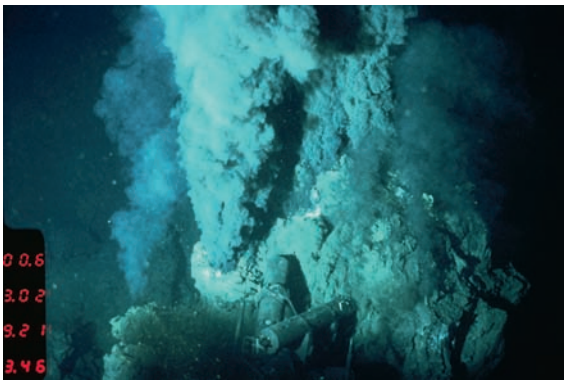
If 112 g of CaO and 224 g of NH_4Cl are mixed, the theoretical yield of NH_3 is 68.0 g (Study Question 12). If only 16.3 g of NH_3 is actually obtained, what is its percent yield?

21. The deep blue compound $Cu(NH_3)_4SO_4$ is made by the reaction of copper(II) sulfate and ammonia.

$$CuSO_4(aq) + 4\ NH_3(aq) \rightarrow Cu(NH_3)_4SO_4(aq)$$

(a) If you use 10.0 g of $CuSO_4$ and excess NH_3, what is the theoretical yield of $Cu(NH_3)_4SO_4$?

(b) If you isolate 12.6 g of $Cu(NH_3)_4SO_4$, what is the percent yield of $Cu(NH_3)_4SO_4$?



22. Black smokers are found in the depths of the oceans. Thinking that the conditions in these smokers might be conducive to the formation of organic compounds, two chemists in Germany found the following reaction could occur in similar conditions.

$$2\ CH_3SH + CO \rightarrow CH_3COSCH_3 + H_2S$$

If you begin with 10.0 g of CH_3SH and excess CO,

(a) What is the theoretical yield of CH_3COSCH_3?

(b) If 8.65 g of CH_3COSCH_3 is isolated, what is its percent yield?

Universal History Archive/UIG, via Getty Images

A black smoker, deep in the Pacific Ocean.

23. The reaction of methane and water is one way to prepare hydrogen for use as a fuel:

$$CH_4(g) + H_2O(g) \rightarrow CO(g) + 3\ H_2(g)$$

If this reaction has a 37% yield under certain conditions, what mass of CH_4 is required to produce 15 g of H_2?

24. Methanol, CH_3OH, can be prepared from carbon monoxide and hydrogen.

$$CO(g) + 2\ H_2(g) \rightarrow CH_3OH(\ell)$$

What mass of hydrogen is required to produce 1.0 L of CH_3OH (d = 0.791 g/mL) if this reaction has a 74% yield under certain conditions?

Analysis of Mixtures

(See Example 4.3.)

25. A mixture of $CuSO_4$ and $CuSO_4 \cdot 5\ H_2O$ has a mass of 1.245 g. After heating to drive off all the water, the mass is only 0.832 g. What is the mass percent of $CuSO_4 \cdot 5\ H_2O$ in the mixture? (See page 98.)

26. A 2.634-g sample containing impure $CuCl_2 \cdot 2\ H_2O$ was heated. The sample mass after heating to drive off the water was 2.125 g. What was the mass percent of $CuCl_2 \cdot 2\ H_2O$ in the original sample?

27. A sample of limestone and other soil materials was heated, and the limestone decomposed to give calcium oxide and carbon dioxide.

$$CaCO_3(s) \rightarrow CaO(s) + CO_2(g)$$

A 1.506-g sample of limestone-containing material gave 0.558 g of CO_2, in addition to CaO, after being heated at a high temperature. What was the mass percent of $CaCO_3$ in the original sample?

28. At higher temperatures, $NaHCO_3$ is converted quantitatively to Na_2CO_3.

$$2\ NaHCO_3(s) \rightarrow Na_2CO_3(s) + CO_2(g) + H_2O(g)$$

Heating a 1.7184-g sample of impure $NaHCO_3$ gives 0.196 g of CO_2. What was the mass percent of $NaHCO_3$ in the original 1.7184-g sample?

29. Nickel(II) sulfide, NiS, occurs naturally as the relatively rare mineral millerite. One of its occurrences is in meteorites. To analyze a mineral sample for the quantity of NiS, the sample is dissolved in nitric acid to form a solution of $Ni(NO_3)_2$.

$$NiS(s) + 4\ HNO_3(aq) \rightarrow Ni(NO_3)_2(aq) + 2\ NO_2(g) + 2\ H_2O(\ell) + S(s)$$

The aqueous solution of $Ni(NO_3)_2$ is then reacted with the organic compound dimethylglyoxime ($C_4H_8N_2O_2$) to give the red solid $Ni(C_4H_7N_2O_2)_2$.

$$Ni(NO_3)_2(aq) + 2\ C_4H_8N_2O_2(aq) \rightarrow Ni(C_4H_7N_2O_2)_2(s) + 2\ HNO_3(aq)$$

Suppose a 0.468-g sample containing millerite produces 0.206 g of red, solid $Ni(C_4H_7N_2O_2)_2$. What is the mass percent of NiS in the sample?

© Cengage Learning/Charles D. Winters

A precipitate of nickel with dimethylglyoxime, $Ni(C_4H_7N_2O_2)_2$

30. ▲ The aluminum in a 0.764-g sample of an unknown material was precipitated as aluminum hydroxide, $Al(OH)_3$, which was then converted to Al_2O_3 by heating strongly. If 0.127 g of Al_2O_3 is obtained from the 0.764-g sample, what is the mass percent of aluminum in the sample?

Using Stoichiometry to Determine Empirical and Molecular Formulas

(See Examples 4.4 and 4.5.)

31. Styrene, the building block of polystyrene, consists of only C and H. If 0.438 g of styrene is burned in oxygen and produces 1.481 g of CO_2 and 0.303 g of H_2O, what is the empirical formula of styrene?

32. Mesitylene is a liquid hydrocarbon. Burning 0.115 g of the compound in oxygen gives 0.379 g of CO_2 and 0.1035 g of H_2O. What is the empirical formula of mesitylene?

33. Naphthalene is a hydrocarbon that once was used in mothballs. If 0.3093 g of the compound is burned in oxygen, 1.0620 g of CO_2 and 0.1739 g of H_2O are isolated.
   (a) What is the empirical formula of naphthalene?
   (b) If a separate experiment gave 128.2 g/mol as the molar mass of the compound, what is its molecular formula?

34. Azulene is a beautiful blue hydrocarbon. If 0.106 g of the compound is burned in oxygen, 0.364 g of CO_2 and 0.0596 g of H_2O are isolated.
   (a) What is the empirical formula of azulene?
   (b) If a separate experiment gave 128.2 g/mol as the molar mass of the compound, what is its molecular formula?

35. An unknown compound has the formula $C_xH_yO_z$. You burn 0.0956 g of the compound and isolate 0.1356 g of CO_2 and 0.0833 g of H_2O. What is the empirical formula of the compound? If the molar mass is 62.1 g/mol, what is the molecular formula?

36. An unknown compound has the formula $C_xH_yO_z$. You burn 0.1523 g of the compound and isolate 0.3718 g of CO_2 and 0.1522 g of H_2O. What is the empirical formula of the compound? If the molar mass is 72.1 g/mol, what is the molecular formula?

37. Nickel forms a compound with carbon monoxide, $Ni_x(CO)_y$. To determine its formula, you carefully heat a 0.0973-g sample in air to convert the nickel to 0.0426 g of NiO and the CO to 0.100 g of CO_2. What is the empirical formula of $Ni_x(CO)_y$?

38. To find the formula of a compound composed of iron and carbon monoxide, $Fe_x(CO)_y$, the compound is burned in pure oxygen to give Fe_2O_3 and CO_2. If you burn 1.959 g of $Fe_x(CO)_y$ and obtain 0.799 g of Fe_2O_3 and 2.200 g of CO_2, what is the empirical formula of $Fe_x(CO)_y$?

Solution Concentration

(See Examples 4.6 and 4.7.)

39. If 6.73 g of Na_2CO_3 is dissolved in enough water to make 250. mL of solution, what is the molar concentration of the sodium carbonate? What are the molar concentrations of the Na^+ and CO_3^{2-} ions?

40. Some potassium dichromate ($K_2Cr_2O_7$), 2.335 g, is dissolved in enough water to make exactly 500. mL of solution. What is the molar concentration of the potassium dichromate? What are the molar concentrations of the K^+ and $Cr_2O_7^{2-}$ ions?

41. What is the mass of solute, in grams, in 250. mL of a 0.0125 M solution of $KMnO_4$?

42. What is the mass of solute, in grams, in 125 mL of a 1.023×10^{-3} M solution of Na_3PO_4? What is the molar concentration of the Na^+ and PO_4^{3-} ion?

43. What volume of 0.123 M NaOH, in milliliters, contains 25.0 g of NaOH?

44. What volume of 2.06 M $KMnO_4$, in liters, contains 322 g of solute?

45. Identify the ions that exist in each aqueous solution, and specify the concentration of each ion.
(a) 0.25 M $(NH_4)_2SO_4$
(b) 0.123 M Na_2CO_3
(c) 0.056 M HNO_3

46. Identify the ions that exist in each aqueous solution, and specify the concentration of each ion.
(a) 0.12 M $BaCl_2$
(b) 0.0125 M $CuSO_4$
(c) 0.500 M $K_2Cr_2O_7$

Preparing Solutions

(See Examples 4.6 and 4.7.)

47. An experiment in your laboratory requires 500. mL of a 0.0200 M solution of Na_2CO_3. You are given solid Na_2CO_3, distilled water, and a 500.-mL volumetric flask. Describe how to prepare the required solution.

48. What mass of oxalic acid, $H_2C_2O_4$, is required to prepare 250. mL of a solution that has a concentration of 0.15 M $H_2C_2O_4$?

49. If you dilute 25.0 mL of 1.50 M hydrochloric acid to 500. mL, what is the molar concentration of the dilute acid?

50. If 4.00 mL of 0.0250 M $CuSO_4$ is diluted to 10.0 mL with pure water, what is the molar concentration of copper(II) sulfate in the diluted solution?

51. Which of the following methods would you use to prepare 1.00 L of 0.125 M H_2SO_4?
(a) Dilute 20.8 mL of 6.00 M H_2SO_4 to a volume of 1.00 L.
(b) Add 950. mL of water to 50.0 mL of 3.00 M H_2SO_4.

52. Which of the following methods would you use to prepare 300. mL of 0.500 M $K_2Cr_2O_7$?
(a) Add 30.0 mL of 1.50 M $K_2Cr_2O_7$ to 270. mL of water.
(b) Dilute 250. mL of 0.600 M $K_2Cr_2O_7$ to a volume of 300. mL.

Serial Dilutions

(See A Closer Look: Serial Dilutions, page 193.)

53. You have 250. mL of 0.136 M HCl. Using a volumetric pipet, you take 25.00 mL of that solution and dilute it to 100.00 mL in a volumetric flask. Now you take 10.00 mL of that solution, using a volumetric pipet, and dilute it to 100.00 mL in a volumetric flask. What is the concentration of hydrochloric acid in the final solution?

54. ▲ Suppose you have 100.00 mL of a solution of a dye and transfer 2.00 mL of the solution to a 100.00-mL volumetric flask. After adding water to the 100.00 mL mark, you take 5.00 mL of that solution and again dilute to 100.00 mL. If you find the dye concentration in the final diluted sample is 0.000158 M, what was the dye concentration in the original solution?

Calculating and Using pH

(See Example 4.8.)

55. A table wine has a pH of 3.40. What is the hydronium ion concentration of the wine? Is it acidic or basic?

56. A saturated solution of milk of magnesia, $Mg(OH)_2$, has a pH of 10.5. What is the hydronium ion concentration of the solution? Is the solution acidic or basic?

57. What is the hydronium ion concentration of a 0.0013 M solution of HNO_3? What is its pH?

58. What is the hydronium ion concentration of a 1.2×10^{-4} M solution of $HClO_4$? What is its pH?

59. Make the following conversions. In each case, tell whether the solution is acidic or basic.

	pH	$[H_3O^+]$
(a)	1.00	_____
(b)	10.50	_____
(c)	_____	1.3×10^{-5} M
(d)	_____	2.3×10^{-8} M

60. Make the following conversions. In each case, tell whether the solution is acidic or basic.

	pH	$[H_3O^+]$
(a)	_____	6.7×10^{-10} M
(b)	_____	2.2×10^{-6} M
(c)	5.25	_____
(d)	_____	2.5×10^{-2} M

Stoichiometry of Reactions in Solution

(See Example 4.9.)

61. What volume of 0.109 M HNO_3, in milliliters, is required to react completely with 2.50 g of $Ba(OH)_2$?

$$2\ HNO_3(aq) + Ba(OH)_2(s) \rightarrow 2\ H_2O(\ell) + Ba(NO_3)_2(aq)$$

62. What mass of Na_2CO_3, in grams, is required for complete reaction with 50.0 mL of 0.125 M HNO_3?

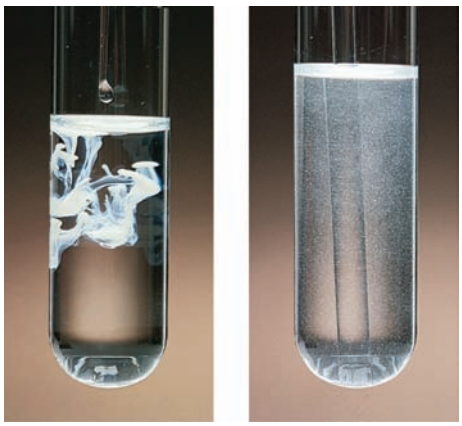
$$Na_2CO_3(aq) + 2\ HNO_3(aq) \rightarrow 2\ NaNO_3(aq) + CO_2(g) + H_2O(\ell)$$

63. When an electric current is passed through an aqueous solution of NaCl, the valuable industrial chemicals $H_2(g)$, $Cl_2(g)$, and NaOH are produced.

$$2\ NaCl(aq) + 2\ H_2O(\ell) \rightarrow H_2(g) + Cl_2(g) + 2\ NaOH(aq)$$

What mass of NaOH can be formed from 15.0 L of 0.35 M NaCl? What mass of chlorine is obtained?

64. Hydrazine, N_2H_4, a base like ammonia, can react with sulfuric acid.



$$2\ N_2H_4(aq) + H_2SO_4(aq) \rightarrow 2\ N_2H_5^+(aq) + SO_4^{2-}(aq)$$

What mass of hydrazine reacts with 250. mL of 0.146 M H_2SO_4?

65. In the photographic developing process, silver bromide is dissolved by adding sodium thiosulfate.

$$AgBr(s) + 2\ Na_2S_2O_3(aq) \rightarrow Na_3Ag(S_2O_3)_2(aq) + NaBr(aq)$$

If you want to dissolve 0.225 g of AgBr, what volume of 0.0138 M $Na_2S_2O_3$, in milliliters, should be used?

Photos: © Cengage Learning/Charles D. Winters

(a) **(b)**

Silver chemistry. **(a)** A precipitate of AgBr formed by adding $AgNO_3(aq)$ to KBr(aq). **(b)** On adding $Na_2S_2O_3(aq)$, sodium thiosulfate, the solid AgBr dissolves.

66. You can dissolve an aluminum soft drink can in an aqueous base such as potassium hydroxide.

$$2\ Al(s) + 2\ KOH(aq) + 6\ H_2O(\ell) \rightarrow 2\ KAl(OH)_4(aq) + 3\ H_2(g)$$

If you place 2.05 g of aluminum in a beaker with 185 mL of 1.35 M KOH, will any aluminum remain? What mass of $KAl(OH)_4$ is produced?

67. What volume of 0.750 M $Pb(NO_3)_2$, in milliliters, is required to react completely with 1.00 L of 2.25 M NaCl solution? The balanced equation is

$$Pb(NO_3)_2(aq) + 2\ NaCl(aq) \rightarrow PbCl_2(s) + 2\ NaNO_3(aq)$$

68. What volume of 0.125 M oxalic acid, $H_2C_2O_4$, is required to react with 35.2 mL of 0.546 M NaOH?

$$H_2C_2O_4(aq) + 2\ NaOH(aq) \rightarrow Na_2C_2O_4(aq) + 2\ H_2O(\ell)$$

Titrations

(See Examples 4.10–4.13.)

69. What volume of 0.812 M HCl, in milliliters, is required to titrate 1.45 g of NaOH to the equivalence point?

$$NaOH(aq) + HCl(aq) \rightarrow H_2O(\ell) + NaCl(aq)$$

70. What volume of 0.955 M HCl, in milliliters, is required to titrate 2.152 g of Na_2CO_3 to the equivalence point?

$$Na_2CO_3(aq) + 2\ HCl(aq) \rightarrow H_2O(\ell) + CO_2(g) + 2\ NaCl(aq)$$

71. If 38.55 mL of HCl is required to titrate 2.150 g of Na_2CO_3 according to the following equation, what is the concentration (mol/L) of the HCl solution?

$$Na_2CO_3(aq) + 2\ HCl(aq) \rightarrow 2\ NaCl(aq) + CO_2(g) + H_2O(\ell)$$

72. Potassium hydrogen phthalate, $KHC_8H_4O_4$, is used to standardize solutions of bases. The acidic anion reacts with strong bases according to the following net ionic equation:

$$HC_8H_4O_4^-(aq) + OH^-(aq) \rightarrow C_8H_4O_4^{2-}(aq) + H_2O(\ell)$$

If a 0.902-g sample of potassium hydrogen phthalate is dissolved in water and titrated to the equivalence point with 26.45 mL of NaOH(aq), what is the molar concentration of the NaOH?

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

73. You have 0.954 g of an unknown acid, H_2A, which reacts with NaOH according to the balanced equation

$$H_2A(aq) + 2\ NaOH(aq) \rightarrow Na_2A(aq) + 2\ H_2O(\ell)$$

If 36.04 mL of 0.509 M NaOH is required to titrate the acid to the second equivalence point, what is the molar mass of the acid?

74. An unknown solid acid is either citric acid or tartaric acid. To determine which acid you have, you titrate a sample of the solid with aqueous NaOH and from this determine the molar mass of the unknown acid. The appropriate equations are as follows:

Citric acid:

$$H_3C_6H_5O_7(aq) + 3\ NaOH(aq) \rightarrow 3\ H_2O(\ell) + Na_3C_6H_5O_7(aq)$$

Tartaric acid:

$$H_2C_4H_4O_6(aq) + 2\ NaOH(aq) \rightarrow 2\ H_2O(\ell) + Na_2C_4H_4O_6(aq)$$

A 0.956-g sample requires 29.1 mL of 0.513 M NaOH to consume the acid completely. What is the unknown acid?

75. To analyze an iron-containing compound, you convert all the iron to Fe^{2+} in aqueous solution and then titrate the solution with standardized $KMnO_4$. The balanced, net ionic equation is

$$MnO_4^-(aq) + 5\ Fe^{2+}(aq) + 8\ H_3O^+(aq) \rightarrow Mn^{2+}(aq) + 5\ Fe^{3+}(aq) + 12\ H_2O(\ell)$$

A 0.598-g sample of the iron-containing compound requires 22.25 mL of 0.0123 M $KMnO_4$ for titration to the equivalence point. What is the mass percent of iron in the sample?

76. Vitamin C has the formula $C_6H_8O_6$. Besides being an acid, it is a reducing agent. One method for determining the amount of vitamin C in a sample is to titrate it with a solution of bromine, Br_2, an oxidizing agent.

$$C_6H_8O_6(aq) + Br_2(aq) \rightarrow 2\ HBr(aq) + C_6H_6O_6(aq)$$

A 1.00-g "chewable" vitamin C tablet requires 27.85 mL of 0.102 M Br_2 for titration to the equivalence point. What is the mass of vitamin C in the tablet?

Spectrophotometry

(See Section 4.9 and Example 4.14. The problems below are adapted from Fundamentals of Analytical Chemistry, *8th ed., by D. A. Skoog, D. M. West, F. J. Holler, and S. R. Crouch, Thomson/Brooks-Cole, Belmont, CA 2004.)*

77. A solution of a dye was analyzed by spectrophotometry, and the following calibration data were collected.

Dye Concentration	Absorbance (*A*) at 475 nm
0.50×10^{-6} M	0.24
1.5×10^{-6} M	0.36
2.5×10^{-6} M	0.44
3.5×10^{-6} M	0.59
4.5×10^{-6} M	0.70

(a) Construct a calibration plot, and determine the slope and intercept.

(b) What is the dye concentration in a solution with $A = 0.52$?

78. The nitrite ion is involved in the biochemical nitrogen cycle. You can determine the nitrite ion content of a sample using spectrophotometry by first using several organic compounds to form a colored compound from the ion. The following data were collected.

NO_2^- Ion Concentration	Absorbance of Solution at 550 nm
2.00×10^{-6} M	0.065
6.00×10^{-6} M	0.205
10.00×10^{-6} M	0.338
14.00×10^{-6} M	0.474
18.00×10^{-6} M	0.598
Unknown solution	0.402

(a) Construct a calibration plot, and determine the slope and intercept.

(b) What is the nitrite ion concentration in the unknown solution?

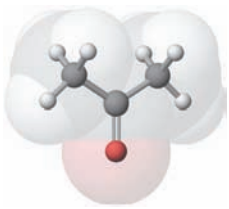
General Questions

These questions are not designated as to type or location in the chapter. They may combine several concepts.

79. Suppose 16.04 g of benzene, C_6H_6, is burned in oxygen.

(a) What are the products of the reaction?



(b) Write a balanced equation for the reaction.

(c) What mass of O_2, in grams, is required for complete combustion of benzene?

(d) What is the total mass of products expected from the combustion of 16.04 g of benzene?

80. The metabolic disorder diabetes causes a buildup of acetone, CH_3COCH_3, in the blood. Acetone, a volatile compound, is exhaled, giving the breath of untreated diabetics a distinctive odor. The acetone is produced by a breakdown of fats in a series of reactions. The equation for the last step, the breakdown of acetoacetic acid to give acetone and CO_2, is

$$CH_3COCH_2CO_2H \rightarrow CH_3COCH_3 + CO_2$$

Acetone, CH_3COCH_3

What mass of acetone can be produced from 125 mg of acetoacetic acid?

81. Your body deals with excess nitrogen by excreting it in the form of urea, NH_2CONH_2. The reaction producing it is the combination of arginine ($C_6H_{14}N_4O_2$) with water to give urea and ornithine ($C_5H_{12}N_2O_2$).

$$\underset{\text{arginine}}{C_6H_{14}N_4O_2} + H_2O \rightarrow \underset{\text{urea}}{NH_2CONH_2} + \underset{\text{ornithine}}{C_5H_{12}N_2O_2}$$

If you excrete 95 mg of urea, what mass of arginine must have been used? What mass of ornithine must have been produced?

82. The reaction of iron metal and chlorine gas to give iron(III) chloride is illustrated below.

© Cengage Learning/Charles D. Winters

The reaction of iron and chlorine gas

(a) Write the balanced chemical equation for the reaction.

(b) Beginning with 10.0 g of iron, what mass of Cl_2, in grams, is required for complete reaction? What mass of $FeCl_3$ can be produced?

(c) If only 18.5 g of $FeCl_3$ is obtained from 10.0 g of iron and excess Cl_2, what is the percent yield?

(d) If 10.0 g each of iron and chlorine are combined, what is the theoretical yield of iron(III) chloride?

83. Some metal halides react with water to produce the metal oxide and the appropriate hydrogen halide (see photo). For example,

$$TiCl_4(\ell) + 2\ H_2O(\ell) \rightarrow TiO_2(s) + 4\ HCl(g)$$

© Cengage Learning/Charles D. Winters

The reaction of $TiCl_4$ with the water in moist air

(a) Name the four compounds involved in this reaction.

(b) If you begin with 14.0 mL of $TiCl_4$ (d = 1.73 g/mL), what mass of water, in grams, is required for complete reaction?

(c) What mass of each product is expected?

84. The reaction of 750. g each of NH_3 and O_2 was found to produce 562 g of NO (see pages 177–179).

$$4\ NH_3(g) + 5\ O_2(g) \rightarrow 4\ NO(g) + 6\ H_2O(\ell)$$

(a) What mass of water is produced by this reaction?

(b) What mass of O_2 is required to consume 750. g of NH_3?

85. Sodium azide, an explosive chemical used in automobile airbags, is made by the following reaction:

$$NaNO_3 + 3\ NaNH_2 \rightarrow NaN_3 + 3\ NaOH + NH_3$$

If you combine 15.0 g of $NaNO_3$ with 15.0 g of $NaNH_2$, what mass of NaN_3 is produced?

86. Iodine is made by the following reaction

$$2\ NaIO_3(aq) + 5\ NaHSO_3(aq) \rightarrow 3\ NaHSO_4(aq) + 2\ Na_2SO_4(aq) + H_2O(\ell) + I_2(aq)$$

(a) Name the two reactants.

(b) If you wish to prepare 1.00 kg of I_2, what masses of $NaIO_3$ and $NaHSO_3$ are required?

(c) What is the theoretical yield of I_2 if you mixed 15.0 g of $NaIO_3$ with 125 mL of 0.853 M $NaHSO_3$?

87. Saccharin, an artificial sweetener, has the formula $C_7H_5NO_3S$. Suppose you have a sample of a saccharin-containing sweetener with a mass of 0.2140 g. After decomposition to free the sulfur and convert it to the SO_4^{2-} ion, the sulfate ion is trapped as water-insoluble $BaSO_4$ (Figure 4.4). The quantity of $BaSO_4$ obtained is 0.2070 g. What is the mass percent of saccharin in the sample of sweetener?

88. ▲ Boron forms a series of compounds with hydrogen, all with the general formula B_xH_y.

$$B_xH_y(s) + \text{excess } O_2(g) \rightarrow \frac{x}{2}\ B_2O_3(s) + \frac{y}{2}\ H_2O(g)$$

If 0.148 g of one of these compounds gives 0.422 g of B_2O_3 when burned in excess O_2, what is its empirical formula?

89. ▲ Silicon and hydrogen form a series of compounds with the general formula Si_xH_y. To find the formula of one of them, a 6.22-g sample of the compound is burned in oxygen. All of the Si is converted to 11.64 g of SiO_2, and all of the H is converted to 6.980 g of H_2O. What is the empirical formula of the silicon compound?

90. ▲ Menthol, from oil of mint, has a characteristic odor. The compound contains only C, H, and O. If 95.6 mg of menthol burns completely in O_2, and gives 269 mg of CO_2 and 111 mg of H_2O, what is the empirical formula of menthol?

91. ▲ Benzoquinone, a chemical used in the dye industry and in photography, is an organic compound containing only C, H, and O. What is the empirical formula of the compound if 0.105 g of the compound gives 0.257 g of CO_2 and 0.0350 g of H_2O when burned completely in oxygen?

92. ▲ Aqueous solutions of iron(II) chloride and sodium sulfide react to form iron(II)sulfide and sodium chloride.

(a) Write the balanced equation for the reaction.

(b) If you combine 40. g each of Na_2S and $FeCl_2$, what is the limiting reactant?

(c) What mass of FeS is produced?

(d) What mass of Na_2S or $FeCl_2$ remains after the reaction?

(e) What mass of $FeCl_2$ is required to react completely with 40. g of Na_2S?

93. Sulfuric acid can be prepared starting with the sulfide ore, cuprite (Cu_2S). If each S atom in Cu_2S leads to one molecule of H_2SO_4, what is the theoretical yield of H_2SO_4 from 3.00 kg of Cu_2S?

94. ▲ In an experiment, 1.056 g of a metal carbonate, containing an unknown metal M, is heated to give the metal oxide and 0.376 g CO_2.

$$MCO_3(s) + \text{heat} \rightarrow MO(s) + CO_2(g)$$

What is the identity of the metal M?

(a) M = Ni

(b) M = Cu

(c) M = Zn

(d) M = Ba

95. ▲ An unknown metal reacts with oxygen to give the metal oxide, MO_2. Identify the metal if a 0.356-g sample of the metal produces 0.452 g of the metal oxide.

96. ▲ Titanium(IV) oxide, TiO_2, is heated in hydrogen gas to give water and a new titanium oxide, Ti_xO_y. If 1.598 g of TiO_2 produces 1.438 g of Ti_xO_y, what is the empirical formula of the new oxide?

97. ▲ Potassium perchlorate is prepared by the following sequence of reactions:

$$Cl_2(g) + 2\ KOH(aq) \rightarrow KCl(aq) + KClO(aq) + H_2O(\ell)$$

$$3\ KClO(aq) \rightarrow 2\ KCl(aq) + KClO_3(aq)$$

$$4\ KClO_3(aq) \rightarrow 3\ KClO_4(aq) + KCl(aq)$$

What mass of $Cl_2(g)$ is required to produce 234 kg of $KClO_4$?

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

98. ▲ Commercial sodium "hydrosulfite" is 90.1% $Na_2S_2O_4$. The sequence of reactions used to prepare the compound is

$$Zn(s) + 2\ SO_2(g) \rightarrow ZnS_2O_4(s)$$

$$ZnS_2O_4(s) + Na_2CO_3(aq) \rightarrow ZnCO_3(s) + Na_2S_2O_4(aq)$$

(a) What mass of pure $Na_2S_2O_4$ can be prepared from 125 kg of Zn, 500. g of SO_2, and an excess of Na_2CO_3?

(b) What mass of the commercial product would contain the $Na_2S_2O_4$ produced using the amounts of reactants in part (a)?

99. What mass of lime, CaO, can be obtained by heating 125 kg of limestone that is 95.0% by mass $CaCO_3$?

$$CaCO_3(s) \rightarrow CaO(s) + CO_2(g)$$

100. ▲ The elements silver, molybdenum, and sulfur combine to form Ag_2MoS_4. What is the maximum mass of Ag_2MoS_4 that can be obtained if 8.63 g of silver, 3.36 g of molybdenum, and 4.81 g of sulfur are combined? (*Hint:* What is the limiting reactant?)

101. ▲ A mixture of butene, C_4H_8, and butane, C_4H_{10}, is burned in air to give CO_2 and water. Suppose you burn 2.86 g of the mixture and obtain 8.80 g of CO_2 and 4.14 g of H_2O. What are the mass percentages of butene and butane in the mixture?

102. ▲ Cloth can be waterproofed by coating it with a silicone layer. This is done by exposing the cloth to $(CH_3)_2SiCl_2$ vapor. The silicon compound reacts with OH groups on the cloth to form a waterproofing film (density = 1.0 g/cm^3) of $[(CH_3)_2SiO]_n$, where n is a large integer number.

$$n\ (CH_3)_2SiCl_2 + 2n\ OH^- \rightarrow 2n\ Cl^- + n\ H_2O + [(CH_3)_2SiO]_n$$

The coating is added layer by layer, with each layer of $[(CH_3)_2SiO]_n$ being 0.60 nm thick. Suppose you want to waterproof a piece of cloth that is 3.00 square meters, and you want 250 layers of waterproofing compound on the cloth. What mass of $(CH_3)_2SiCl_2$ do you need?

103. ▲ Copper metal can be prepared by roasting copper ore, which can contain cuprite (Cu_2S) and copper(II) sulfide.

$$Cu_2S(s) + O_2(g) \rightarrow 2\ Cu(s) + SO_2(g)$$

$$CuS(s) + O_2(g) \rightarrow Cu(s) + SO_2(g)$$

Suppose an ore sample contains 11.0% impurity in addition to a mixture of CuS and Cu_2S. Heating 100.0 g of the mixture produces 75.4 g of copper metal with a purity of 89.5%. What is the weight percent of CuS in the ore? The weight percent of Cu_2S?

104. An Alka-Seltzer tablet contains exactly 100. mg of citric acid, $H_3C_6H_5O_7$, plus some sodium bicarbonate. What mass of sodium bicarbonate is required to consume 100. mg of citric acid by the following reaction?

$$H_3C_6H_5O_7(aq) + 3\ NaHCO_3(aq) \rightarrow 3\ H_2O(\ell) + 3\ CO_2(g) + Na_3C_6H_5O_7(aq)$$

105. ▲ Sodium bicarbonate and acetic acid react according to the equation

$$NaHCO_3(aq) + CH_3CO_2H(aq) \rightarrow NaCH_3CO_2(aq) + CO_2(g) + H_2O(\ell)$$

What mass of sodium acetate can be obtained from mixing 15.0 g of $NaHCO_3$ with 125 mL of 0.15 M acetic acid?

106. A noncarbonated soft drink contains an unknown amount of citric acid, $H_3C_6H_5O_7$. If 100. mL of the soft drink requires 33.51 mL of 0.0102 M NaOH to neutralize the citric acid completely, what mass of citric acid does the soft drink contain per 100. mL? The reaction of citric acid and NaOH is

$$H_3C_6H_5O_7(aq) + 3\ NaOH(aq) \rightarrow Na_3C_6H_5O_7(aq) + 3\ H_2O(\ell)$$

107. Sodium thiosulfate, $Na_2S_2O_3$, is used as a "fixer" in black-and-white photography. Suppose you have a bottle of sodium thiosulfate and want to determine its purity. The thiosulfate ion can be oxidized with I_2 according to the balanced, net ionic equation

$$I_2(aq) + 2\ S_2O_3^{2-}(aq) \rightarrow 2\ I^-(aq) + S_4O_6^{2-}(aq)$$

If you use 40.21 mL of 0.246 M I_2 in a titration, what is the weight percent of $Na_2S_2O_3$ in a 3.232-g sample of impure material?

108. You have a mixture of oxalic acid, $H_2C_2O_4$, and another solid that does not react with sodium hydroxide. If 29.58 mL of 0.550 M NaOH is required to titrate the oxalic acid in the 4.554-g sample to the second equivalence point, what is the mass percent of oxalic acid in the mixture? Oxalic acid and NaOH react according to the equation

$$H_2C_2O_4(aq) + 2\ NaOH(aq) \rightarrow Na_2C_2O_4(aq) + 2\ H_2O(\ell)$$

109. (a) What is the pH of a 0.105 M HCl solution?

(b) What is the hydronium ion concentration in a solution with a pH of 2.56? Is the solution acidic or basic?

(c) A solution has a pH of 9.67. What is the hydronium ion concentration in the solution? Is the solution acidic or basic?

(d) A 10.0-mL sample of 2.56 M HCl is diluted with water to 250. mL. What is the pH of the dilute solution?

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

110. A solution of hydrochloric acid has a volume of 125 mL and a pH of 2.56. What mass of $NaHCO_3$ must be added to completely consume the HCl?

111. ▲ One half liter (500. mL) of 2.50 M HCl is mixed with 250. mL of 3.75 M HCl. Assuming the total solution volume after mixing is 750. mL, what is the concentration of hydrochloric acid in the resulting solution? What is its pH?

112. A solution of hydrochloric acid has a volume of 250. mL and a pH of 1.92. Exactly 250. mL of 0.0105 M NaOH is added. What is the pH of the resulting solution?

113. ▲ You place 2.56 g of $CaCO_3$ in a beaker containing 250. mL of 0.125 M HCl. When the reaction has ceased, does any calcium carbonate remain? What mass of $CaCl_2$ can be produced?

$$CaCO_3(s) + 2\ HCl(aq) \rightarrow CaCl_2(aq) + CO_2(g) + H_2O(\ell)$$

114. The cancer drug cisplatin, $Pt(NH_3)_2Cl_2$, can be made by reacting $(NH_4)_2PtCl_4$ with ammonia in aqueous solution. Besides cisplatin, the other product is NH_4Cl.

(a) Write a balanced equation for this reaction.

(b) To obtain 12.50 g of cisplatin, what mass of $(NH_4)_2PtCl_4$ is required? What volume of 0.125 M NH_3 is required?

(c) ▲ Cisplatin can react with the organic compound pyridine, C_5H_5N, to form a new compound.

$$Pt(NH_3)_2Cl_2(aq) + x\ C_5H_5N(aq) \rightarrow Pt(NH_3)_2Cl_2(C_5H_5N)_x(s)$$

Suppose you treat 0.150 g of cisplatin with what you believe is an excess of liquid pyridine (1.50 mL; $d = 0.979$ g/mL). When the reaction is complete, you can find out how much pyridine was not used by titrating the solution with standardized HCl. If 37.0 mL of 0.475 M HCl is required to titrate the excess pyridine,

$$C_5H_5N(aq) + HCl(aq) \rightarrow C_5H_5NH^+(aq) + Cl^-(aq)$$

what is the formula of the unknown compound $Pt(NH_3)_2Cl_2(C_5H_5N)_x$?

115. ▲ You need to know the volume of water in a small swimming pool, but, owing to the pool's irregular shape, it is not a simple matter to determine its dimensions and calculate the volume. To solve the problem, you stir in a solution of a dye (1.0 g of methylene blue, $C_{16}H_{18}ClN_3S$, in 50.0 mL of water). After the dye has mixed with the water in the pool, you take a sample of the water. Using a spectrophotometer, you determine that the concentration of the dye in the pool is 4.1×10^{-8} M. What is the volume of water in the pool?

116. ▲ Calcium and magnesium carbonates occur together in the mineral dolomite. Suppose you heat a sample of the mineral to obtain the oxides, CaO and MgO, and then treat the oxide sample with hydrochloric acid. If 7.695 g of the oxide sample requires 125 mL of 2.55 M HCl,

$$CaO(s) + 2\ HCl(aq) \rightarrow CaCl_2(aq) + H_2O(\ell)$$

$$MgO(s) + 2\ HCl(aq) \rightarrow MgCl_2(aq) + H_2O(\ell)$$

what is the weight percent of each oxide (CaO and MgO) in the sample?

117. Gold can be dissolved from gold-bearing rock by treating the rock with sodium cyanide in the presence of oxygen.

$$4\ Au(s) + 8\ NaCN(aq) + O_2(g) + 2\ H_2O(\ell) \rightarrow 4\ NaAu(CN)_2(aq) + 4\ NaOH(aq)$$

(a) Name the oxidizing and reducing agents in this reaction. What has been oxidized, and what has been reduced?

(b) If you have exactly one metric ton (1 metric ton = 1000 kg) of gold-bearing rock, what volume of 0.075 M NaCN, in liters, do you need to extract the gold if the rock is 0.019% gold?

118. ▲ You mix 25.0 mL of 0.234 M $FeCl_3$ with 42.5 mL of 0.453 M NaOH.

(a) What mass of $Fe(OH)_3$ (in grams) will precipitate from this reaction mixture?

(b) One of the reactants ($FeCl_3$ or NaOH) is present in a stoichiometric excess. What is the molar concentration of the excess reactant remaining in solution after $Fe(OH)_3$ has been precipitated?

119. **ATOM ECONOMY:** One type of reaction used in the chemical industry is a substitution, where one atom or group is exchanged for another. In this reaction, an alcohol, 1-butanol, is transformed into 1-bromobutane by substituting Br for the –OH group in the presence of sulfuric acid.

$$CH_3CH_2CH_2CH_2OH + NaBr + H_2SO_4 \rightarrow CH_3CH_2CH_2CH_2Br + NaHSO_4 + H_2O$$

Calculate the % atom economy for the desired product, $CH_3CH_2CH_2CH_2Br$.

120. **ATOM ECONOMY:** Ethylene oxide, C_2H_4O, is an important industrial chemical [as it is the starting place to make such important chemicals as ethylene glycol (antifreeze) and various polymers]. One way to make the compound is called the "chlorohydrin route."

$$C_2H_4 + Cl_2 + Ca(OH)_2 \rightarrow C_2H_4O + CaCl_2 + H_2O$$

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Another route is the modern catalytic reaction.

$$C_2H_4 + 1/2\ O_2 \rightarrow C_2H_4O$$

(a) Calculate the % atom economy for the production of C_2H_4O in each of these reactions. Which is the more efficient method?

(b) What is the percent yield of C_2H_4O if 867 g of C_2H_4 is used to synthesize 762 g of the product by the catalytic reaction?

In the Laboratory

121. Suppose you dilute 25.0 mL of a 0.110 M solution of Na_2CO_3 to exactly 100.0 mL. You then take exactly 10.0 mL of this diluted solution and add it to a 250-mL volumetric flask. After filling the volumetric flask to the mark with distilled water (indicating the volume of the new solution is 250. mL), what is the concentration of the diluted Na_2CO_3 solution?

122. ▲ In some laboratory analyses, the preferred technique is to dissolve a sample in an excess of acid or base and then "back-titrate" the unreacted acid or base with a standard base or acid. To assess the purity of a sample of $(NH_4)_2SO_4$ you dissolve a 0.475-g sample of impure $(NH_4)_2SO_4$ in aqueous KOH.

$$(NH_4)_2SO_4(aq) + 2\ KOH(aq) \rightarrow 2\ NH_3(aq) + K_2SO_4(aq) + 2\ H_2O(\ell)$$

The NH_3 liberated in the reaction is distilled from the solution into a flask containing 50.0 mL of 0.100 M HCl. The ammonia reacts with the acid to produce NH_4Cl, but not all of the HCl is used in this reaction. The amount of excess acid is determined by titrating the solution with standardized NaOH. This titration consumes 11.1 mL of 0.121 M NaOH. What is the weight percent of $(NH_4)_2SO_4$ in the 0.475-g sample?

123. Oyster beds in the oceans require chloride ions for growth. The minimum concentration is 8 mg/L (8 parts per million). To analyze for the amount of chloride ion in a 50.0-mL sample of water, you add a few drops of aqueous potassium chromate and then titrate the sample with 25.60 mL of 0.001036 M silver nitrate. The silver nitrate reacts with chloride ion, and, when the ion is completely removed, the silver nitrate reacts with potassium chromate to give a red precipitate.

(a) Write a balanced net ionic equation for the reaction of silver nitrate with chloride ions.

(b) Write a complete balanced equation and a net ionic equation for the reaction of silver nitrate with potassium chromate, indicating whether each compound is water-soluble or not.

(c) What is the concentration of chloride ions in the sample? Is it sufficient to promote oyster growth?

124. ▲ A compound consisting of yttrium(III) ions, barium(II) ions, both copper(II) and copper(III) ions, and oxide ions is a superconducting material at low temperatures (pages 158–159). It has the formula $YBa_2Cu_3O_{7-x}$ where x is a variable between 1 and 0. To find out the value of x, you dissolve 34.02 mg of the compound in 5 mL of 1.0 M HCl. Bubbles of oxygen gas (O_2) are observed as the following reaction occurs:

$$YBa_2Cu_3O_{7-x}(s) + 13\ H^+(aq) \rightarrow Y^{3+}(aq) + 2\ Ba^{2+}(aq) + 3\ Cu^{2+}(aq) + 1/4(1 - 2x)\ O_2(g) + 13/2\ H_2O(\ell)$$

You then boil the solution, cool it, and add 10 mL of 0.70 M KI under argon. The following reaction occurs:

$$2\ Cu^{2+}(aq) + 5\ I^-(aq) \rightarrow 2\ CuI(s) + I_3^-(aq)$$

When this reaction is complete, a titration of the resulting solution with sodium thiosulfate requires 1.542×10^{-4} mol $S_2O_3^{2-}(aq)$.

$$I_3^-(aq) + 2\ S_2O_3^{2-}(aq) \rightarrow 3\ I^-(aq) + S_4O_6^{2-}(aq)$$

What is the value of x in $YBa_2Cu_3O_{7-x}$?

125. You wish to determine the weight percent of copper in a copper-containing alloy. After dissolving a 0.251-g sample of the alloy in acid, an excess of KI is added, and the Cu^{2+} and I^- ions undergo the reaction

$$2\ Cu^{2+}(aq) + 5\ I^-(aq) \rightarrow 2\ CuI(s) + I_3^-(aq)$$

The liberated I_3^- is titrated with sodium thiosulfate according to the equation

$$I_3^-(aq) + 2\ S_2O_3^{2-}(aq) \rightarrow S_4O_6^{2-}(aq) + 3\ I^-(aq)$$

(a) Designate the oxidizing and reducing agents in the two reactions above.

(b) If 26.32 mL of 0.101 M $Na_2S_2O_3$ is required for titration to the equivalence point, what is the weight percent of Cu in the alloy?

126. ▲ A compound has been isolated that can have either of two possible formulas: (a) $K[Fe(C_2O_4)_2(H_2O)_2]$ or (b) $K_3[Fe(C_2O_4)_3]$. To find which is correct, you dissolve a weighed sample of the compound in acid, forming oxalic acid, $H_2C_2O_4$. You then titrate this acid with potassium permanganate, $KMnO_4$ (the source of the MnO_4^- ion). The balanced, net ionic equation for the titration is

$$5\ H_2C_2O_4(aq) + 2\ MnO_4^-(aq) + 6\ H_3O^+(aq) \rightarrow 2\ Mn^{2+}(aq) + 10\ CO_2(g) + 14\ H_2O(\ell)$$

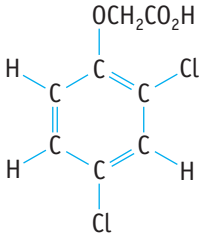
Titration of 1.356 g of the compound requires 34.50 mL of 0.108 M $KMnO_4$. Which is the correct formula of the iron-containing compound: (a) or (b)?

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

127. ▲ Chromium(III) chloride forms many compounds with ammonia. To find the formula of one of these compounds, you titrate the NH_3 in the compound with standardized acid.

$$Cr(NH_3)_xCl_3(aq) + x\ HCl(aq) \rightarrow x\ NH_4^+(aq) + Cr^{3+}(aq) + (x + 3)\ Cl^-(aq)$$



Assume that 24.26 mL of 1.500 M HCl is used to titrate 1.580 g of $Cr(NH_3)_xCl_3$. What is the value of x?

128. ▲ Thioridazine, $C_{21}H_{26}N_2S_2$, is a pharmaceutical agent used to regulate dopamine. (Dopamine, a neurotransmitter, affects brain processes that control movement, emotional response, and ability to experience pleasure and pain.) A chemist can analyze a sample of the pharmaceutical for the thioridazine content by decomposing it to convert the sulfur in the compound to sulfate ion. This is then "trapped" as water-insoluble barium sulfate (see Figure 4.4).

$$SO_4^{2-}(aq, \text{ from thioridazine}) + BaCl_2(aq) \rightarrow BaSO_4(s) + 2\ Cl^-(aq)$$

Suppose a 12-tablet sample of the drug yielded 0.301 g of $BaSO_4$. What is the thioridazine content, in milligrams, of each tablet?

129. ▲ A herbicide contains 2,4-D (2,4-dichlorophenoxyacetic acid), $C_8H_6Cl_2O_3$. A 1.236-g sample of the herbicide was decomposed to liberate the chlorine as Cl^- ion. This was precipitated as AgCl, with a mass of 0.1840 g. What is the mass percent of 2,4-D in the sample?

2,4-D (2,4-dichlorophenoxyacetic acid)

130. ▲ Sulfuric acid is listed in a catalog with a concentration of 95–98%. A bottle of the acid in the stockroom states that 1.00 L has a mass of 1.84 kg. To determine the concentration of sulfuric acid in the stockroom bottle, a student dilutes 5.00 mL to 500. mL. She then takes four 10.00-mL samples and titrates each with standardized sodium hydroxide (c = 0.1760 M).

Sample	1	2	3	4
Volume NaOH (mL)	20.15	21.30	20.40	20.35

(a) What is the average concentration of the diluted sulfuric acid sample?

(b) What is the mass percent of H_2SO_4 in the original bottle of the acid?

131. ▲ Anhydrous calcium chloride is a good drying agent because it will rapidly pick up water. Suppose you have stored some carefully dried $CaCl_2$ in a desiccator. Unfortunately, someone did not close the top of the desiccator tightly, and the $CaCl_2$ became partially hydrated. A 150-g sample of this partially hydrated material was dissolved in 80 g of hot water. When the solution was cooled to 20 °C, 74.9 g of $CaCl_2 \cdot 6\ H_2O$ precipitated. Knowing the solubility of calcium chloride in water at 20 °C is 74.5 g $CaCl_2$/100 g water, determine the water content of the 150-g sample of partially hydrated calcium chloride (in moles of water per mole of $CaCl_2$).

132. ▲ A 0.5510-g sample consisting of a mixture of iron and iron(III) oxide was dissolved completely in acid to give a solution containing iron(II) and iron(III) ions. A reducing agent was added to convert all of the iron to iron(II) ions, and the solution was then titrated with the standardized $KMnO_4$ (0.04240 M); 37.50 mL of the $KMnO_4$ solution was required. Calculate the mass percent of Fe and Fe_2O_3 in the 0.5510-g sample. (Example 4.13 gives the equation for the reaction of iron(II) ions and $KMnO_4$.)

133. ▲ Phosphate in urine can be determined by spectrophotometry. After removing protein from the sample, it is treated with a molybdenum compound to give, ultimately, a deep blue polymolybdate. The absorbance of the blue polymolybdate can be measured at 650 nm and is directly related to the urine phosphate concentration. A 24-hour urine sample was collected from a patient; the volume of urine was 1122 mL. The phosphate in a 1.00 mL portion of the urine sample was converted to the blue polymolybdate and diluted to 50.00 mL. A calibration curve was prepared using phosphate-containing solutions. (Concentrations are reported in grams of phosphorus (P) per liter of solution.)

Solution (mass P/L)	Absorbance at 650 nm in a 1.0-cm cell
1.00×10^{-6} g	0.230
2.00×10^{-6} g	0.436
3.00×10^{-6} g	0.638
4.00×10^{-6} g	0.848
Urine sample	0.518

(a) What are the slope and intercept of the calibration curve?

(b) What is the mass of phosphorus per liter of urine?

(c) What mass of phosphate did the patient excrete in the one-day period?

134. ▲ A 4.000-g sample containing KCl and $KClO_4$ was dissolved in sufficient water to give 250.00 mL of solution. A 50.00-mL portion of the solution required 41.00 mL of 0.0750 M $AgNO_3$ in a Mohr titration (page 209). Next, a 25.00-mL portion of the original solution was treated with $V_2(SO_4)_3$ to reduce the perchlorate ion to chloride,

$$8\ V^{3+}(aq) + ClO_4^-(aq) + 12\ H_2O(\ell) \rightarrow Cl^-(aq) + 8\ VO^{2+}(aq) + 8\ H_3O^+(aq)$$

and the resulting solution was titrated with $AgNO_3$. This titration required 38.12 mL of 0.0750 M $AgNO_3$. What is the mass percent of KCl and $KClO_4$ in the mixture?

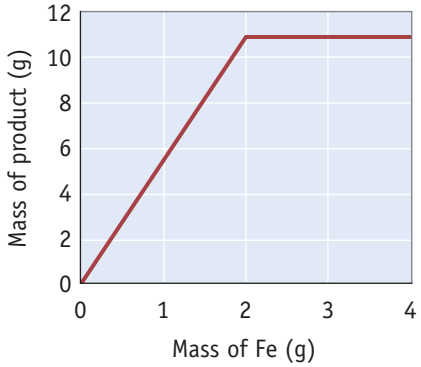
Summary and Conceptual Questions

The following questions may use concepts from this and previous chapters.

135. Two beakers sit on a balance; the total mass is 167.170 g. One beaker contains a solution of KI; the other contains a solution of $Pb(NO_3)_2$. When the solution in one beaker is poured completely into the other, the following reaction occurs:

$$2\ KI(aq) + Pb(NO_3)_2(aq) \rightarrow 2\ KNO_3(aq) + PbI_2(s)$$

Solutions of KI and $Pb(NO_3)_2$ before reaction



Solutions after reaction

Photos: © Cengage Learning/ Charles D. Winters

What is the total mass of the beakers and solutions after reaction? Explain completely.

136. ▲ A weighed sample of iron (Fe) is added to liquid bromine (Br_2) and allowed to react completely. The reaction produces a single product, which can be isolated and weighed. The experiment was repeated a number of times with different masses of iron but with the same mass of bromine (see graph below).

(a) What mass of Br_2 is used when the reaction consumes 2.0 g of Fe?

(b) What is the mole ratio of Br_2 to Fe in the reaction?

(c) What is the empirical formula of the product?

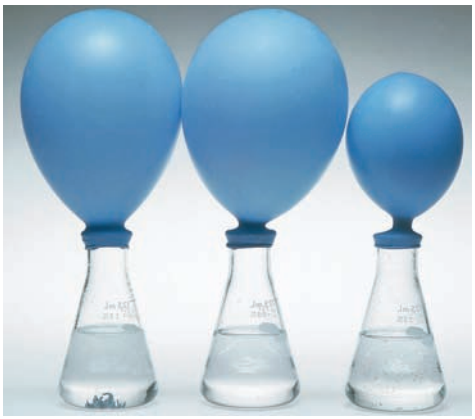
(d) Write the balanced chemical equation for the reaction of iron and bromine.

(e) What is the name of the reaction product?

(f) Which statement or statements best describe the experiments summarized by the graph?

(i) When 1.00 g of Fe is added to the Br_2, Fe is the limiting reagent.

(ii) When 3.50 g of Fe is added to the Br_2, there is an excess of Br_2.



(iii) When 2.50 g of Fe is added to the Br_2, both reactants are used up completely.

(iv) When 2.00 g of Fe is added to the Br_2, 10.8 g of product is formed. The percent yield must therefore be 20.0%.

137. Let us explore a reaction with a limiting reactant. Here, zinc metal is added to a flask containing aqueous HCl, and H_2 gas is a product.

$$Zn(s) + 2\ HCl(aq) \rightarrow ZnCl_2(aq) + H_2(g)$$

The three flasks each contain 0.100 mol of HCl. Zinc is added to each flask in the following quantities.

© Cengage Learning/Charles D. Winters

Flask 1: 7.00 g Zn **Flask 2: 3.27 g Zn** **Flask 3: 1.31 g Zn**

When the reactants are combined, the H_2 inflates the balloon attached to the flask. The results are as follows:

Flask 1: Balloon inflates completely, but some Zn remains when inflation ceases.

Flask 2: Balloon inflates completely. No Zn remains.

Flask 3: Balloon does not inflate completely. No Zn remains.

Explain these results. Perform calculations that support your explanation.

138. Antacids are chemical compounds that can give immediate relief from indigestion or heartburn because they contain carbonate or hydroxide ions that neutralize stomach acids. Some common active ingredients include $NaHCO_3$, $KHCO_3$, $CaCO_3$, $Mg(OH)_2$, and $Al(OH)_3$. Although these compounds give quick relief, they are not recommended for prolonged consumption. Calcium carbonate may contribute to the growth of kidney stones, and calcium carbonate and aluminum hydroxide may cause constipation. Magnesium hydroxide, on the other hand, is a mild laxative that can cause diarrhea. Antacids containing magnesium, therefore, are often combined with aluminum hydroxide since the aluminum counteracts the laxative properties of the magnesium.

(a) Which of the compounds listed above produce gas-forming reactions when combined with HCl?

(b) One tablet of Tums Regular Strength Antacid™ contains 500. mg $CaCO_3$.

(i) Write a balanced chemical equation for the reaction of $CaCO_3$ and stomach acid (HCl).

(ii) What volume (in mL) of 0.500 M HCl(aq) will react completely with one tablet of Tums™?

(c) The active ingredients in Rolaids™ are $CaCO_3$ and $Mg(OH)_2$.

(i) Write a balanced chemical equation for the reaction of $Mg(OH)_2$ and HCl.

(ii) If 29.52 mL of 0.500 M HCl is required to titrate one tablet of Rolaids™ and the tablet contains 550 mg of $CaCO_3$, what mass of $Mg(OH)_2$ is present in one tablet?

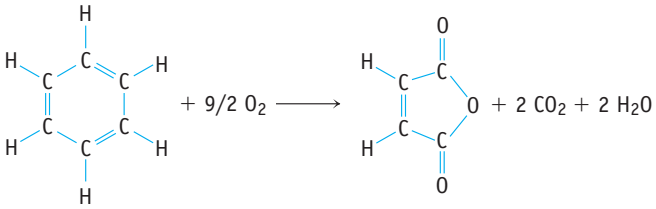
(d) Maalox™ may be purchased in either a liquid or solid form. One teaspoon of the liquid form of Maalox™ contains a mixture of 200. mg of $Al(OH)_3$ and 200. mg of $Mg(OH)_2$. What volume of 0.500 M HCl(aq) will react completely with one teaspoon of Maalox™?

(e) Which product neutralizes the greatest amount of acid when taken in the quantities presented above: one tablet of Tums™ or Rolaids™ or one teaspoon of Maalox™?

139. ▲ Two students titrate different samples of the same solution of HCl using 0.100 M NaOH solution and phenolphthalein indicator (Figure 4.12). The first student pipets 20.0 mL of the HCl solution into a flask, adds 20 mL of distilled water and a few drops of phenolphthalein solution, and titrates until a lasting pink color appears. The second student pipets 20.0 mL of the HCl solution into a flask, adds 60 mL of distilled water and a few drops of phenolphthalein solution, and titrates to the first lasting pink color. Each student correctly calculates the molarity of an HCl solution. What will the second student's result be?

(a) four times less than the first student's result

(b) four times greater than the first student's result



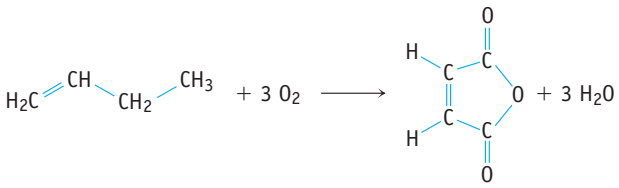
(c) two times less than the first student's result

(d) two times greater than the first student's result

(e) the same as the first student's result

140. In most states, a person will receive a "driving while intoxicated" (DWI) ticket if the blood alcohol level (BAL) is 80 mg per deciliter (dL) of blood or higher. Suppose a person is found to have a BAL of 0.033 mol of ethanol (C_2H_5OH) per liter of blood. Will the person receive a DWI ticket?

141. **ATOM ECONOMY:** Benzene, C_6H_6, is a common compound, and it can be oxidized to give maleic anhydride, $C_4H_2O_3$, which is used in turn to make other important compounds.



(a) What is the % atom economy for the synthesis of maleic anhydride from benzene by this reaction?

(b) If 972 g of maleic anhydride is produced from exactly 1.00 kg of benzene, what is the percent yield of the anhydride? What mass of the by-product CO_2 is also produced?

CHAPTER OUTLINE

5.1 Energy: Some Basic Principles

5.2 Specific Heat Capacity: Heating and Cooling

5.3 Energy and Changes of State

5.4 The First Law of Thermodynamics

5.5 Enthalpy Changes for Chemical Reactions

5.6 Calorimetry

5.7 Enthalpy Calculations

5.8 Product- or Reactant-Favored Reactions and Thermodynamics

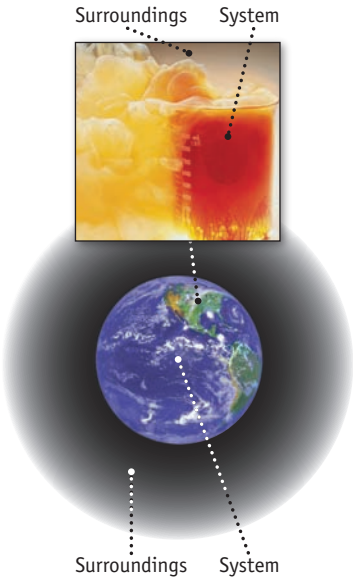
5.1 Energy: Some Basic Principles

Goals for Section 5.1

- Recognize and use the language of thermodynamics: the system and its surroundings; exothermic and endothermic reactions.
- Describe the nature of energy transfers as heat.
- Understand the sign conventions of thermodynamics.

The importance of energy is evident in our daily lives—in heating and cooling our homes, in powering our appliances, and in propelling our vehicles, among other things. Most of the energy we use for these purposes is obtained by carrying out chemical reactions, largely by burning fossil fuels. We use natural gas for heating, coal and natural gas to generate most of our electric power, and fuels derived from petroleum for automobiles and for heat. In addition, energy is required for living: Chemical reactions in our bodies provide the energy for body functions, for movement, and to maintain body temperature.

In Chapter 1, we defined energy as the capacity to do work and stated that energy could be divided into two basic categories: kinetic energy (the energy associated with motion) and potential energy (the energy that results from an object's position, composition, or state). Chemists often use the term **thermal energy** when referring to the kinetic energy of molecules. As you will soon see, thermal energy is associated with the transfer of energy as heat between a hotter object and a cooler one.



World Energy Consumption In 2014, burning fossil fuels provided over 86% of the total energy used by people on our planet. Nuclear power contributed 4.4%, and hydroelectric 6.8%. Less than 2.5% was provided from renewable sources such as solar, wind, biomass, and geothermal.

Units of Energy The SI unit for energy (the joule) is discussed on page 33.

◀ **The reaction of potassium and water.** This reaction involves the transfer of energy between the system and surroundings in the form of heat (thermal energy), work, and light.

Figure 5.1 Systems and their surroundings. Earth can be considered a thermodynamic system, with the rest of the universe as its surroundings. A chemical reaction (here the reaction of Al and Br_2) occurring in a laboratory is also a system, with the laboratory as its surroundings.

One type of potential energy is chemical energy, the energy associated with the forces holding atoms together as molecules or binding atoms and molecules together as solids or liquids. In a chemical reaction, chemical energy (potential energy) is converted to other forms of energy such as heat or light (kinetic energy).

Also in Chapter 1 you learned that, although energy can be converted from one type into another, the total amount of energy is conserved. This is formally stated in the **law of conservation of energy**: *Energy can neither be created nor destroyed.* Or, stated differently, *the total energy of the universe is constant*. In order to understand the importance of this law, we need to introduce some new terminology and carefully consider the implications of a number of experiments.

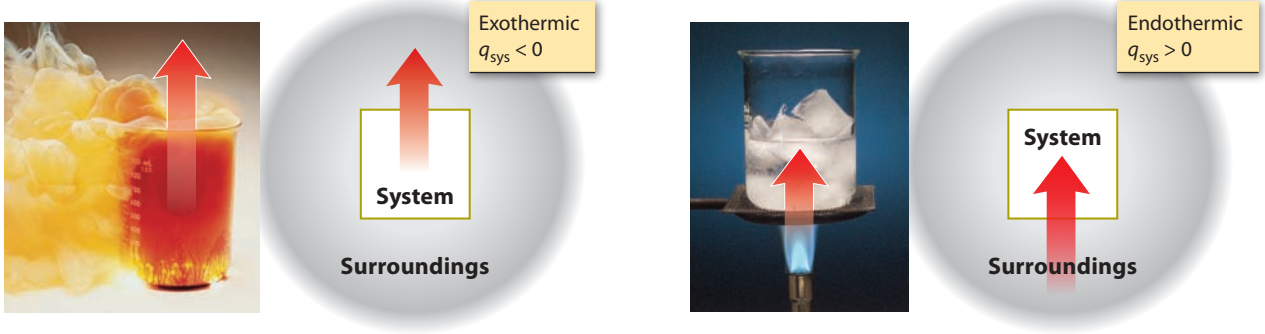
Systems and Surroundings

In thermodynamics, the terms *system and surroundings* have precise and important meanings. A **system** is defined as an object, or collection of objects, being studied (Figure 5.1). The **surroundings** include everything outside the system that can exchange energy and/or matter with the system. In the discussion that follows, we will need to define systems precisely. If we are studying the energy evolved in a chemical reaction carried out in solution, for example, the system might be defined as the reactants, products, and solvent. The surroundings would be the reaction flask and the air in the room and anything else in contact with the flask with which it might exchange energy or matter. At the atomic level, the system could be a single atom or molecule, and the surroundings would be the atoms or molecules in its vicinity. This concept of a system and its surroundings applies to nonchemical situations as well. To study the energy balance on our planet, we might choose to define Earth as the system and outer space as the surroundings. On a cosmic level, the solar system might be defined as the system being studied, and the rest of the galaxy would be the surroundings. How the system and its surroundings for each situation are defined depends on the information we are trying to obtain or convey.

Directionality and Extent of Transfer of Heat: Thermal Equilibrium

Energy can be transferred between a system and its surroundings or between different parts of the system. One way that energy can be transferred is as heat. Energy is transferred as heat if two objects at different temperatures are brought into contact. In Figure 5.2, for example, the beaker of water and the piece of metal being heated in a Bunsen burner flame have different temperatures. When the hot metal is plunged into the cold water, energy is transferred as heat from the metal to the water. The thermal energy (molecular motion) of the water molecules increases, and the thermal energy of the metal atoms decreases. Eventually, the two objects reach the same temperature, and the system has reached **thermal equilibrium**. The distinguishing feature of thermal equilibrium is that, on the macroscopic scale, no further temperature change occurs; both the metal and water are at the same temperature.

Thermal Equilibrium A general feature of systems at equilibrium is that there is no change on a macroscopic level but that processes still occur at the particulate level. (Section 3.3, page 128.)



Photos: © Cengage Learning/Charles D. Winters

Figure 5.2 Energy transfer.

Energy transfer as heat occurs from the hotter metal cylinder to the cooler water. Eventually, the water and metal reach the same temperature and are said to be in thermal equilibrium.

Exothermic: energy transferred from system to surroundings

Endothermic: energy transferred from surroundings to system

Figure 5.3 Exothermic and endothermic processes. The symbol q represents the energy transferred as heat, and the subscript sys refers to the system.

Submerging a hot metal bar in water and following the temperature change may seem like a rather simple experiment with an obvious outcome. However, the experiment illustrates two important principles:

- Energy transfer as heat will occur spontaneously from an object at a higher temperature to an object at a lower temperature; the object whose temperature increases gains thermal energy and the object whose temperature decreases loses thermal energy.
- Transfer of energy as heat continues until both objects are at the same temperature and thermal equilibrium is achieved.

For the specific case where energy is transferred only as heat within an isolated system (that is, a system that cannot transfer either energy or matter with its surroundings), we can also say that the quantity of energy lost as heat by the hotter object and the quantity of energy gained as heat by the cooler object are numerically equal. This is required by the law of conservation of energy.

When energy is transferred as heat between a system and its surroundings, we describe the directionality of this transfer as **exothermic** or **endothermic** (Figure 5.3).

- In an **exothermic process**, energy is transferred as heat from a system to its surroundings. The energy of the system decreases and the energy of the surroundings increases. We designate energy transferred as heat by the symbol q. For an exothermic process, $q_{sys} < 0$.
- An **endothermic process** is the opposite of an exothermic process. Energy is transferred as heat from the surroundings to the system, increasing the energy of the system and decreasing the energy of the surroundings. For an endothermic process, $q_{sys} > 0$.

5.2 Specific Heat Capacity: Heating and Cooling

Goal for Section 5.2

- Use specific heat capacity in calculations of energy transfers as heat involving temperature changes.

When an object is heated or cooled, the quantity of energy transferred depends on three things: the quantity of material, the magnitude of the temperature change, and the identity, including the phase (g, ℓ, aq, or s), of the material gaining or losing energy. To mathematically relate the quantity of energy transferred to the quantity of material and the temperature change, for a given substance, we use the **specific heat capacity (*C*)**. This is defined as *the energy transferred as heat that is required to raise*

Specific Heat Capacities of Some Elements, Compounds, and Substances

Substances	Specific Heat Capacity (J/g · K)	Molar Heat Capacity (J/mol · K)
Al, aluminum	0.897	24.2
Fe, iron	0.449	25.1
Cu, copper	0.385	24.5
Au, gold	0.129	25.4
Water (liquid)	4.184	75.4
Water (ice)	2.06	37.1
Water (steam)	1.86	33.6
$HOCH_2CH_2OH(\ell)$, ethylene glycol (antifreeze)	2.39	14.8
Wood	1.8	—
Glass	0.8	—

All metals have molar heat capacities near 25 J/mol · K

Figure 5.4 Specific heat capacity. Metals have different values of specific heat capacity. However, their molar heat capacities are all near 25 J/mol · K.

the temperature of 1 gram of a substance by one kelvin. It has units of joules per gram per kelvin (J/g · K). A few specific heat capacities are listed in Figure 5.4, and a longer list is given in Appendix D (Table 11).

Heat capacity can also be expressed on a per-mole basis. The amount of energy that is transferred as heat in raising the temperature of one mole of a substance by one kelvin is the **molar heat capacity**. For water, the molar heat capacity is 75.4 J/mol · K. The molar heat capacity of metals at room temperature is always near 25 J/mol · K.

The energy gained or lost as heat when a given mass of a substance is warmed or cooled can be calculated using Equation 5.1.

$$q = C \times m \times \Delta T \tag{5.1}$$

Here, q is the energy gained or lost as heat by a given mass of substance (m), C is the specific heat capacity, and ΔT is the change in temperature, which is calculated as the final temperature minus the initial temperature.

$$\Delta T = T_{\text{final}} - T_{\text{initial}} \tag{5.2}$$

Calculating a change in temperature using Equation 5.2 will give a result with an algebraic sign that indicates the direction of energy transfer. For example, we can use the specific heat capacity of copper, 0.385 J/g · K, to calculate the energy that must be transferred from the surroundings to a 10.0-g sample of copper if the metal's temperature is raised from 298 K (25 °C) to 598 K (325 °C).

$$q = \left(0.385 \frac{\text{J}}{\text{g} \cdot \text{K}}\right)(10.0\ \text{g})(598\ \text{K} - 298\ \text{K}) = +1160\ \text{J}$$

T_{final} Final temp. T_{initial} Initial temp.

Notice that the answer has a positive sign. This indicates that the energy of the sample of copper has *increased* by 1160 J, which is in accord with energy being transferred as heat to the copper (the system) from the surroundings.

A CLOSER LOOK

What Is Heat?

Two hundred years ago, scientists characterized heat as a real substance called caloric fluid. The caloric hypothesis supposed that when a fuel burned and a pot of water was heated, for example, caloric fluid was transferred from the fuel to the water. Burning the fuel released caloric fluid, and the temperature of the water increased as the caloric fluid was absorbed.

We know now that the caloric fluid idea is not correct. Experiments by James Joule (1818–1889) and Benjamin Thompson (1753–1814) that showed the interrelationship between heat and other forms of energy such as mechanical energy provided the key to disproving this idea. Even so, some of our everyday language retains the influence of this early theory. For example, we often speak of heat "flowing" as if it were a fluid.

From our discussion so far, we know one thing that "heat" is not—but what is it?

Benjamin Thompson (1753–1814). Thompson, also known as Count Rumford, established his scientific reputation through research on the explosive force of gunpowder. His experience with explosives led to an interest in heat. Rumford designed a classic experiment that showed the relationship between work and heat.

Musee de la Ville de Paris, Musee Carnavalet, Paris, France/Archives Charmet/The Bridgeman Art Library

Heat is said to be a "process quantity." It is the *process* by which energy is transferred across the boundary of a system owing to a difference in temperature between the two sides of the boundary. In this process, the energy of the object at the lower temperature increases, and the energy of the object at the higher temperature decreases.

Heat is not the only process by which energy can be transferred. Another process that can transfer energy between objects is work (as described on pages 240–242).

The idea of energy transfer by the processes of heat and work is embodied in the definition of thermodynamics: the science of heat and work.

The relationship between energy, mass, and specific heat capacity has numerous implications. The high specific heat capacity of liquid water, 4.184 J/g · K, is a major reason that large bodies of water have a profound influence on climate. In spring, lakes warm up more slowly than the air. In autumn, the energy transferred by a large lake as it cools moderates the drop in air temperature. The relevance of specific heat capacity is also illustrated when food is wrapped in aluminum foil (specific heat capacity 0.897 J/g · K) and heated in an oven. You can remove the foil with your fingers after taking the food from the oven. The food and the aluminum foil are very hot, but the small mass of aluminum foil used and its low specific heat capacity result in only a small quantity of energy being transferred to your fingers (which have a larger mass and a higher specific heat capacity).

stockcreations/Shutterstock.com

A practical example of knowing about specific heat capacity. If you are careful, it is possible to remove the salmon from the grill by grasping the edges of the aluminum foil with unprotected hands. Due to the small quantity of aluminum and its low specific heat capacity, only a small quantity of energy is transferred.

EXAMPLE 5.1

Specific Heat Capacity

Problem How much energy must be transferred to raise the temperature of a cup of coffee (250 mL) from 20.5 °C (293.7 K) to 95.6 °C (368.8 K)? Assume that water and coffee have the same density (1.00 g/mL) and specific heat capacity (4.184 J/g · K).

What Do You Know? The energy required to warm a substance is related to its specific heat capacity (*C*), the mass of the substance, and the temperature change (Equation 5.1). The mass of coffee, initial and final temperatures, and the value for *C* are given in the problem.

Strategy You can calculate the mass of coffee from the volume and density (mass = volume × density) and the temperature change from the initial and final temperatures ($\Delta T = T_{final} - T_{initial}$). Use Equation 5.1 to solve for q.

Solution

$$\text{Mass of coffee} = (250\ \text{mL})(1.00\ \text{g/mL}) = 250\ \text{g}$$

$$\Delta T = T_{final} - T_{initial} = 368.8\ \text{K} - 293.7\ \text{K} = 75.1\ \text{K}$$

$$q = C \times m \times \Delta T$$

$$q = (4.184\ \text{J/g} \cdot \text{K})(250\ \text{g})(75.1\ \text{K})$$

$$q = 79{,}000\ \text{J (or 79 kJ)}$$

Think about Your Answer The positive sign in the answer indicates that energy has been transferred to the coffee. The thermal energy of the coffee is now higher.

Check Your Understanding

You did an experiment in which you found that 59.8 J was required to raise the temperature of 25.0 g of ethylene glycol (a compound used as antifreeze in automobile engines) by 1.00 K. Calculate the specific heat capacity of ethylene glycol from these data.

Quantitative Aspects of Energy Transferred as Heat

Specific heat capacity is a characteristic intensive property of a pure substance. It can be determined experimentally by accurately measuring temperature changes that occur when energy is transferred as heat from the substance to a known quantity of water (whose specific heat capacity is known).

Suppose a 55.0-g piece of metal is heated in boiling water to 99.8 °C and then dropped into cool water in an insulated beaker (Figure 5.5). Assume the beaker contains 225 g of water and its initial temperature (before the metal was dropped in) was 21.0 °C. The final temperature of the metal and water is 23.1 °C. What is the specific heat capacity of the metal? Here are the important aspects of this experiment.

- Let's define the metal and the water as the system and the beaker and environment as the surroundings and assume that energy as heat is transferred only within the system. (This means that energy is not transferred between the system and the surroundings. This assumption is good, but not perfect; for a more accurate result, we would also want to account for any energy transfer to the surroundings.)

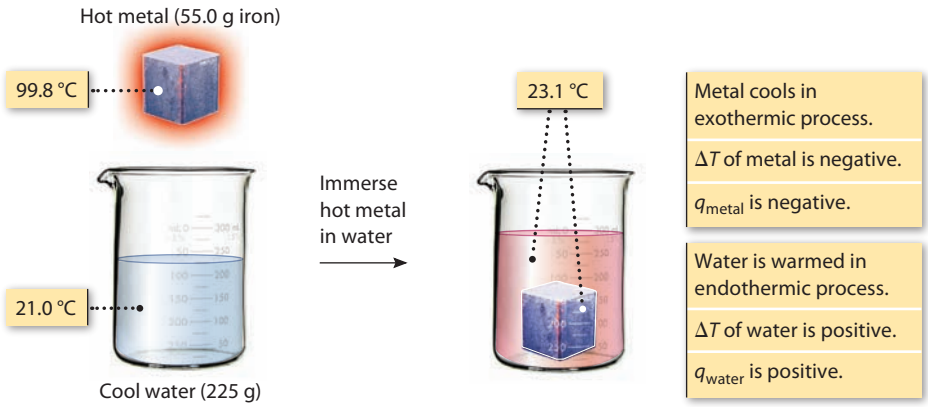

Figure 5.5 Transfer of energy as heat. When energy is transferred as heat from a hot metal to cool water, the thermal energy of the metal decreases and that of the water increases. The value of q_{metal} is thus negative and the value of q_{water} is positive.

Problem Solving Tip 5.1 Calculating ΔT

Virtually all calculations that involve temperature in chemistry require expressing temperature in kelvins. In calculating ΔT, however, we can use Celsius temperatures because a kelvin and a Celsius degree are the same size. That is, the difference between two temperatures is the same on both scales. For example, the difference between the boiling and freezing points of water is

$$\Delta T, \text{ Celsius} = 100\ ^\circ\text{C} - 0\ ^\circ\text{C} = 100\ ^\circ\text{C}$$

$$\Delta T, \text{ kelvin} = 373\ \text{K} - 273\ \text{K} = 100\ \text{K}$$

- The water and the metal end up at the same temperature. (T_{final} is the same for both.)
- We will also assume energy is transferred *only as heat* within the system.
- The energy transferred as heat from the metal to the water, q_{metal}, has a negative value because the temperature of the metal decreases. Conversely, q_{water} has a positive value because its temperature increases.
- The values of q_{water} and q_{metal} are numerically equal but are opposite in sign.

Because of the law of conservation of energy, *in an isolated system the sum of the energy changes within the system must be zero.* If energy is transferred only as heat, then

$$q_1 + q_2 + q_3 + \ldots = 0 \tag{5.3}$$

where the quantities q_1, q_2, and so on represent the energies transferred as heat for the individual parts of the system. For this specific problem, there are thermal energy changes associated with the two components of the system, water and metal, q_{water} and q_{metal}; thus

$$q_{water} + q_{metal} = 0$$

Each of these quantities is related individually to specific heat capacities, masses, and changes of temperature, as defined by Equation 5.1. Thus

$$[C_{water} \times m_{water} \times (T_{final} - T_{initial,\ water})] + [C_{metal} \times m_{metal} \times (T_{final} - T_{initial,\ metal})] = 0$$

The specific heat capacity of the metal, C_{metal}, is the unknown in this problem. Using the specific heat capacity of water (4.184 J/g · K) and converting Celsius to kelvin temperatures gives

$$[(4.184\ \text{J/g} \cdot \text{K})(225\ \text{g})(296.3\ \text{K} - 294.2\ \text{K})] + [(C_{metal})(55.0\ \text{g})(296.3\ \text{K} - 373.0\ \text{K})] = 0$$

$$C_{metal} = 0.47\ \text{J/g} \cdot \text{K}$$

EXAMPLE 5.2

Using Specific Heat Capacity

Problem In an experiment like that in Figure 5.5, an 88.5-g piece of iron whose temperature is 78.8 °C (352.0 K) is placed in a beaker containing 244 g of water at 18.8 °C (292.0 K). When thermal equilibrium is reached, what is the final temperature? (Assume no energy is transferred to warm the beaker and its surroundings.)

What Do You Know? Iron cools and the water warms until thermal equilibrium is reached. The energies associated with the two changes are determined by the specific heat capacities, masses, and temperature changes for each species. If we define the system as the iron and water, the sum of these two energy quantities will be zero. The final temperature is the unknown in this problem. Masses and initial temperatures are given; the specific heat capacities of iron and water can be found in Appendix D or Figure 5.4.

Strategy The sum of the two energy quantities, q_{Fe} and q_{water}, is zero ($q_{Fe} + q_{water} = 0$). Each energy quantity is defined using Equation 5.1; the value of ΔT in each is $T_{final} - T_{initial}$. We can use either kelvin or Celsius temperatures (Problem Solving Tip 5.1). Substitute the given information into Equation 5.3 and solve.

SOLUTION

$$[C_{water} \times m_{water} \times (T_{final} - T_{initial,\ water})] + [C_{Fe} \times m_{Fe} \times (T_{final} - T_{initial,\ Fe})] = 0$$

$$[(4.184\ J/g \cdot K)(244\ g)(T_{final} - 292.0\ K)] + [(0.449\ J/g \cdot K)(88.5\ g)(T_{final} - 352.0\ K)] = 0$$

$$T_{final} = 294\ K\ (21\ °C)$$

Think about Your Answer Be sure to notice that $T_{initial}$ for the metal and $T_{initial}$ for the water in this problem have different values. Also, the low specific heat capacity and smaller quantity of iron result in the temperature of iron being reduced by about 60 degrees; in contrast, the temperature of the water has been raised by only a few degrees. Finally, as expected, T_{final} (294 K) is between $T_{initial,\ Fe}$ and $T_{initial,\ water}$.

Check Your Understanding

A 15.5-g piece of chromium, heated to 100.0 °C, is dropped into 55.5 g of water at 16.5 °C. The final temperature of the metal and the water is 18.9 °C. What is the specific heat capacity of chromium? (Assume no energy is lost to the container or to the surrounding air.)

5.3 Energy and Changes of State

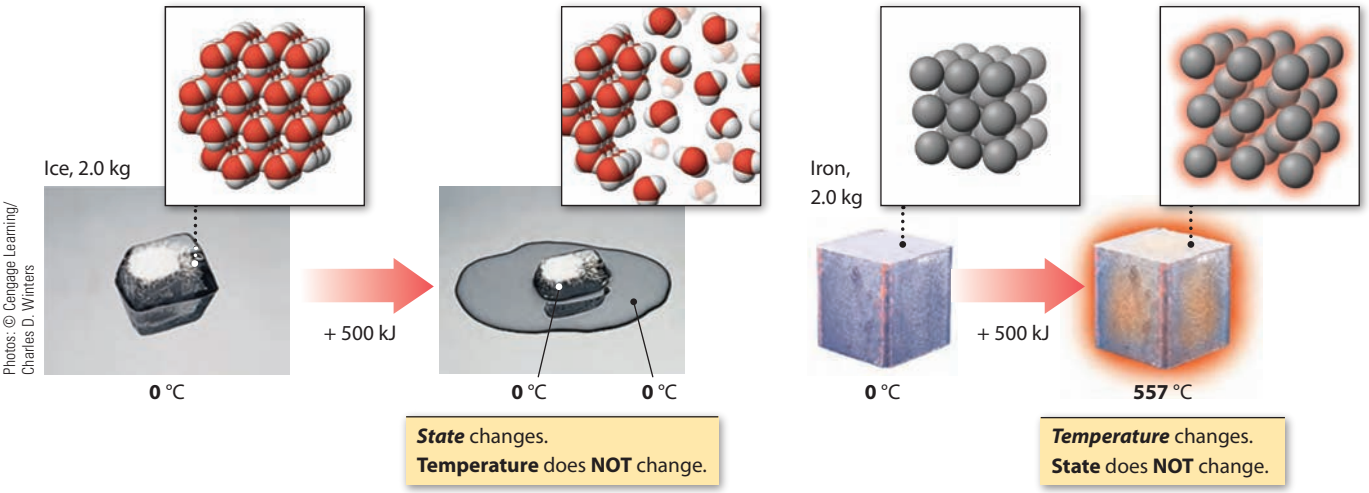
Goal for Section 5.3

- Use heat of fusion and heat of vaporization to calculate the energy transferred as heat in changes of state.

A *change of state* refers to changes between the three states of matter: solid, liquid, and gas. When a solid melts, its atoms, molecules, or ions move about vigorously enough to break free of the attractive forces holding them in rigid positions in the solid lattice. When a liquid boils, the particles move much farther apart from one another, to distances at which attractive forces are minimal. In both cases, energy must be furnished to overcome attractive forces among the particles.

The energy transferred as heat that is required to convert a substance from a solid at its melting point to a liquid is called the **heat of fusion**. The energy transferred as heat to convert a liquid at its boiling point to a vapor is called the **heat of vaporization**. Values for a few common substances are given in Appendix D (Table 12).

Temperature Dependence of the Heat of Vaporization The heat of vaporization of a substance is dependent on temperature. For example, the heat of vaporization of water at 25 °C is 2442 J/g. This value is slightly larger than the value at 100 °C (2256 J/g).



It is important to recognize that *temperature is constant throughout a change of state* (Figures 5.6). During a change of state, the added energy is used to overcome the forces holding one molecule to another, not to increase the temperature.

For water, the heat of fusion at 0 °C is 333 J/g, and the heat of vaporization at 100 °C is 2256 J/g. These values can be used to calculate the energy required for a given mass of water to melt or evaporate, respectively. For example, the energy required to convert 500. g of water from the liquid to gaseous state at 100 °C is

$$(2256\ J/g)(500.\ g) = 1.13 \times 10^6\ J\ (= 1130\ kJ)$$

Transferring 500 kJ of energy as heat to 2.0 kg of ice at 0 °C will cause 1.5 kg of ice to melt to water at 0 °C (and 0.5 kg of ice will remain). No temperature change occurs.

In contrast, transferring 500 kJ of energy as heat to 2.0 kg of iron at 0 °C will cause the temperature to increase to 557 °C (and the metal to expand slightly but not melt).

Figure 5.6 **Contrast between a change of state and an increase in temperature as a result of adding energy.**

In contrast, to melt the same mass of ice to form liquid water at 0 °C requires only 167 kJ.

$$(333\ \text{J/g})(500.\ \text{g}) = 1.67 \times 10^5\ \text{J}\ (= 167\ \text{kJ})$$

Figure 5.7 gives a profile of the energy changes occurring as 500. g of ice at −50 °C is converted to water vapor at 200 °C. This involves a series of steps: (1) warming ice to 0 °C, (2) conversion to liquid water at 0 °C, (3) warming liquid water to 100 °C, (4) evaporation at 100 °C, and (5) warming the water vapor to 200 °C. Each step requires the input of energy. The energy transferred as heat to raise the temperature of solid, liquid, and vapor can be calculated with Equation 5.1, using the specific heat capacities of ice, liquid water, and water vapor (which are different), and the energies for the changes of state can be calculated using heats of fusion and vaporization. These calculations are shown in Example 5.3.

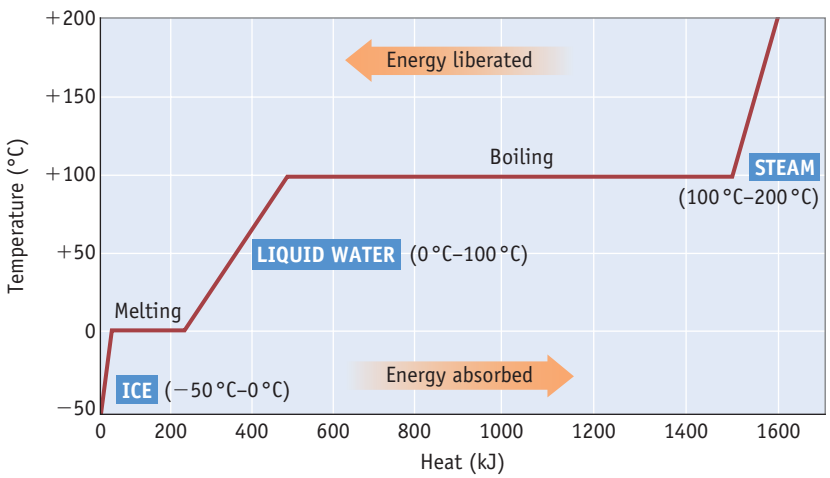

Figure 5.7 **Energy transfer as heat and the temperature change as 500. g of water warms from −50 °C to 200 °C (at 1 atm).**

EXAMPLE 5.3

Energy and Changes of State

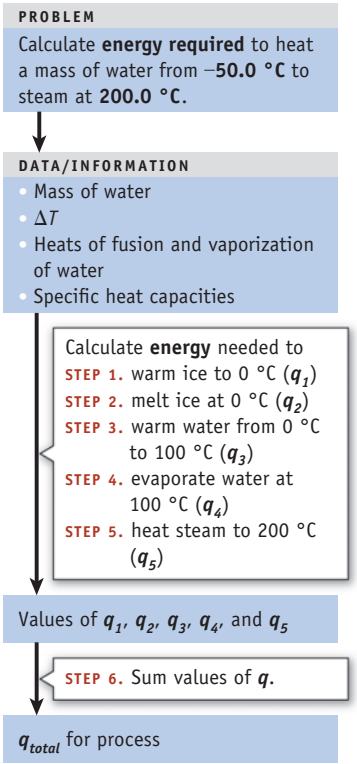
Problem Calculate the energy needed to convert 500. g of ice at −50.0 °C to steam at 200.0 °C (Figure 5.7). The heat of fusion of water is 333 J/g, and the heat of vaporization is 2256 J/g. The specific heat capacities of ice, liquid water, and water vapor are given in Appendix D.

What Do You Know? The overall process of converting ice at −50 °C to steam at 200 °C involves both temperature changes and changes of state; all require input of energy as heat. Recall that melting occurs at 0 °C and boiling at 100 °C (at 1 atm pressure). You know the mass of the water and will need the specific heat capacities of ice, liquid water, and steam from Appendix D. The heat of fusion of water (333 J/g), and the heat of vaporization (2256 J/g) are given.

Strategy The problem is broken down into a series of steps:

Step 1: *Warm the ice from −50 °C to 0 °C.*

Step 2: *Melt the ice at 0 °C.*



Step 3: *Raise the temperature of the liquid water from 0 °C to 100 °C.*

Step 4: *Evaporate the water at 100 °C.*

Step 5: *Raise the temperature of the steam from 100 °C to 200 °C.*

Use Equation 5.1 and the specific heat capacities of solid, liquid, and gaseous water to calculate the energy transferred as heat associated with the temperature changes. Use the heats of fusion and of vaporization to calculate the energy transferred as heat associated with changes of state. The total energy transferred as heat is the sum of the energies of the individual steps.

Strategy Map 5.3

SOLUTION

Step 1. *(to warm ice from −50.0 °C to 0.0 °C)*

$$q_1 = (2.06\ \text{J/g} \cdot \text{K})(500.\ \text{g})(273.2\ \text{K} - 223.2\ \text{K}) = 5.150 \times 10^4\ \text{J}$$

Step 2. *(to melt ice at 0.0 °C)*

$$q_2 = (500.\ \text{g})(333\ \text{J/g}) = 1.665 \times 10^5\ \text{J}$$

Step 3. *(to raise temperature of liquid water from 0.0 °C to 100.0 °C)*

$$q_3 = (4.184\ \text{J/g} \cdot \text{K})(500.\ \text{g})(373.2\ \text{K} - 273.2\ \text{K}) = 2.092 \times 10^5\ \text{J}$$

Step 4. *(to evaporate water at 100.0 °C)*

$$q_4 = (500.\ \text{g})(2256\ \text{J/g}) = 1.128 \times 10^6\ \text{J}$$

Step 5. *(to raise temperature of water vapor from 100.0 °C to 200.0 °C)*

$$q_5 = (1.86\ \text{J/g} \cdot \text{K})(500.\ \text{g})(473.2\ \text{K} - 373.2\ \text{K}) = 9.300 \times 10^4\ \text{J}$$

The total energy transferred as heat is the sum of the energies of the individual steps.

$$q_{\text{total}} = q_1 + q_2 + q_3 + q_4 + q_5$$

$$q_{\text{total}} = 1.65 \times 10^6\ \text{J (or 1650 kJ)}$$

Think about Your Answer The conversion of liquid water to steam is the largest increment of energy by a considerable margin. (You may have noticed that when water is heated at a steady rate on a stove it takes much less time to heat the water to boiling than it takes to boil off the water.)

Check Your Understanding

Calculate the amount of energy necessary to raise the temperature of 1.00 L of ethanol ($d = 0.7849$ g/cm^3) from 25.0 °C to its boiling point (78.3 °C) and then to vaporize the liquid. ($C_{ethanol} = 2.44$ J/g · K; heat of vaporization at 78.3 °C = 38.56 kJ/mol.)

EXAMPLE 5.4

Change of State

Problem What is the minimum mass of ice at 0 °C that must be added to the contents of a can of diet cola (340. mL) to cool the cola from 20.5 °C to 0.0 °C? Assume that the specific heat capacity and density of diet cola are the same as for water.

What Do You Know? The final temperature is 0 °C. Melting ice requires energy as heat, and cooling the cola evolves energy as heat. The sum of the energy changes for the two components in the system is zero; that is, the two energy changes (melting ice, cooling cola) will be the same magnitude but opposite in sign. (You also need to assume there is no transfer of energy between the surroundings and the system.) You will need the density and specific heat capacity of water (Appendix D).

Strategy Assuming only energy changes within the system, $q_{cola} + q_{ice} = 0$. The energy evolved as the cola cools, q_{cola}, is calculated using Equation 5.1. The initial temperature is 20.5 °C and the final temperature is 0 °C. The mass of cola is calculated from the volume and density. The energy as heat required to melt the ice, q_{ice}, is determined from the heat of fusion (333 J/g). The mass of ice is the unknown.

SOLUTION The mass of cola is 340. g [(340. mL)(1.00 g/mL) = 340. g], and its temperature changes from 293.7 K to 273.2 K. The heat of fusion of water is 333 J/g, and the mass of ice is the unknown.

$$q_{cola} + q_{ice} = 0$$

$$C_{cola} \times m_{cola} \times (T_{final} - T_{initial}) + (\text{heat of fusion of water})(m_{ice}) = 0$$

$$[(4.184 \text{ J/g} \cdot \text{K})(340. \text{ g})(273.2 \text{ K} - 293.7 \text{ K})] + [(333 \text{ J/g})(m_{ice})] = 0$$

$$m_{ice} = 87.6 \text{ g}$$

Think about Your Answer If more than 87.6 g of ice is added, the final temperature will still be 0 °C when thermal equilibrium is reached, but some ice will remain (see problem below). If less than 87.6 g of ice is added, the final temperature will be greater than 0 °C. In this case, all the ice will melt, and the liquid water formed by melting the ice will absorb additional energy to warm up to the final temperature (an example is given in Study Question 79, page 268).

Check Your Understanding

To make a glass of iced tea, you pour 250 mL of tea, whose temperature is 18.2 °C, into a glass containing five ice cubes. Each cube has a mass of 15 g. What quantity of ice will melt, and how much ice will remain floating in the tea? Assume iced tea has a density of 1.0 g/mL and a specific heat capacity of 4.2 J/g · K, that energy is transferred only as heat within the system, ice is at 0.0 °C, and no energy is transferred between system and surroundings.

5.4 The First Law of Thermodynamics

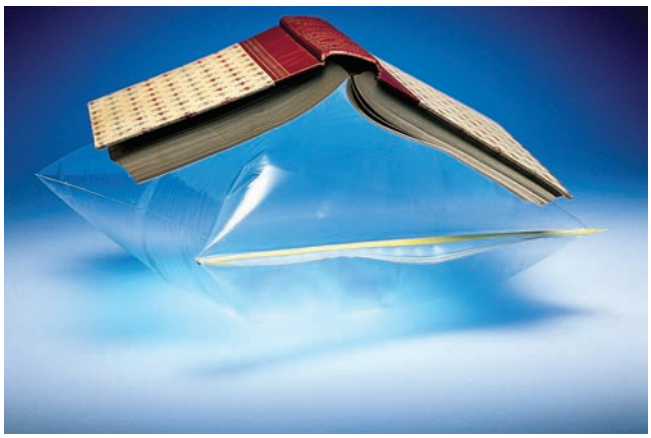
Goals for Section 5.4

- Recognize how energy transferred as heat and work done on or by a system contributes to changes in the internal energy of a system.
- Calculate the work done by a system by the expansion of a gas against a constant pressure.
- Calculate changes in enthalpy and internal energy.
- Recognize state functions whose values are determined only by the state of the system and not by the pathway by which the state was achieved.

Recall that *thermodynamics is the science of heat and work.* To this point, we have only considered energy being transferred as heat, but now we need to broaden the discussion to include work. Work done by a system or on a system will also affect the energy in the system. If a system does work on its surroundings, energy must be expended by the system, and the system's energy will decrease. Conversely, if work is done by the surroundings on a system, the energy of the system will increase.

A system doing work on its surroundings is illustrated in Figure 5.8. A small quantity of dry ice, solid CO_2, is sealed inside a plastic bag, and a weight (a book) is placed on top of the bag. When energy is transferred as heat from the surroundings to the dry ice, the dry ice changes directly from solid to gas at −78 °C in a process called **sublimation**:

$$CO_2(s, -78\ °C) \rightarrow CO_2(g, -78\ °C)$$



As sublimation proceeds, gaseous CO_2 expands within the plastic bag, lifting the book against the force of gravity. The system (the CO_2 inside the bag) is expending energy to do this work.

Even if the book had not been on top of the plastic bag, work would have been done by the expanding gas because the gas must push back the atmosphere when it expands. Instead of raising a book, the expanding gas moves a part of the atmosphere.

Now let us think about this example in terms of thermodynamics. First, we must identify the system and the surroundings. The system is the CO_2, initially a solid and later a gas. The surroundings consist of objects that exchange energy with

(a) Pieces of dry ice [$CO_2(s), -78$ °C] are placed in a plastic bag. The dry ice will sublime (change directly from a solid to a gas) upon the input of energy.

(b) Energy is absorbed by $CO_2(s)$ when it sublimes, and the system (the contents of the bag) does work on its surroundings by lifting the book against the force of gravity.

the system. This includes the plastic bag, the book, the table-top, and the surrounding air. Sublimation requires energy, which is transferred as heat to the system (the CO_2) from the surroundings. At the same time, the system does work on the surroundings by lifting the book. An energy balance for the system will include both quantities, energy transferred as heat and energy transferred as work.

This example can be generalized. For any system, we can identify energy transfers both as heat and as work between the system and surroundings. The change in energy for a system is given explicitly by Equation 5.4,

Change in energy content ↓ $\Delta U = q + w$ ↑ Energy transferred as heat to or from the system

Energy transferred as work to or from the system ↓

(5.4)

which is a mathematical statement of the **first law of thermodynamics**: The energy change for a system (ΔU) is the sum of the energy transferred as heat (q) between the system and its surroundings and the energy transferred as work (w) between the system and its surroundings.

The equation defining the first law of thermodynamics is just a restatement of the general principle of conservation of energy. Because energy is conserved, we must be able to account for any change in the energy of the system. All energy transfers between a system and its surroundings occur by the processes of heat and work. Equation 5.4 thus states that the change in the energy of the system is exactly equal to the sum of the energy transfers (heat and/or work) from or to the surroundings.

The quantity U in Equation 5.4 has a formal name—**internal energy**. The internal energy in a chemical system is the sum of the potential and kinetic energies inside the system, that is, the energies of the atoms, molecules, or ions in the system. The potential energy here is the energy associated with the attractive and repulsive forces between all the nuclei and electrons in the system. It includes the energy associated with bonds in molecules, forces between ions, and forces between molecules. The kinetic energy is the energy of motion of the atoms, ions, and molecules in the system. Actual values of internal energy are rarely determined or needed. Instead, in most instances, we are interested in the *change* in internal energy, a measurable quantity. In fact, Equation 5.4 tells us how to determine ΔU: *Measure the energy transferred as heat and work to or from the system.*

The sign conventions for Equation 5.4 are important and are outlined in the following table.

Sign Conventions for *q* and *w* of the System

Energy transferred as . . .	Sign Convention	Effect On U_{system}
Heat to the system (endothermic)	$q > 0$ (+)	U increases
Heat from the system (exothermic)	$q < 0$ (−)	U decreases
Work done on system	$w > 0$ (+)	U increases
Work done by system	$w < 0$ (−)	U decreases

The work in the example involving the sublimation of CO_2 (Figure 5.8) is of a specific type, called P–V (pressure–volume) work. It is the work (w) associated with a change in volume (ΔV) that occurs against a resisting external pressure (P). For a

A CLOSER LOOK

P–V Work

The example of a gas sealed in a cylinder with a movable piston can be used to understand the work done by a system on its surroundings (or vice versa) when the volume of a system changes. If the gas in the cylinder is heated, it expands, pushing the piston upward until the internal gas pressure equals the (constant) downward external pressure applied by the piston and the atmosphere (see figure). Ideally, the piston moves without friction, so that none of the work done by an expanding gas is lost to heating the cylinder walls.

The work required to move the piston is calculated from a law of physics, $w = F \times d$, that is, work equals the magnitude of the force (F) applied times the distance (d) over which the force is applied. Pressure is defined as a force divided by the area over which the force is applied: $P = F/A$, where the force is a function of the piston's mass, the external air pressure, and the Earth's gravity. In this example, the force is applied to a piston with an area A. Substituting $P \times A$ for F in the equation for work gives $w = (P \times A) \times d$. The product of $A \times d$ is equal to the change in the volume of the gas in the cylinder, and, because $\Delta V = V_{final} - V_{initial}$, this change in volume is positive. Finally, because work done by a system on the surroundings is defined as negative, this means that $w = -P\Delta V$. Expanding the gas and moving the piston upward means the system has done work on the surroundings.

This equation applies specifically to expansion of a gas against a constant pressure. For processes in which the pressure is not constant (for example, compression of the gas in a cylinder) calculation of P-V work is more complicated, though possible.

system in which the external pressure is constant, the value of P–V work can be calculated using Equation 5.5,

$$w = -P \times \Delta V \qquad (5.5)$$

(Work (at constant pressure); Change in volume; Pressure)

Calculating Work The SI unit of pressure is the pascal (1 Pa = 1 kg/m · s^2), which when multiplied by the volume change in m^3, gives work in joules (1 J = 1 kg · m^2/s^2).

To calculate this work in units of joules, the pressure is measured in pascals (1 Pa = 1 kg/m · s^2) and the volume change is measured in cubic meters (m^3).

In a constant-volume process, $\Delta V = 0$. This means the energy transferred as work will also be zero. Thus, the change in internal energy of the system under constant-volume conditions is equal only to the energy transferred as heat (q_v).

$$\Delta U = q_v + w_v$$

$$\Delta U = q_v + 0 \text{ when } w_v = 0 \text{ because } \Delta V = 0$$

$$\text{and so } \Delta U = q_v$$

Enthalpy

Most experiments in a chemical laboratory are carried out in beakers or flasks open to the atmosphere, where the external pressure is constant. Similarly, chemical processes that occur in living systems are open to the atmosphere. Because so many processes in chemistry and biology are carried out under conditions of constant pressure, it is useful to have a specific measure of the energy transferred as heat under this circumstance.

Under conditions of constant pressure,

$$\Delta U = q_p + w_p$$

where the subscript p indicates conditions of constant pressure. If the only type of work that occurs is P–V work, then

$$\Delta U = q_p - P\Delta V$$

Rearranging this gives

$$q_p = \Delta U + P\Delta V$$

We now introduce a new thermodynamic function called **enthalpy**, H, which is defined as

$$H = U + PV$$

The *change* in enthalpy for a system at constant pressure would be calculated from the following equation:

$$\Delta H = \Delta U + P\Delta V$$

Energy Transferred as Heat
Processes at constant V:
$\Delta U = q_v$
Processes at constant P:
$\Delta H = q_p$

Thus,

$$\Delta H = q_p$$

For a system where the only type of work possible is P–V work, the change in enthalpy, ΔH, is equal to the energy transferred as heat at constant pressure, q_p. The directionality of energy transfer (under conditions of constant pressure) is indicated by the sign of ΔH.

- Negative values of ΔH: energy is transferred as heat from the system to the surroundings (exothermic process).
- Positive values of ΔH: energy is transferred as heat from the surroundings to the system (endothermic process).

Under conditions of constant pressure and where the only type of work possible is P–V work, ΔU ($= q_p - P\Delta V$) and ΔH ($= q_p$) differ by $P\Delta V$ (the energy transferred to or from the system as work). We observe that in many processes—such as the melting of ice—the volume change, ΔV, is small, and hence the amount of energy transferred as work is small. Under these circumstances, ΔU and ΔH have almost the same value. The amount of energy transferred as work will be significant, however, when the volume change is large, as when gases are formed or consumed. Thus, ΔU and ΔH have significantly different values for processes such as the evaporation or condensation of water, the sublimation of CO_2, and chemical reactions in which the number of moles of gas changes.

Enthalpy and Internal Energy Differences The difference between ΔH and ΔU will be quite small unless a large volume change occurs. For example, the difference between ΔH and ΔU for the conversion of ice to liquid water is 0.142 J/mol at 1 atm pressure. For the conversion of liquid water to water vapor at 373 K (and 1 atm pressure), the difference is 3100 J/mol.

EXAMPLE 5.5

Energy and Work

Problem Nitrogen gas (1.50 L) is confined in a cylinder under constant atmospheric pressure (1.01×10^5 pascals). The gas expands to a volume of 2.18 L when 882 J of energy is transferred as heat from the surroundings to the gas. What is the change in internal energy of the gas?

What Do You Know? Energy as heat (882 J) is transferred at constant pressure into the system; thus, $q_p = +882$ J. The system does work on the surroundings when the gas expands from 1.50 L to 2.18 L under a constant pressure of 1.01×10^5 pascals, thereby transferring some energy back to the surroundings.

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Strategy Calculate the work done by the system using $w_p = -P(\Delta V)$. The unit of work is joules, provided that SI units are used for pressure and volume. The pressure is given in SI units (pascals, Pa, where 1 Pa = 1 kg/(m · s^2). To calculate work, the volume must be converted to m^3 (1 m^3 = 1000 L). The change in internal energy of the gas is the sum of the enthalpy change of the gas and the work done by the gas on the surroundings ($\Delta U = q_p + w_p$).

SOLUTION The change in volume of the gas is

$$(2.18\ \text{L} - 1.50\ \text{L N}_2\ \text{gas})(1\ \text{m}^3/1000\ \text{L}) = 6.8 \times 10^{-4}\ \text{m}^3$$

The work done by the system is

$$w_p = -P(\Delta V) = -(1.01 \times 10^5\ \text{kg/m} \cdot \text{s}^2)(6.8 \times 10^{-4}\ \text{m}^3)$$
$$= -68.7\ \text{kg} \cdot \text{m}^2/\text{s}^2 = -68.7\ \text{J}$$

Finally, the change in internal energy is calculated.

$$\Delta U = q_p + w_p = 882\ \text{J} + (-68.7\ \text{J}) = 813\ \text{J}$$

Think about Your Answer The internal energy of a gas increases upon heating. However, the gas does work on the surroundings as it expands against pressure, giving some of its energy to the surroundings.

Check Your Understanding

Nitrogen gas (2.75 L) is confined in a cylinder under constant atmospheric pressure (1.01 × 10^5 pascals). The volume of gas decreases to 2.10 L when 485 J of energy is transferred as heat to the surroundings. What is the change in internal energy of the gas?

Vixit/Shutterstock.com

Figure 5.9 State functions. There are many ways to climb a mountain, but the change in altitude from the base of the mountain to its summit is the same. The change in altitude is a state function. The distance traveled to reach the summit is not.

State Functions

Internal energy and enthalpy share a significant characteristic—namely, changes in these quantities depend only on the initial and final states. They do not depend on the path taken on going from the initial state to the final state. No matter how you go from reactants to products in a reaction the values of ΔH and ΔU are always the same. A quantity that has this property is called a **state function**.

Many commonly measured quantities, such as the pressure of a gas, the volume of a gas or liquid, and the temperature of a substance are state functions. For example, if the final temperature of a substance is 75 °C and its initial temperature was 25 °C, the change in temperature, ΔT, is calculated as $T_{\text{final}} - T_{\text{initial}} = 75\ ^\circ\text{C} - 25\ ^\circ\text{C} = 50\ ^\circ\text{C}$. It does not matter if the substance was heated directly from 25 °C to 75 °C or if the substance was heated from 25 °C to 95 °C and then cooled to 75 °C; the overall change in temperature is still the same, 50 °C.

Not all quantities are state functions; some depend on the pathway taken to get from the initial condition to the final condition. For instance, distance traveled is not a state function (Figure 5.9). The travel distance from New York City to Denver depends on the route taken. Nor is the elapsed time of travel between these two locations a state function. In contrast, a change in altitude is a state function; in going from New York City (at sea level) to Denver (1600 m above sea level), there is an altitude change of 1600 m, regardless of the route followed.

Significantly, in the expansion of a gas, neither the energy transferred as heat nor the energy transferred as work individually is a state function. However, their sum, the change in internal energy, ΔU, is. The value of ΔU is fixed by U_{initial} and U_{final}. A transition between the initial and final states can be accomplished by different routes having different values of q and w, but the sum of q and w for each path must always give the same ΔU.

5.5 Enthalpy Changes for Chemical Reactions

Goal for Section 5.5

- Understand and use the enthalpy change for the conversion of reactants to products in their standard states, $\Delta_r H°$.

Enthalpy changes accompany chemical reactions. For example, the **standard reaction enthalpy**, $\Delta_r H°$, for the decomposition of water vapor to hydrogen and oxygen at 25 °C is +241.8 kJ/mol-rxn.

$$H_2O(g) \rightarrow H_2(g) + \tfrac{1}{2}\, O_2(g) \qquad \Delta_r H° = +241.8 \text{ kJ/mol-rxn}$$

The positive sign of $\Delta_r H°$ indicates that the decomposition is an endothermic process. There are several important things to know about $\Delta_r H°$.

- The designation of $\Delta_r H°$ as a "standard enthalpy change" (where the superscript ° indicates standard conditions) means that the pure, unmixed reactants in their standard states have formed pure, unmixed products in their standard states. The **standard state** of an element or a compound is defined as the most stable form of the substance in the physical state that exists at a pressure of 1 bar and at a specified temperature. [Most sources report standard reaction enthalpies at 25 °C (298 K).]
- The "per mol-rxn" designation in the units for $\Delta_r H°$ means this is the enthalpy change for a "mole of reaction" (where *rxn* is an abbreviation for reaction). One mole of reaction is said to have occurred when a chemical reaction occurs exactly in the amounts specified by the coefficients of the balanced chemical equation. For example, for the reaction $H_2O(g) \rightarrow H_2(g) + 1/2\ O_2(g)$, a mole of reaction has occurred when 1 mol of water vapor has been converted completely to 1 mol of H_2 and 1/2 mol of O_2 gas.

Notation for Thermodynamic Parameters NIST and IUPAC (International Union of Pure and Applied Chemistry) specify that descriptors of functions such as ΔH should be written as a subscript, between the Δ and the thermodynamic function. Among the subscripts you will see are a lowercase r for "reaction," f for "formation," c for "combustion," fus for "fusion," and vap for "vaporization."

Now consider the opposite reaction, the combination of hydrogen and oxygen to form 1 mol of water. The magnitude of the enthalpy change for this reaction is the same as that for the decomposition reaction, but the sign of $\Delta_r H°$ is reversed. The exothermic formation of 1 mol of water vapor from 1 mol of H_2 and 1/2 mol of O_2 transfers 241.8 kJ to the surroundings (Figure 5.10).

$$H_2(g) + \tfrac{1}{2}\, O_2(g) \rightarrow H_2O(g) \qquad \Delta_r H° = -241.8 \text{ kJ/mol-rxn}$$

Moles of Reaction, Mol-rxn This concept was also described in one of the methods shown for solving limiting reactant problems on page 181.

The value of $\Delta_r H°$ depends on the chemical equation used. Let us write the equation for the formation of water again but without a fractional coefficient for O_2.

$$2\ H_2(g) + O_2(g) \rightarrow 2\ H_2O(g) \qquad \Delta_r H° = -483.6 \text{ kJ/mol-rxn}$$

The value of $\Delta_r H°$ for 1 mol of this reaction, the formation of 2 mol of water, is *twice* the value for the formation of 1 mol of water.

Fractional Stoichiometric Coefficients When writing balanced equations to define thermodynamic quantities, chemists often use fractional stoichiometric coefficients. For example, to define $\Delta_r H$ for the decomposition or formation of 1 mol of H_2O, the coefficient for O_2 must be 1/2.

It is important to identify the states of reactants and products in a reaction because the magnitude of $\Delta_r H°$ depends on whether they are solids, liquids, or gases. For the formation of 1 mol of *liquid water* from the elements, the enthalpy change is −285.8 kJ.

$$H_2(g) + \tfrac{1}{2}\, O_2(g) \rightarrow H_2O(\ell) \qquad \Delta_r H° = -285.8 \text{ kJ/mol-rxn}$$

Notice that this value is not the same as $\Delta_r H°$ for the formation of 1 mol of *water vapor* from hydrogen and oxygen. The difference between the two values is equal to the enthalpy change for the condensation of 1 mol of water vapor to 1 mol of liquid water.

These examples illustrate several general features of enthalpy changes for chemical reactions.

- Enthalpy changes are specific to the reaction being carried out. The identities of reactants and products and their states (s, ℓ, g) are important, as are the amounts of reactants and products.
- The enthalpy change depends on the number of moles of reaction, that is, the number of times the reaction *as written* is carried out.

Changes in Chemical Energy in a Chemical Reaction

- If a reaction is exothermic, the potential energy of the reactants is *greater* than that of the products ($PE_{react} > PE_{prod}$).
- If a reaction is endothermic, the potential energy of the reactants is *less* than that of the products ($PE_{react} < PE_{prod}$).

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

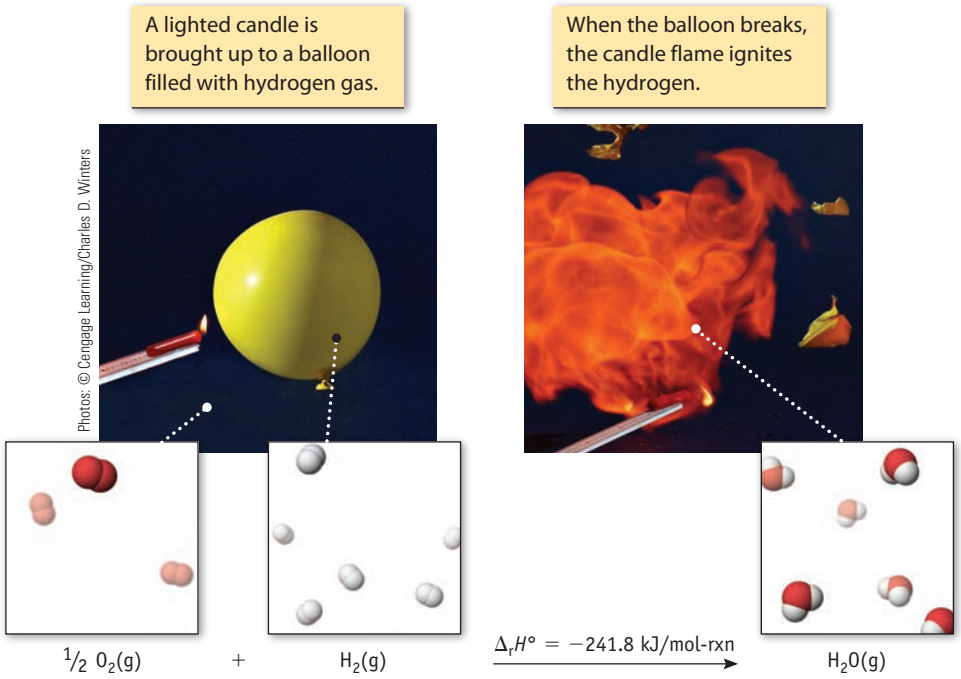

Figure 5.10 The exothermic combustion of hydrogen. The reaction involves the transfer of energy between the system and surroundings in the form of heat, work, and light.

- $\Delta_r H°$ has a negative value for an exothermic reaction; it has a positive value for an endothermic reaction.
- Values of $\Delta_r H°$ are numerically the same, but opposite in sign, for chemical reactions that are the reverse of each other.

Standard reaction enthalpies can be used to calculate the energy transferred as heat under conditions of constant pressure for any given mass of a reactant or product. Suppose you want to know the energy transferred to the surroundings as heat if 454 g of propane, C_3H_8, is burned (at constant pressure), given the equation for the exothermic combustion and the enthalpy change for the reaction.

$$C_3H_8(g) + 5\ O_2(g) \rightarrow 3\ CO_2\ (g) + 4\ H_2O(\ell) \qquad \Delta_r H° = -2220\ \text{kJ/mol-rxn}$$

Two steps are needed. First, find the amount of propane present in the sample:

$$454\ \text{g}\ C_3H_8 \left(\frac{1\ \text{mol}\ C_3H_8}{44.10\ \text{g}\ C_3H_8} \right) = 10.29\ \text{mol}\ C_3H_8$$

Second, use $\Delta_r H°$ to determine $\Delta H°$ for this amount of propane:

$$\Delta H° = 10.29\ \text{mol}\ CH_8 \left(\frac{1\ \text{mol-rxn}}{1\ \text{mol}\ C_3H_8} \right) \left(\frac{-2220\ \text{kJ}}{1\ \text{mol-rxn}} \right) = -22{,}900\ \text{kJ}$$

EXAMPLE 5.6

Calculating the Enthalpy Change for a Reaction

Problem Sucrose (table sugar, $C_{12}H_{22}O_{11}$) can be oxidized to CO_2 and H_2O, and the enthalpy change for the reaction can be measured.

$$C_{12}H_{22}O_{11}(s) + 12\ O_2(g) \rightarrow 12\ CO_2(g) + 11\ H_2O(\ell) \qquad \Delta_r H° = -5645\ \text{kJ/mol-rxn}$$

What is the enthalpy change when 5.00 g of sugar is burned under conditions of constant pressure?

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

What Do You Know? The balanced equation for the combustion and the value of $\Delta_r H°$ are given. Also, the mass of sugar is given.

Strategy First determine the amount (mol) of sucrose in 5.00 g, and then use this with the value given for the enthalpy change for the oxidation of 1 mol of sucrose.

SOLUTION

$$5.00\ \text{g sucrose} \times \frac{1\ \text{mol sucrose}}{342.3\ \text{g sucrose}} = 1.461 \times 10^{-2}\ \text{mol sucrose}$$

$$\Delta H° = 1.461 \times 10^{-2}\ \text{mol sucrose} \left(\frac{1\ \text{mol-rxn}}{1\ \text{mol sucrose}} \right) \left(\frac{-5645\ \text{kJ}}{1\ \text{mol-rxn}} \right)$$

$$\Delta H° = -82.5\ \text{kJ}$$

Think about Your Answer The calculated value is negative, as expected for a combustion reaction. The magnitude of $\Delta H°$ agrees with the fact that the mass of sucrose used, 5.00 g, is significantly less than the mass of one mole of sucrose (342.3 g).

Check Your Understanding

The combustion of ethane, C_2H_6, has an enthalpy change of -2857.3 kJ for the reaction as written below. Calculate $\Delta H°$ for the combustion of 15.0 g of C_2H_6.

$$2\ C_2H_6(g) + 7\ O_2(g) \rightarrow 4\ CO_2(g) + 6\ H_2O(g) \qquad \Delta_r H° = -2857.3\ \text{kJ/mol-rxn}$$

Burning Sugar and Gummi Bears

A person on a diet might note that a (level) teaspoonful of sugar (about 3.5 g) supplies about 15 Calories (dietary Calories; the conversion is 4.184 kJ = 1 Cal). As diets go, a single spoonful of sugar doesn't have a large caloric content. But will you use just one level teaspoonful? Or just one Gummi Bear?

© Cengage Learning/Charles D. Winters

5.6 Calorimetry

Goal for Section 5.6

- Describe how to measure and calculate the quantity of energy transferred as heat in a reaction by calorimetry.

The energy evolved or absorbed as heat in a chemical or physical process can be measured by **calorimetry**. The apparatus used in this kind of experiment is a *calorimeter*.

Constant-Pressure Calorimetry, Measuring ΔH

A constant-pressure calorimeter can be used to measure the amount of energy transferred as heat under constant-pressure conditions, that is, the enthalpy change for a chemical reaction.

The constant-pressure calorimeter used in general chemistry laboratories is often a "coffee-cup calorimeter." This inexpensive device consists of two nested Styrofoam coffee cups with a loose-fitting lid and a thermometer (Figure 5.11) or thermocouple. Styrofoam, a fairly good insulator, minimizes energy transfer as heat between the system and the surroundings. The reaction is carried out in solution in the cup. If the reaction is exothermic, it releases energy as heat to the solution, and the temperature of the solution rises. If the reaction is endothermic, energy is absorbed as heat from the solution, and a decrease in the temperature of the solution will be seen. The change in temperature of the solution is measured. Knowing the mass and specific heat capacity of the solution and the temperature change, the enthalpy change for the reaction can be calculated.

In this type of calorimetry experiment, it is convenient to define the chemicals and the solution as the system. The surroundings are the cup and everything beyond the cup. As noted above, we assume there is no energy transfer to the cup or beyond and that energy is transferred only as heat within the system. Two energy changes occur within the system. One is the change that takes place as the chemical reaction occurs, either releasing the potential energy stored in the reactants or absorbing

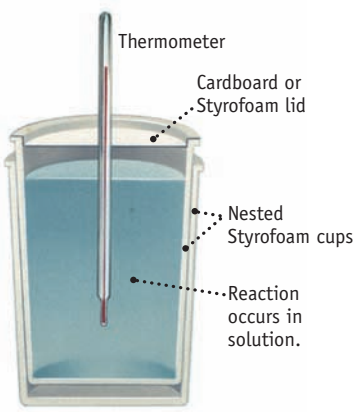

Figure 5.11 A coffee-cup calorimeter. A chemical reaction produces a change in temperature of the solution in the calorimeter. The Styrofoam container is fairly effective in preventing the transfer of energy as heat between the solution and its surroundings. Because the cup is open to the atmosphere, this is a constant-pressure measurement.

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

energy and converting it to potential energy stored in the products. We label this energy as q_r. The other energy change is the energy gained or lost as heat by the solution ($q_{solution}$). Based on the law of conservation of energy,

$$q_r + q_{solution} = 0$$

The value of $q_{solution}$ can be calculated from the specific heat capacity, mass, and change in temperature of the solution. The quantity of energy evolved or absorbed as heat for the reaction (q_r) is the unknown in the equation.

The accuracy of a calorimetry experiment depends on the accuracy of the measured quantities (temperature, mass, specific heat capacity). In addition, it depends on how closely the assumption is followed that there is no energy transfer beyond the solution. A coffee-cup calorimeter is a simple apparatus, and the results obtained with it are not highly accurate, largely because this assumption is poorly met. In research laboratories, calorimeters are used that more effectively limit the energy transfer between system and surroundings. In addition, it is also possible to correct for the minimal energy transfer that does occur between the system and the surroundings.

EXAMPLE 5.7

Using a Coffee-Cup Calorimeter

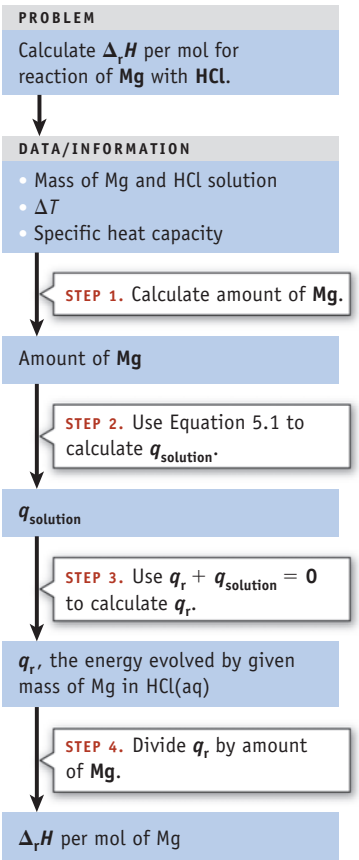
Problem You place 0.0500 g of magnesium chips in a coffee-cup calorimeter and then add 100.0 mL of 1.00 M HCl. The reaction that occurs is

$$Mg(s) + 2\ HCl(aq) \rightarrow H_2(g) + MgCl_2(aq)$$

The temperature of the solution increases from 22.21 °C (295.36 K) to 24.46 °C (297.61 K). What is the enthalpy change for the reaction per mole of Mg? Assume that the specific heat capacity of the solution is 4.20 J/g · K, the density of the HCl solution is 1.00 g/mL, and that no energy as heat is lost to the surroundings.

What Do You Know? You know that energy is evolved as heat in this reaction because the temperature of the solution rises. The sum of the energy evolved as heat in the reaction, q_r, and the energy absorbed as heat by the solution, $q_{solution}$, will be zero, that is, $q_r + q_{solution} = 0$. The value of $q_{solution}$ can be calculated from data given; q_r is the unknown.

Strategy Solving the problem has four steps.



Step 1: *Calculate the amount of magnesium.*

Step 2: *Calculate $q_{solution}$ from the values of the mass, specific heat capacity, and ΔT using Equation 5.1.*

Step 3: *Calculate q_r, assuming no energy transfer as heat occurs beyond the solution, that is, $q_r + q_{solution} = 0$.*

Step 4: *Use the value of q_r and the amount of Mg to calculate the enthalpy change per mole of Mg.*

Strategy Map 5.7

SOLUTION

Step 1. *Calculate the amount of Mg.*

$$0.0500\ g\ Mg \times \frac{1\ mol\ Mg}{24.31\ g\ Mg} = 0.002057\ mol\ Mg$$

Step 2. *Calculate $q_{solution}$. The mass of the solution is the mass of the 100.0 mL of HCl plus the mass of magnesium.*

$$q_{solution} = (100.0\ g\ HCl\ solution + 0.0500\ g\ Mg)(4.20\ J/g \cdot K)(297.61\ K - 295.36\ K)$$
$$= 945.5\ J$$

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Step 3. *Calculate q_r.*

$$q_r + q_{solution} = 0$$

$$q_r + 945.5\ \text{J} = 0$$

$$q_r = -945.5\ \text{J}$$

Step 4. *Calculate the value of $\Delta_r H$ per mole of Mg. The value of q_r found in Step 2 resulted from the reaction of 0.002057 mol of Mg. The enthalpy change per mole of Mg is therefore*

$$\Delta_r H = (-945.5\ \text{J}/0.002057\ \text{mol Mg})$$

$$= -4.60 \times 10^5\ \text{J/mol Mg}\ (= -4.60 \times 10^2\ \text{kJ/mol Mg})$$

Think about Your Answer The calculation gives the correct sign of q_r and $\Delta_r H$. The negative sign indicates that this is an exothermic reaction. The balanced equation states that one mole of magnesium is involved in one mole of reaction. The calculated enthalpy change per mole of reaction, $\Delta_r H$, is therefore −460. kJ/mol-rxn.

Check Your Understanding

Assume 200. mL of 0.400 M HCl is mixed with 200. mL of 0.400 M NaOH in a coffee-cup calorimeter. The temperature of the solutions before mixing was 25.10 °C; after mixing and allowing the reaction to occur, the temperature is 27.78 °C. What is the enthalpy change when one mole of acid is neutralized? (Assume that the densities of all solutions are 1.00 g/mL and their specific heat capacities are 4.20 J/g · K.)

Constant-Volume Calorimetry, Measuring ΔU

Constant-volume calorimetry is often used to evaluate the energy released by the combustion of fuels and the caloric value of foods. A weighed sample of a combustible solid or liquid is placed inside a "bomb," often a cylinder about the size of a large fruit juice can with thick steel walls and ends (Figure 5.12). The bomb is placed in a water-filled container with well-insulated walls. After filling the bomb with pure oxygen, the sample is ignited, usually by an electric spark. The heat

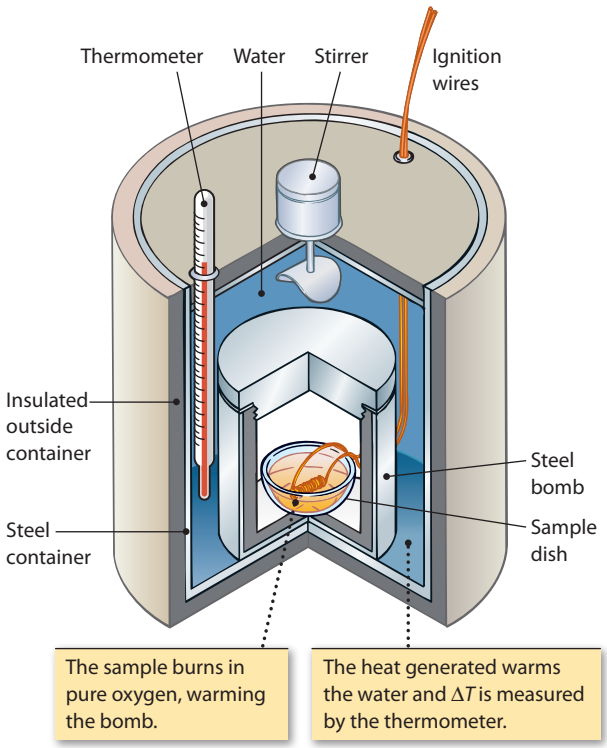


Figure 5.12 Constant-volume calorimeter. A combustible sample is burned in pure oxygen in a sealed metal container or "bomb," that is inside a water-filled container. Energy transferred as heat from the reaction warms the bomb and the water surrounding it. By measuring the increase in temperature, the energy transferred as heat in the reaction can be determined.

Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Calorimetry, ΔU, and ΔH The two types of calorimetry (constant volume and constant pressure) highlight the differences between enthalpy and internal energy. The energy transferred as heat at constant pressure, q_p, is, by definition, ΔH, whereas the energy transferred as heat at constant volume, q_v, is ΔU.

generated by the combustion reaction warms the system. The bomb, its contents, and the water are defined as the system. Assessment of energy transfers as heat within the system shows that

$$q_r + q_{bomb} + q_{water} = 0$$

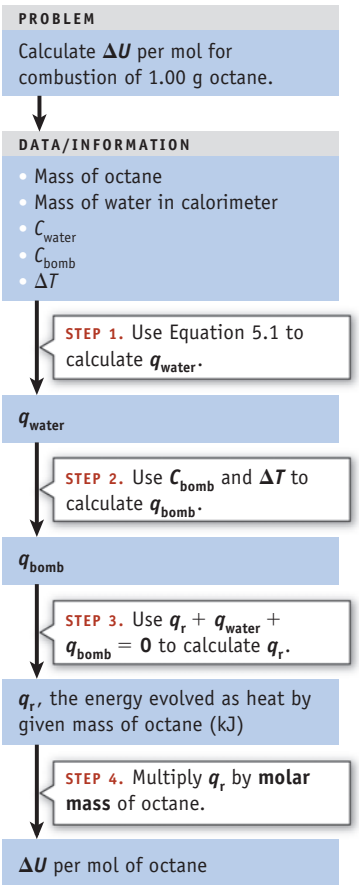
where q_r is the energy released as heat by the reaction, q_{bomb} is the energy involved in heating the calorimeter bomb, and q_{water} is the energy involved in heating the water in the calorimeter. Because the volume does not change in a constant-volume calorimeter, energy transfer as work does not occur. Therefore, the energy transferred as heat at constant volume (q_v) is equal to the change in internal energy, ΔU.

EXAMPLE 5.8

Constant-Volume Calorimetry

Problem Octane, C_8H_{18}, a primary constituent of gasoline, burns in air:

$$C_8H_{18}(\ell) + 25/2\ O_2(g) \rightarrow 8\ CO_2(g) + 9\ H_2O(\ell)$$



A 1.00-g sample of octane is burned in a constant-volume calorimeter similar to that shown in Figure 5.12. The calorimeter is in an insulated container with 1.20 kg of water. The temperature of the water and the bomb rises from 25.00 °C (298.15 K) to 33.20 °C (306.35 K). The heat required to raise the bomb's temperature (its heat capacity), C_{bomb}, is 837 J/K. (a) What is the heat of combustion per gram of octane? (b) What is the heat of combustion per mole of octane?

What Do You Know? There are energy changes for the three components of this system: the energy evolved in the reaction, q_r; the energy absorbed by the water, q_{water}; and the energy absorbed by the calorimeter, q_{bomb}. You know the following: the molar mass of octane, masses of the sample and the calorimeter water, $T_{initial}$, T_{final}, C_{bomb}, and C_{water}. You can assume no energy loss to the surroundings.

Strategy

- The sum of all the energies transferred as heat in the system $= q_r + q_{bomb} + q_{water} = 0$. The first term, q_r, is the unknown. The second and third terms in the equation can be calculated from the data given: q_{bomb} is calculated from the bomb's heat capacity and ΔT, and q_{water} is determined from the specific heat capacity, mass, and ΔT for water.
- The value of q_r is the energy evolved in the combustion of 1.00 g of octane. Use this and the molar mass of octane (114.2 g/mol) to calculate the energy evolved as heat per mole of octane.

Strategy Map 5.8

SOLUTION

(a) $q_{water} = C_{water} \times m_{water} \times \Delta T = (4.184\ J/g \cdot K)(1.20 \times 10^3\ g)(306.35\ K - 298.15\ K)$
$= +4.117 \times 10^4\ J$

$q_{bomb} = (C_{bomb})\ (\Delta T) = (837\ J/K)(306.35\ K - 298.15\ K) = 6.863 \times 10^3\ J$

$q_r + q_{water} + q_{bomb} = 0$

$q_r + 4.117 \times 10^4\ J + 6.863 \times 10^3\ J = 0$

$q_r = -4.803 \times 10^4\ J$ (or -48.03 kJ)

Heat of combustion per gram $= -48.0$ kJ

(b) Heat of combustion per mole of octane $= (-48.03\ kJ/g)(114.2\ g/mol)$
$= -5.49 \times 10^3\ kJ/mol$

Think about Your Answer Because the volume does not change, no energy transfer in the form of work occurs. The change of internal energy, $\Delta_r U$, for the combustion of $C_8H_{18}(\ell)$ is -5.49×10^3 kJ/mol. Also note that C_{bomb} has no mass units. It is the energy as heat required to warm the particular bomb used in this experiment by 1 kelvin.

Check Your Understanding

A 1.00-g sample of ordinary table sugar (sucrose, $C_{12}H_{22}O_{11}$) is burned in a bomb calorimeter. The temperature of 1.50×10^3 g of water in the calorimeter rises from 25.00 °C to 27.32 °C. The heat capacity of the bomb is 837 J/K, and the specific heat capacity of the water is 4.20 J/g · K. Calculate (a) the heat evolved per gram of sucrose and (b) the heat evolved per mole of sucrose.

5.7 Enthalpy Calculations

Goals for Section 5.7

- Apply Hess's law to find the enthalpy change, $\Delta_r H°$, for a reaction.
- Know how to draw and interpret energy level diagrams.
- Use standard molar enthalpies of formation, $\Delta_f H°$, to calculate the enthalpy change for a reaction, $\Delta_r H°$.

Enthalpy changes for an enormous number of chemical and physical processes are available on the World Wide Web and in reference books. This section outlines how to use these data.

Hess's Law

The enthalpy change for a reaction can be measured by calorimetry for many, but not all, chemical processes. Consider, for example, the oxidation of carbon to form carbon monoxide.

$$C(s) + {}^1/_2\, O_2(g) \rightarrow CO(g)$$

The primary product of the reaction is CO_2 and not CO, even if a deficiency of oxygen is used. As soon as CO is formed, it will react with O_2 to form CO_2. It is not possible to measure the change in enthalpy for this reaction by calorimetry because the reaction cannot be carried out in a way that allows CO to be the sole product.

The enthalpy change for the reaction forming CO(g) from C(s) and O_2(g) can be determined indirectly, however, from enthalpy changes for other reactions for which values of $\Delta_r H°$ can be measured. The calculation is based on **Hess's law**, which states that *if a reaction is the sum of two or more other reactions, $\Delta_r H°$ for the overall process is the sum of the $\Delta_r H°$ values of those reactions.*

The oxidation of C(s) to CO(g) can be determined indirectly from thermochemical data obtained from two reactions that can be studied by calorimetry. These reactions are the oxidation of CO(g) and the oxidation of C(s), both of which form CO_2(g) as the sole product.

Equation 1:	$CO(g) + {}^1/_2\, O_2(g) \rightarrow CO_2(g)$	$\Delta_r H°_1 = -283.0$ kJ/mol-rxn
Equation 2:	$C(s) + O_2(g) \rightarrow CO_2(g)$	$\Delta_r H°_2 = -393.5$ kJ/mol-rxn

The equations above can be manipulated so that when added together they yield the desired net equation. To have CO(g) appear as a product in the net equation, Equation 1 is reversed. The sign of the standard enthalpy change is also reversed (Section 5.5). Equation 2 contains C(s) on the correct side of the equation and in the correct stoichiometric amount; it is left unchanged. Adding these two equations gives the equation for the oxidation of C(s) to CO(g).

Equation 1′:	$CO_2(g) \rightarrow CO(g) + {}^1/_2\, O_2(g)$	$\Delta_r H°_{1'} = +283.0$ kJ/mol-rxn
Equation 2:	$C(s) + O_2(g) \rightarrow CO_2(g)$	$\Delta_r H°_2 = -393.5$ kJ/mol-rxn
Equation 3:	$C(s) + {}^1/_2\, O_2(g) \rightarrow CO(g)$	$\Delta_r H°_3 = -110.5$ kJ/mol-rxn

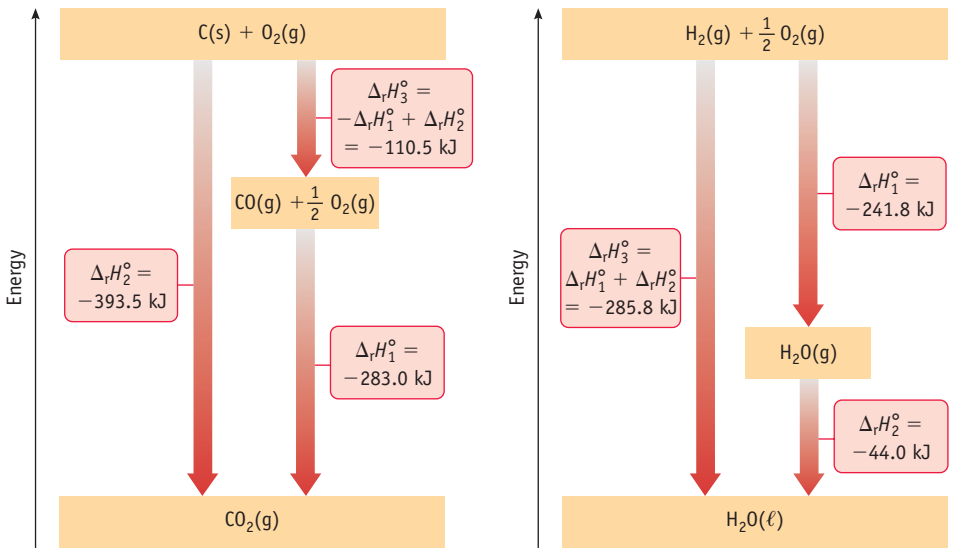
Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Hess's law tells us that the enthalpy change for the overall reaction ($\Delta_r H^\circ_3$) will equal the sum of the enthalpy changes for reactions 1′ and 2.

$$\Delta_r H^\circ_3 = \Delta_r H^\circ_{1'} + \Delta_r H^\circ_2$$

$$\Delta_r H^\circ_3 = +283.0 \text{ kJ/mol-rxn} + (-393.5 \text{ kJ/mol-rxn})$$

$$\Delta_r H^\circ_3 = -110.5 \text{ kJ/mol-rxn}$$



Hess's law also applies to physical processes. The enthalpy change for the reaction of $H_2(g)$ and $O_2(g)$ to form 1 mol of H_2O vapor is different from the enthalpy change to form 1 mol of liquid H_2O. The difference is the negative of the *enthalpy of vaporization* of water, $\Delta_r H^\circ_2$ ($= -\Delta_{vap} H^\circ$) as shown in the following analysis

Equation 1:	$H_2(g) + \frac{1}{2}\, O_2(g) \rightarrow H_2O(g)$	$\Delta_r H^\circ_1 = -241.8$ kJ/mol-rxn
Equation 2:	$H_2O(g) \rightarrow H_2O(\ell)$	$\Delta_r H^\circ_2 = -44.0$ kJ/mol-rxn
Equation 3:	$H_2(g) + \frac{1}{2}\, O_2(g) \rightarrow H_2O(\ell)$	$\Delta_r H^\circ_3 = -285.8$ kJ/mol-rxn

Energy Level Diagrams

When using Hess's law, it is often helpful to represent enthalpy data schematically in an energy level diagram. In such drawings, the various substances being studied—the reactants and products in a chemical reaction, for example—are placed on an arbitrary energy scale. The relative enthalpy of each substance is given by its position on the vertical axis, and numerical differences in enthalpy between them are shown by vertical arrows. Such diagrams can give us a visual perspective on the magnitude and direction of enthalpy changes and show how the enthalpies of the substances are related.

Energy level diagrams that summarize the two examples of Hess's law discussed earlier are shown in Figure 5.13. In Figure 5.13a, the elements C(s) and $O_2(g)$ are at the highest enthalpy. The reaction of carbon and oxygen to form $CO_2(g)$ lowers the enthalpy by 393.5 kJ. This can occur either in a single step, shown on the left in Figure 5.13a, or in two steps via initial formation of CO(g), as shown on the right. Similarly, in Figure 5.13b, the mixture of $H_2(g)$ and $O_2(g)$ is at the highest enthalpy. Both liquid and gaseous water have lower enthalpies, with the difference between the two being the enthalpy of vaporization.

(a) The formation of CO_2 can occur in a single step or in a succession of steps. $\Delta_r H^\circ$ for the overall process is −393.5 kJ, no matter which path is followed.

(b) The formation of $H_2O(\ell)$ can occur in a single step or in a succession of steps. $\Delta_r H^\circ$ for the overall process is −285.8 kJ, no matter which path is followed.

Figure 5.13 Energy level diagrams. (a) Relating enthalpy changes in the formation of $CO_2(g)$. **(b)** Relating enthalpy changes in the formation of $H_2O(\ell)$. Enthalpy changes associated with changes between energy levels are given alongside the vertical arrows.

Problem Solving Tip 5.2 Using Hess's Law

How do we know how the three equations should be adjusted in Example 5.9? Here is a general strategy for solving this type of problem.

Step 1. Arrange the given equations to get the reactants and products in the equation whose $\Delta_r H°$ you wish to calculate on the correct sides of the equations. You may need to reverse some of the given equations in order to do this. In Example 5.9, the reactants, C(s) and $H_2(g)$, are reactants in Equations 1 and 2, but the product, $CH_4(g)$, is a reactant in Equation 3. Equation 3 is reversed to get CH_4 on the product side.

Step 2. Get the correct amounts of the substances on each side. In Example 5.9, only one adjustment is needed. There is 1 mol of H_2 on the left (reactant side) in Equation 2. We need 2 mol of H_2 in the overall equation; this requires doubling the quantities in Equation 2.

Step 3. Make sure other substances in the equations cancel when the equations are added. In Example 5.9, equal amounts of O_2, H_2O, and CO_2 appear on the left and right sides in the three equations, and they cancel when the equations are added together.

The enthalpy change for a reaction is a state function; that is, the enthalpy change from reactants to products does not depend on the path taken. Energy diagrams illustrate this point. Chemists often want to know the enthalpy change for one step of a reaction. If we know the overall enthalpy change, and the enthalpy changes for all the steps but one, then the unknown change can be calculated.

EXAMPLE 5.9

Using Hess's Law

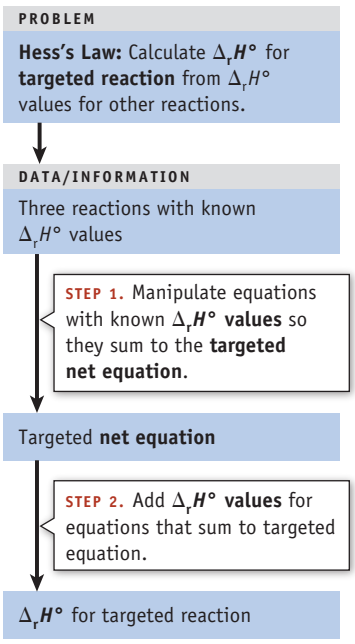
Problem Suppose you want to know the enthalpy change for the formation of methane, CH_4, from solid carbon (as graphite) and hydrogen gas:

$$C(s) + 2\ H_2(g) \rightarrow CH_4(g) \qquad \Delta_r H° = ?$$

The enthalpy change for this reaction cannot be measured in the laboratory because the reaction is very slow. We can, however, measure enthalpy changes for the combustion of carbon, hydrogen, and methane.

Equation 1: $C(s) + O_2(g) \rightarrow CO_2(g)$ $\qquad \Delta_r H°_1 = -393.5$ kJ/mol-rxn

Equation 2: $H_2(g) + \frac{1}{2}\ O_2(g) \rightarrow H_2O(\ell)$ $\qquad \Delta_r H°_2 = -285.8$ kJ/mol-rxn



Equation 3: $CH_4(g) + 2\ O_2(g) \rightarrow CO_2(g) + 2\ H_2O(\ell)$ $\qquad \Delta_r H°_3 = -890.3$ kJ/mol-rxn

Use this information to calculate $\Delta_r H°$ for the formation of methane from its elements.

What Do You Know? This is a Hess's law problem. You need to adjust the three equations so they can be added together to give the desired equation, $C(s) + 2\ H_2(g) \rightarrow CH_4(g)$. When an adjustment in an equation is made, you also need to adjust the enthalpy change.

Strategy The three reactions (1, 2, and 3), as written, cannot be added together to obtain the equation for the formation of CH_4 from its elements. Methane, CH_4, is a product in the reaction for which we wish to calculate $\Delta_r H°$, but it is a reactant in Equation 3. Water appears in two of these equations although it is not a component of the reaction forming CH_4 from carbon and hydrogen. To use Hess's law to solve this problem, you first have to manipulate the equations and adjust $\Delta_r H°$ values accordingly before adding equations. Recall, from Section 5.5, that writing an equation in the reverse direction reverses the sign of $\Delta_r H°$ and that doubling the amount of reactants and products doubles the value of $\Delta_r H°$. Adjustments to Equations 2 and 3 will produce new equations that, along with Equation 1, can be combined to give the desired net reaction.

Strategy Map 5.9

SOLUTION To have CH_4 appear as a product in the overall reaction, reverse Equation 3, which changes the sign of its $\Delta_r H°$.

Equation 3′: $CO_2(g) + 2\ H_2O(\ell) \rightarrow CH_4(g) + 2\ O_2(g)$

$\Delta_r H°_{3'} = -\Delta_r H°_3 = +890.3$ kJ/mol-rxn

Next, you see that 2 mol of $H_2(g)$ is on the reactant side in our desired equation. Equation 2 is written for only 1 mol of $H_2(g)$ as a reactant. Therefore, multiply the stoichiometric coefficients in Equation 2 by 2 and multiply the value of its $\Delta_r H°$ by 2.

Equation 2′: $2\ H_2(g) + O_2(g) \rightarrow 2\ H_2O(\ell)$

$\Delta_r H°_{2'} = 2\ \Delta_r H°_2 = 2\ (-285.8$ kJ/mol-rxn$) = -571.6$ kJ/mol-rxn

You now have three equations that, when added together, will give the equation for the formation of methane from carbon and hydrogen. In this summation process, $O_2(g)$, $H_2O(\ell)$, and $CO_2(g)$ all cancel.

Equation 1: $C(s) + O_2(g) \rightarrow CO_2(g)$ $\quad \Delta_r H°_1 = -393.5$ kJ/mol-rxn

Equation 2′: $2\ H_2(g) + O_2(g) \rightarrow 2\ H_2O(\ell)$ $\quad \Delta_r H°_{2'} = 2\ \Delta_r H°_2 = -571.6$ kJ/mol-rxn

Equation 3′: $CO_2(g) + 2\ H_2O(\ell) \rightarrow CH_4(g) + 2\ O_2(g)$

$\Delta_r H°_{3'} = -\Delta_r H°_3 = +890.3$ kJ/mol-rxn

Net Equation: $C(s) + 2\ H_2(g) \rightarrow CH_4(g)$ $\quad \Delta_r H°_{net} = \Delta_r H°_1 + \Delta_r H°_{2'} + \Delta_r H°_{3'}$

$\Delta_r H°_{net} = (-393.5$ kJ/mol-rxn$) + (-571.6$ kJ/mol-rxn$)$
$+ (+890.3$ kJ/mol-rxn$)$
$= -74.8$ kJ/mol-rxn

Thus, for the formation of 1 mol of $CH_4(g)$ from the elements, $\Delta_r H° = -74.8$ kJ/mol-rxn.

Think about Your Answer Notice that the enthalpy change for the formation of the compound from its elements is exothermic, as it is for the great majority of compounds.

Check Your Understanding

Use Hess's law to calculate the enthalpy change for the formation of $CS_2(\ell)$ from C(s) and S(s) [$C(s) + 2\ S(s) \rightarrow CS_2(\ell)$] from the following enthalpy values.

$C(s) + O_2(g) \rightarrow CO_2(g)$ $\quad \Delta_r H°_1 = -393.5$ kJ/mol-rxn

$S(s) + O_2(g) \rightarrow SO_2(g)$ $\quad \Delta_r H°_2 = -296.8$ kJ/mol-rxn

$CS_2(\ell) + 3\ O_2(g) \rightarrow CO_2(g) + 2\ SO_2(g)$ $\quad \Delta_r H°_3 = -1103.9$ kJ/mol-rxn

Standard Enthalpies of Formation

Calorimetry and the application of Hess's law have made available a great many $\Delta_r H°$ values for chemical reactions. The table in Appendix L, for example, lists **standard molar enthalpies of formation, $\Delta_f H°$**. *The standard molar enthalpy of formation is the enthalpy change for the formation of 1 mol of a compound directly from its component elements in their standard states.*

Several examples of standard molar enthalpies of formation will be helpful to illustrate this definition.

$\Delta_f H°$ for NaCl(s): At 25 °C and a pressure of 1 bar, Na is a solid, and Cl_2 is a gas. The standard enthalpy of formation of NaCl(s) is defined as the enthalpy change that occurs when 1 mol of NaCl(s) is formed from 1 mol of Na(s) and $\frac{1}{2}$ mol of $Cl_2(g)$.

$Na(s) + \frac{1}{2}\ Cl_2(g) \rightarrow NaCl(s)$ $\quad \Delta_f H° = -411.12$ kJ/mol

$\Delta_f H°$ Values Consult the National Institute for Standards and Technology website (webbook.nist.gov/chemistry) for an extensive compilation of enthalpies of formation.

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Notice that a fraction is required as the coefficient for the chlorine gas in this equation because the definition of $\Delta_f H°$ specifies the formation of *one* mole of NaCl(s).

$\Delta_f H°$ for NaCl(aq): The standard enthalpy of formation for an aqueous solution of a compound refers to the enthalpy change for the formation of a 1 mol/L solution of the compound starting with the elements. It is thus the enthalpy of formation of NaCl(s) plus the enthalpy change that occurs when the substance dissolves in water.

$$Na(s) + \tfrac{1}{2}\, Cl_2(g) \rightarrow NaCl(aq) \qquad \Delta_f H° = -407.27 \text{ kJ/mol}$$

$\Delta_f H°$ for $C_2H_5OH(\ell)$: At 25 °C and 1 bar, the standard states of the elements are C(s, graphite), $H_2(g)$, and $O_2(g)$. The standard enthalpy of formation of $C_2H_5OH(\ell)$ is defined as the enthalpy change that occurs when 1 mol of $C_2H_5OH(\ell)$ is formed from 2 mol of C(s), 3 mol of $H_2(g)$, and 1/2 mol of $O_2(g)$.

$$2\, C(s) + 3\, H_2(g) + \tfrac{1}{2}\, O_2(g) \rightarrow C_2H_5OH(\ell) \qquad \Delta_f H° = -277.0 \text{ kJ/mol}$$

Notice that the reaction defining the enthalpy of formation for liquid ethanol is not a reaction a chemist can carry out in the laboratory. This illustrates an important point: *The enthalpy of formation of a compound does not necessarily correspond to a reaction that can be carried out.*

Appendix L lists values of $\Delta_f H°$ for some common substances, and a review of these values leads to some important observations.

- *The standard enthalpy of formation for an element in its standard state is zero.*
- Most $\Delta_f H°$ values are negative, indicating that formation of most compounds from the elements is exothermic. Very few values are positive, and these represent compounds that are unstable with respect to decomposition to the elements. (One example is NO(g) with $\Delta_f H° = +90.29$ kJ/mol.)
- Values of $\Delta_f H°$ can often be used to compare the stabilities of related compounds. Consider the values of $\Delta_f H°$ for the hydrogen halides. Hydrogen fluoride is the most stable of these compounds with respect to decomposition to the elements, whereas HI is the least stable (as indicated by $\Delta_f H°$ of HF being the most negative value and that of HI being the most positive).

Units for Enthalpy of Formation The units for values of $\Delta_f H°$ are usually given simply as kJ/mol rather than as kJ/mol-rxn. However, because an enthalpy of formation is defined as the change in enthalpy for the formation of 1 mol of compound, it is understood that "per mol" also means "per mol-rxn."

$\Delta_f H°$ Values of Hydrogen Halides

Compound	$\Delta_f H°$ (kJ/mol)
HF(g)	−273.3
HCl(g)	−92.31
HBr(g)	−35.29
HI(g)	+25.36

Enthalpy Change for a Reaction

Using standard molar enthalpies of formation and Equation 5.6, it is possible to calculate the enthalpy change for a reaction under standard conditions.

$$\Delta_r H° = \Sigma n \Delta_f H°(\text{products}) - \Sigma n \Delta_f H°(\text{reactants}) \qquad (5.6)$$

In this equation, the symbol Σ (the Greek capital letter sigma) means "take the sum." To find $\Delta_r H°$, add up the molar enthalpies of formation of the products, each multiplied by its stoichiometric coefficient n, and subtract from this the sum of the molar enthalpies of formation of the reactants, each multiplied by its stoichiometric coefficient. This equation is a logical consequence of the definition of $\Delta_f H°$ and Hess's law (see *A Closer Look: Hess's Law and Equation 5.6*, page 256).

Suppose you want to know how much energy is required to decompose 1 mol of calcium carbonate (limestone) to calcium oxide (lime) and carbon dioxide under standard conditions:

$$CaCO_3(s) \rightarrow CaO(s) + CO_2(g) \qquad \Delta_r H° = ?$$

You would use the following enthalpies of formation (from Appendix L):

Compound	$\Delta_f H°$ (kJ/mol)
$CaCO_3(s)$	−1207.6
$CaO(s)$	−635.1
$CO_2(g)$	−393.5

Stoichiometric Coefficients In Equation 5.6 a stoichiometric coefficient, n, is represented as the number of moles of the substance per mole of reaction.

Δ = Final − Initial Equation 5.6 is another example of the convention that a change (Δ) is always calculated by subtracting the value for the initial state (the reactants) from the value for the final state (the products).

A CLOSER LOOK

Hess's Law and Equation 5.6

Equation 5.6 is an application of Hess's law. To illustrate this, let us look further at the decomposition of calcium carbonate.

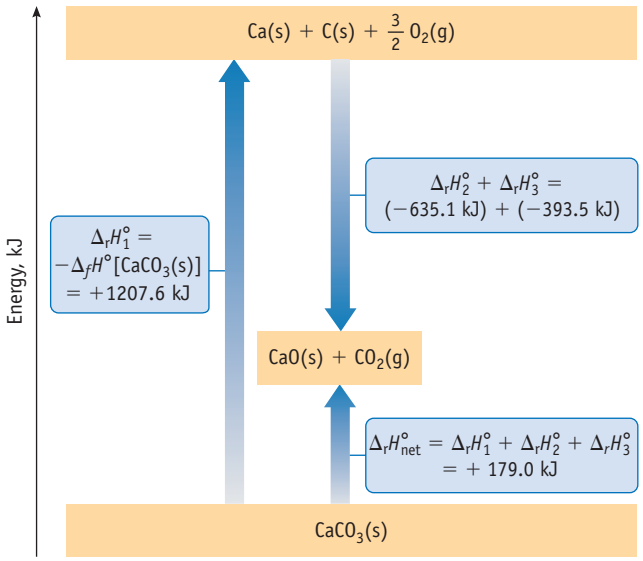
$$CaCO_3(s) \rightarrow CaO(s) + CO_2(g) \qquad \Delta_r H° = ?$$

Because enthalpy is a state function, the change in enthalpy for this reaction is independent of the route from reactants to products (see page 245). We can imagine an alternate route from reactant to products that involves first converting the reactant ($CaCO_3$) to elements in their standard states, then recombining these elements to give the reaction products. Notice that the enthalpy changes for these processes are the enthalpies of formation of the reactants and products in the equation above:

$$CaCO_3(s) \rightarrow Ca(s) + C(s) + 3/2\ O_2(g) \qquad -\Delta_f H°[CaCO_3(s)] = \Delta_r H°_1$$

$$C(s) + O_2(g) \rightarrow CO_2(g) \qquad \Delta_f H°[CO_2(g)] = \Delta_r H°_2$$

$$Ca(s) + \tfrac{1}{2}\ O_2(g) \rightarrow CaO(s) \qquad \Delta_f H°[CaO(s)] = \Delta_r H°_3$$



$$CaCO_3(s) \rightarrow CaO(s) + CO_2(g) \qquad \Delta_r H°_{net}$$

$$\Delta_r H°_{net} = \Delta_r H°_1 + \Delta_r H°_2 + \Delta_r H°_3$$

$$\Delta_r H° = \Delta_f H°[CaO(s)] + \Delta_f H°[CO_2(g)] - \Delta_f H°[CaCO_3(s)]$$

That is, the change in enthalpy for the reaction is equal to the enthalpies of formation of products (CO_2 and CaO) minus the enthalpy of formation of the reactant ($CaCO_3$), which is, of course, what you do when using Equation 5.6. The relationship among these enthalpy quantities is illustrated in the energy-level diagram.

Energy level diagram for the decomposition of $CaCO_3(s)$

and then use Equation 5.6 to find the standard enthalpy change for the reaction, $\Delta_r H°$.

$$\Delta_r H° = \left[\left(\frac{1\ \text{mol CaO}}{1\ \text{mol-rxn}}\right)\left(\frac{-635.1\ \text{kJ}}{\text{mol CaO}}\right) + \left(\frac{1\ \text{mol CO}_2}{1\ \text{mol-rxn}}\right)\left(\frac{-393.5\ \text{kJ}}{1\ \text{mol CO}_2}\right)\right] - \left[\left(\frac{1\ \text{mol CaCO}_3}{1\ \text{mol-rxn}}\right)\left(\frac{-1207.6\ \text{kJ}}{1\ \text{mol CaCO}_3}\right)\right]$$

$$= +179.0\ \text{kJ/mol-rxn}$$

The decomposition of limestone to lime and CO_2 is endothermic. That is, energy (179.0 kJ) must be supplied to decompose 1 mol of $CaCO_3(s)$ to CaO(s) and $CO_2(g)$.

EXAMPLE 5.10

Using Enthalpies of Formation

Problem Nitroglycerin, $C_3H_5(NO_3)_3$, is a powerful explosive that forms four different gases when detonated:

$$2\ C_3H_5(NO_3)_3(\ell) \rightarrow 3\ N_2(g) + \tfrac{1}{2}\ O_2(g) + 6\ CO_2(g) + 5\ H_2O(g)$$

Calculate the enthalpy change that occurs when 10.0 g of nitroglycerin is detonated. The standard enthalpy of formation of nitroglycerin, $\Delta_f H°$, is −364 kJ/mol. Use Appendix L to find other $\Delta_f H°$ values that are needed.

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

What Do You Know? From Appendix L, $\Delta_f H°[CO_2(g)] = -393.5$ kJ/mol, $\Delta_f H°[H_2O(g)] = -241.8$ kJ/mol, and $\Delta_f H° = 0$ for $N_2(g)$ and $O_2(g)$. The mass and $\Delta_f H°$ for nitroglycerin are also given.

Strategy Substitute the enthalpy of formation values for products and reactants into Equation 5.6 to determine the enthalpy change for 1 mol of reaction. This represents the enthalpy change for detonation of 2 mol of nitroglycerin. Determine the amount (mol) represented by 10.0 g of nitroglycerin, then use this value with $\Delta_r H°$ and the relationship between moles of nitroglycerin and moles of reaction to obtain the answer.

SOLUTION Using Equation 5.6, we find the enthalpy change for the explosion of 2 mol of nitroglycerin is

$$\Delta_r H° = \left(\frac{6 \text{ mol } CO_2}{1 \text{ mol-rxn}}\right)\Delta_f H°[CO_2(g)] + \left(\frac{5 \text{ mol } H_2O}{1 \text{ mol-rxn}}\right)\Delta_f H°[H_2O(g)] - \left(\frac{2 \text{ mol } C_3H_5(NO_3)_3}{1 \text{ mol-rxn}}\right)\Delta_f H°[C_3H_5(NO_3)_3(\ell)]$$

$$\Delta_r H° = \left(\frac{6 \text{ mol } CO_2}{1 \text{ mol-rxn}}\right)\left(\frac{-393.5 \text{ kJ}}{1 \text{ mol } CO_2}\right) + \left(\frac{5 \text{ mol } H_2O}{1 \text{ mol-rxn}}\right)\left(\frac{-241.8 \text{ kJ}}{1 \text{ mol } H_2O}\right) - \left(\frac{2 \text{ mol } C_3H_5(NO_3)_3}{1 \text{ mol-rxn}}\right)\left(\frac{-364 \text{ kJ}}{1 \text{ mol } C_3H_5(NO_3)_3}\right) = -2842.0 \text{ kJ/mol-rxn}$$

The problem asks for the enthalpy change using 10.0 g of nitroglycerin. You next need to determine the amount of nitroglycerin in 10.0 g.

$$10.0 \text{ g nitroglycerin}\left(\frac{1 \text{ mol nitroglycerin}}{227.1 \text{ g nitroglycerin}}\right) = 0.04403 \text{ mol nitroglycerin}$$

The enthalpy change for the detonation of 0.04403 mol of nitroglycerin is

$$\Delta_r H° = 0.04403 \text{ mol nitroglycerin}\left(\frac{1 \text{ mol-rxn}}{2 \text{ mol nitroglycerin}}\right)\left(\frac{-2842.0 \text{ kJ}}{1 \text{ mol-rxn}}\right) = -62.6 \text{ kJ}$$

Think about Your Answer The large negative value of $\Delta_r H°$ is in accord with the fact that this reaction is highly exothermic.

Check Your Understanding

Calculate the standard enthalpy of combustion for benzene, C_6H_6.

$$C_6H_6(\ell) + 15/2\ O_2(g) \rightarrow 6\ CO_2(g) + 3\ H_2O(\ell) \qquad \Delta_r H° = ?$$

The enthalpy of formation of benzene is known [$\Delta_f H°[C_6H_6(\ell)] = +49.0$ kJ/mol], and other values needed can be found in Appendix L.

Strategy Map 5.10

PROBLEM
Calculate $\Delta_r H°$ for reaction of a **given mass** of compound.

↓

DATA/INFORMATION
- Mass and $\Delta_f H°$ of compound
- $\Delta_f H°$ values for products
- Balanced equation

STEP 1. Calculate $\Delta_r H°$ for reaction of compound using $\Delta_f H°$ **values** for reactants and products.

$\Delta_r H°$ for reaction of compound

STEP 2. Determine **amount** of compound.

Amount of compound

STEP 3. Convert from **mol** of compound to **mol-rxn** and then multiply by $\Delta_r H°$.

$\Delta_r H°$ for reaction of **given mass** of compound

5.8 Product- or Reactant-Favored Reactions and Thermodynamics

An extensive study of thermodynamics will ultimately provide answers to four questions.

- How do we measure and calculate the energy changes associated with physical changes and chemical reactions?

Figure 5.14 The product-favored oxidation of iron. Iron powder, sprayed into a bunsen burner flame, is rapidly oxidized. The reaction is exothermic and is product-favored.

- What is the relationship between energy changes, heat, and work?
- How can we determine whether a chemical reaction is product-favored or reactant-favored at equilibrium?
- How can we determine whether a chemical reaction or physical process will occur spontaneously, that is, without outside intervention?

The first two questions were addressed in this chapter, but the other two questions still remain. They will be considered in detail in Chapter 18.

We can, however, set the stage for consideration of these issues. In Chapter 3, we learned that chemical reactions proceed toward equilibrium, and spontaneous changes occur in a way that allows a system to approach equilibrium. Reactions in which reactants are largely converted to products when equilibrium is reached are said to be *product-favored at equilibrium*. Reactions in which only small amounts of products are present at equilibrium are called *reactant-favored at equilibrium* (pages 128–130).

Look back at the many chemical reactions that we have seen. For example, all combustion reactions are exothermic, and the oxidation of iron (Figure 5.14) is clearly exothermic.

$$4\ Fe(s) + 3\ O_2(g) \rightarrow 2\ Fe_2O_3(s)$$

$$\Delta_r H° = 2\ \Delta_f H°[Fe_2O_3(s)] = \left(\frac{2\ \text{mol}\ Fe_2O_3}{1\ \text{mol-rxn}}\right)\left(\frac{-825.5\ \text{kJ}}{1\ \text{mol}\ Fe_2O_3}\right) = -1651.0\ \text{kJ/mol-rxn}$$

The reaction has a negative value for $\Delta_r H°$, and it is also product-favored at equilibrium.

Conversely, the decomposition of calcium carbonate is endothermic.

$$CaCO_3(s) \rightarrow CaO(s) + CO_2(g) \qquad \Delta_r H° = +179.0\ \text{kJ/mol-rxn}$$

The decomposition of $CaCO_3$ proceeds to an equilibrium that favors the reactants; that is, it is reactant-favored at equilibrium.

Are all exothermic reactions product-favored at equilibrium and all endothermic reactions reactant-favored at equilibrium? From these examples, we might formulate that idea as a hypothesis that can be tested by experiment and by examination of other examples. You would find that *in most cases, product-favored reactions have negative values of* $\Delta_r H°$, *and reactant-favored reactions have positive values of* $\Delta_r H°$. But this is not *always* true; there are exceptions.

Clearly, a further discussion of thermodynamics must be tied to the concept of equilibrium. This relationship, and the complete discussion of the third and fourth questions, will be presented in Chapter 18.

APPLYING CHEMICAL PRINCIPLES

5.1 Gunpowder

Gunpowder has been used in fireworks, explosives, and firearms for over one thousand years. Until the late 1800s, gunpowder was a mixture of saltpeter (KNO_3), charcoal (largely C), and sulfur. Today, this mixture is known as *black powder*. A simplified version of the reaction occurring when it explodes is the following:

$$2\ KNO_3(s) + 3\ C(s) + S(s) \rightarrow K_2S(s) + N_2(g) + 3\ CO_2(g)$$

Although black powder was used for hundreds of years, it has some disadvantages as a propellant: it produces a large quantity of white smoke, and the residues from the reaction are corrosive.

Modern firearms use smokeless powders. These powders are primarily composed of nitrocellulose (also known as guncotton) or a mixture of nitrocellulose and nitroglycerin. Nitrocellulose is the product of the reaction of cotton (cellulose, with an empirical formula of $C_6H_{10}O_5$) with nitric acid. The fully nitrated product has the empirical formula $C_6H_7(NO_3)_3O_2$. Decomposition of nitrocellulose and nitroglycerin releases more energy than the comparable mass of black powder. Just as important, this is a better propellant because all of the products are gaseous.

Black gunpowder. Black gunpowder has been known for over 1000 years. This photo shows one of the disadvantages of black powder: the great amount of smoke produced.

Questions:

1. The standard enthalpies of formation of $KNO_3(s)$ and $K_2S(s)$ are −494.6 kJ/mol and −376.6 kJ/mol, respectively.
   a. Determine the standard enthalpy change for the reaction of black powder according to the balanced equation on the previous page.
   b. Determine the enthalpy change that occurs when 1.00 g of black powder decomposes according to the stoichiometry of the balanced equation above. (Even though black powder is a mixture, assume that we can designate 1 mol of black powder as consisting of exactly 2 mol of KNO_3, 3 mol of C, and 1 mol of S.)
2. The enthalpy of reaction of guncotton depends on the degree of nitration of the cellulose. For a particular sample, when 0.725 g of guncotton is decomposed in a bomb calorimeter, the temperature of the system increases by 1.32 K. Assuming the bomb has a heat capacity of 691 J/K and the calorimeter contains 1.200 kg of water, what is the energy of reaction per gram of guncotton?
3. The decomposition of nitroglycerin ($C_3H_5N_3O_9$) produces carbon dioxide, nitrogen, water, and oxygen gases.
   a. Write a balanced chemical equation for the decomposition of nitroglycerin.
   b. If the decomposition of 1.00 g nitroglycerin releases 6.23 kJ/g of energy in the form of heat, what is the standard molar enthalpy of formation of nitroglycerin?

5.2 The Fuel Controversy—Alcohol and Gasoline

It is clear that supplies of fossil fuels are declining and their prices are increasing, just as the nations of the Earth have ever greater energy needs. One way to alleviate impending shortages, and move away from a reliance of fossil fuels, is to use renewable fuels from biological sources. Therefore, there has been a movement to replace some fraction of the gasoline sold with ethanol (C_2H_5OH).

In 2007, the U.S. Congress passed an energy bill stating that ethanol production should be 20.5 billion gallons a year by 2015, up from about 4.7 billion gallons in 2007. The actual ethanol production in 2016 was about 14.9 billion gallons.

Most ethanol-containing fuels currently used in the United States are a mixture of 10% ethanol and 90% gasoline (E10). A small fraction of fuel is sold as E85—a blend of gasoline with 51–85% ethanol. However, this can only be used in vehicles with engines designed for fuels with a high ethanol content (so-called "flexible fuel" engines). In 2016 there were about 2700 E85 stations in the U.S., and over 17 million vehicles were equipped to use it.

Is a goal of replacing gasoline completely with ethanol reasonable? This is a lofty goal, given that present gasoline consumption in the U.S. is about 140 billion gallons annually. Heretofore, ethanol was obtained from the fermentation of corn. The problem is that even if all of the corn grown in the U.S. is converted to ethanol, the supply will still be inadequate. It is clear that there must be more emphasis on ways to derive ethanol from other sources, such as cellulose from cornstalks and various grasses.

fotog/Tetra images/Getty Images

Ethanol available at a service station. E85 fuel is a blend of gasoline with 51–85% ethanol. Be aware that you can only use E85 in vehicles designed for the fuel. In an ordinary vehicle, the ethanol leads to deterioration of seals in the engine and fuel system.

Beyond this, there are other problems associated with ethanol. One is that it cannot be distributed through a pipeline system as gasoline can. Any water in the pipeline is miscible with ethanol, which causes the fuel value to decline.

Questions:

For the purposes of this analysis, let us use octane (C_8H_{18}) as a substitute for the complex mixture of hydrocarbons in gasoline. Data you will need for this question (in addition to the data in Appendix L) are:

$$\Delta_f H° \ [C_8H_{18}(\ell)] = -250.1 \text{ kJ/mol}$$

$$\text{Density of ethanol} = 0.785 \text{ g/mL}$$

$$\text{Density of octane} = 0.699 \text{ g/mL}$$

1. Calculate $\Delta_r H°$ for the combustion of ethanol and octane, and compare the values per mole and per gram. Which provides more energy per mole? Which provides more energy per gram?
2. Compare the energy produced per liter of the two fuels. Which produces more energy for a given volume (something useful to know when filling your gas tank)?
3. What mass of CO_2, a greenhouse gas, is produced per liter of fuel (assuming complete combustion)?
4. Now compare the fuels on an energy-equivalent basis. What volume of ethanol would have to be burned to get the same energy as 1.00 L of octane? When you burn enough ethanol to have the same energy as a liter of octane, which fuel produces more CO_2?
5. On the basis of this analysis and assuming the same price per liter, which fuel will propel your car farther? Which will produce less greenhouse gas?

CHAPTER GOALS REVISITED

The goals for this chapter are keyed to specific Study Questions to help you organize your review.

5.1 Energy: Some Basic Principles

- Recognize and use the language of thermodynamics: the system and its surroundings; exothermic and endothermic reactions. **1, 3, 4, 67.**
- Describe the nature of energy transfers as heat. **2.**
- Understand the sign conventions of thermodynamics. **3, 4.**

5.2 Specific Heat Capacity: Heating and Cooling

- Use specific heat capacity in calculations of energy transfers as heat involving temperature changes. **7–16, 75, 93, 94.**

5.3 Energy and Changes of State

- Use enthalpy (heat) of fusion and enthalpy (heat) of vaporization to calculate the energy transferred as heat in changes of state. **17–24, 76–80.**

5.4 The First Law of Thermodynamics

- Recognize how energy transferred as heat and work done on or by a system contributes to changes in the internal energy of a system. **70.**
- Calculate the work done by a system by the expansion of a gas against a constant pressure. **25–28, 119.**
- Calculate changes in enthalpy and internal energy. **29–32, 120.**
- Recognize state functions whose values are determined only by the state of the system and not by the pathway by which the state was achieved. **102.**

5.5 Enthalpy Changes for Chemical Reactions

- Understand and use the enthalpy change for the conversion of reactants to products in their standard states at constant pressure, $\Delta_r H°$. **33–36.**

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

5.6 Calorimetry

- Describe how to measure and calculate the quantity of energy transferred as heat in a reaction by calorimetry. **37–48, 97, 98.**

5.7 Enthalpy Calculations

- Apply Hess's law to find the enthalpy change, $\Delta_r H°$, for a reaction. **49–52, 81, 87, 116.**
- Know how to draw and interpret energy level diagrams. **61, 62, 81, 82, 87, 111, 115.**
- Use standard molar enthalpies of formation, $\Delta_f H°$, to calculate the enthalpy change for a reaction, $\Delta_r H°$. **55–59, 62, 83–86.**

KEY EQUATIONS

Equation 5.1 (page 232) The energy transferred as heat when the temperature of a substance changes. Calculated from the specific heat capacity (C), mass (m), and change in temperature (ΔT).

$$q(\text{J}) = C(\text{J/g} \cdot \text{K}) \times m(\text{g}) \times \Delta T(\text{K})$$

Equation 5.2 (page 232) Temperature changes are always calculated as final temperature minus initial temperature.

$$\Delta T = T_{\text{final}} - T_{\text{initial}}$$

Equation 5.3 (page 235) If no energy is transferred between a system and its surroundings and if energy is transferred within the system only as heat, the sum of the thermal energy changes within the system equals zero.

$$q_1 + q_2 + q_3 + \ldots = 0$$

Equation 5.4 (page 241) The first law of thermodynamics: The change in internal energy (ΔU) in a system is the sum of the energy transferred as heat (q) and the energy transferred as work (w).

$$\Delta U = q + w$$

Equation 5.5 (page 242) P–V work (w) at constant pressure is the product of pressure (P) and change in volume (ΔV)

$$w = -P \times \Delta V$$

Equation 5.6 (page 255) This equation is used to calculate the standard enthalpy change of a reaction ($\Delta_r H°$) when the enthalpies of formation ($\Delta_f H°$) of all of the reactants and products are known. The parameter n is the stoichiometric coefficient of each product or reactant in the balanced chemical equation.

$$\Delta_r H° = \Sigma n \Delta_f H°(\text{products}) - \Sigma n \Delta_f H°(\text{reactants})$$

STUDY QUESTIONS

▲ denotes challenging questions. **blue-numbered questions** have answers in Appendix N and fully worked solutions in the *Student Solutions Manual*.

Practicing Skills

Energy: Some Basic Principles

(See Section 5.1.)

1. Define the terms *system* and *surroundings*. What does it mean to say that a system and its surroundings are in thermal equilibrium?
2. What determines the directionality of energy transfer as heat?
3. Identify whether the following processes are exothermic or endothermic. Is the sign on q_{sys} positive or negative?
   (a) combustion of methane
   (b) melting of ice
   (c) raising the temperature of water from 25 °C to 100 °C
   (d) heating $CaCO_3(s)$ to form $CaO(s)$ and $CO_2(g)$
4. Identify whether the following processes are exothermic or endothermic. Is the sign on q_{sys} positive or negative?
   (a) the reaction of $Na(s)$ and $Cl_2(g)$
   (b) cooling and condensing gaseous N_2 to form liquid N_2
   (c) cooling a soft drink from 25 °C to 0 °C
   (d) heating $HgO(s)$ to form $Hg(\ell)$ and $O_2(g)$

Specific Heat Capacity

(See Section 5.2 and Examples 5.1 and 5.2.)

5. The molar heat capacity of mercury is 28.1 J/mol · K. What is the specific heat capacity of this metal in J/g · K?
6. The specific heat capacity of benzene (C_6H_6) is 1.74 J/g · K. What is its molar heat capacity (in J/mol · K)?
7. The specific heat capacity of copper metal is 0.385 J/g · K. How much energy is required to heat 168 g of copper from −12.2 °C to +25.6 °C?
8. How much energy as heat is required to raise the temperature of 50.00 mL of water from 25.52 °C to 28.75 °C? (Density of water at this temperature = 0.997 g/mL.)
9. The initial temperature of a 344-g sample of iron is 18.2 °C. If the sample absorbs 2.25 kJ of energy as heat, what is its final temperature?
10. After absorbing 1.850 kJ of energy as heat, the temperature of a 0.500-kg block of copper is 37 °C. What was its initial temperature?
11. A 45.5-g sample of copper at 99.8 °C is dropped into a beaker containing 152 g of water at 18.5 °C. What is the final temperature when thermal equilibrium is reached?
12. One beaker contains 156 g of water at 22 °C, and a second beaker contains 85.2 g of water at 95 °C. The water in the two beakers is mixed. What is the final water temperature?
13. A 182-g sample of gold at some temperature was added to 22.1 g of water. The initial water temperature was 25.0 °C, and the final temperature was 27.5 °C. If the specific heat capacity of gold is 0.128 J/g · K, what was the initial temperature of the gold sample?
14. When 108 g of water at a temperature of 22.5 °C is mixed with 65.1 g of water at an unknown temperature, the final temperature of the resulting mixture is 47.9 °C. What was the initial temperature of the second sample of water?
15. A 13.8-g piece of zinc is heated to 98.8 °C in boiling water and then dropped into a beaker containing 45.0 g of water at 25.0 °C. When the water and metal come to thermal equilibrium, the temperature is 27.1 °C. What is the specific heat capacity of zinc?
16. A 237-g piece of molybdenum, initially at 100.0 °C, is dropped into 244 g of water at 10.0 °C. When the system comes to thermal equilibrium, the temperature is 15.3 °C. What is the specific heat capacity of molybdenum?

Changes of State

(See Section 5.3 and Examples 5.3 and 5.4.)

17. How much energy is evolved as heat when 1.0 L of water at 0 °C solidifies to ice? (The heat of fusion of water is 333 J/g.)

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

18. The energy required to melt 1.00 g of ice at 0 °C is 333 J. If one ice cube has a mass of 62.0 g and a tray contains 16 ice cubes, what quantity of energy is required to melt a tray of ice cubes to form liquid water at 0 °C?

19. How much energy is required to vaporize 125 g of benzene, C_6H_6, at its boiling point, 80.1 °C? (The heat of vaporization of benzene is 30.8 kJ/mol.)

20. Chloromethane, CH_3Cl, arises from microbial fermentation and is found throughout the environment. It is also produced industrially, is used in the manufacture of various chemicals, and has been used as a topical anesthetic. How much energy is required to convert 92.5 g of liquid to a vapor at its boiling point, −24.09 °C? (The heat of vaporization of CH_3Cl is 21.40 kJ/mol.)

21. The freezing point of mercury is −38.8 °C. What quantity of energy, in joules, is released to the surroundings if 1.00 mL of mercury is cooled from 23.0 °C to −38.8 °C and then frozen to a solid? (The density of liquid mercury is 13.6 g/cm^3. Its specific heat capacity is 0.140 J/g · K and its heat of fusion is 11.4 J/g.)

22. What quantity of energy, in joules, is required to raise the temperature of 454 g of tin from room temperature, 25.0 °C, to its melting point, 231.9 °C, and then melt the tin at that temperature? (The specific heat capacity of tin is 0.227 J/g · K, and the heat of fusion of this metal is 59.2 J/g.)

23. Ethanol, C_2H_5OH, boils at 78.29 °C. How much energy, in joules, is required to raise the temperature of 1.00 kg of ethanol from 20.0 °C to the boiling point and then to change the liquid to vapor at that temperature? (The specific heat capacity of liquid ethanol is 2.44 J/g · K, and its enthalpy of vaporization is 855 J/g.)

24. A 25.0-mL sample of benzene at 19.9 °C was cooled to its melting point, 5.5 °C, and then frozen. How much energy was given off as heat in this process? (The density of benzene is 0.80 g/mL, its specific heat capacity is 1.74 J/g · K, and its heat of fusion is 127 J/g.)

Heat, Work, and Internal Energy

(See Section 5.4 and Example 5.5.)

25. As a gas cools, it is compressed from 2.50 L to 1.25 L under a constant pressure of 1.01 × 10^5 Pa. Calculate the work (in J) required to compress the gas.

26. A balloon expands from 0.75 L to 1.20 L as it is heated under a constant pressure of 1.01 × 10^5 Pa. Calculate the work (in J) done by the balloon on the environment.

27. A balloon does 324 J of work on the surroundings as it expands under a constant pressure of 7.33 × 10^4 Pa. What is the change in volume (in L) of the balloon?

28. As the gas trapped in a cylinder with a movable piston cools, 1.34 kJ of work is done on the gas by the surroundings. If the gas is at a constant pressure of 1.33 × 10^5 Pa, what is the change of volume (in L) of the gas?

29. When 745 J of energy in the form of heat is transferred from the environment to a gas, the expansion of the gas does 312 J of work on the environment. What is the change in internal energy of the gas?

30. The internal energy of a gas decreases by 1.65 kJ when it transfers 1.87 kJ of energy in the form of heat to the surroundings.

(a) Calculate the work done by the gas on the surroundings.

(b) Does the volume of gas increase or decrease?

31. A volume of 1.50 L of argon gas is confined in a cylinder with a movable piston under a constant pressure of 1.22 × 10^5 Pa. When 1.25 kJ of energy in the form of heat is transferred from the surroundings to the gas, the internal energy of the gas increases by 1.11 kJ. What is the final volume of argon gas in the cylinder?

32. Nitrogen gas is confined in a cylinder with a movable piston under a constant pressure of 9.95 × 10^4 Pa. When 695 J of energy in the form of heat is transferred from the gas to the surroundings, its volume decreases by 1.88 L. What is the change in internal energy of the gas?

Enthalpy Changes

(See Section 5.5 and Example 5.6.)

33. Nitrogen monoxide, a gas recently found to be involved in a wide range of biological processes, reacts with oxygen to give brown NO_2 gas.

$$2\ NO(g) + O_2(g) \rightarrow 2\ NO_2(g) \qquad \Delta_r H° = -114.1\ kJ/mol\text{-}rxn$$

Is this reaction endothermic or exothermic? What is the enthalpy change if 1.25 g of NO is converted completely to NO_2?

Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

34. Calcium carbide, CaC_2, is manufactured by the reaction of CaO with carbon at a high temperature. (Calcium carbide is then used to make acetylene.)

$$CaO(s) + 3\ C(s) \rightarrow CaC_2(s) + CO(g) \qquad \Delta_r H° = +464.8\ \text{kJ/mol-rxn}$$

Is this reaction endothermic or exothermic? What is the enthalpy change if 10.0 g of CaO is allowed to react with an excess of carbon?

35. Isooctane (2,2,4-trimethylpentane), one of the many hydrocarbons that make up gasoline, burns in air to give water and carbon dioxide.

$$2\ C_8H_{18}(\ell) + 25\ O_2(g) \rightarrow 16\ CO_2(g) + 18\ H_2O(\ell) \qquad \Delta_r H° = -10{,}922\ \text{kJ/mol-rxn}$$

What is the enthalpy change if you burn 1.00 L of isooctane ($d = 0.69$ g/mL)?

36. Acetic acid, CH_3CO_2H, is made industrially by the reaction of methanol and carbon monoxide.

$$CH_3OH(\ell) + CO(g) \rightarrow CH_3CO_2H(\ell) \qquad \Delta_r H° = -134.6\ \text{kJ/mol-rxn}$$

What is the enthalpy change for producing 1.00 L of acetic acid ($d = 1.044$ g/mL) by this reaction?

Calorimetry

(See Section 5.6 and Examples 5.7 and 5.8.)

37. Assume you mix 100.0 mL of 0.200 M CsOH with 50.0 mL of 0.400 M HCl in a coffee-cup calorimeter. The following reaction occurs:

$$CsOH(aq) + HCl(aq) \rightarrow CsCl(aq) + H_2O(\ell)$$

The temperature of both solutions before mixing was 22.50 °C, and it rises to 24.28 °C after the acid–base reaction. What is the enthalpy change for the reaction per mole of CsOH? Assume the densities of the solutions are all 1.00 g/mL and the specific heat capacities of the solutions are 4.2 J/g · K.

38. You mix 125 mL of 0.250 M CsOH with 50.0 mL of 0.625 M HF in a coffee-cup calorimeter, and the temperature of both solutions rises from 21.50 °C before mixing to 24.40 °C after the reaction.

$$CsOH(aq) + HF(aq) \rightarrow CsF(aq) + H_2O(\ell)$$

What is the enthalpy of reaction per mole of CsOH? Assume the densities of the solutions are all 1.00 g/mL, and the specific heat capacities of the solutions are 4.2 J/g · K.

39. A piece of titanium metal with a mass of 20.8 g is heated in boiling water to 99.5 °C and then dropped into a coffee-cup calorimeter containing 75.0 g of water at 21.7 °C. When thermal equilibrium is reached, the final temperature is 24.3 °C. Calculate the specific heat capacity of titanium.

40. A piece of chromium metal with a mass of 24.26 g is heated in boiling water to 98.3 °C and then dropped into a coffee-cup calorimeter containing 82.3 g of water at 23.3 °C. When thermal equilibrium is reached, the final temperature is 25.6 °C. Calculate the specific heat capacity of chromium.

41. Adding 5.44 g of $NH_4NO_3(s)$ to 150.0 g of water in a coffee-cup calorimeter (with stirring to dissolve the salt) resulted in a decrease in temperature from 18.6 °C to 16.2 °C. Calculate the enthalpy change for dissolving $NH_4NO_3(s)$ in water, in kJ/mol. Assume the solution (whose mass is 155.4 g) has a specific heat capacity of 4.2 J/g · K. (Cold packs take advantage of the fact that dissolving ammonium nitrate in water is an endothermic process.)

© Cengage Learning/Charles D. Winters

A cold pack uses the endothermic enthalpy of solution of ammonium nitrate.

42. You should use care when dissolving H_2SO_4 in water because the process is highly exothermic. To measure the enthalpy change, 5.2 g of concentrated $H_2SO_4(\ell)$ was added (with stirring) to 135 g of water in a coffee-cup calorimeter. This resulted in an increase in temperature from 20.2 °C to 28.8 °C. Calculate the enthalpy change for the process $H_2SO_4(\ell) \rightarrow H_2SO_4(aq)$, in kJ/mol.

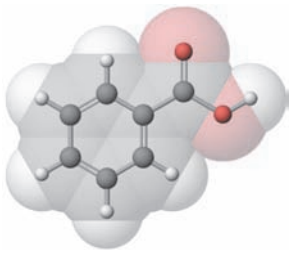
43. Sulfur (2.56 g) was burned in a constant-volume calorimeter with excess $O_2(g)$. The temperature increased from 21.25 °C to 26.72 °C. The bomb has a heat capacity of 923 J/K, and the calorimeter contained 815 g of water. Calculate ΔU per mole of SO_2 formed for the reaction

$$S_8(s) + 8\ O_2(g) \rightarrow 8\ SO_2(g)$$

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

© Cengage Learning/Charles D. Winters



Sulfur burns in oxygen with a bright blue flame to give $SO_2(g)$.

44. Suppose you burned 0.300 g of C(s) in an excess of $O_2(g)$ in a constant-volume calorimeter to give $CO_2(g)$.

$$C(s) + O_2(g) \rightarrow CO_2(g)$$

The temperature of the calorimeter, which contained 775 g of water, increased from 25.00 °C to 27.38 °C. The heat capacity of the bomb is 893 J/K. Calculate ΔU per mole of carbon.

45. Suppose you burned 1.500 g of benzoic acid, $C_6H_5CO_2H$, in a constant-volume calorimeter and found that the temperature increased from 22.50 °C to 31.69 °C. The calorimeter contained 775 g of water, and the bomb had a heat capacity of 893 J/K. Calculate ΔU per mole of benzoic acid.

Benzoic acid, $C_6H_5CO_2H$, occurs naturally in many berries. Its heat of combustion is well known, so it is used as a standard to calibrate calorimeters.

46. A 0.692-g sample of glucose, $C_6H_{12}O_6$, was burned in a constant-volume calorimeter. The temperature rose from 21.70 °C to 25.22 °C. The calorimeter contained 575 g of water, and the bomb had a heat capacity of 650 J/K. What is ΔU per mole of glucose?

47. An "ice calorimeter" can be used to determine the specific heat capacity of a metal. A piece of hot metal is dropped onto a weighed quantity of ice. The energy transferred from the metal to the ice can be determined from the amount of ice melted. Suppose you heated a 50.0-g piece of silver to 99.8 °C and then dropped it onto ice. When the metal's temperature had dropped to 0.0 °C, it is found that 3.54 g of ice had melted. What is the specific heat capacity of silver?

48. A 9.36-g piece of platinum was heated to 98.6 °C in a boiling water bath and then dropped onto ice. (See Study Question 47.) When the metal's temperature had dropped to 0.0 °C, it was found that 0.37 g of ice had melted. What is the specific heat capacity of platinum?

Hess's Law

(See Section 5.7 and Example 5.9.)

49. The enthalpy changes for the following reactions can be measured:

$$CH_4(g) + 2\ O_2(g) \rightarrow CO_2(g) + 2\ H_2O(g) \qquad \Delta_r H° = -802.4 \text{ kJ/mol-rxn}$$

$$CH_3OH(g) + {}^3/_2\ O_2(g) \rightarrow CO_2(g) + 2\ H_2O(g) \qquad \Delta_r H° = -676 \text{ kJ/mol-rxn}$$

(a) Use these values and Hess's law to determine the enthalpy change for the reaction

$$CH_4(g) + {}^1/_2\ O_2(g) \rightarrow CH_3OH(g)$$

(b) Draw an energy level diagram that shows the relationship between the energy quantities involved in this problem.

50. The enthalpy changes of the following reactions can be measured:

$$C_2H_4(g) + 3\ O_2(g) \rightarrow 2\ CO_2(g) + 2\ H_2O(\ell) \qquad \Delta_r H° = -1411.1 \text{ kJ/mol-rxn}$$

$$C_2H_5OH(\ell) + 3\ O_2(g) \rightarrow 2\ CO_2(g) + 3\ H_2O(\ell) \qquad \Delta_r H° = -1367.5 \text{ kJ/mol-rxn}$$

(a) Use these values and Hess's law to determine the enthalpy change for the reaction

$$C_2H_4(g) + H_2O(\ell) \rightarrow C_2H_5OH(\ell)$$

(b) Draw an energy level diagram that shows the relationship between the energy quantities involved in this problem.

51. Enthalpy changes for the following reactions can be determined experimentally:

$$N_2(g) + 3\ H_2(g) \rightarrow 2\ NH_3(g) \qquad \Delta_r H° = -91.8 \text{ kJ/mol-rxn}$$

$$4\ NH_3(g) + 5\ O_2(g) \rightarrow 4\ NO(g) + 6\ H_2O(g) \qquad \Delta_r H° = -906.2 \text{ kJ/mol-rxn}$$

$$H_2(g) + {}^1/_2\ O_2(g) \rightarrow H_2O(g) \qquad \Delta_r H° = -241.8 \text{ kJ/mol-rxn}$$

Use these values to determine the enthalpy change for the formation of NO(g) from the elements (an enthalpy change that cannot be measured directly because the reaction is reactant-favored).

$${}^1/_2\ N_2(g) + {}^1/_2\ O_2(g) \rightarrow NO(g) \qquad \Delta_r H° = ?$$

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

52. You wish to know the enthalpy change for the formation of liquid PCl_3 from the elements.

$$P_4(s) + 6\ Cl_2(g) \rightarrow 4\ PCl_3(\ell) \qquad \Delta_r H^\circ = ?$$

The enthalpy change for the formation of PCl_5 from the elements can be determined experimentally, as can the enthalpy change for the reaction of $PCl_3(\ell)$ with more chlorine to give $PCl_5(s)$:

$$P_4(s) + 10\ Cl_2(g) \rightarrow 4\ PCl_5(s) \qquad \Delta_r H^\circ = -1774.0\ \text{kJ/mol-rxn}$$

$$PCl_3(\ell) + Cl_2(g) \rightarrow PCl_5(s) \qquad \Delta_r H^\circ = -123.8\ \text{kJ/mol-rxn}$$

Use these data to calculate the enthalpy change for the formation of 1.00 mol of $PCl_3(\ell)$ from phosphorus and chlorine.

Standard Enthalpies of Formation

(See Section 5.7 and Example 5.10.)

53. Write a balanced chemical equation for the formation of $CH_3OH(\ell)$ from the elements in their standard states. Find the value for $\Delta_f H^\circ$ for $CH_3OH(\ell)$ in Appendix L.

54. Write a balanced chemical equation for the formation of $CaCO_3(s)$ from the elements in their standard states. Find the value for $\Delta_f H^\circ$ for $CaCO_3(s)$ in Appendix L.

55. (a) Write a balanced chemical equation for the formation of 1 mol of $Cr_2O_3(s)$ from Cr and O_2 in their standard states. (Find the value for $\Delta_f H^\circ$ for $Cr_2O_3(s)$ in Appendix L.)

(b) What is the standard enthalpy change if 2.4 g of chromium is oxidized to $Cr_2O_3(s)$?

56. (a) Write a balanced chemical equation for the formation of 1 mol of MgO(s) from the elements in their standard states. (Find the value for $\Delta_f H^\circ$ for MgO(s) in Appendix L.)

(b) What is the standard enthalpy change for the reaction of 2.5 mol of Mg with oxygen?

57. Use standard enthalpies of formation in Appendix L to calculate enthalpy changes for the following:

(a) 1.0 g of white phosphorus burns, forming $P_4O_{10}(s)$

(b) 0.20 mol of NO(g) decomposes to $N_2(g)$ and $O_2(g)$

(c) 2.40 g of NaCl(s) is formed from Na(s) and excess $Cl_2(g)$

(d) 250 g of iron is oxidized with oxygen to $Fe_2O_3(s)$

58. Use standard enthalpies of formation in Appendix L to calculate enthalpy changes for the following:

(a) 0.054 g of sulfur burns, forming $SO_2(g)$

(b) 0.20 mol of HgO(s) decomposes to $Hg(\ell)$ and $O_2(g)$

(c) 2.40 g of $NH_3(g)$ is formed from $N_2(g)$ and excess $H_2(g)$

(d) 1.05×10^{-2} mol of carbon is oxidized to $CO_2(g)$

59. The first step in the production of nitric acid from ammonia involves the oxidation of NH_3.

$$4\ NH_3(g) + 5\ O_2(g) \rightarrow 4\ NO(g) + 6\ H_2O(g)$$

(a) Use standard enthalpies of formation to calculate the standard enthalpy change for this reaction.

(b) How much energy is evolved or absorbed as heat in the oxidation of 10.0 g of NH_3?

60. The Romans used calcium oxide, CaO, to produce a strong mortar to build stone structures. Calcium oxide was mixed with water to give $Ca(OH)_2$, which reacted slowly with CO_2 in the air to give $CaCO_3$.

$$Ca(OH)_2(s) + CO_2(g) \rightarrow CaCO_3(s) + H_2O(g)$$

(a) Calculate the standard enthalpy change for this reaction.

(b) How much energy is evolved or absorbed as heat if 1.00 kg of $Ca(OH)_2$ reacts with a stoichiometric amount of CO_2?

61. The standard enthalpy of formation of solid barium oxide, BaO, is −553.5 kJ/mol, and the standard enthalpy of formation of barium peroxide, BaO_2, is −634.3 kJ/mol.

(a) Calculate the standard enthalpy change for the following reaction. Is the reaction exothermic or endothermic?

$$2\ BaO_2(s) \rightarrow 2\ BaO(s) + O_2(g)$$

(b) Draw an energy level diagram that shows the relationship between the enthalpy change of the decomposition of BaO_2 to BaO and O_2 and the enthalpies of formation of BaO(s) and $BaO_2(s)$.

Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

62. An important step in the production of sulfuric acid is the oxidation of SO_2 to SO_3.

$$SO_2(g) + {}^1/_2\ O_2(g) \rightarrow SO_3(g)$$

Formation of SO_3 from the air pollutant SO_2 is also a key step in the formation of acid rain.

(a) Use standard enthalpies of formation to calculate the enthalpy change for the reaction. Is the reaction exothermic or endothermic?

(b) Draw an energy level diagram that shows the relationship between the enthalpy change for the oxidation of SO_2 to SO_3 and the enthalpies of formation of $SO_2(g)$ and $SO_3(g)$.

63. The enthalpy change for the oxidation of naphthalene, $C_{10}H_8$, is measured by calorimetry.

$$C_{10}H_8(s) + 12\ O_2(g) \rightarrow 10\ CO_2(g) + 4\ H_2O(\ell) \qquad \Delta_r H° = -5156.1\ \text{kJ/mol-rxn}$$

Use this value, along with the standard enthalpies of formation of $CO_2(g)$ and $H_2O(\ell)$, to calculate the enthalpy of formation of naphthalene, in kJ/mol.

64. The enthalpy change for the oxidation of styrene, C_8H_8, is measured by calorimetry.

$$C_8H_8(\ell) + 10\ O_2(g) \rightarrow 8\ CO_2(g) + 4\ H_2O(\ell) \qquad \Delta_r H° = -4395.0\ \text{kJ/mol-rxn}$$

Use this value, along with the standard enthalpies of formation of $CO_2(g)$ and $H_2O(\ell)$, to calculate the enthalpy of formation of styrene, in kJ/mol.

General Questions

These questions are not designated as to type or location in the chapter. They may combine several concepts.

65. The following terms are used extensively in thermodynamics. Define each and give an example.

(a) exothermic and endothermic

(b) system and surroundings

(c) specific heat capacity

(d) state function

(e) standard state

(f) enthalpy change, ΔH

(g) standard enthalpy of formation

66. For each of the following, tell whether the process is exothermic or endothermic. (No calculations are required.)

(a) $H_2O(\ell) \rightarrow H_2O(s)$

(b) $2\ H_2(g) + O_2(g) \rightarrow 2\ H_2O(g)$

(c) $H_2O(\ell, 25\ °C) \rightarrow H_2O(\ell, 15\ °C)$

(d) $H_2O(\ell) \rightarrow H_2O(g)$

67. For each of the following, define a system and its surroundings, and give the direction of energy transfer between system and surroundings.

(a) Methane burns in a gas furnace in your home.

(b) Water drops, sitting on your skin after a swim, evaporate.

(c) Water, at 25 °C, is placed in the freezing compartment of a refrigerator, where it cools and eventually solidifies.

(d) Aluminum and $Fe_2O_3(s)$ are mixed in a flask sitting on a laboratory bench. A reaction occurs, and a large quantity of energy is evolved as heat.

68. What does the term *standard state* mean? What are the standard states of the following substances at 298 K: H_2O, NaCl, Hg, CH_4?

69. Use Appendix L to find the standard enthalpies of formation of oxygen atoms, oxygen molecules (O_2), and ozone (O_3). What is the standard state of oxygen? Is the formation of oxygen atoms from O_2 exothermic? What is the enthalpy change for the formation of 1 mol of O_3 from O_2?

70. You have a large balloon containing 1.0 mol of gaseous water vapor at 80 °C. How will each step affect the internal energy of the system?

(a) The temperature of the system is raised to 90 °C.

(b) The vapor is condensed to a liquid, at 40 °C.

71. Determine whether energy as heat is evolved or required, and whether work was done on the system or whether the system does work on the surroundings, in the following processes at constant pressure:

(a) Liquid water at 100 °C is converted to steam at 100 °C.

(b) Dry ice, $CO_2(s)$, sublimes to give $CO_2(g)$.

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

72. Determine whether energy as heat is evolved or required, and whether work was done on the system or whether the system does work on the surroundings, in the following processes at constant pressure:

(a) Ozone, O_3, decomposes to form O_2.

(b) Methane burns:

$$CH_4(g) + 2\ O_2(g) \rightarrow CO_2(g) + 2\ H_2O(\ell)$$

73. Use standard enthalpies of formation to calculate the enthalpy change that occurs when 1.00 g of $SnCl_4(\ell)$ reacts with excess $H_2O(\ell)$ to form $SnO_2(s)$ and HCl(aq).

74. Which evolves more energy on cooling from 50 °C to 10 °C: 50.0 g of water or 100. g of ethanol ($C_{ethanol} = 2.46$ J/g · K)?

75. You determine that 187 J of energy as heat is required to raise the temperature of 93.45 g of silver from 18.5 °C to 27.0 °C. What is the specific heat capacity of silver?

76. Calculate the quantity of energy required to convert 60.1 g of $H_2O(s)$ at 0.0 °C to $H_2O(g)$ at 100.0 °C. The enthalpy of fusion of ice at 0 °C is 333 J/g; the enthalpy of vaporization of liquid water at 100 °C is 2256 J/g.

77. You add 100.0 g of water at 60.0 °C to 100.0 g of ice at 0.00 °C. Some of the ice melts and cools the water to 0.00 °C. When the ice and water mixture reaches thermal equilibrium at 0 °C, how much ice has melted?

78. ▲ Three 45-g ice cubes at 0 °C are dropped into 5.00×10^2 mL of tea to make iced tea. The tea was initially at 20.0 °C; when thermal equilibrium was reached, the final temperature was 0 °C. How much of the ice melted, and how much remained floating in the beverage? Assume the specific heat capacity of tea is the same as that of pure water.

79. ▲ Suppose that only two 45-g ice cubes had been added to your glass containing 5.00×10^2 mL of tea (see Study Question 78). When thermal equilibrium is reached, all of the ice will have melted, and the temperature of the mixture will be somewhere between 20.0 °C and 0 °C. Calculate the final temperature of the beverage. (*Note:* The 90 g of water formed when the ice melts must be warmed from 0 °C to the final temperature.)

80. You take a diet cola from the refrigerator and pour 240 mL of it into a glass. The temperature of the beverage is 10.5 °C. You then add one ice cube (45 g) at 0 °C. Which of the following describes the system when thermal equilibrium is reached?

(a) The temperature is 0 °C, and some ice remains.

(b) The temperature is 0 °C, and no ice remains.

(c) The temperature is higher than 0 °C, and no ice remains.

Determine the final temperature and the amount of ice remaining, if any.

81. ▲ The standard molar enthalpy of formation of diborane, $B_2H_6(g)$, cannot be determined directly because the compound cannot be prepared by the reaction of boron and hydrogen. It can be calculated from other enthalpy changes, however. The following enthalpy changes can be measured.

$$4\ B(s) + 3\ O_2(g) \rightarrow 2\ B_2O_3(s) \qquad \Delta_r H° = -2543.8\ \text{kJ/mol-rxn}$$

$$H_2(g) + {}^1/_2\ O_2(g) \rightarrow H_2O(g) \qquad \Delta_r H° = -241.8\ \text{kJ/mol-rxn}$$

$$B_2H_6(g) + 3\ O_2(g) \rightarrow B_2O_3(s) + 3\ H_2O(g) \qquad \Delta_r H° = -2032.9\ \text{kJ/mol-rxn}$$

(a) Show how these equations can be added together to give the equation for the formation of $B_2H_6(g)$ from B(s) and $H_2(g)$ in their standard states. Assign enthalpy changes to each reaction.

(b) Calculate $\Delta_f H°$ for $B_2H_6(g)$.

(c) Draw an energy level diagram that shows how the various enthalpies in this problem are related.

(d) Is the formation of $B_2H_6(g)$ from its elements exo- or endothermic?

82. Chloromethane, CH_3Cl, a compound found throughout the environment, is formed in the reaction of chlorine atoms with methane.

$$CH_4(g) + 2\ Cl(g) \rightarrow CH_3Cl(g) + HCl(g)$$

(a) Calculate the enthalpy change for the reaction of $CH_4(g)$ and Cl atoms to give $CH_3Cl(g)$ and HCl(g). Is the reaction exo- or endothermic?

(b) Draw an energy level diagram that shows how the various enthalpies in this problem are related.

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

83. When heated to a high temperature, coke (mainly carbon, obtained by heating coal in the absence of air) and steam produce a mixture called *water gas*, which can be used as a fuel or as a starting place for other reactions. The equation for the production of water gas is

$$C(s) + H_2O(g) \rightarrow CO(g) + H_2(g)$$

(a) Use standard enthalpies of formation to determine the enthalpy change for this reaction.

(b) Is the reaction exo- or endothermic?

(c) What is the enthalpy change if 1000.0 kg (1 metric ton) of carbon is converted to water gas?

84. Camping stoves are fueled by propane (C_3H_8), butane [$C_4H_{10}(g)$, $\Delta_f H° = -127.1$ kJ/mol], gasoline, or ethanol (C_2H_5OH). Calculate the enthalpy of combustion per gram of each of these fuels. [Assume that gasoline is represented by isooctane, $C_8H_{18}(\ell)$, with $\Delta_f H° = -259.3$ kJ/mol.] Do you notice any great differences among these fuels? How are these differences related to their composition?

© Cengage Learning/Charles D. Winters

A camping stove that uses butane as a fuel.

85. Methanol, CH_3OH, a compound that can be made relatively inexpensively from coal, is a promising substitute for gasoline. The alcohol has a smaller energy content than gasoline, but, with its higher octane rating, it burns more efficiently than gasoline in combustion engines. (It has the added advantage of contributing to a lesser degree to some air pollutants.) Compare the enthalpy of combustion per gram of CH_3OH and C_8H_{18} (isooctane), the latter being representative of the compounds in gasoline. ($\Delta_f H° = -259.3$ kJ/mol for isooctane.)

86. Hydrazine and 1,1-dimethylhydrazine both react spontaneously with O_2 and can be used as rocket fuels.

$$\underset{\text{hydrazine}}{N_2H_4(\ell)} + O_2(g) \rightarrow N_2(g) + 2\ H_2O(g)$$

$$\underset{\text{1,1-dimethylhydrazine}}{N_2H_2(CH_3)_2(\ell)} + 4\ O_2(g) \rightarrow 2\ CO_2(g) + 4\ H_2O(g) + N_2(g)$$

The molar enthalpy of formation of $N_2H_4(\ell)$ is +50.6 kJ/mol, and that of $N_2H_2(CH_3)_2(\ell)$ is +48.9 kJ/mol. Use these values, with other $\Delta_f H°$ values, to decide whether the reaction of hydrazine or 1,1-dimethylhydrazine with oxygen provides more energy per gram.

NASA

Space vehicles, such as the Space Shuttle when it was still flying, use hydrazine as a fuel in control rockets.

87. (a) Calculate the enthalpy change, $\Delta_r H°$, for the formation of 1.00 mol of strontium carbonate (the material that gives the red color in fireworks) from its elements.

$$Sr(s) + C(s) + {}^3/_2\ O_2(g) \rightarrow SrCO_3(s)$$

The experimental information available is

$$Sr(s) + {}^1/_2\ O_2(g) \rightarrow SrO(s) \qquad \Delta_f H° = -592 \text{ kJ/mol-rxn}$$

$$SrO(s) + CO_2(g) \rightarrow SrCO_3(s) \qquad \Delta_r H° = -234 \text{ kJ/mol-rxn}$$

$$C(\text{graphite}) + O_2(g) \rightarrow CO_2(g) \qquad \Delta_f H° = -394 \text{ kJ/mol-rxn}$$

(b) Draw an energy level diagram relating the energy quantities in this problem.

Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

88. You drink 350 mL of diet soda that is at a temperature of 5 °C.

(a) How much energy will your body expend to raise the temperature of this liquid to body temperature (37 °C)? Assume that the density and specific heat capacity of diet soda are the same as for water.

(b) Compare the value in part (a) with the caloric content of the beverage. (The label says that it has a caloric content of 1 Calorie.) What is the net energy change in your body resulting from drinking this beverage? (1 Calorie = 1000 kcal = 4184 J.)

(c) Carry out a comparison similar to that in part (b) for a nondiet beverage whose label indicates a caloric content of 240 Calories.

89. ▲ Chloroform, $CHCl_3$, is formed from methane and chlorine in the following reaction.

$$CH_4(g) + 3\ Cl_2(g) \rightarrow 3\ HCl(g) + CHCl_3(g)$$

Calculate $\Delta_r H°$, the enthalpy change for this reaction, using the enthalpies of formation of $CO_2(g)$, $H_2O(\ell)$, and $CHCl_3(g)$ ($\Delta_f H° = -103.1$ kJ/mol), and the enthalpy changes for the following reactions:

$$CH_4(g) + 2\ O_2(g) \rightarrow 2\ H_2O(\ell) + CO_2(g) \qquad \Delta_r H° = -890.4 \text{ kJ/mol-rxn}$$

$$2\ HCl(g) \rightarrow H_2(g) + Cl_2(g) \qquad \Delta_r H° = +184.6 \text{ kJ/mol-rxn}$$

90. Water gas, a mixture of carbon monoxide and hydrogen, is produced by treating carbon (in the form of coke or coal) with steam at high temperatures. (See Study Question 83.)

$$C(s) + H_2O(g) \rightarrow CO(g) + H_2(g)$$

Not all of the carbon available is converted to water gas since some is burned to provide the heat for the endothermic reaction of carbon and water. What mass of carbon must be burned (to CO_2 gas) to provide the energy to convert 1.00 kg of carbon to water gas?

91. Using standard enthalpies of formation, verify that 2680 kJ of energy is released in combustion of 100.0 g of ethanol.

$$C_2H_5OH(\ell) + 3\ O_2(g) \rightarrow 2\ CO_2(g) + 3\ H_2O(g)$$

92. According to the Nutrient Data Laboratory website (www.ars.usda.gov/ba/bhnrc/ndl), corn oil contains 3766 kJ of energy per 100. g serving.

(a) What is the energy content of 100. g of corn oil in units of nutritional calories (Cal)?

(b) How many tablespoons of corn oil have an energy content equivalent to 1500 nutritional calories? (1.0 Tbsp = 14 g of corn oil)

(c) What mass of water can be heated from 25.0 °C to its boiling point of 100.0 °C using the energy of combustion of 1.00 Tbsp of corn oil?

In the Laboratory

93. A piece of lead with a mass of 27.3 g was heated to 98.90 °C and then dropped into 15.0 g of water at 22.50 °C. The final temperature was 26.32 °C. Calculate the specific heat capacity of lead from these data.

94. A 192-g piece of copper is heated to 100.0 °C in a boiling water bath and then dropped into a beaker containing 751 g of water (density = 1.00 g/cm^3) at 4.0 °C. What was the final temperature of the copper and water after thermal equilibrium was reached? ($C_{Cu} = 0.385$ J/g · K.)

95. Insoluble AgCl(s) precipitates when solutions of $AgNO_3(aq)$ and NaCl(aq) are mixed.

$$AgNO_3(aq) + NaCl(aq) \rightarrow AgCl(s) + NaNO_3(aq) \qquad \Delta_r H° = ?$$

To measure the energy evolved in this reaction, 250. mL of 0.16 M $AgNO_3(aq)$ and 125 mL of 0.32 M NaCl(aq) are mixed in a coffee-cup calorimeter. The temperature of the mixture rises from 21.15 °C to 22.90 °C. Calculate the enthalpy change for the precipitation of AgCl(s), in kJ/mol. (Assume the density of the solution is 1.0 g/mL and its specific heat capacity is 4.2 J/g · K.)

96. Insoluble $PbBr_2(s)$ precipitates when solutions of $Pb(NO_3)_2(aq)$ and NaBr(aq) are mixed.

$$Pb(NO_3)_2(aq) + 2\ NaBr(aq) \rightarrow PbBr_2(s) + 2\ NaNO_3(aq) \qquad \Delta_r H° = ?$$

To measure the enthalpy change, 200. mL of 0.75 M $Pb(NO_3)_2(aq)$ and 200. mL of 1.5 M NaBr(aq) are mixed in a coffee-cup calorimeter. The temperature of the mixture rises by 2.44 °C. Calculate the enthalpy change for the precipitation of $PbBr_2(s)$, in kJ/mol. (Assume the density of the solution is 1.0 g/mL, and its specific heat capacity is 4.2 J/g · K.)

Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

97. The value of ΔU for the decomposition of 7.647 g of ammonium nitrate can be measured in a bomb calorimeter. The reaction that occurs is

$$NH_4NO_3(s) \rightarrow N_2O(g) + 2\ H_2O(g)$$

The temperature of the calorimeter, which contains 415 g of water, increases from 18.90 °C to 20.72 °C. The heat capacity of the bomb is 155 J/K. What is the value of ΔU for this reaction, in kJ/mol?

© Cengage Learning/Charles D. Winters

The decomposition of ammonium nitrate is clearly exothermic.

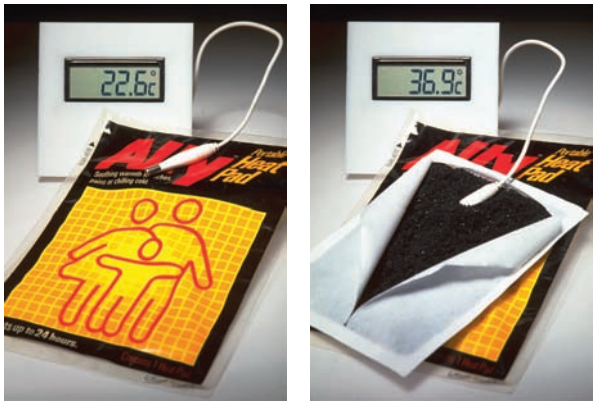
98. A bomb calorimetric experiment was run to determine the enthalpy of combustion of ethanol. The reaction is

$$C_2H_5OH(\ell) + 3\ O_2(g) \rightarrow 2\ CO_2(g) + 3\ H_2O(\ell)$$

The bomb had a heat capacity of 550 J/K, and the calorimeter contained 650 g of water. Burning 4.20 g of ethanol, $C_2H_5OH(\ell)$ resulted in a rise in temperature from 18.5 °C to 22.3 °C. Calculate ΔU for the combustion of ethanol, in kJ/mol.

99. The meals-ready-to-eat (MREs) in the military can be heated on a flameless heater. You can purchase a similar product called "Heater Meals." Just pour water into the heater unit, wait a few minutes, and you have a hot meal. The source of energy in the heater is

$$Mg(s) + 2\ H_2O(\ell) \rightarrow Mg(OH)_2(s) + H_2(g)$$



© Cengage Learning/Charles D. Winters

The "heater meal" uses the reaction of magnesium with water as a source of energy as heat.

Calculate the enthalpy change under standard conditions, in joules, for this reaction. What quantity of magnesium is needed to supply the energy required to warm 25 mL of water (d = 1.00 g/mL) from 25 °C to 85 °C? (See W. Jensen: *Journal of Chemical Education*, Vol. 77, pp. 713–717, 2000.)

100. On a cold day, you can warm your hands with a "heat pad," a device that uses the oxidation of iron to produce energy as heat.

$$4\ Fe(s) + 3\ O_2(g) \rightarrow 2\ Fe_2O_3(s)$$

Photos: © Cengage Learning/Charles D. Winters

A hand warmer uses the oxidation of iron as a source of thermal energy.

What mass of iron is needed to supply the energy required to warm 15 mL of water (d = 1.00 g/mL) from 23 °C to 37 °C?

Summary and Conceptual Questions

The following questions may use concepts from this and previous chapters.

101. Without doing calculations, decide whether each of the following is exo- or endothermic.
   (a) the combustion of natural gas
   (b) the decomposition of glucose, $C_6H_{12}O_6$, to carbon and water

102. Which of the following are state functions?
   (a) the volume of a balloon
   (b) the time it takes to drive from your home to your college or university
   (c) the temperature of the water in a coffee cup
   (d) the potential energy of a ball held in your hand

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

103. ▲ You want to determine the value for the enthalpy of formation of $CaSO_4(s)$, but the reaction cannot be done directly.

$$Ca(s) + S(s) + 2\ O_2(g) \rightarrow CaSO_4(s)$$

You know, however, that (a) both calcium and sulfur react with oxygen to produce oxides in reactions that can be studied calorimetrically, and (b) the basic oxide CaO reacts with the acidic oxide $SO_3(g)$ to produce $CaSO_4(s)$ with $\Delta_r H° = -402.7$ kJ. Outline a method for determining $\Delta_f H°$ for $CaSO_4(s)$, and identify the information that must be collected by experiment. Using information in Appendix L, confirm that $\Delta_f H°$ for $CaSO_4(s) = -1433.5$ kJ/mol.

104. Prepare a graph of specific heat capacities for metals versus their atomic weights. Combine the data in Figure 5.4 and the values in the following table. What is the relationship between specific heat capacity and atomic weight? Use this relationship to predict the specific heat capacity of platinum. The specific heat capacity for platinum is given in the literature as 0.133 J/g · K. How good is the agreement between the predicted and actual values?

Metal	Specific Heat Capacity (J/g · K)
Chromium	0.450
Lead	0.127
Silver	0.236
Tin	0.227
Titanium	0.522

105. Observe the molar heat capacity values for the metals in Figure 5.4. What observation can you make about these values—specifically, are they widely different or very similar? Using this information, estimate the specific heat capacity for silver. Compare this estimate with the correct value for silver, 0.236 J/g · K.

106. ▲ You are attending summer school and living in a very old dormitory. The day is oppressively hot, there is no air conditioner, and you can't open the windows of your room. There is a refrigerator in the room, however. In a stroke of genius, you open the door of the refrigerator, and cool air cascades out. The relief does not last long, though. Soon the refrigerator motor and condenser begin to run, and not long thereafter the room is hotter than it was before. Why did the room warm up?

107. You want to heat the air in your house with natural gas (CH_4). Assume your house has 275 m^2 (about 2800 ft^2) of floor area and that the ceilings are 2.50 m from the floors. The air in the house has a molar heat capacity of 29.1 J/mol · K. (The number of moles of air in the house can be found by assuming that the average molar mass of air is 28.9 g/mol and that the density of air at these temperatures is 1.22 g/L.) What mass of methane do you have to burn to heat the air from 15.0 °C to 22.0 °C?

108. Water can be decomposed to its elements, H_2 and O_2, using electrical energy or in a series of chemical reactions. The following sequence of reactions is one possibility:

$$CaBr_2(s) + H_2O(g) \rightarrow CaO(s) + 2\ HBr(g)$$

$$Hg(\ell) + 2\ HBr(g) \rightarrow HgBr_2(s) + H_2(g)$$

$$HgBr_2(s) + CaO(s) \rightarrow HgO(s) + CaBr_2(s)$$

$$HgO(s) \rightarrow Hg(\ell) + \tfrac{1}{2}\ O_2(g)$$

(a) Show that the net result of this series of reactions is the decomposition of water to its elements.

(b) If you use 1000. kg of water, what mass of H_2 can be produced?

(c) Calculate the value of $\Delta_r H°$ for each step in the series. Are the reactions predicted to be exo- or endothermic?

$$\Delta_f H°\ [CaBr_2(s)] = -683.2\ \text{kJ/mol}$$

$$\Delta_f H°\ [HgBr_2(s)] = -169.5\ \text{kJ/mol}$$

(d) Comment on the commercial feasibility of using this series of reactions to produce $H_2(g)$ from water.

109. Suppose that an inch (2.54 cm) of rain falls over a square mile of ground (2.59×10^6 m^2). (Density of water is 1.0 g/cm^3.) The enthalpy of vaporization of water at 25 °C is 44.0 kJ/mol. How much energy is transferred as heat to the surroundings from the condensation of water vapor in forming this quantity of liquid water? (The huge number tells you how much energy is "stored" in water vapor and why we think of storms as such great forces of energy in nature. It is interesting to compare this result with the energy given off, 4.2×10^6 kJ, when a ton of dynamite explodes.)

110. ▲ Peanuts and peanut oil are organic materials and burn in air. How many burning peanuts does it take to provide the energy to boil a cup of water (250 mL of water)? To solve this problem, we assume each peanut, with an average mass of 0.73 g, is 49% peanut oil and 21% starch; the remainder is noncombustible. We further assume peanut oil is palmitic acid, $C_{16}H_{32}O_2$, with an enthalpy of formation of −848.4 kJ/mol. Starch is a long chain of $C_6H_{10}O_5$ units, each unit having an enthalpy of formation of −960 kJ.

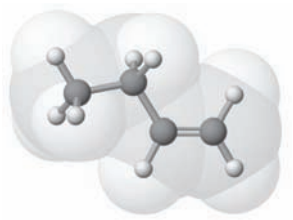
© Cengage Learning/Charles D. Winters

How many burning peanuts are required to provide the energy to boil 250 mL of water?

111. ▲ Isomers are molecules with the same elemental composition but a different atomic arrangement. Three isomers with the formula C_4H_8 are shown in the models below. The enthalpy of combustion ($\Delta_c H°$) of each isomer, determined using a calorimeter, is as follows:

Compound	$\Delta_c H°$ (kJ/mol butene)
cis-2-butene	−2709.8
trans-2-butene	−2706.6
1-butene	−2716.8

(a) Draw an energy level diagram relating the energy content of the three isomers to the energy content of the combustion products, $CO_2(g)$ and $H_2O(\ell)$.



(b) Use the $\Delta_c H°$ data in part (a), along with the enthalpies of formation of $CO_2(g)$ and $H_2O(\ell)$ from Appendix L, to calculate the enthalpy of formation for each of the isomers.

(c) Draw an energy level diagram that relates the enthalpies of formation of the three isomers to the energy of the elements in their standard states.

(d) What is the enthalpy change for the conversion of *cis*-2-butene to *trans*-2-butene?

***Cis*-2-butene** ***Trans*-2-butene**

1-butene

112. Several standard enthalpies of formation (from Appendix L) are given below. Use these data to calculate

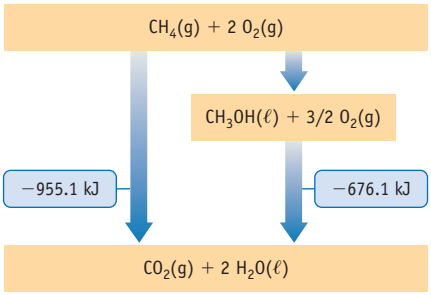
(a) the standard enthalpy of vaporization of bromine.

(b) the energy required for the reaction $Br_2(g) \rightarrow 2\ Br(g)$. (This is the Br—Br bond dissociation enthalpy.)

Species	$\Delta_f H°$ (kJ/mol)
Br(g)	111.9
$Br_2(\ell)$	0
$Br_2(g)$	30.9

113. When 0.850 g of Mg was burned in oxygen in a constant-volume calorimeter, 25.4 kJ of energy as heat was evolved. The calorimeter was in an insulated container with 750. g of water at an initial temperature of 18.6 °C. The heat capacity of the bomb in the calorimeter is 820. J/K.

(a) Calculate ΔU for the oxidation of Mg (in kJ/mol Mg).



(b) What will be the final temperature of the water and the bomb calorimeter in this experiment?

114. ▲ A piece of gold (10.0 g, $C_{Au} = 0.129$ J/g · K) is heated to 100.0 °C. A piece of copper (also 10.0 g, $C_{Cu} = 0.385$ J/g · K) is chilled in an ice bath to 0 °C. Both pieces of metal are placed in a beaker containing 150. g H_2O at 20 °C. Will the temperature of the water be greater than or less than 20 °C when thermal equilibrium is reached? Calculate the final temperature.

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

115. Methane, CH_4, can be converted to methanol, which, like ethanol, can be used as a fuel. The energy level diagram shown here presents relationships between energies of the fuels and their oxidation products. Use the information in the diagram to answer the following questions. (The energy terms are per mol-rxn.)

(a) Which fuel, methanol or methane, yields the most energy per mole when burned?

(b) Which fuel yields the most energy per gram when burned?

(c) What is the enthalpy change for the conversion of methane to methanol by reaction with $O_2(g)$?

(d) Each arrow on the diagram represents a chemical reaction. Write the equation for the reaction that converts methane to methanol.

116. Calculate $\Delta_r H°$ for the reaction

$$2\ C(s) + 3\ H_2(g) + {}^1/_2\ O_2(g) \rightarrow C_2H_5OH(\ell)$$

given the information below.

$$C(s) + O_2(g) \rightarrow CO_2(g) \qquad \Delta_r H° = -393.5\ \text{kJ/mol-rxn}$$

$$2\ H_2(g) + O_2(g) \rightarrow 2\ H_2O(\ell) \qquad \Delta_r H° = -571.6\ \text{kJ/mol-rxn}$$

$$C_2H_5OH(\ell) + 3\ O_2(g) \rightarrow 2\ CO_2(g) + 3\ H_2O(\ell) \qquad \Delta_r H° = -1367.5\ \text{kJ/mol-rxn}$$

117. ▲ You have the six pieces of metal listed below, plus a beaker of water containing 3.00×10^2 g of water. The water temperature is 21.00 °C.

Metals	Specific Heat (J/g K)	Mass (g)
1. Al	0.9002	100.0
2. Al	0.9002	50.0
3. Au	0.1289	100.0
4. Au	0.1289	50.0
5. Zn	0.3860	100.0
6. Zn	0.3860	50.0

(a) In your first experiment you select one piece of metal and heat it to 100 °C, and then select a second piece of metal and cool it to −10 °C. Both pieces of metal are then placed in the beaker of water and the temperatures equilibrated. You want to select two pieces of metal to use, such that the final temperature of the water is as high as possible. What piece of metal will you heat? What piece of metal will you cool? What is the final temperature of the water?

(b) The second experiment is done in the same way as the first. However, your goal now is to cause the temperature to change the least, that is, the final temperature should be as near to 21.00 °C as possible. What piece of metal will you heat? What piece of metal will you cool? What is the final temperature of the water?

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

118. In the lab, you plan to carry out a calorimetry experiment to determine $\Delta_r H$ for the exothermic reaction of $Ca(OH)_2(s)$ and $HCl(aq)$. Predict how each of the following will affect the calculated value of $\Delta_r H$. (The value calculated for $\Delta_r H$ for this reaction is a negative value so choose your answer from the following:
$\Delta_r H$ will be too low [that is, a larger negative value], $\Delta_r H$ will be unaffected, $\Delta_r H$ will be too high [that is, a smaller negative value].)

(a) You spill a little bit of the $Ca(OH)_2$ on the benchtop before adding it to the calorimeter.

(b) Because of a miscalculation, you add an excess of HCl to the measured amount of $Ca(OH)_2$ in the calorimeter.

(c) $Ca(OH)_2$ readily absorbs water from the air. The $Ca(OH)_2$ sample you weighed had been exposed to the air prior to weighing and had absorbed some water.

(d) After weighing out $Ca(OH)_2$, the sample sat in an open beaker and absorbed water.

(e) You delay too long in recording the final temperature.

(f) The insulation in your coffee-cup calorimeter was poor, so some energy as heat was lost to the surroundings during the experiment.

(g) You have ignored the fact that energy as heat also raised the temperature of the stirrer and the thermometer in your system.

119. Sublimation of 1.0 g of dry ice, $CO_2(s)$, forms 0.36 L of $CO_2(g)$ (at -78 °C and 1.01×10^5 Pa). The expanding gas can do work on the surroundings (Figure 5.8). Calculate the amount of work done on the surroundings.

120. In the reaction of two moles of gaseous hydrogen and one mole of gaseous oxygen to form two moles of gaseous water vapor, two moles of products are formed from three moles of reactants. If this reaction is done at 1.01×10^5 Pa (and at 0 °C), the volume is reduced by 22.4 L.

(a) In this reaction, how much work is done on the system (H_2, O_2, H_2O) by the surroundings?

(b) The enthalpy change for this reaction is -483.6 kJ. Use this value, along with the answer to (a), to calculate $\Delta_r U$, the change in internal energy in the system.

CHAPTER OUTLINE

6.1 Electromagnetic Radiation

6.2 Quantization: Planck, Einstein, Energy, and Photons

6.3 Atomic Line Spectra and Niels Bohr

6.4 Particle–Wave Duality: Prelude to Quantum Mechanics

6.5 The Modern View of Electronic Structure: Wave or Quantum Mechanics

6.6 The Shapes of Atomic Orbitals

6.7 One More Electron Property: Electron Spin

6.1 Electromagnetic Radiation

Goals for Section 6.1

- Mathematically relate the wavelength (λ) and frequency (ν) of electromagnetic radiation and the speed of light (c).
- Recognize the relative wavelength (or frequency) of the various types of electromagnetic radiation.

In Chapter 2, we described atoms as consisting of protons, neutrons, and electrons. The protons and neutrons are located in a small very dense nucleus, and the electrons occupy the space around the nucleus. In this chapter and the next, we explore the arrangement of electrons in atoms in more detail.

Experiments on the interaction between atoms and electromagnetic radiation were essential to developing theories of this electronic structure of atoms. To understand these experiments we first need to describe the features of electromagnetic radiation.

In 1864, James Clerk Maxwell (1831–1879) developed a mathematical theory to describe light and other forms of radiation in terms of oscillating, or wave-like, electric and magnetic fields (Figure 6.1). Visible light, microwaves, television and radio signals, x-rays, and other forms of radiation are now called **electromagnetic radiation**.

Electromagnetic radiation is characterized by its wavelength and frequency.

- **Wavelength**, symbolized by the Greek letter *lambda* (λ), is defined as the distance between a given point on a wave and the corresponding point in the next cycle of the wave; it is often measured as the distance between successive crests or high points of a wave (or between successive troughs or low points).

◀ **Fireworks.** Fireworks involve a lot of chemistry! The beautiful colors of fireworks result from the transition of electrons from one energy level to another. For more on this topic, see *Applying Chemical Principles 6.2: What Makes the Colors in Fireworks?* on pages 299–300.

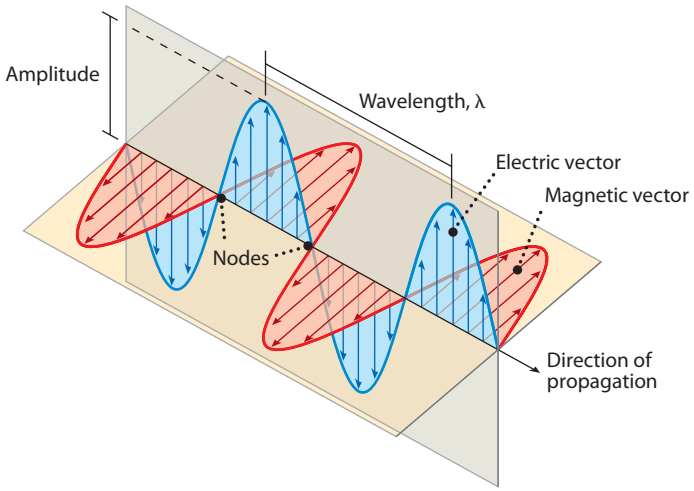

Figure 6.1 Electromagnetic radiation is characterized by its wavelength and frequency. All forms of electromagnetic radiation are propagated through space as vibrating electric and magnetic fields at right angles to one another. Each field is described mathematically by a sine wave. Such oscillating fields emanate from vibrating charges in sources such as lightbulbs or your cell phone.

- **Frequency**, symbolized by the Greek letter *nu* (ν), refers to the number of waves that pass a given point in some unit of time, usually per second. The unit for frequency, written either as s^{-1} or 1/s and standing for 1 oscillation per second, is called a **hertz** (Hz).

Wavelength and frequency are related to the speed (c) at which the wave is propagated (Equation 6.1).

$$c\ (\text{m/s}) = \lambda\ (\text{m}) \times \nu\ (1/\text{s}) \tag{6.1}$$

The speed of visible light and all other forms of electromagnetic radiation in a vacuum is a constant: $c = 2.99792458 \times 10^8$ m/s (approximately 186,000 miles/s or 1.079×10^9 km/h).

As illustrated in Figure 6.2, visible light is only a tiny portion of the total spectrum of electromagnetic radiation. Ultraviolet (UV) radiation, the radiation that can lead to sunburn, has wavelengths shorter than those of visible light. X-rays and γ-rays, the latter emitted in the process of the radioactive disintegration of some atoms, have even shorter wavelengths. At wavelengths longer than those of visible light, we first encounter infrared radiation (IR). The wavelengths of the radiation used in microwave ovens, in television and radio transmissions, in MRI instruments, and for cell phones are longer still.

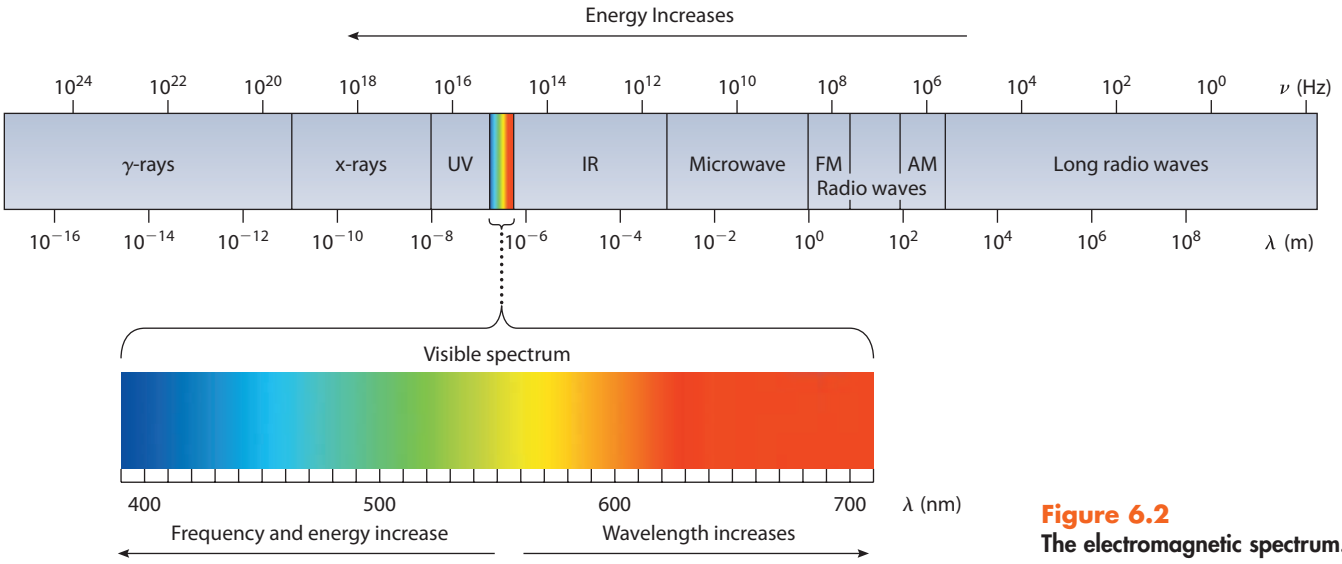

Figure 6.2 The electromagnetic spectrum.

EXAMPLE 6.1

Wavelength-Frequency Conversions

Problem The frequency of the radiation used in cell phones covers a range from about 800 MHz to 2 GHz. (MHz stands for "megahertz," where 1 MHz $= 10^6$ 1/s; GHz stands for "gigahertz," where 1 GHz $= 10^9$ 1/s.) What is the wavelength (in meters) of a cell phone signal operating at 1.12 GHz?

What Do You Know? You are given a frequency of radiation, in GHz, and a factor to convert frequency from GHz to Hz. To calculate the wavelength of this radiation using Equation 6.1, you will need the value of the speed of light, $c = 2.998 \times 10^8$ m/s.

Strategy First convert ν to the units 1/s. Rearrange Equation 6.1 to solve for λ. Substitute the values for the speed of light and the frequency into the equation and solve.

SOLUTION

$$\lambda = \frac{c}{\nu} = \frac{2.998 \times 10^8 \text{ m/s}}{1.12 \times 10^9 \text{ 1/s}} = 0.268 \text{ m}$$

Think about Your Answer A wavelength of 0.268 m falls in the microwave region of the electromagnetic spectrum (Figure 6.2). Make sure you pay attention to units when solving this problem. Note that by choosing frequency in 1/s and the speed of light in m/s the calculated wavelength will be in meters (m).

Check Your Understanding

(a) Which color in the visible spectrum has the highest frequency? Which has the lowest frequency?

(b) Is the wavelength of the radiation used in a microwave oven (2.45 GHz) longer or shorter than that from your favorite FM radio station (for example, 91.7 MHz)?

(c) Are the wavelengths of x-rays longer or shorter than those of ultraviolet light?

(d) Calculate the frequency of green light with a wavelength of 510. nm.

6.2 Quantization: Planck, Einstein, Energy, and Photons

Goals for Section 6.2

- Understand the photoelectric effect.
- Understand that the energy of a photon, a massless particle of radiation, is proportional to its frequency.

Planck's Equation

If a piece of metal is heated to a high temperature, electromagnetic radiation is emitted with wavelengths that depend on temperature (Figure 6.3). At lower temperatures, the color is a dull red. As the temperature increases, the red color brightens, and at even higher temperatures a brilliant white light is emitted. Your eyes detect the emitted radiation in the visible region of the electromagnetic spectrum. Although not seen, both ultraviolet and infrared radiation are also given off by the hot metal (Figure 6.3). The wavelength of the most intense radiation is related to temperature: As the temperature of the metal is raised, the maximum intensity shifts toward shorter wavelengths, that is, toward the ultraviolet. This corresponds to the change in color observed as the temperature is raised.

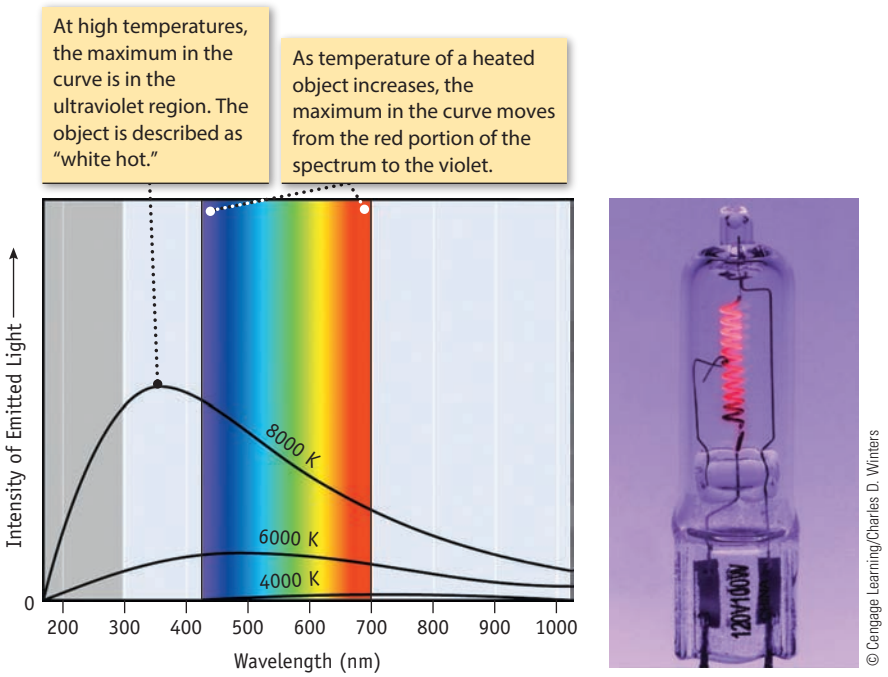

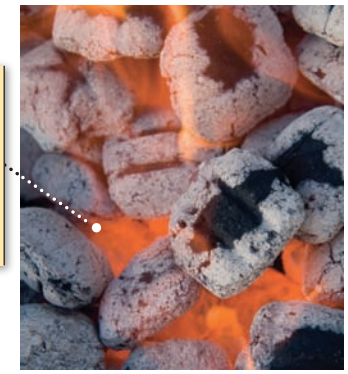

Figure 6.3 The radiation given off by a heated body. When an object is heated, it emits radiation covering a spectrum of wavelengths.

Blackbody radiation. In physics a blackbody is something that absorbs all radiation that falls on it. However, it will emit energy with a temperature-dependent wavelength. The color of the emitted light depends on the temperature.

At the end of the 19th century, scientists were not able to explain the relationship between the intensity and the wavelength for radiation given off by a heated object (often called *blackbody radiation*). Theories available at the time predicted that, as a solid is heated, the intensity should increase continuously with decreasing wavelength, instead of reaching a maximum and then declining as is actually observed. This perplexing situation became known as the *ultraviolet catastrophe* because predictions failed in the ultraviolet region.

In 1900, a German physicist, Max Planck (1858–1947), offered an explanation for the ultraviolet catastrophe: The emitted electromagnetic radiation originated in vibrating atoms (called *oscillators*) in the heated object. He proposed that each oscillator had a fundamental frequency (ν) of oscillation and that these oscillators could only oscillate at either this frequency or whole-number multiples of it ($n\nu$). Because of this, the emitted radiation could have only certain energies, given by the equation

$$E = nh\nu$$

where n must be a positive integer. That is, Planck proposed that the energy is *quantized*. **Quantization** means that only certain energies are allowed. The proportionality constant h in the equation is now called **Planck's constant,** and its experimental value is $6.6260700 \times 10^{-34}$ J · s. The unit of frequency is 1/s, so the energy calculated using this equation is in joules (J). If an oscillator changes from a higher energy to a lower one, energy is emitted as electromagnetic radiation, where the difference in energy between the higher and lower energy states is

$$\Delta E = E_{\text{higher } n} - E_{\text{lower } n} = \Delta nh\nu$$

If the value of Δn is 1, which corresponds to changing from one energy level to the next lower one for that oscillator, then the energy change for the oscillator and the electromagnetic radiation emitted would have an energy equal to

$$E = h\nu \tag{6.2}$$

This equation is called **Planck's equation.**

Night Vision Goggles Even at ambient temperatures objects emit radiation. Some night vision goggles operate by detecting differences in the amount of infrared radiation emitted by different objects. Warmer human bodies, for example, emit more infrared radiation than do cooler objects.

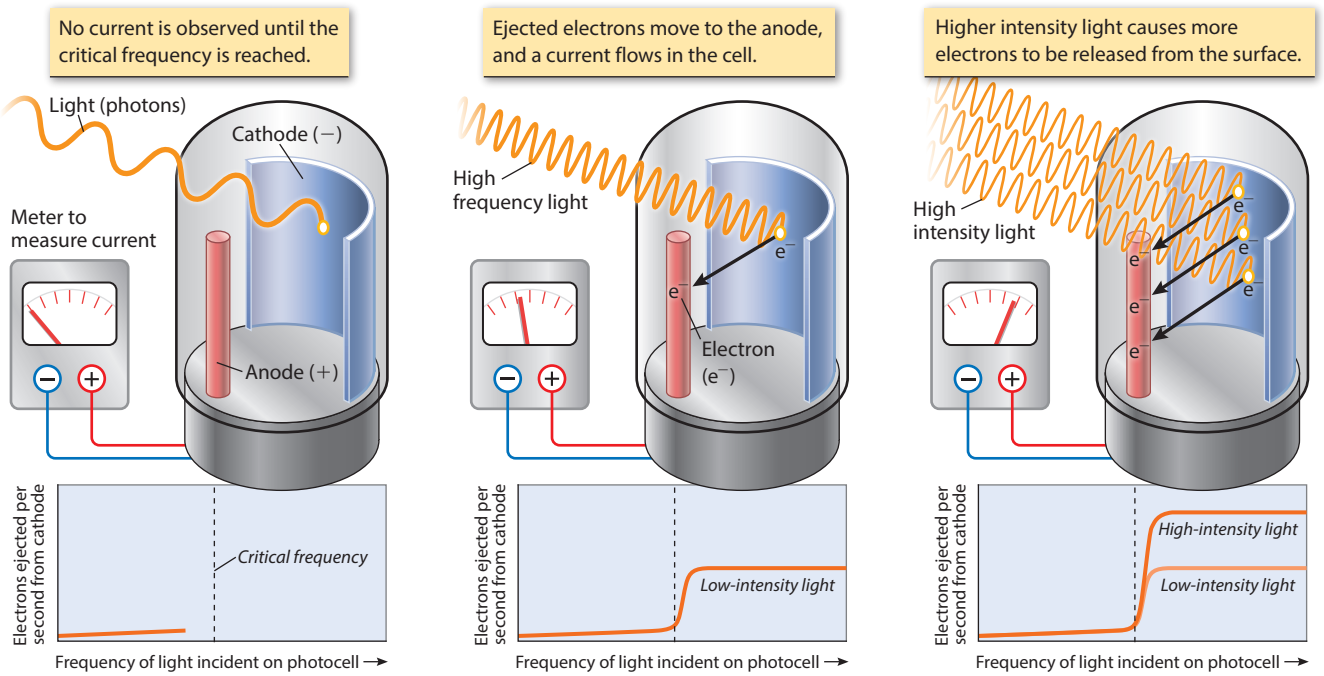
Now, assume as Planck did that there must be a *distribution* of oscillators in an object—some are vibrating at a high frequency, some are vibrating at a low frequency, but most have some intermediate frequency. The few oscillators with high-frequency vibrations are responsible for some of the light, say in the ultraviolet region, and those few with low-frequency vibrations for energies in the infrared region. However, most of the light must come from the majority of the oscillators that have intermediate vibrational frequencies. That is, a spectrum of light is emitted with a maximum intensity at some intermediate wavelength, in accord with experiment. The intensity should not become greater and greater on approaching the ultraviolet region. With this realization, the ultraviolet catastrophe was resolved.

The key aspects of Planck's theory important in general chemistry are that Planck introduced the idea of quantized energies and the equation $E = h\nu$, an equation that was to have an important impact on the work of Albert Einstein in explaining another puzzling phenomenon.

The relationship of energy, wavelength, and frequency

As frequency (ν) increases, energy (E) increases



$$E = h\nu = \frac{hc}{\lambda}$$

As wavelength (λ) decreases, energy (E) increases

Einstein and the Photoelectric Effect

A few years after Planck's work, Albert Einstein (1879–1955) incorporated Planck's ideas into an explanation of the *photoelectric effect* and in doing so changed the description of electromagnetic radiation.

In the photoelectric effect, electrons are ejected when light strikes the surface of a metal (Figure 6.4), but only if the frequency of the light is high enough. If light with a lower frequency is used, no electrons are ejected, regardless of the light's intensity (its brightness). If the frequency is at or above a minimum, critical frequency, increasing the light intensity causes more electrons to be ejected.

(a) A photocell operates by the photoelectric effect. The main part of the cell is a light-sensitive cathode. This is a material, usually a metal, that ejects electrons if struck by photons of light of sufficient energy.

(b) When light with a greater frequency than the critical frequency is used, the excess energy of the photon allows the electron to escape the atom with greater velocity.

(c) If higher intensity light is used, more electrons will be released from the surface. The onset of current is observed at the same frequency as with lower intensity light, but more current flows.

Figure 6.4 A photoelectric cell.

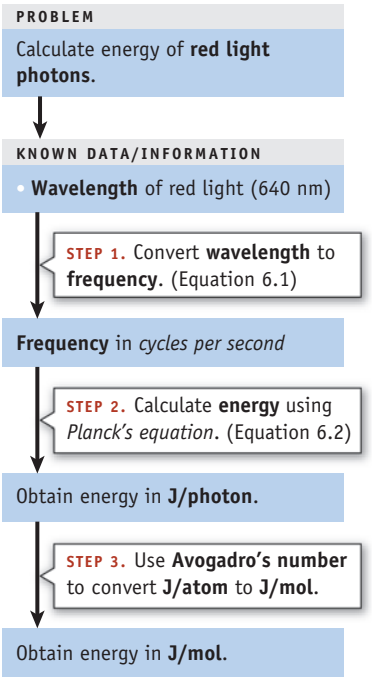
Einstein decided the experimental observations could be explained by combining Planck's equation ($E = h\nu$) with a new idea, that light has particle-like properties. Einstein characterized these massless particles, now called **photons,** as packets of energy, and stated that the energy of each photon is proportional to the frequency of the radiation as defined by Planck's equation. In the photoelectric effect, photons striking atoms on a metal surface will cause electrons to be ejected only if the photons have high enough energy. The greater the number of photons that strike the surface at or above the threshold energy, the greater the number of electrons dislodged. The metal atoms will not lose electrons, however, if no individual photon has enough energy to dislodge an electron from an atom.



EXAMPLE 6.2

Energy and Chemistry: Using Planck's Equation

Problem DVD players use lasers that emit red light with a wavelength of 640 nm. What is the energy of one photon of this light? What is the energy of 1.0 mol of photons of red light?

What Do You Know? You are given a wavelength of electromagnetic radiation, in nm. You also know the relationship between wavelength and frequency (Equation 6.1) and also between the energy per photon and frequency (Equation 6.2). Finally, you know that one mole of photons corresponds to 6.022×10^{23} photons.

Strategy Map 6.2

Strategy

- Convert the wavelength from units of nanometers to units of meters.
- Use Equation 6.1 to determine the frequency of the light.
- Use Equation 6.2 to determine the energy per photon.
- Use the energy per photon and Avogadro's number to calculate the energy per mole of photons.

SOLUTION The wavelength (640 nm) expressed in meters is 6.4×10^{-7} m. The frequency is determined using Equation 6.1

$$\nu = \frac{c}{\lambda} = \frac{2.998 \times 10^{8}\ \text{m/s}}{6.4 \times 10^{-7}\ \text{m}} = 4.68 \times 10^{14}\ \text{1/s}$$

and then the frequency is used to calculate the energy per photon.

$$E \text{ per photon} = h\nu = (6.626 \times 10^{-34}\ \text{J} \cdot \text{s/photon}) \times (4.68 \times 10^{14}\ \text{1/s})$$
$$= 3.10 \times 10^{-19}\ \text{J/photon} = 3.1 \times 10^{-19}\ \text{J/photon}$$

Finally, the energy of a mole of photons is calculated by multiplying the energy per photon by Avogadro's number:

$$E \text{ per mole} = (3.10 \times 10^{-19}\ \text{J/photon}) \times (6.022 \times 10^{23}\ \text{photons/mol})$$
$$= 1.9 \times 10^{5}\ \text{J/mol (or 190 kJ/mol)}$$

Think about Your Answer Keep in mind that wavelength and frequency are inversely proportional whereas energy per photon and frequency are directly proportional. Red light is at the long wavelength end of the visible spectrum, so the frequency and energy per photon are lower than those of the other colors.

Check Your Understanding

Calculate the energy per mole of photons for the laser used in Blu-ray players ($\lambda = 405$ nm).

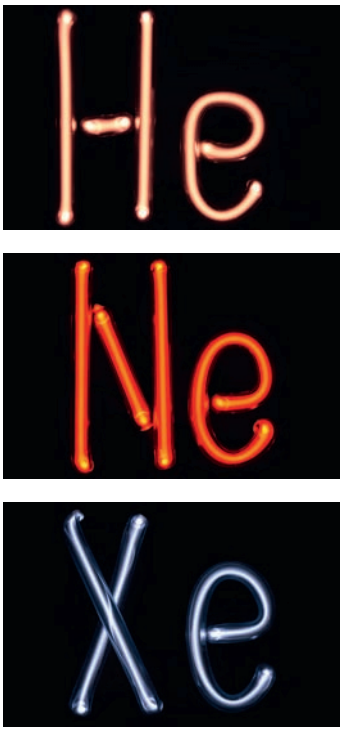
We know that electromagnetic radiation has wave properties, but we have also seen that there are experiments, such as the photoelectric effect, for which it is best to model it as particles called photons. But, how can electromagnetic radiation be both a particle and a wave? In part, we are facing limitations in language; the words *particle* and *wave* accurately describe things encountered on a macroscopic scale, but we are using them to model something—electromagnetic radiation—that is not fully explained by either term. In addition, no single experiment has yet been done to show electromagnetic radiation behaving *simultaneously* as a wave and a particle. Scientists now accept this **wave–particle duality**—that is, the idea that electromagnetic radiation has the properties of both a wave and a particle (see Section 6.4).

6.3 Atomic Line Spectra and Niels Bohr

Goals for Section 6.3



- Describe the Bohr model of the atom, its ability to account for the emission line spectra of excited hydrogen atoms, and the limitations of the model.
- Calculate the energy absorbed or emitted when an electron in a hydrogen atom moves from one energy level to another.

If a high voltage is applied to atoms of an element in the gas phase at low pressure, the atoms absorb energy and are said to be "excited." The excited atoms can then emit light. A familiar example is the colored light from "neon" advertising signs.

The light from excited atoms is composed of only a few different wavelengths of light. We can demonstrate this by passing a beam of light from excited neon or hydrogen atoms through a prism (Figure 6.5); only a few colored lines are seen. The spectrum obtained in this manner is called a **line emission spectrum.** This is in contrast to the light falling on Earth from the Sun, or the light emitted by a very hot object, which consists of a continuous spectrum of wavelengths (Figures 6.2 and 6.3).

Every element has a unique emission spectrum, as illustrated by the spectra for hydrogen, mercury, and neon in Figure 6.6. Indeed, the characteristic lines in the emission spectrum of an element can be used in chemical analysis, both to identify the element and to determine how much of it is present in a mixture.

A goal of scientists in the late 19th century was to explain why excited gaseous atoms emit light of only certain frequencies. One approach was to look for

Photos: Phillip Slawinski

"Neon" signs. Not all lighted signs contain neon. Other gases can emit light in the visible spectrum when excited. Alternatively, the glass tubes containing the gases are coated inside with light-emitting phosphors (as in fluorescent lights).

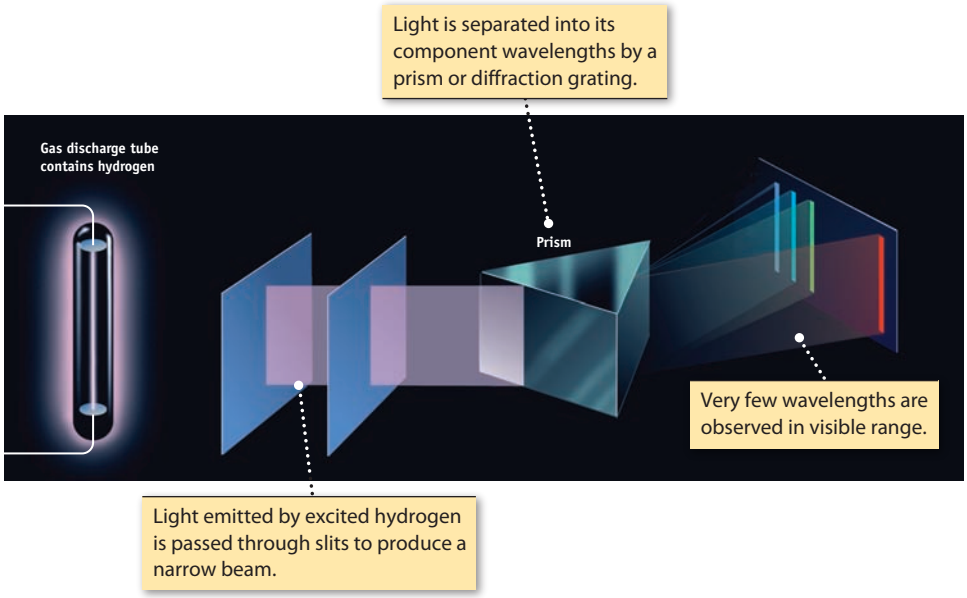


Figure 6.5 The visible emission spectrum of hydrogen. Based on the appearance, the name *line spectrum* is used for the light emitted by a glowing gas.

a mathematical relationship among the observed wavelengths because a regular pattern of information implies a logical explanation. The first steps in this direction were taken by Johann Balmer (1825–1898) and later by Johannes Rydberg (1854–1919). From their studies, an equation—now called the **Balmer equation** (Equation 6.3)—was found that could be used to calculate the wavelength of the red, green, and blue lines in the visible emission spectrum of hydrogen (Figure 6.6).

$$\frac{1}{\lambda} = R\left(\frac{1}{2^2} - \frac{1}{n^2}\right) \text{ when } n > 2 \qquad (6.3)$$

In this equation n is an integer, and R, now called the **Rydberg constant,** has the value $1.0974 \times 10^7\ \text{m}^{-1}$. If $n = 3$, for example, the wavelength of the red line in the hydrogen spectrum is obtained (6.56×10^{-7} m, or 656 nm). If $n = 4$, the wavelength for the green line is calculated. Using $n = 5$ and $n = 6$ in the equation gives the wavelengths of the blue lines. The four visible lines in the spectrum of hydrogen atoms are now known as the **Balmer series**.

The Bohr Model of the Hydrogen Atom

Early in the 20th century, the Danish physicist Niels Bohr (1885–1962) proposed a model for the electronic structure of atoms and with it an explanation for the emission spectra of excited atoms. Bohr proposed a planetary structure for the hydrogen atom in which the electron moved in a circular orbit around the nucleus, similar to a planet revolving about the Sun. In proposing this model, however, he had to contradict the laws of classical physics. According to classical theories, a charged electron moving in the positive electric field of the nucleus should lose energy; a consequence of the loss of energy is that the electron would eventually crash into the nucleus. This is clearly not the case; if it were, matter would eventually self-destruct. To solve this contradiction, Bohr postulated that there are certain orbits corresponding to particular energy levels where this would not occur. As long as an electron occupies one of these energy levels, the system is stable. That is, Bohr introduced *quantization* into the description of electronic structure. By combining this quantization postulate with Coulomb's law and the laws of motion from classical physics, Bohr derived Equation 6.4 for the total energy possessed by the single electron in the nth orbit (energy level) of the H atom.

Equation 6.4 and Coulomb's Law Bohr's derivation of Equation 6.4 began with the postulate that the stability of the electron in an orbit requires that the Coulombic force of attraction between the electron and the nucleus must be balanced by the centrifugal force due to the electron's circular motion: $e^2/r^2 = mv^2/r$ (where e is the electron charge, r is the electron-nucleus separation, m is the electron mass, and v is the electron velocity).

$$\text{Total energy of electron in the } n\text{th level} = E_n = -\frac{Rhc}{n^2} \qquad (6.4)$$

(Planck's constant, Rydberg constant, Speed of light; Principal quantum number)

Here, E_n is the energy of the electron (in J); and R, h, and c are constants (the Rydberg constant, Planck's constant, and the speed of light, respectively). The symbol n

is a positive, unitless integer called the **principal quantum number**. It can have integral values of 1, 2, 3, and so on.

Figure 6.7 illustrates how Equation 6.4 applies to the electron of the hydrogen atom.

- The quantum number n defines the energies of the allowed electron orbits in the H atom.
- The energy of the system has a negative value when the electron is in an orbit because the atom has a lower energy than when the electron is infinitely separated from the nucleus. The zero of energy occurs when $n = \infty$, that is, when the electron is infinitely separated from the nucleus.
- An atom with its electrons in the lowest possible energy levels is said to be in its **ground state**; for the hydrogen atom, this is the level defined by the quantum number $n = 1$. The energy of this state is $-Rhc/1^2$, meaning that it has an amount of energy equal to *Rhc below* the energy of the infinitely separated electron and nucleus.
- States for the H atom with higher energies (and $n > 1$) are called **excited states**.
- Because the energy is dependent on $1/n^2$, the energy levels are progressively closer together as n increases.
- An electron in the $n = 1$ orbit is closest to the nucleus and has the lowest (most negative) energy. As the value of n increases, the distance of the electron from the nucleus increases, and the energy of the electron becomes higher (less negative).

EXAMPLE 6.3

Energies of the Ground and Excited States of the H Atom

Problem Calculate the energies of the $n = 1$ and $n = 2$ states of the hydrogen atom in joules per atom and in kilojoules per mole. What is the difference in energy of these two states in kJ/mol?

What Do You Know? The $n = 1$ and $n = 2$ states are the first and second states (lowest and next to lowest energy state) in the Bohr description of the hydrogen atom. Use Equation 6.4 to calculate the energy of each state. For the calculations you will need the following constants: R (Rydberg constant) $= 1.097 \times 10^7\ m^{-1}$; h (Planck's constant) $= 6.626 \times 10^{-34}\ J \cdot s$; c (speed of light) $= 2.998 \times 10^8$ m/s; and N_A (Avogadro's number) $= 6.022 \times 10^{23}$ atoms/mol.

Strategy For each energy level, substituting the appropriate values into Equation 6.4 and solving gives the energy in J/atom. Multiply this value by N_A to find the energy in J/mol. Subtract the energy for the $n = 1$ level from the energy of the $n = 2$ level to obtain the energy difference.

SOLUTION When $n = 1$, the energy of an electron in a single H atom is

$$E_1 = -Rhc$$

$$E_1 = -(1.097 \times 10^7\ m^{-1})(6.626 \times 10^{-34}\ J \cdot s)(2.998 \times 10^8\ m/s)$$

$$= -2.1792 \times 10^{-18}\ J/atom = -2.179 \times 10^{-18}\ J/atom$$

In units of kJ/mol,

$$E_1 = \frac{-2.1792 \times 10^{-18}\ J}{atom} \times \frac{6.022 \times 10^{23}\ atoms}{mol} \times \frac{1\ kJ}{1000\ J}$$

$$= -1312.3\ kJ/mol = -1312\ kJ/mol$$

When $n = 2$, the energy is

$$E_2 = -\frac{Rhc}{2^2} = -\frac{E_1}{4} = -\frac{2.1792 \times 10^{-18}\ J/atom}{4}$$

$$= -5.4479 \times 10^{-19}\ J/atom = -5.448 \times 10^{-19}\ J/atom$$

In units of kJ/mol,

$$E_2 = \frac{-5.4479 \times 10^{-19}\ J}{atom} \times \frac{6.022 \times 10^{23}\ atoms}{mol} \times \frac{1\ kJ}{1000\ J}$$

$$= -328.07\ kJ/mol = -328.1\ kJ/mol$$

The difference in energy, ΔE, between the first two energy states of the H atom is

$$\Delta E = E_2 - E_1 = (-328.07\ kJ/mol) - (-1312.3\ kJ/mol) = 984\ kJ/mol$$

Think about Your Answer The calculated energies are negative, with E_1 more negative than E_2. The $n = 2$ state is higher in energy than the $n = 1$ state by 984 kJ/mol. Also, be sure to notice that 1312 kJ/mol is the value of Rhc multiplied by Avogadro's number N_A (that is, N_ARhc). *This value, 1312 kJ/mol, will be useful in future calculations.*

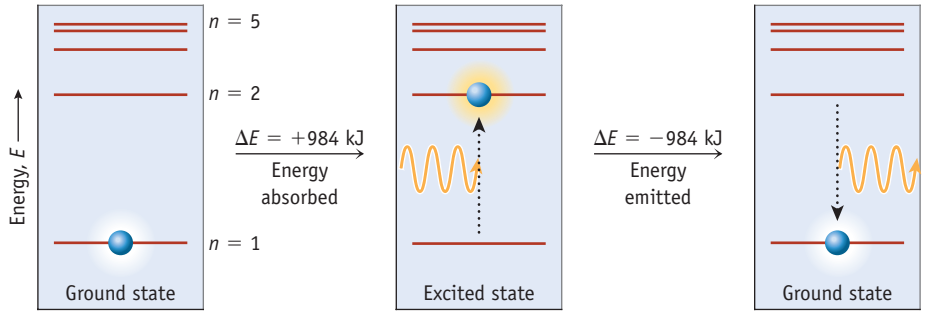

Figure 6.8 Absorption of energy by the atom as the electron moves to an excited state. Energy is absorbed when an electron moves from the $n = 1$ state to the $n = 2$ state ($\Delta E > 0$). When the electron returns to the $n = 1$ state from $n = 2$, energy is evolved ($\Delta E < 0$). The energy emitted is 984 kJ/mol, as calculated in Example 6.3.

The Bohr Theory and the Spectra of Excited Atoms

Bohr's theory describes electrons as having only specific orbits and energies. If an electron moves from one energy level to another, then energy must be absorbed or evolved. This idea allowed Bohr to relate energies of electrons and the emission spectrum of hydrogen atoms.

To move an electron from the $n = 1$ state to an excited state, energy must be transferred to the atom (from the surroundings). When E_{final} has $n = 2$ and $E_{initial}$ has $n = 1$, then $0.75Rhc = 1.63 \times 10^{-18}$ J/atom (or 984 kJ/mol) of energy must be transferred (Figure 6.8 and Example 6.3), no more and no less. If $0.7Rhc$ or $0.8Rhc$ is provided, no transition between states is possible. Requiring a specific and precise amount of energy is a consequence of quantization.

The opposite process, in which an electron "falls" from a level of higher n to one of lower n, leads to emission of energy, a transfer of energy, usually as radiation, from the atom to its surroundings. For example, for a transition from the $n = 2$ level to $n = 1$ level,

$$\Delta E = E_{final} - E_{initial} = -1.63 \times 10^{-18} \text{ J/atom } (= -984 \text{ kJ/mol})$$

The negative sign indicates 1.63×10^{-18} J/atom (or 984 kJ/mol) is *emitted*.

Now we can visualize the mechanism by which the characteristic line emission spectrum of hydrogen originates according to the Bohr model. Energy is provided to the atoms from an electric discharge or by heating. Depending on how much energy is added, some atoms have their electrons excited from the $n = 1$ state to the $n = 2$, 3, or even higher states. After absorbing energy, these electrons can return to any lower level (either directly or in a series of steps), releasing energy (Figure 6.9). We observe this released energy as photons of electromagnetic radiation, and, because only certain energy levels are possible, only photons with particular energies and wavelengths are emitted.

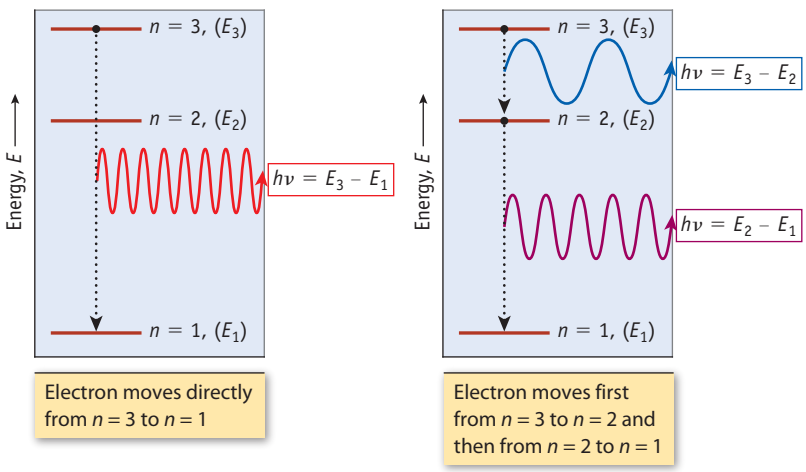

Figure 6.9 Radiation emitted on changes in energy levels. An electron excited to $n = 3$ can return directly to $n = 1$, or it can drop to $n = 2$ and then to $n = 1$. These three possible transitions are observed as three different wavelengths of emitted radiation. The energies and frequencies are in the order $(E_3 - E_1) > (E_2 - E_1) > (E_3 - E_2)$.

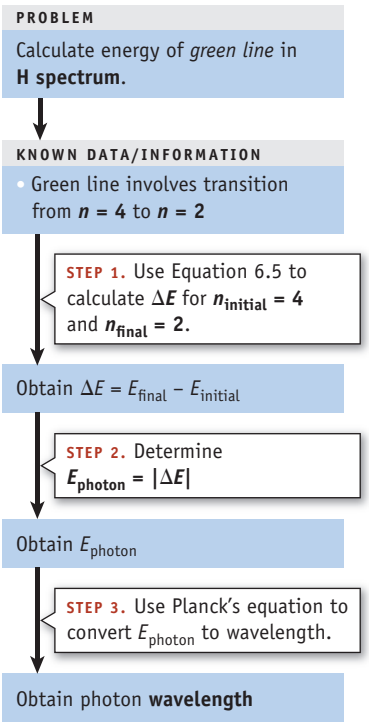
The energy of any emission line (in J/atom) for excited hydrogen atoms can be calculated using Equation 6.5.

$$\Delta E = E_{final} - E_{initial} = -Rhc\left(\frac{1}{n_{final}^2} - \frac{1}{n_{initial}^2}\right) \quad (6.5)$$

Equation 6.5 and the Balmer Equation Equation 6.5 has the same form as the Balmer Equation (Equation 6.3) where $n_{final} = 2$.

The value of ΔE *in J/atom can be related to the wavelength or frequency of radiation using Planck's equation* ($\Delta E = h\nu$).

For hydrogen, a series of emission lines having energies in the ultraviolet region (called the **Lyman series**; Figure 6.10) arises from electrons moving from states with $n > 1$ to the $n = 1$ state. The series of lines that have energies in the visible region—the **Balmer series**—arises from electrons moving from states with $n > 2$ to the $n = 2$ state. There are also series of lines in the infrared spectral region, arising from transitions from higher levels to the $n = 3$, 4, or 5 levels.



EXAMPLE 6.4

Energies of Emission Lines for Excited Atoms

Problem Calculate the wavelength of the green line in the visible spectrum of excited H atoms (Figure 6.10).

What Do You Know? The green line in the spectrum of hydrogen arises from the electron transition from the $n = 4$ state ($n_{initial}$) to the $n = 2$ state (n_{final}).

Strategy Map 6.4

Strategy

- Calculate the difference in energy between the states using Equation 6.5. You can simplify this calculation by using the value of *Rhc* from Example 6.3.
- Relate the difference in energy to the wavelength of light using the equation $E = hc/\lambda$. (This equation is derived by combining Equations 6.1 and 6.2.)

SOLUTION Calculate ΔE.

$$\begin{aligned}\Delta E &= E_{final} - E_{initial} = -Rhc\left(\frac{1}{2^2} - \frac{1}{4^2}\right)\\ &= -Rhc\left(\frac{1}{4} - \frac{1}{16}\right) = -Rhc\,(0.1875)\\ &= -\left(2.1792 \times 10^{-18}\ \text{J}\right)(0.1875) = -4.0859 \times 10^{-19}\ \text{J/photon}\end{aligned}$$

Recognize that, while the change in energy has a sign indicating the "direction" of energy transfer, the energy of the photon emitted, E_{photon}, does not have a sign, $E_{photon} = |\Delta E| = 4.0859 \times 10^{-19}$ J/photon, that is, the absolute value of the energy found above. Now apply Planck's equation to calculate the wavelength ($E_{photon} = h\nu = hc/\lambda$, and so $\lambda = hc/E_{photon}$).

$$\lambda = \frac{hc}{E_{photon}} = \frac{\left(6.626 \times 10^{-34}\ \frac{\text{J}\cdot\text{s}}{\text{photon}}\right)\left(2.998 \times 10^{8}\ \frac{\text{m}}{\text{s}}\right)}{4.0859 \times 10^{-19}\ \text{J/photon}}$$

$$= 4.8617 \times 10^{-7}\ \text{m}$$

$$= (4.8617 \times 10^{-7}\ \text{m})(1 \times 10^{9}\ \text{nm/m})$$

$$= 486.2\ \text{nm}$$

Think about Your Answer You might recall that visible light has wavelengths of 400 to 700 nm. The calculated value is in this region and has a value appropriate for the green line. The answer is in excellent agreement with the experimentally determined value of 486.1 nm.

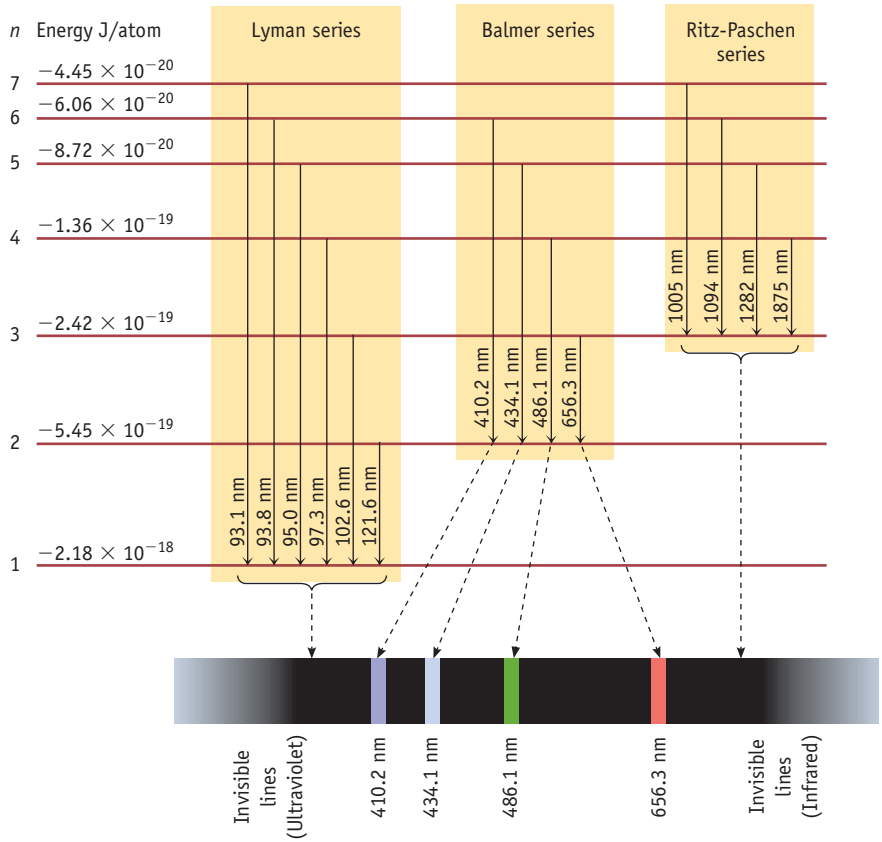

Figure 6.10 Some of the electronic transitions that can occur in an excited H atom.

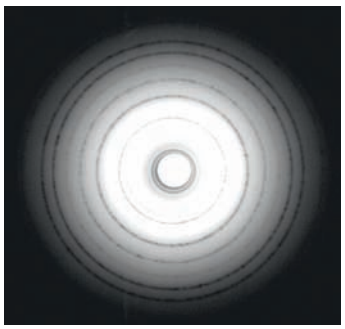
- **Lyman** series: ultraviolet region, transitions to the $n = 1$ level.
- **Balmer** series: visible region, transitions from levels with values of $n > 2$ to $n = 2$.
- **Ritz-Paschen** series: infrared region, transitions from levels with $n > 3$ to the $n = 3$ level.
- Transitions from $n = 8$ and higher levels to lower levels occur but are not shown in this figure.

Check Your Understanding

The Lyman series of spectral lines for the H atom, in the ultraviolet region, arises from transitions from higher levels to $n = 1$. Calculate the frequency and wavelength of the least energetic line in this series.

Bohr's model, introducing quantization into a description of the atom, tied the unseen (the structure of the atom) to the seen (the observable lines in the hydrogen spectrum). This is important because agreement between theory and experiment is taken as evidence that the theoretical model is valid. Nonetheless, the theory was imperfect. This model of the atom explained only the spectrum of hydrogen atoms and of other systems having one electron (such as He^+), but it failed for all other systems. A better model of electronic structure was needed.

6.4 Particle–Wave Duality: Prelude to Quantum Mechanics



Goals for Section 6.4

- Understand that in the modern view of the atom, electrons can be described either as particles or as waves.
- Calculate the wavelength of a particle using de Broglie's equation.

The photoelectric effect demonstrated that light, usually considered to be a wave, can also have the properties of particles, albeit without mass. That is, there is a wave-particle duality associated with light. Is there anything else that exhibits

R. K. Bohn, Department of Chemistry, University of Connecticut

Diffraction and the wave nature of electrons. A beam of electrons was passed through a thin film of MgO. The atoms in the MgO lattice diffracted the electron beam, producing this pattern. Diffraction is best explained by assuming electrons have wave properties.

wave-particle duality? The particle properties of matter, electrons for example, are well known. Cathode ray tubes, such as were used by J. J. Thomson in his experiment to determine the charge-to-mass ratio of an electron (page 66), generate a beam of electrons. When the electrons impact the screen, the beam gives rise to tiny flashes of colored light. Such phenomena are best explained if we picture electrons as being particles.

But does matter also exhibit wave properties? This question was pondered by Louis Victor de Broglie (1892–1987), who, in 1925, proposed that a free electron of mass m moving with a velocity v should have an associated wavelength λ, calculated by Equation 6.6.

$$\lambda = \frac{h}{mv} \tag{6.6}$$

De Broglie called the wave corresponding to the wavelength calculated from this equation a "matter wave."

De Broglie's revolutionary idea linked the particle properties of the electron (mass and velocity) with a wave property (wavelength). Experimental proof was soon produced. In 1927, C. J. Davisson (1881–1958) and L. H. Germer (1896–1971) found that diffraction, a property of waves, was observed when a beam of electrons was directed at a thin sheet of metal foil. Furthermore, assuming the electron beam to be a matter wave, de Broglie's relation was followed quantitatively. This was taken as evidence that in certain experiments electrons can be described as having wave properties.

For the wavelength of a matter wave to be measurable, the product of m and v must be very small because h is so small. A 46-g golf ball, traveling at 150 mph, for example, has a large mv product (3.1 kg · m/s) and therefore an incredibly small wavelength, 2.1×10^{-34} m! Such a small value cannot be measured with any instrument now available, nor is such a value meaningful. As a consequence, wave properties are never assigned to a golf ball or any other massive object. It is possible to observe wave-like properties only for particles of extremely small mass, such as protons, electrons, and neutrons.

Like electromagnetic radiation, matter thus exhibits a wave-particle duality. In some experiments, electrons behave as if they are made of particles; in others, they behave as if they are waves. This wave-particle duality is central to an understanding of the modern model of the atom.

EXAMPLE 6.5

Using de Broglie's Equation

Problem Calculate the wavelength associated with an electron of mass $m = 9.109 \times 10^{-28}$ g that travels at 40.0% of the speed of light.

What Do You Know? The equation proposed by de Broglie, $\lambda = h/mv$, relates wavelength to the mass and velocity of a moving particle. Here you are given the mass of the electron and its velocity; you will need Planck's constant, $h = 6.626 \times 10^{-34}$ J · s. Note also that 1 J = 1 kg · m^2/s^2 (page 33).

Strategy

- So that the units in the problem are consistent, first express the electron mass in kg and electron velocity in m/s.
- Substitute values of m (in kg), v (in m/s), and h in the de Broglie equation and solve for λ.

SOLUTION

Electron mass $= 9.109 \times 10^{-31}$ kg

Electron speed (40.0% of light speed) $= (0.400)(2.998 \times 10^8 \text{ m/s}) = 1.199 \times 10^8$ m/s

Substituting these values into de Broglie's equation, we have

$$\lambda = \frac{h}{mv} = \frac{6.626 \times 10^{-34} \ (\text{kg} \cdot \text{m}^2/\text{s}^2)(\text{s})}{(9.109 \times 10^{-31} \text{ kg})(1.199 \times 10^8 \text{ m/s})} = 6.07 \times 10^{-12} \text{ m}$$

In nanometers, the wavelength is

$$\lambda = (6.07 \times 10^{-12} \text{ m})(1 \times 10^9 \text{ nm/m}) = 6.07 \times 10^{-3} \text{ nm}$$

Think about Your Answer This wavelength is measureable and is about 1/12 of the diameter of the H atom. Also notice the care taken to monitor units in this problem.

Check Your Understanding

Calculate the wavelength associated with a neutron having a mass of 1.675×10^{-24} g and a kinetic energy of 6.21×10^{-21} J. (The kinetic energy of a moving particle is $E = \frac{1}{2}mv^2$.)

6.5 The Modern View of Electronic Structure: Wave or Quantum Mechanics

Goals for Section 6.5

- Understand that the position of an electron in an atom is not known with certainty; only the probability of the electron being at a given point of space can be calculated. This is a consequence of the Heisenberg uncertainty principle.
- Understand that the modern view of atoms describes electrons as waves and identifies orbitals as allowed quantized energies. Describe the allowed energy states of the orbitals in an atom using three quantum numbers: n, ℓ, and m_ℓ.

How does wave–particle duality affect our model of the arrangement of electrons in atoms? Following World War I, German scientists Erwin Schrödinger (1887–1961), Max Born (1882–1970), and Werner Heisenberg (1901–1976) provided the answer.

Erwin Schrödinger received the Nobel Prize in physics in 1933 for a comprehensive theory of the behavior of electrons in atoms. Starting with de Broglie's hypothesis that *an electron could be described as a matter wave*, Schrödinger developed a model for electrons in atoms that has come to be called **quantum mechanics** or **wave mechanics.** Unlike Bohr's model, Schrödinger's model can be difficult to visualize, and the mathematical equations are complex. Nonetheless, understanding its implications is essential to understanding the modern view of the atom.

Let us start by describing the behavior of an electron in the atom as a **standing wave**. If you tie down a string at both ends, as you would the string of a guitar, and then pluck it, the string vibrates as a standing wave (Figure 6.11), and you could show that there are only certain vibrations allowed for these standing waves. That is, the vibrations are quantized. Similarly, as Schrödinger showed, only certain matter waves are possible for an electron in an atom.

To describe these matter waves, physicists defined a series of mathematical equations called **wavefunctions**, designated by the Greek letter ψ (psi). When these equations are solved for energy, we find the following important outcomes:

- Only certain wavefunctions are found to be acceptable, and each is associated with an allowed energy value. That is, *the energy of the electron in the atom is quantized.*

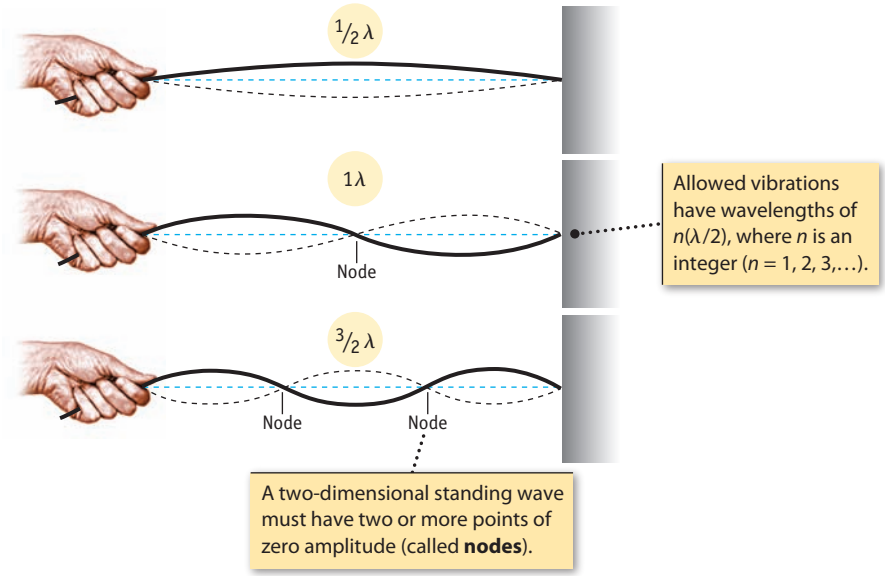

Figure 6.11 Standing waves. Only certain vibrations are possible.

Wavefunctions and Energy In Bohr's theory, the electron energy for the H atom is given by $E_n = -Rhc/n^2$. Schrödinger's electron wave model gives the same result.

- The solutions to Schrödinger's equation for an electron in three-dimensional space depend on three integers, n, ℓ, and m_ℓ, which are called **quantum numbers**. Only certain combinations of their values are possible, as we shall outline below.

The next step in understanding the quantum mechanical view is to explore the physical significance of the wavefunction, ψ (psi). Here we owe much to Max Born's interpretation. He said that

- the value of the wavefunction ψ at a given point in space (x, y, z) is the amplitude (height) of the electron matter wave. This value has both a magnitude and a sign, which can be either positive or negative. (Visualize a vibrating string; Figure 6.11.) Points of positive amplitude are above the axis of the wave, and points of negative amplitude are below it.
- the square of the value of the wavefunction (ψ^2) at a point is related to the *probability* of finding an electron around that point. Scientists refer to ψ^2 as a **probability density**. Just as we can calculate the mass of an object from the product of its density and volume, we can calculate the *probability* of finding an electron in a tiny volume from the product of ψ^2 and the volume.

There is one more important concept to touch on as we try to understand the modern quantum mechanical model. In Bohr's model of the atom, both the energy and location (the orbit) for the electron in the hydrogen atom can be described accurately. However, Werner Heisenberg postulated that, for a tiny object such as an electron in an atom, it is impossible to determine accurately *both* its position and its energy. That is, any attempt to determine accurately either the location or the energy will leave the other uncertain. This is now known as the **Heisenberg uncertainty principle**: *If we choose to know the energy of an electron in an atom with only a small uncertainty, then we must accept a correspondingly large uncertainty in its position.* The importance of this idea is that we can assess only the likelihood, or probability, of finding an electron with a given energy within a given region of space. Because energy is the key to understanding the chemistry of an atom, chemists accept the notion of knowing only the approximate location of the electron.

Orbits and Orbitals In Bohr's model of the H atom, the electron is confined to a prescribed path around the nucleus, its *orbit*, so we should be able to define its position and energy at a given moment in time. In the modern view, the term *orbital* is used. We know the energy of the electron but only the region of space within which it is probably located, that is, its orbital.

Quantum Numbers and Orbitals

The wavefunction for an electron in an atom describes an **atomic orbital**. We know the energy of this electron, but we only know the region of space within which it is most probably located. When an electron has a particular wavefunction, it is said to "occupy" a particular orbital with a given energy.

Each orbital is described by three quantum numbers: n, ℓ, and m_ℓ. Let us first describe the quantum numbers and the information they provide and then discuss the connection between quantum numbers and the energies and shapes of atomic orbitals.

n, the Principal Quantum Number ($n = 1, 2, 3, \ldots$)

The principal quantum number n can have any integer value from 1 to infinity. The value of n is the primary factor in determining the *energy* of an orbital. It also defines the *size* of an orbital: for a given atom, the greater the value of n, the greater the size of the orbital.

In atoms having more than one electron, two or more electrons may have the same n value. These electrons are then said to be in the same **electron shell.**

ℓ, the Orbital Angular Momentum Quantum Number ($\ell = 0, 1, 2, 3, \ldots, n - 1$)

Orbitals of a given electron shell can be grouped into **subshells**, where each subshell is characterized by a different value of the quantum number ℓ. The quantum number ℓ, referred to as the "orbital angular momentum" quantum number, can have any integer value from 0 to a maximum of $n - 1$. This quantum number defines the *characteristic shape of an orbital*; different ℓ values correspond to different orbital shapes.

Energy and Quantum Numbers The energy of the H atom depends only on the value of n. In atoms with more electrons, the energy depends on both n and ℓ.

The value of n limits the number of subshells possible for each shell. The number of possible subshells increases as n increases. For the shell with $n = 1$, ℓ must equal 0; thus, only one subshell is possible. When $n = 2$, ℓ can be either 0 or 1. Two values of ℓ are now possible, and it follows that there are two subshells in the $n = 2$ electron shell.

Subshells are usually identified by letters. For example, an $\ell = 1$ subshell is called a "p subshell," and an orbital in that subshell is called a "p orbital."

Value of ℓ	Subshell Label
0	s
1	p
2	d
3	f

m_ℓ, the Magnetic Quantum Number ($m_\ell = 0, \pm1, \pm2, \pm3, \ldots, \pm\ell$)

The magnetic quantum number, m_ℓ, is related to the *orientation in space of the orbitals within a subshell*. Orbitals in a given subshell differ in their orientation in space, not in their energy.

The value of m_ℓ can range from $+\ell$ to $-\ell$, with 0 included. For example, when $\ell = 2$, m_ℓ can have five values: -2, -1, 0, $+1$, and $+2$. The number of values of m_ℓ for a given subshell ($= 2\ell + 1$) specifies the number of orbitals in the subshell.

Shells and Subshells

Allowed values of the three quantum numbers are summarized in Table 6.1. By analyzing the sets of quantum numbers in this table, you will discover the following:

- n = the number of subshells in a shell
- $2\ell + 1$ = the number of orbitals in a subshell = the number of values of m_ℓ
- n^2 = the number of orbitals in a shell

Shells, Subshells, and Orbitals—A Summary Electrons in atoms are arranged in shells. Within each shell, there can be one or more electron subshells, each composed of one or more orbitals.

	Quantum Number
Shell	n
Subshell	ℓ
Orbital	m_ℓ

The First Electron Shell, $n = 1$

When $n = 1$, the value of ℓ can only be 0, so m_ℓ must also have a value of 0. This means that, in the shell closest to the nucleus, only one subshell exists, and that subshell consists of only a single orbital, the 1s orbital.

TABLE 6.1 Summary of the Quantum Numbers, Their Interrelationships, and the Orbital Information Conveyed

PRINCIPAL QUANTUM NUMBER	ANGULAR MOMENTUM QUANTUM NUMBER	MAGNETIC QUANTUM NUMBER	NUMBER AND TYPE OF ORBITALS IN THE SUBSHELL
Symbol = n Values = 1, 2, 3, . . .	Symbol = ℓ Values = 0 . . . $n - 1$	Symbol = m_ℓ Values = $-\ell$ . . . 0 . . . $+\ell$	n = number of subshells Number of orbitals in shell = n^2 and number of orbitals in subshell = $2\ell + 1$
1	0	0	one 1*s* orbital (one orbital of one type in the $n = 1$ shell)
2	0 1	0 −1, 0, +1	one 2*s* orbital three 2*p* orbitals (four orbitals of two types in the $n = 2$ shell)
3	0 1 2	0 −1, 0, +1 −2, −1, 0, +1, +2	one 3*s* orbital three 3*p* orbitals five 3*d* orbitals (nine orbitals of three types in the $n = 3$ shell)
4	0 1 2 3	0 −1, 0, +1 −2, −1, 0, +1, +2 −3, −2, −1, 0, +1, +2, +3	one 4*s* orbital three 4*p* orbitals five 4*d* orbitals seven 4*f* orbitals (16 orbitals of four types in the $n = 4$ shell)

The Second Electron Shell, $n = 2$

When $n = 2$, ℓ can have two values (0 and 1), so there are two subshells in the second shell. One of these is the 2*s subshell* ($n = 2$ and $\ell = 0$), and the other is the 2*p* subshell ($n = 2$ and $\ell = 1$). When $\ell = 1$, the values of m_ℓ can be −1, 0, and +1; three 2*p* orbitals exist. All three orbitals have the same shape. However, each has a different m_ℓ value, that is, the three orbitals differ in their orientation in space.

The Third Electron Shell, $n = 3$

When $n = 3$, three subshells are possible for an electron; there are three values of ℓ: 0, 1, and 2. The first two subshells within the $n = 3$ shell are the 3*s* ($\ell = 0$, one orbital) and 3*p* ($\ell = 1$, three orbitals) subshells. The third subshell is labeled 3*d* ($n = 3$, $\ell = 2$). Because m_ℓ can have five values (−2, −1, 0, +1, and +2) for $\ell = 2$, there are five *d* orbitals in this *d* subshell.

The Fourth Electron Shell, $n = 4$

There are four subshells in the $n = 4$ shell. In addition to 4*s*, 4*p*, and 4*d* subshells, there is the 4*f* subshell for which $\ell = 3$. Seven such orbitals exist because there are seven values of m_ℓ when $\ell = 3$ (−3, −2, −1, 0, +1, +2, and +3).

6.6 The Shapes of Atomic Orbitals

Goal for Section 6.6

- Describe the shapes of atomic orbitals.

We often say an electron is assigned to, or "occupies," an orbital. But what does this mean? What is an orbital? What does it look like? To answer these questions, we have to look at the wavefunctions for the orbitals. (To answer the question of *why*

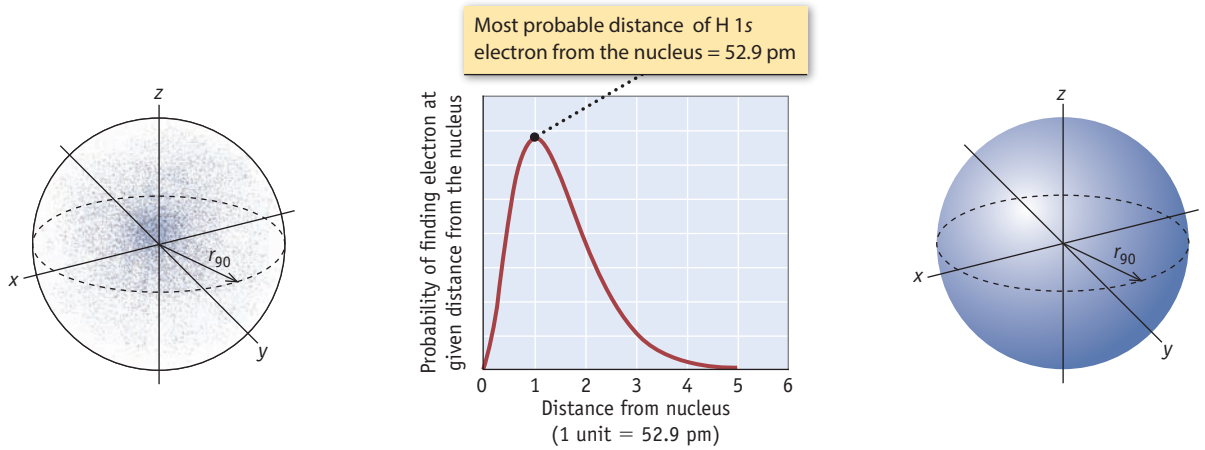
the quantum numbers—small, whole numbers—can be related to orbital shape and energy, see *A Closer Look: More about H Atom Orbital Shapes and Wavefunctions* on page 298.)



s Orbitals

A 1*s* orbital is associated with the quantum numbers $n = 1$ and $\ell = 0$. If we could photograph a 1*s* electron at one-second intervals for a few thousand seconds, the composite picture would look like the drawing in Figure 6.12a. This resembles a cloud of dots, and chemists often refer to such representations as *electron cloud pictures.* In Figure 6.12a, the density of dots is greater close to the nucleus, that is, the electron cloud is denser close to the nucleus. This indicates that the 1*s* electron is most likely to be found near the nucleus. The density of dots declines on moving away from the nucleus and so, therefore, does the probability of finding the electron.

The thinning of the electron cloud at increasing distance is illustrated in a different way in Figure 6.12b. Here we have plotted the square of the wavefunction for the electron in a 1*s* orbital (ψ^2), times 4π and the distance squared (r^2), as a function of the distance of the electron from the nucleus. This plot represents the probability of finding the electron in a thin spherical shell at a distance r from the nucleus. Chemists refer to the plot of $4\pi r^2\psi^2$ vs. r as a **surface density plot** or **radial distribution plot.** For the 1*s* orbital, $4\pi r^2\psi^2$ is zero at the nucleus—there is no probability the electron will be exactly at the nucleus (where $r = 0$)—but the probability rises rapidly on moving away from the nucleus, reaches a maximum a short distance from the nucleus (for a hydrogen atom, this is at 52.9 pm), and then decreases rapidly as the distance from the nucleus increases. Notice that the probability of finding the electron approaches but never quite reaches zero, even at very large distances.

For the 1*s* orbital, the probability of finding an electron is the same at a given distance from the nucleus, no matter in which direction you proceed from the nucleus. Consequently, the *1s orbital is spherical in shape.*

Because the probability of finding the electron approaches but never quite reaches zero, there is no sharp boundary beyond which the electron is never found (although the probability is very small at large distances). Nonetheless, the *s* orbital

(a) Dot picture of an electron in a 1*s* orbital. Each dot represents the position of the electron at a different instant in time. Note that the dots cluster closest to the nucleus. r_{90} is the radius of a sphere within which the electron is found 90% of the time.

(b) A plot of the surface density ($4\pi r^2\psi^2$) as a function of distance for a hydrogen atom 1*s* orbital. This gives the probability of finding the electron at a given distance from the nucleus.

(c) The surface of the sphere within which the electron is found 90% of the time for a 1*s* orbital. This surface is often called a "boundary surface."

Figure 6.12 Different views of a 1*s* ($n = 1$, $\ell = 0$) orbital. In panel **(b)** the horizontal axis is marked in units called "Bohr radii," where 1 Bohr radius = 52.9 pm. This is common practice when plotting wavefunctions.

(and other types of orbitals as well) is often depicted as having a **boundary surface** (Figure 6.12c), largely because it is easier to draw such pictures. To create Figure 6.12c, we drew a sphere centered on the nucleus in such a way that there is a 90% probability of finding the electron somewhere inside the sphere. The choice of 90% is arbitrary—we could have chosen a different value—and if we do, the shape would be the same, but the size of the sphere would be different.

All *s* orbitals (1*s*, 2*s*, 3*s* . . .) are spherical in shape. However, for any atom, the size of *s* orbitals increases as *n* increases (Figure 6.13). For a given atom, the 1*s* orbital is more compact than the 2*s* orbital, which is in turn more compact than the 3*s* orbital.

It is important to recognize several features of this description.

- There is not an impenetrable surface within which the electron is "contained."
- The probability of finding the electron is not the same throughout the volume enclosed by the surface in Figure 6.12c. (An electron in the 1*s* orbital of an H atom has a greater probability of being 52.9 pm from the nucleus than of being closer or farther away.)
- The terms "electron cloud" and "electron distribution" imply that the electron is a particle, but the basic premise in quantum mechanics is that the electron is treated as a wave, not a particle.

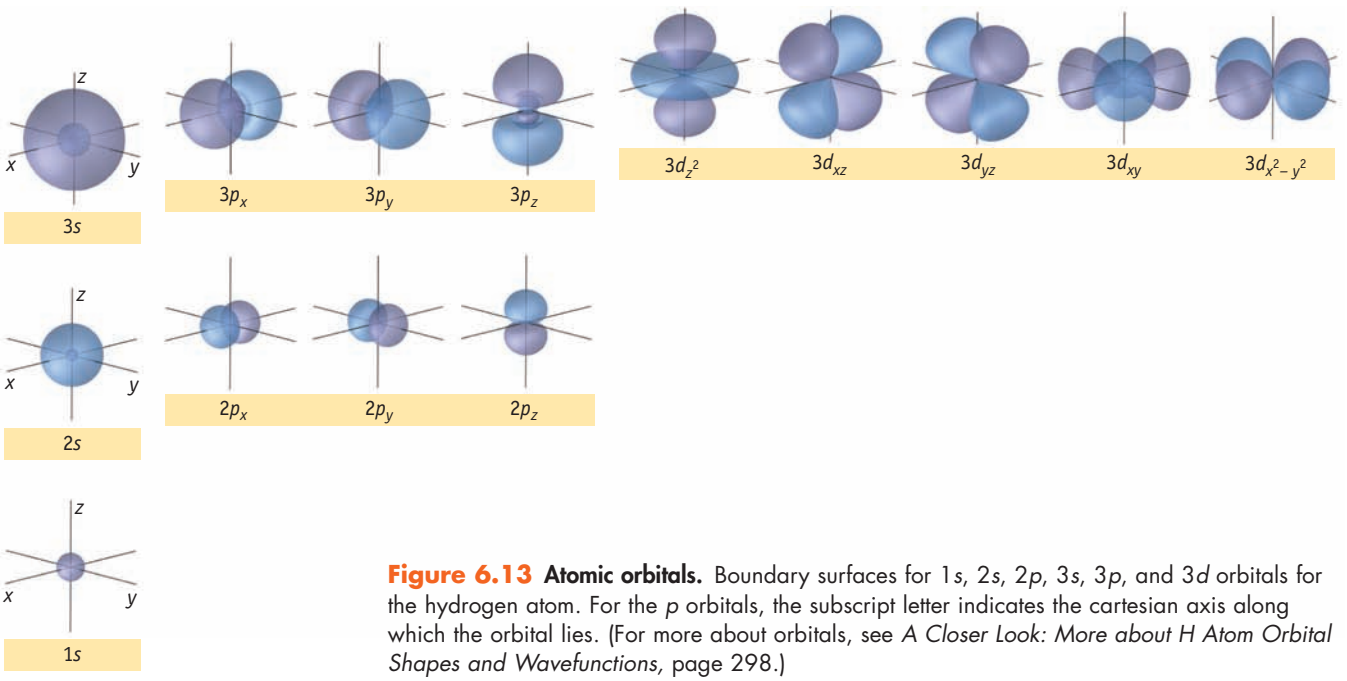
ℓ and Nodal Surfaces The number of nodal surfaces passing through the nucleus for an orbital = ℓ.

Orbital	ℓ	Number of Nodal Surfaces through the Nucleus
s	0	0
p	1	1
d	2	2
f	3	3

p Orbitals

All atomic orbitals for which $\ell = 1$ (*p* orbitals) have the same basic shape. If you enclose 90% of the electron density for a *p* orbital within a surface, the electron cloud is often described as having a shape like a weight lifter's "dumbbell," and chemists describe *p* orbitals as having dumbbell shapes (Figures 6.13 and 6.14). A *p* orbital has a **nodal surface**—a surface on which the probability of finding the electron is zero—that passes through the nucleus. (The nodal surface is a consequence of the wavefunction for *p* orbitals, which has a value of zero at all points on this surface, including at the nucleus itself. See *A Closer Look: More about H Atom Orbital Shapes and Wavefunctions*, page 298.)

There are three *p* orbitals in a *p* subshell, and all have the same basic shape with one nodal plane through the nucleus. Usually, *p* orbitals are drawn along the *x*-, *y*-, and *z*-axes and labeled according to the axis along which they lie (p_x, p_y, or p_z).



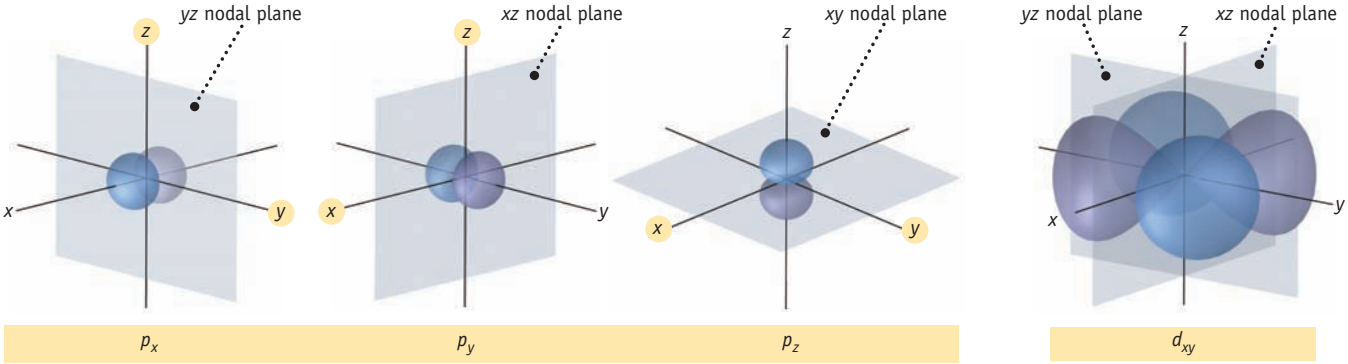


Figure 6.13 Atomic orbitals. Boundary surfaces for 1*s*, 2*s*, 2*p*, 3*s*, 3*p*, and 3*d* orbitals for the hydrogen atom. For the *p* orbitals, the subscript letter indicates the cartesian axis along which the orbital lies. (For more about orbitals, see *A Closer Look: More about H Atom Orbital Shapes and Wavefunctions*, page 298.)

(a) The three *p* orbitals each have one nodal plane ($\ell = 1$) that is perpendicular to the axis along which the orbital lies.

(b) The d_{xy} orbital. All five *d* orbitals have two nodal surfaces ($\ell = 2$) passing through the nucleus. Here, the nodal surfaces are the *xz*- and *yz*-planes, so the regions of electron density lie between the *x*- and *y*-axes in the *xy*-plane.

Figure 6.14 Nodal surfaces of *p* and *d* orbitals. A nodal surface is a surface on which the probability of finding the electron is zero.

d Orbitals

Orbitals with $\ell = 0$, *s* orbitals, have no nodal surfaces through the nucleus, and *p* orbitals, for which $\ell = 1$, have one nodal surface through the nucleus. *The value of ℓ is equal to the number of nodal surfaces slicing through the nucleus*. It follows that the five *d* orbitals, for which $\ell = 2$, have two nodal surfaces through the nucleus, resulting in four regions of electron density. The d_{xy} orbital, for example, lies in the *xy*-plane, and the two nodal surfaces are the *xz*- and *yz*-planes (Figure 6.14). Two other orbitals, d_{xz} and d_{yz}, lie in planes defined by the *xz- and yz*-axes, respectively; they also have two, mutually perpendicular nodal surfaces (Figure 6.13).

Of the two remaining *d* orbitals, the $d_{x^2-y^2}$ orbital is easier to visualize. In the $d_{x^2-y^2}$ orbital, the nodal planes bisect the *x*- and *y*-axes, so the regions of electron density lie along the *x*- and *y*-axes. The d_{z^2} orbital has two main regions of electron density along the *z*-axis, and a "doughnut" of electron density also occurs in the *xy*-plane. This orbital has two cone-shaped nodal surfaces.

Nodal Surfaces Nodal surfaces that cut through the nucleus occur for all *p*, *d*, and *f* orbitals. These surfaces are usually flat, so they are often referred to as *nodal planes*. In some cases (for example, d_{z^2}), however, the "plane" is not flat and so is better referred to as a *nodal surface*.

f Orbitals

Seven *f* orbitals arise with $\ell = 3$. Three nodal surfaces through the nucleus cause the electron density to lie in up to eight regions of space. One of the *f* orbitals is illustrated in Figure 6.15.

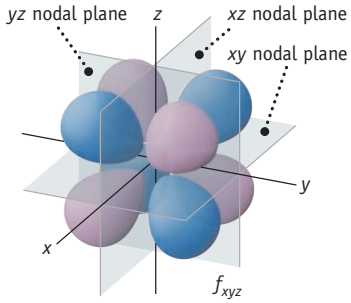

Figure 6.15 One of the seven possible *f* orbitals. Notice the presence of three nodal planes as required by an orbital with $\ell = 3$.

6.7 One More Electron Property: Electron Spin

Goal for Section 6.7

- Recognize that electrons also have a spin quantum number, m_s, which has values of $\pm 1/2$.

There is one more property of the electron that plays an important role in the arrangement of electrons in atoms: electron spin. In 1921 Otto Stern and Walther Gerlach performed an experiment that probed the magnetic behavior of atoms by passing a beam of silver atoms in the gas phase through a magnetic field. The results were best interpreted by *imagining* the electron has a spin and behaves as a tiny magnet that can be attracted or repelled by another magnet. If atoms with a single unpaired electron are placed in a magnetic field, the Stern-Gerlach experiment showed there are two orientations for the atoms: with the electron spin aligned with the field or opposed to the field. That is, *the electron spin is quantized*. This fact is accounted for by introducing a fourth quantum number, the **electron spin quantum**

A CLOSER LOOK

More about H Atom Orbital Shapes and Wavefunctions

How do quantum numbers, which are small, integer numbers, relate to the shape of atomic orbitals? The answer lies in the orbital wavefunctions (ψ), which are mathematical equations. These equations are the product of two functions: the *radial function* and the *angular function*. You need to look at each type to get a picture of an orbital.

Let's first consider the *radial function*, which depends on n and ℓ. This tells us how the value of ψ depends on the distance from the nucleus. The radial functions for the hydrogen atom 1*s* ($n = 1$ and $\ell = 0$), 2*s* ($n = 2$ and $\ell = 0$) orbitals, and 2*p* orbitals ($n = 2$ and $\ell = 1$) are plotted in Figure A. (The horizontal axis has units of a_0, where a_0 is equal to 52.9 pm.)

Waves have crests, troughs, and nodes, and plots of the wavefunctions show this. For the 1*s* orbital of the H atom, the radial wavefunction ψ_{1s} approaches a maximum at the nucleus (Figure A), but the wave's amplitude declines rapidly at points farther removed from the nucleus. The sign of ψ_{1s} is positive at all points in space.

For a 2*s* orbital, there is a different profile: the sign of ψ_{2s} is positive near the nucleus, drops to zero (there is a node at $r = 2a_0 = 2 \times 52.9$ pm), and then becomes negative with increasing r before approaching zero at greater distances.

Now to the *angular portion* of the wavefunction: this reflects changes that occur when you travel outward from the nucleus in different directions. It is a function of the quantum numbers ℓ and m_ℓ.

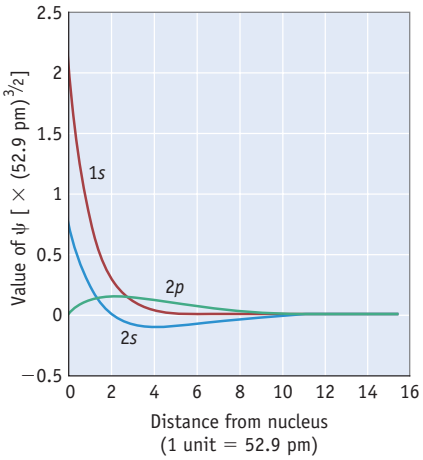

Figure A Plot of the wavefunctions for 1*s*, 2*s*, and 2*p* orbitals for an H atom versus distance from the nucleus. As in other plots of wavefunctions, the horizontal axis is marked in units called "Bohr radii," where 1 Bohr radius = 52.9 pm.

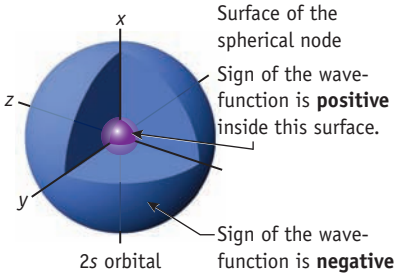

Figure B Wavefunction for a 2*s* orbital. A 2*s* orbital for the H atom showing the spherical node (at $2a_0 = 105.8$ pm) around the nucleus.

As illustrated in Figure 6.12 the value of ψ_{1s} is the same in every direction. This is a reflection of the fact that, while the radial portion of the wavefunction for *s* orbitals changes with *r*, the angular portion for all *s* orbitals is a constant. As a consequence, all *s* orbital are spherical.

For the 2*s* orbital, you see a node in Figure A at 105.8 pm ($= 2a_0$) when plotting the radial portion of the wavefunction. However, because the angular part of ψ_{2s} has the same value in all directions, this means there is a node—a *spherical nodal surface*—at the same distance in every direction (as illustrated in Figure B). For any orbital, the number of spherical nodes is $n - \ell - 1$.

Now let's look at a *p* orbital, first the radial portion and then the angular portion. For a *p* orbital the radial portion of the wavefunction is 0 when $r = 0$. Thus, the value of ψ_{2p} is zero at the nucleus and a nodal surface passes through the nucleus (Figures A and C). This is true for all *p* orbitals.

What happens as you move away from the nucleus in one direction, say along the *x*-axis in the case of the $2p_x$ orbital? The value of ψ_{2p} rises to a maximum at 105.9 pm ($= 2a_0$) before falling off at greater distances (Figures A and C).

Next, look at Figure C for the $2p_x$ orbital. Moving away along the $-x$ direction, the value of ψ_{2p} is the same but opposite in sign to the value in the $+x$ direction. The 2*p* electron is a wave with a node at the nucleus. (In drawing orbitals, we indicate this with + or − signs or with two different colors as in Figure 6.13.)

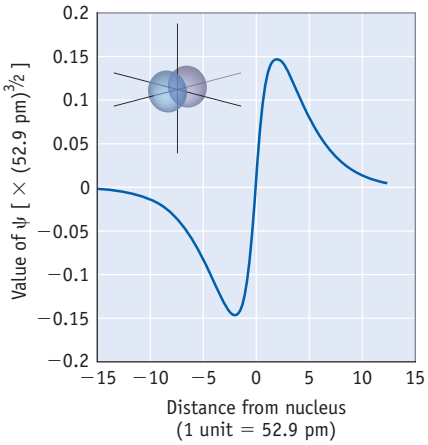

Figure C Wavefunctions for a 2*p* orbital for an H atom. The sign of ψ for a 2*p* orbital is positive on one side of the nucleus and negative on the other (but it has a 0 value at the nucleus). A nodal plane separates the two lobes of this "dumbbell-shaped" orbital. (The vertical axis is the value of ψ, and the horizontal axis is the distance from the nucleus, where 1 unit = 52.9 pm.)

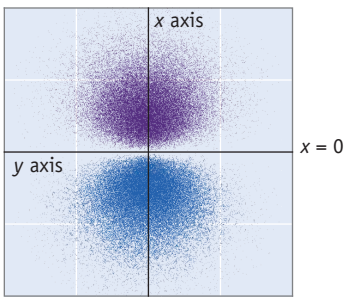
What about the *angular portion* of the wavefunction for $2p_x$? The angular portion for all three *p* orbitals has the same general form: $c(x/r)$ for the p_x orbital, $c(y/r)$ for the p_y orbital, and $c(z/r)$ for the p_z orbital (where c is a constant). Consider a $2p_x$ orbital in Figure D. As long as *x* has a nonzero value, the wavefunction has a nonzero value. But when $x = 0$ (in the *yz* plane), then ψ is zero. This is the nodal plane for the *x* orbital. Similarly, the angular portion of the wavefunction for the $2p_y$ orbital means its nodal plane is the *xz* plane.



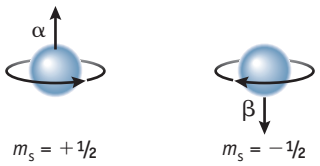


Figure D The $2p_x$ orbital for an H atom. The wavefunction is equal to zero when $x = 0$, that is, the *yz* plane is a nodal plane.

number, m_s. One orientation is associated with a value of m_s of $+1/2$ and the other with m_s of $-1/2$.

When it was recognized that electron spin is quantized, scientists realized that a complete description of an electron in any atom requires four quantum numbers, n, ℓ, m_ℓ, and m_s. The important consequences of this fact are explored in Chapter 7.

APPLYING CHEMICAL PRINCIPLES

6.1 Sunburn, Sunscreens, and Ultraviolet Radiation

Have you ever had a sunburn? The primary cause is ultraviolet (UV) radiation from the Sun with wavelengths between 200 and 400 nm. In addition to causing sunburns, exposure to ultraviolet radiation is a risk factor for developing various types of skin cancer.

Why is exposure to UV light so much more dangerous than even long exposures to visible light? UV light has a frequency that is higher than the frequency of visible light, and thus the energy delivered per photon is greater. The high energy of ultraviolet photons is sufficient to cause chemical bonds to break in molecules in our bodies, such as in proteins and DNA. This is the underlying cause of sunburns and also of the damage to cells that can lead to skin cancer.

UV radiation can be classified into three main categories: UV-A (315–400 nm), UV-B (280–315 nm), and UV-C (200–280 nm). Based upon their energies you would think you would need to be most worried about exposure to UV-C, and this would indeed be the case were it not for the atmosphere of Earth. Oxygen and ozone in the atmosphere absorb all of the UV-C coming to Earth from the Sun, so this most dangerous ultraviolet radiation is not a worry for us. Ozone in the atmosphere also absorbs most, but not all, of the UV-B reaching Earth. In fact, sunburn is caused primarily by UV-B, whereas both UV-A and UV-B exposure are risk factors for skin cancer.

What can you do to avoid the dangers of UV radiation? Clearly, the best solution is to avoid exposure by remaining indoors or wearing protective clothing when sunlight is most intense. If, however, this is not possible, then use a sunscreen. Sunscreens contain molecules that absorb UV radiation. The sun protection factor (SPF) rating of a sunscreen indicates the amount of UV required to get a sunburn when the sunscreen has been applied compared to the amount of UV required without the sunscreen. Because sunburn is caused primarily by UV-B, the higher the SPF factor, the better the protection against UV-B. Even with a high SPF, however, a sunscreen might not protect against UV-A, which can also cause skin cancer. In 2011, new U.S. Food and Drug Administration (FDA) guidelines were approved requiring sunscreen makers to label if their products protect against both UV-B and UV-A. If they do, the product can be labeled "Broad Spectrum." In choosing a sunscreen the FDA now recommends that you choose one with an SPF of 15 or higher and that it be labeled "Broad Spectrum."

©iStockphoto.com/markokg

Sunscreens and damage from radiation. Sunscreens contain organic compounds that absorb UV radiation, preventing it from reaching your skin.

Questions:

1. Which has the longer wavelength, visible light or ultraviolet light? The higher frequency? The higher energy per photon?
2. Calculate the energy per mole of photons (in kJ/mol) for red light with a wavelength of 700 nm. Calculate the energy per mole of photons (in kJ/mol) for UV-B light with a wavelength of 300 nm. How many times more energetic is this UV-B than this red light?

6.2 What Makes the Colors in Fireworks?

Fireworks involve lots of chemistry! For example, there must be an oxidizer and something to oxidize. Today, the oxidizer is usually a perchlorate, chlorate, or nitrate salt, and they are almost always potassium salts. The reason for using potassium and not sodium salts is that sodium salts have two important drawbacks. They are hygroscopic—they absorb water from the air—and so do not remain dry on storage. Also, when heated, sodium salts give off an intense, yellow light that is so bright it can mask other colors.

The parts of any fireworks display we remember best are the vivid colors and brilliant flashes. White light can be produced by oxidizing magnesium or aluminum metal at high temperatures. The flashes you see at rock concerts, for example, are typically Mg/$KClO_4$ mixtures.

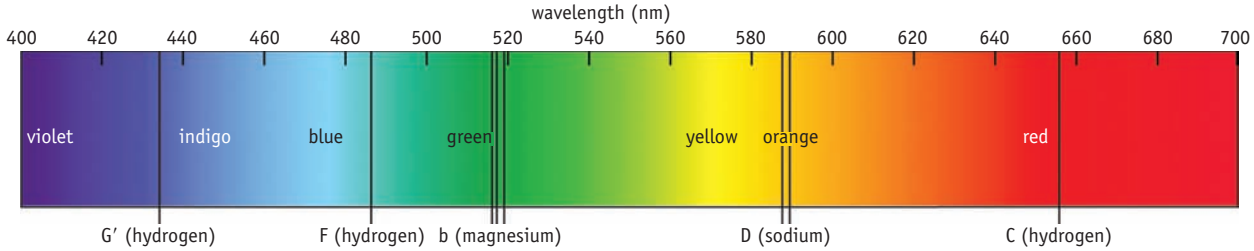
Yellow light is easiest to produce because sodium salts give an intense light with a wavelength of 589 nm. Fireworks mixtures usually contain sodium in the form of nonhygroscopic compounds such as cryolite, Na_3AlF_6. Strontium salts are most often used to produce a red light, and green is produced by barium salts such as $Ba(NO_3)_2$.

The next time you see a fireworks display, watch for the ones that are blue. Blue has always been the most difficult color to produce, but fireworks designers have found that a really good blue is obtained using copper(I) chloride (CuCl) mixed with $KClO_4$, copper powder, and the organic chlorine-containing compound hexachloroethane, C_2Cl_6.

Questions:

1. The main lines in the emission spectrum of sodium are at wavelengths (nm) of 313.5, 589, 590, 818, and 819. Which one or ones are most responsible for the characteristic yellow color of excited sodium atoms?
2. Does the main emission line for $SrCl_2$ have a longer or shorter wavelength than that of the yellow line from NaCl?
3. Mg is oxidized by $KClO_4$ to make white flashes. One product of the reaction is KCl. Write a balanced equation for the reaction.

The design of an aerial rocket for a fireworks display. When the fuse is ignited, it burns quickly to the delay fuses at the top of the red star mixture as well as to the black powder propellant at the bottom. The propellant ignites, sending the shell into the air. Meanwhile, the delay fuses burn. If the timing is correct, the shell bursts high in the sky into a red star. This is followed by a blue burst and then a flash and sound.



6.3 Chemistry of the Sun

An optical spectrum of our Sun reveals a continuous emission of radiation in the visible region with sharp, darkened lines at hundreds of different wavelengths. These lines are named Fraunhofer lines, after the German physicist Joseph von Fraunhofer who observed them in 1814. Fraunhofer was able to observe over 570 of these lines, but over one thousand dark lines may be observed with modern instrumentation. In 1859, Gustav Robert Kirchhoff and Robert Bunsen deduced that the dark lines are the result of absorption of sunlight by elements in the outer layers of the Sun.

The fact that atoms of a particular element absorb or emit light of only a few wavelengths may be used to identify elements (page 284). Most stars are rich in hydrogen, so the Balmer series (page 289) is commonly observed in their spectra. The discovery and naming of helium is credited to Sir Joseph Norman Lockyer (1836–1920), who observed its yellow spectral line during a total solar eclipse in 1868. Helium is common in stars, but less common on Earth.

Questions:

1. Helium absorbs light at 587.6 nm. What is the frequency of this light?
2. Iron atoms absorb light at a frequency of $5.688 \times 10^{14}\ s^{-1}$. What is the wavelength of this light (in nm)?
3. Sodium atoms are responsible for a closely spaced pair of lines in the yellow region of the Sun's visible spectrum at 589.00 nm and 589.59 nm. Determine the energy (in joules) of a photon at each of these wavelengths. Determine the difference in energy between the two photons.
4. Hydrogen has an absorption line at 434.1 nm. What is the energy (in kilojoules per mole) of photons with this wavelength?
5. What are the final and initial electronic states (n) for the hydrogen line (in the Balmer series) labeled F in the figure?

The spectrum of sunlight with Fraunhofer lines. The German physicist Joseph von Fraunhofer (1787–1826) discovered the dark lines in the spectrum of sunlight and carefully mapped and measured them. He designated the principal lines with letters A through K and less prominent lines with lowercase letters.

CHAPTER GOALS REVISITED

The goals for this chapter are keyed to specific Study Questions to help you organize your review.

6.1 Electromagnetic Radiation

- Mathematically relate the wavelength (λ) and frequency (ν) of electromagnetic radiation and the speed of light (c). **3, 4.**
- Recognize the relative wavelength (or frequency) of the various types of electromagnetic radiation. **1, 2, 55, 66.**

6.2 Quantization: Planck, Einstein, Energy, and Photons

- Understand the photoelectric effect. **11, 12, 47.**
- Understand that the energy of a photon, a massless particle of radiation, is proportional to its frequency. **5–8, 56–58, 63, 64, 70, 72.**

6.3 Atomic Line Spectra and Niels Bohr

- Describe the Bohr model of the atom, its ability to account for the emission line spectra of excited hydrogen atoms, and the limitations of the model. **15–20, 48, 60, 75, 81.**
- Calculate the energy absorbed or emitted when an electron in a hydrogen atom moves from one energy level to another. **21, 22, 54, 59, 69.**

6.4 Particle-Wave Duality: Prelude to Quantum Mechanics

- Understand that in the modern view of the atom, electrons can be described either as particles or as waves. **77.**
- Calculate the wavelength of a particle using de Broglie's equation. **23–26, 82.**

6.5 The Modern View of Electronic Structure: Wave or Quantum Mechanics

- Understand that the position of the electron is not known with certainty; only the probability of the electron being at a given point of space can be calculated. This is a consequence of the Heisenberg uncertainty principle. **74, 76, 79, 84.**
- Understand that the modern view of atoms describes electrons as waves and identifies orbitals as allowed quantized energies. Describe the allowed energy states of the orbitals in an atom using three quantum numbers: n, ℓ, and m_ℓ. **27–36, 39–44, 49–51, 61, 62, 80.**

6.6 The Shapes of Atomic Orbitals

- Describe the shapes of atomic orbitals. **45, 46, 52, 53.**

6.7 One More Electron Property: Electron Spin

- Recognize that electrons also have a spin quantum number, m_s, which has values of $\pm 1/2$. **37, 38.**

KEY EQUATIONS

Equation 6.1 (page 278) The product of the wavelength (λ) and frequency (ν) of electromagnetic radiation is equal to the speed of light (c).

$$c = \lambda \times \nu$$

Equation 6.2 (page 280) Planck's equation: The energy of a photon, a massless particle of radiation, is proportional to its frequency (ν). The proportionality constant, h, is called Planck's constant (6.626×10^{-34} J · s).

$$E = h\nu$$

Equation 6.3 (page 284) The Balmer equation can be used to calculate the wavelengths of the lines in the Balmer series of the hydrogen spectrum. The Rydberg constant, R, is 1.0974×10^{7} m^{-1}, and n is 3 or larger.

$$\frac{1}{\lambda} = R\left(\frac{1}{2^2} - \frac{1}{n^2}\right) \text{ when } n > 2$$

Equation 6.4 (page 284) In Bohr's theory, the energy of the electron, E_n, in the nth quantum level of the H atom is proportional to $1/n^2$, where n is a positive integer (the principal quantum number) and $Rhc = 2.179 \times 10^{-18}$ J/atom or $N_A Rhc = 1312$ kJ/mol.

$$E_n = -\frac{Rhc}{n^2}$$

Equation 6.5 (page 288) The energy change for an electron moving between two quantum levels (n_{final} and n_{initial}) in the H atom.

$$\Delta E = E_{\text{final}} - E_{\text{initial}} = -Rhc\left(\frac{1}{n^2_{\text{final}}} - \frac{1}{n^2_{\text{initial}}}\right)$$

Equation 6.6 (page 290) De Broglie's equation: The wavelength (λ) of a particle is related to its mass (m) and speed (v) and to Planck's constant (h).

$$\lambda = \frac{h}{mv}$$

STUDY QUESTIONS

▲ denotes challenging questions. **Blue-numbered questions** have answers in Appendix N and fully worked solutions in the *Student Solutions Manual*.

Practicing Skills

Electromagnetic Radiation

(See Example 6.1 and Figure 6.2.)

1. Answer the following questions based on Figure 6.2:
   (a) Which type of radiation involves less energy, x-rays or microwaves?
   (b) Which radiation has the higher frequency, radar or red light?
   (c) Which radiation has the longer wavelength, ultraviolet or infrared light?

2. Consider the colors of the visible spectrum.
   (a) Which colors of light involve less energy than green light?
   (b) Which color of light has photons of greater energy, yellow or blue?
   (c) Which color of light has the higher frequency, blue or green?

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

3. Traffic signals are often now made of LEDs (light-emitting diodes). Amber and green ones are pictured here.
   (a) The light from an amber signal has a wavelength of 595 nm, and that from a green signal has a wavelength of 500 nm. Which has the higher frequency?
   (b) Calculate the frequency of amber light.

Photos: Mike Condren/UW/MRSEC

(a) (b)

4. Suppose you are standing 225 m from a radio transmitter. What is your distance from the transmitter in terms of the number of wavelengths if
   (a) the station is broadcasting at 1150 kHz (on the AM radio band)? (1 kHz = 1×10^3 Hz)
   (b) the station is broadcasting at 98.1 MHz (on the FM radio band)? (1 MHz $\times$ 10^6 Hz)

Electromagnetic Radiation and Planck's Equation

(See Example 6.2.)

5. Green light has a wavelength of 5.0×10^2 nm. What is the energy, in joules, of one photon of green light? What is the energy, in joules, of 1.0 mol of photons of green light?

6. Violet light has a wavelength of about 410 nm. What is its frequency? Calculate the energy of one photon of violet light. What is the energy of 1.0 mol of violet photons? Compare the energy of photons of violet light with those of red light. Which is more energetic?

7. The most prominent line in the emission spectrum of aluminum is at 396.15 nm. What is the frequency of this line? What is the energy of one photon with this wavelength? Of 1.00 mol of these photons?

8. The most prominent line in the emission spectrum of magnesium is 285.2 nm. Other lines are found at 383.8 and 518.4 nm. In what region of the electromagnetic spectrum are these lines found? Which is the most energetic line? What is the energy of 1.00 mol of photons with the wavelength of the most energetic line?

9. Place the following types of radiation in order of increasing energy per photon:
   (a) yellow light from a sodium lamp
   (b) x-rays from an instrument in a dentist's office
   (c) microwaves in a microwave oven
   (d) your favorite FM music station at 91.7 MHz

10. Place the following types of radiation in order of increasing energy per photon:
   (a) radiation within a microwave oven
   (b) your favorite radio station
   (c) gamma rays from a nuclear reaction
   (d) red light from a neon sign
   (e) ultraviolet radiation from a sun lamp

Photoelectric Effect

(See Example 6.2 and Figure 6.4.)

11. An energy of 3.3×10^{-19} J/atom is required to cause a cesium atom on a metal surface to lose an electron. Calculate the longest possible wavelength of light that can ionize a cesium atom. In what region of the electromagnetic spectrum is this radiation found?

12. You are an engineer designing a switch that works by the photoelectric effect. The metal you wish to use in your device requires 6.7×10^{-19} J/atom to remove an electron. Will the switch work if the light falling on the metal has a wavelength of 540 nm or greater? Why or why not?

Atomic Spectra and the Bohr Atom

(See Examples 6.3 and 6.4 and Figures 6.5–6.10.)

13. The most prominent line in the spectrum of mercury is at 253.652 nm. Other lines are located at 365.015 nm, 404.656 nm, 435.833 nm, and 1013.975 nm.
   (a) Which of these lines represents the most energetic light?
   (b) What is the frequency of the most prominent line? What is the energy of one photon with this wavelength?
   (c) Are any of these lines found in the spectrum of mercury shown in Figure 6.6? What color or colors are these lines?

14. The most prominent line in the spectrum of neon is found at 865.438 nm. Other lines are located at 837.761 nm, 878.062 nm, 878.375 nm, and 885.387 nm.
   (a) In what region of the electromagnetic spectrum are these lines found?
   (b) Are any of these lines found in the spectrum of neon shown in Figure 6.6?
   (c) Which of these lines represents the most energetic radiation?
   (d) What is the frequency of the most prominent line? What is the energy of one photon with this wavelength?

15. A line in the Balmer series of emission lines of excited H atoms has a wavelength of 410.2 nm (Figure 6.10). What color is the light emitted in this transition? What quantum levels are involved in this emission line? That is, what are the values of $n_{initial}$ and n_{final}?

16. What are the wavelength and frequency of the radiation involved in the least energetic emission line in the Lyman series? What are the values of $n_{initial}$ and n_{final}?

17. Consider only transitions involving the $n = 1$ through $n = 5$ energy levels for the H atom (see Figures 6.7 and 6.10).
    (a) How many emission lines are possible, considering only the five quantum levels?
    (b) Photons of the highest frequency are emitted in a transition from the level with $n =$ _____ to a level with $n =$ _____.
    (c) The emission line having the longest wavelength corresponds to a transition from the level with $n =$ _____ to the level with $n =$ _____.

18. Consider only transitions involving the $n = 1$ through $n = 4$ energy levels for the hydrogen atom (see Figures 6.7 and 6.10).
    (a) How many emission lines are possible, considering only the four quantum levels?
    (b) Photons of the lowest energy are emitted in a transition from the level with $n =$ _____ to a level with $n =$ _____.
    (c) The emission line having the shortest wavelength corresponds to a transition from the level with $n =$ _____ to the level with $n =$ _____.

19. The energy emitted when an electron moves from a higher energy state to a lower energy state in any atom can be observed as electromagnetic radiation.
    (a) Which involves the emission of less energy in the H atom, an electron moving from $n = 4$ to $n = 2$ or an electron moving from $n = 3$ to $n = 2$?
    (b) Which involves the emission of more energy in the H atom, an electron moving from $n = 4$ to $n = 1$ or an electron moving from $n = 5$ to $n = 2$? Explain fully.

20. If energy is absorbed by a hydrogen atom in its ground state, the atom is excited to a higher energy state. For example, the excitation of an electron from $n = 1$ to $n = 3$ requires radiation with a wavelength of 102.6 nm. Which of the following transitions would require radiation of *longer wavelength* than this?
    (a) $n = 2$ to $n = 4$
    (b) $n = 1$ to $n = 4$
    (c) $n = 1$ to $n = 5$
    (d) $n = 3$ to $n = 5$

21. Calculate the wavelength and frequency of light emitted when an electron changes from $n = 3$ to $n = 1$ in the H atom. In what region of the spectrum is this radiation found?

22. Calculate the wavelength and frequency of light emitted when an electron changes from $n = 4$ to $n = 3$ in the H atom. In what region of the spectrum is this radiation found?

De Broglie and Matter Waves

(See Example 6.5.)

23. An electron moves with a velocity of 2.5×10^8 cm/s. What is its wavelength?

24. A beam of electrons ($m = 9.11 \times 10^{-31}$ kg/electron) has an average speed of 1.3×10^8 m/s. What is the wavelength of electrons having this average speed?

25. Calculate the wavelength, in nanometers, associated with a 46-g golf ball moving at 30. m/s (about 67 mph). At what speed must the ball travel to have a wavelength of 5.6×10^{-3} nm?

26. A rifle bullet (mass = 1.50 g) has a velocity of 7.00×10^2 mph (miles per hour). What is the wavelength associated with this bullet?

Quantum Mechanics

(See Sections 6.5–6.7.)

27. (a) When $n = 4$, what are the possible values of ℓ?
    (b) When ℓ is 2, what are the possible values of m_ℓ?
    (c) For a 4*s* orbital, what are the possible values of n, ℓ, and m_ℓ?
    (d) For a 4*f* orbital, what are the possible values of n, ℓ, and m_ℓ?

28. (a) When $n = 4$, $\ell = 2$, and $m_\ell = -1$, to what orbital type does this refer? (Give the orbital label, such as 1*s*.)
    (b) How many orbitals occur in the $n = 5$ electron shell? How many subshells? What are the letter labels of the subshells?
    (c) How many orbitals occur in an *f* subshell? What are the values of m_ℓ?

29. A possible excited state of the H atom has the electron in a 4*p* orbital. List all possible sets of quantum numbers n, ℓ, and m_ℓ for this electron.

30. A possible excited state for the H atom has an electron in a 5*d* orbital. List all possible sets of quantum numbers n, ℓ, and m_ℓ for this electron.

31. How many subshells occur in the electron shell with the principal quantum number $n = 4$?

32. How many subshells occur in the electron shell with the principal quantum number $n = 5$?

33. Explain briefly why each of the following is *not* a possible set of quantum numbers for an electron in an atom.

(a) $n = 2, \ell = 2, m_\ell = 0$

(b) $n = 3, \ell = 0, m_\ell = -2$

(c) $n = 6, \ell = 0, m_\ell = 1$

34. Which of the following represent valid sets of quantum numbers? For a set that is invalid, explain briefly why it is not correct.

(a) $n = 3, \ell = 3, m_\ell = 0$

(b) $n = 2, \ell = 1, m_\ell = 0$

(c) $n = 6, \ell = 5, m_\ell = -1$

(d) $n = 4, \ell = 3, m_\ell = -4$

35. What is the maximum number of orbitals that can be identified by each of the following sets of quantum numbers? When "none" is the correct answer, explain your reasoning.

(a) $n = 3, \ell = 0, m_\ell = +1$

(b) $n = 5, \ell = 1$

(c) $n = 7, \ell = 5$

(d) $n = 4, \ell = 2, m_\ell = -2$

36. What is the maximum number of orbitals that can be identified by each of the following sets of quantum numbers? When "none" is the correct answer, explain your reasoning.

(a) $n = 4, \ell = 3$

(b) $n = 5$

(c) $n = 2, \ell = 2$

(d) $n = 3, \ell = 1, m_\ell = -1$

37. Explain briefly why each of the following is not a possible set of quantum numbers for an electron in an atom. In each case, change the incorrect value (or values) to make the set valid.

(a) $n = 4, \ell = 2, m_\ell = 0, m_s = 0$

(b) $n = 3, \ell = 1, m_\ell = -3, m_s = -1/2$

(c) $n = 3, \ell = 3, m_\ell = -1, m_s = +1/2$

38. Explain briefly why each of the following is not a possible set of quantum numbers for an electron in an atom. In each case, change the incorrect value (or values) to make the set valid.

(a) $n = 2, \ell = 2, m_\ell = 0, m_s = +1/2$

(b) $n = 2, \ell = 1, m_\ell = -1, m_s = 0$

(c) $n = 3, \ell = 1, m_\ell = -2, m_s = +1/2$

39. State which of the following orbitals cannot exist according to the quantum theory: 2*s*, 2*d*, 3*p*, 3*f*, 4*f*, and 5*s*. Briefly explain your answers.

40. State which of the following orbitals cannot exist according to the quantum theory: 3*p*, 4*s*, 2*f*, and 1*p*. Briefly explain your answers.

41. Write a complete set of quantum numbers (n, ℓ, and m_ℓ) that quantum theory allows for each of the following orbitals: (a) 2*p*, (b) 3*d*, and (c) 4*f*.

42. Write a complete set of quantum numbers (n, ℓ, and m_ℓ) for each of the following orbitals: (a) 5*f*, (b) 4*d*, and (c) 2*s*.

43. A particular orbital has $n = 4$ and $\ell = 2$. What must this orbital be: (a) 3*p*, (b) 4*p*, (c) 5*d*, or (d) 4*d*?

44. A given orbital has a magnetic quantum number of $m_\ell = -1$. This could *not* be a(n)

(a) *f* orbital (c) *p* orbital

(b) *d* orbital (d) *s* orbital

45. How many nodal surfaces through the nucleus (planar nodes) are associated with each of the following orbitals?

(a) 2*s* (b) 5*d* (c) 5*f*

46. How many nodal surfaces through the nucleus (planar nodes) are associated with each of the following atomic orbitals?

(a) 4*f* (b) 2*p* (c) 6*s*

General Questions

These questions are not designated as to type or location in the chapter. They may combine several concepts.

47. Which of the following are applicable when explaining the photoelectric effect? Correct any statements that are wrong.

(a) Light is electromagnetic radiation.

(b) The intensity of a light beam is related to its frequency.

(c) Light can be thought of as consisting of massless particles whose energy is given by Planck's equation, $E = h\nu$.

48. In what region of the electromagnetic spectrum for hydrogen is the Lyman series of lines found? The Balmer series?

49. Give the number of nodal surfaces through the nucleus (planar nodes) for each orbital type: *s*, *p*, *d*, and *f*.

50. What is the maximum number of *s* orbitals found in a given electron shell? The maximum number of *p* orbitals? Of *d* orbitals? Of *f* orbitals?

51. Match the values of ℓ shown in the table with orbital type (*s*, *p*, *d*, or *f*).

ℓ Value	Orbital Type
3	_____
0	_____
1	_____
2	_____

52. Sketch a picture of the 90% boundary surface of an *s* orbital and the p_x orbital. Be sure the latter drawing shows why the *p* orbital is labeled p_x and not p_y, for example.

53. Complete the following table.

Orbital Type	Number of Orbitals in a Given Subshell	Number of Nodal Surfaces through the Nucleus
s	_____	_____
p	_____	_____
d	_____	_____
f	_____	_____

54. Excited H atoms have many emission lines. One series of lines, called the *Pfund series,* occurs in the infrared region. It results when an electron changes from higher energy levels to a level with $n = 5$. Calculate the wavelength and frequency of the lowest energy line of this series.

55. An advertising sign gives off red light and green light.
(a) Which light has higher-energy photons?
(b) One of the colors has a wavelength of 680 nm, and the other has a wavelength of 500 nm. Which color has which wavelength?
(c) Which light has the higher frequency?

56. Radiation in the ultraviolet region of the electromagnetic spectrum is quite energetic. It is this radiation that causes dyes to fade and your skin to develop a sunburn. If you are bombarded with 1.00 mol of photons with a wavelength of 375 nm, what amount of energy, in kilojoules per mole of photons, are you being subjected to?

57. A cell phone sends signals at about 850 MHz (where 1 MHz = 1×10^6 Hz or cycles per second).
(a) What is the wavelength of this radiation?
(b) What is the energy of 1.0 mol of photons with a frequency of 850 MHz?
(c) Compare the energy in part (b) with the energy of a mole of photons of violet light (420 nm).
(d) Comment on the difference in energy between 850 MHz radiation and violet light.

58. Assume your eyes receive a signal consisting of blue light, $\lambda = 470$ nm. The energy of the signal is 2.50×10^{-14} J. How many photons reach your eyes?

59. If sufficient energy is absorbed by an atom, an electron can be lost by the atom and a positive ion formed. The amount of energy required is called the ionization energy. In the H atom, the ionization energy is that required to change the electron from $n = 1$ to $n =$ infinity. Calculate the ionization energy for the He^+ ion. Is the ionization energy of the He^+ more or less than that of H? (Bohr's theory applies to He^+ because it, like the H atom, has a single electron. The electron energy, however, is now given by $E = -Z^2Rhc/n^2$, where Z is the atomic number of helium.)

60. Suppose hydrogen atoms absorb energy so that electrons are excited to the $n = 7$ energy level. Electrons then undergo these transitions, among others: (a) $n = 7 \rightarrow n = 1$; (b) $n = 7 \rightarrow n = 6$; and (c) $n = 2 \rightarrow n = 1$. Which of these transitions produces a photon with (i) the smallest energy, (ii) the highest frequency, and (iii) the shortest wavelength?

61. Rank the following orbitals in the H atom in order of increasing energy: 3*s*, 2*s*, 2*p*, 4*s*, 3*p*, 1*s*, and 3*d*.

62. How many orbitals correspond to each of the following designations?
(a) 3*p* (b) 4*p* (c) $4p_x$ (d) 6*d* (e) 5*d* (f) 5*f* (g) $n = 5$ (h) 7*s*

63. Cobalt-60 is a radioactive isotope used in medicine for the treatment of certain cancers. It produces β particles and γ rays, the latter having energies of 1.173 and 1.332 MeV. (1 MeV = 10^6 electron-volts and 1 eV = 1.6022×10^{-19} J.) What are the wavelength and frequency of a γ-ray photon with an energy of 1.173 MeV?

64. ▲ Exposure to high doses of microwaves can cause tissue damage. Estimate how many photons, with $\lambda = 12$ cm, must be absorbed to raise the temperature of your eye by 3.0 °C. Assume the mass of an eye is 11 g and its specific heat capacity is 4.0 J/g · K.

65. When the Sojourner spacecraft landed on Mars in 1997, the planet was approximately 7.8×10^7 km from Earth. How long did it take for the television picture signal to reach Earth from Mars?

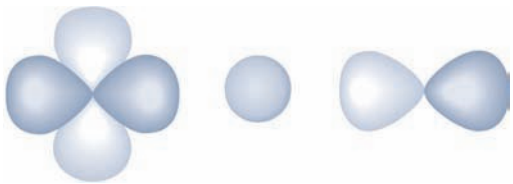
66. The most prominent line in the emission spectrum of chromium is found at 425.4 nm. Other lines in the chromium spectrum are found at 357.9 nm, 359.3 nm, 360.5 nm, 427.5 nm, 429.0 nm, and 520.8 nm.

(a) Which of these lines represents the most energetic light?

(b) What color is light of wavelength 425.4 nm?

67. Answer the following questions as a summary quiz on the chapter.

(a) The quantum number n describes the _____ of an atomic orbital.



(b) The shape of an atomic orbital is given by the quantum number _____.

(c) A photon of green light has _____ (less or more) energy than a photon of orange light.

(d) The maximum number of orbitals that may be associated with the set of quantum numbers $n = 4$ and $\ell = 3$ is _____.

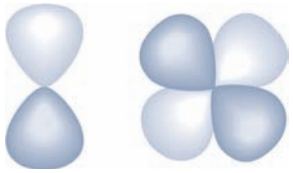
(e) The maximum number of orbitals that may be associated with the quantum number set $n = 3$, $\ell = 2$, and $m_\ell = -2$ is _____.

(f) Label each of the following orbital pictures with the appropriate letter:

(g) When $n = 5$, the possible values of ℓ are _____.

(h) The number of orbitals in the $n = 4$ shell is _____.

68. Answer the following questions as a summary quiz on this chapter.



(a) The quantum number n describes the _____ of an atomic orbital, and the quantum number ℓ describes its _____.

(b) When $n = 3$, the possible values of ℓ are _____.

(c) What type of orbital corresponds to $\ell = 3$? _____

(d) For a 4*d* orbital, the value of n is _____, the value of ℓ is _____, and a possible value of m_ℓ is _____.

(e) Each of the following drawings represents a type of atomic orbital. Give the letter designation for the orbital, give its value of ℓ, and specify the number of planar nodes.

Letter = _____ _____

ℓ value = _____ _____

Planar nodes = _____ _____

(f) An atomic orbital with three planar nodes through the nucleus is a(n) _____ orbital.

(g) Which of the following orbitals cannot exist according to modern quantum theory: 2*s*, 3*p*, 2*d*, 3*f*, 5*p*, 6*p*?

(h) Which of the following is not a valid set of quantum numbers?

n	ℓ	m_ℓ	m_s
3	2	1	$-\frac{1}{2}$
2	1	2	$+\frac{1}{2}$
4	3	0	0

(i) What is the maximum number of orbitals that can be associated with each of the following sets of quantum numbers? (One possible answer is "none.")

(i) $n = 2$ and $\ell = 1$

(ii) $n = 3$

(iii) $n = 3$ and $\ell = 3$

(iv) $n = 2$, $\ell = 1$, and $m_\ell = 0$

69. For an electron in a hydrogen atom, calculate the energy of the photon emitted when an electron falls in energy from the $n = 5$ level to the $n = 2$ state. What are the frequency and wavelength of this electromagnetic radiation?

In the Laboratory

70. A solution of $KMnO_4$ absorbs light at 540 nm (page 206). What is the frequency of the light absorbed? What is the energy of one mole of photons with $\lambda = 540$ nm?

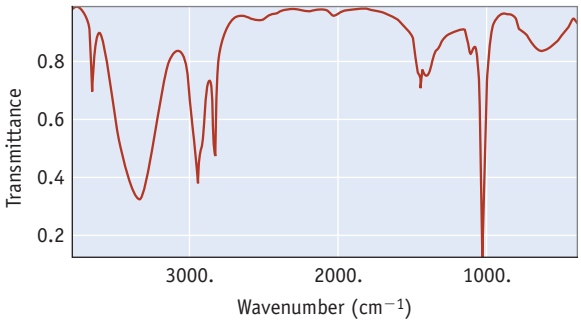
71. A large pickle is attached to two electrodes, which are then attached to a 110-V power supply. As the voltage is increased across the pickle, it begins to glow with a yellow color. Knowing that pickles are made by soaking the vegetable in a concentrated salt solution, describe why the pickle might emit light when electrical energy is added.

© Cengage Learning/ Charles D. Winter



The "electric pickle"

72. The spectrum shown here is for aspirin. The vertical axis is the amount of light absorbed, and the horizontal axis is the wavelength of incident light (in nm). (For more on spectrophotometry, see Section 4.9.)

What is the frequency of light with a wavelength of 278 nm? What is the energy of one mole of photons with $\lambda = 278$ nm? What region of the electromagnetic spectrum is covered by the spectrum above? Knowing that aspirin only absorbs light in the region depicted by this spectrum, what is the color of aspirin?

73. The infrared spectrum for methanol, CH_3OH, is illustrated below. It shows the amount of light in the infrared region that methanol transmits as a function of wavelength. The vertical axis is the amount of light transmitted. At points near the top of the graph, most of the incident light is being transmitted by the sample (or, conversely, little light is absorbed). Therefore, the "peaks" or "bands" that descend from the top indicate light absorbed; the longer the band, the more light is being absorbed. The horizontal scale is in units of "wavenumbers," abbreviated cm^{-1}. The energy of light is given by Planck's law as $E = hc/\lambda$; that is, E is proportional to $1/\lambda$. Therefore, the horizontal scale is in units of $1/\lambda$ and reflects the energy of the light incident on the sample.

(a) One point on the horizontal axis is marked as 2000 cm^{-1}. What is the wavelength of light at this point?

(b) Which is the low energy end of this spectrum (left or right), and which is the high energy end?

(c) The broad absorption at about 3300–3400 cm^{-1} indicates that infrared radiation is interacting with the OH group of the methanol molecule. The narrower absorptions around 2800–3000 cm^{-1} are for interactions with C—H bonds. Which interaction requires more energy, with O—H or with C—H?

Summary and Conceptual Questions

The following questions may use concepts from this and previous chapters.

74. Bohr pictured the electrons of the atom as being located in definite orbits about the nucleus, just as the planets orbit the Sun. Criticize this model.

75. Light is given off by a sodium- or mercury-containing streetlight when the atoms are excited. The light you see arises for which of the following reasons?

(a) Electrons are moving from a given energy level to one of higher energy.

(b) Electrons are being removed from the atom, thereby creating a metal cation.

(c) Electrons are moving from a given energy level to one of lower energy.

76. How do we interpret the physical meaning of the square of the wavefunction? What are the units of $4\pi r^2\psi^2$?

77. What does "wave–particle duality" mean? What are its implications in our modern view of atomic structure?

78. Which of these are observable?

(a) position of an electron in an H atom

(b) frequency of radiation emitted by H atoms

(c) path of an electron in an H atom

(d) wave motion of electrons

(e) diffraction patterns produced by electrons

(f) diffraction patterns produced by light

(g) energy required to remove electrons from H atoms

(h) an atom

(i) a molecule

(j) a water wave

79. In principle, which of the following can be determined?

(a) the energy of an electron in the H atom with high precision and accuracy

(b) the position of a high-speed electron with high precision and accuracy

(c) at the same time, both the position and the energy of a high-speed electron with high precision and accuracy

80. ▲ Suppose you live in a different universe where a different set of quantum numbers is required to describe the atoms of that universe. These quantum numbers have the following rules:

N, principal	1, 2, 3, . . . , ∞
L, orbital	$= N$
M, magnetic	-1, 0, $+1$

How many orbitals are there altogether in the first three electron shells?

81. A photon with a wavelength of 93.8 nm strikes a hydrogen atom, and light is emitted by the atom. How many emission lines would be observed? At what wavelengths? Explain briefly (see Figure 6.10).

82. Explain why you could or could not measure the wavelength of a golf ball in flight.

83. The radioactive element technetium is not found naturally on Earth; it must be synthesized in the laboratory. It is a valuable element, however, because it has medical uses. For example, the element in the form of sodium pertechnetate ($NaTcO_4$) is used in imaging studies of the brain, thyroid, and salivary glands and in renal blood flow studies, among other things.

(a) In what group and period of the periodic table is the element found?

(b) The valence electrons of technetium are found in the 5*s* and 4*d* subshells. What is a set of quantum numbers (n, ℓ, and m_ℓ) for one of the electrons of the 5*s* subshell?

(c) Technetium emits a γ-ray with an energy of 0.141 MeV. (1 MeV = 10^6 electron-volts, where 1 eV = 1.6022×10^{-19} J.) What are the wavelength and frequency of a γ-ray photon with an energy of 0.141 MeV?

(d) To make $NaTcO_4$, the metal is dissolved in nitric acid.

$$7\ HNO_3(aq) + Tc(s) \rightarrow HTcO_4(aq) + 7\ NO_2(g) + 3\ H_2O(\ell)$$

and the product, $HTcO_4$, is treated with NaOH to make $NaTcO_4$.

(i) Write a balanced equation for the reaction of $HTcO_4$ with NaOH.

(ii) If you begin with 4.5 mg of Tc metal, what mass of $NaTcO_4$ can be made? What mass of NaOH, in grams, is required to convert all of the $HTcO_4$ into $NaTcO_4$?

(e) If you synthesize 1.5 micromoles of $NaTcO_4$, what mass of compound do you have? If the compound is dissolved in 10.0 mL of solution, what is the concentration?

84. ▲ Figure 6.12b shows the probability of finding a hydrogen 1*s* electron at various distances from the nucleus. To create the graph in this figure, the electron cloud is first divided into a series of thin concentric shells about the nucleus and then the probability of finding the electron in each shell is evaluated. The volume of each shell is given by the equation $V = 4\pi r^2(d)$, where d is the thickness of the shell and r is the distance of the shell from the nucleus. The probability of finding the electron in each shell is

$$\text{Probability} = 4\pi r^2 \psi^2(d)$$

where ψ is the 1*s* wavefunction for hydrogen (a_o in this equation is 52.9 pm).

$$\psi = \frac{1}{(\pi a_0^3)^{1/2}} e^{-r/a_0}$$

(a) The most probable distance for a 1s electron in the hydrogen atom is at 52.9 pm. Evaluate the probability of finding the electron in a concentric shell 1.0 pm thick at this distance from the nucleus.

(b) Calculate the probability of finding the electron in a shell 1.0 pm thick at distances from the nucleus of 0.50 a_o and 4 a_o. Compare the results with the probabilities at a_o. Are these probabilities in accord with the surface density plot shown in Figure 6.12b?

CHAPTER OUTLINE

7.1 The Pauli Exclusion Principle

7.2 Atomic Subshell Energies and Electron Assignments

7.3 Electron Configurations of Atoms

7.4 Electron Configurations of Ions

7.5 Atomic Properties and Periodic Trends

7.6 Periodic Trends and Chemical Properties

7.1 The Pauli Exclusion Principle

Goals for Section 7.1

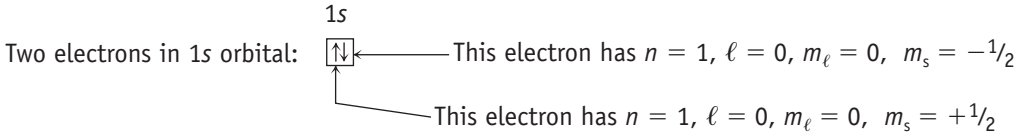
- Recognize that each electron in an atom has a different set of the four quantum numbers, n, ℓ, m_ℓ, and m_s.
- Understand the Pauli exclusion principle: no atomic orbital can be assigned more than two electrons and the two electrons in an orbital must have opposite spins (different values of m_s).

To make the quantum theory consistent with experiment, the Austrian physicist Wolfgang Pauli (1900–1958) stated in 1925 his **exclusion principle:** *No more than two electrons can be assigned to the same orbital, and, if there are two electrons in the same orbital, they must have opposite spins.* This leads to the general statement that *no two electrons in an atom can have the same set of four quantum numbers* (n, ℓ, m_ℓ, and m_s).

An electron assigned to the 1*s* orbital of the H atom may have the set of quantum numbers $n = 1$, $\ell = 0$, $m_\ell = 0$, and $m_s = +1/2$. If we represent an orbital by a box and the electron spin by an arrow (↑ or ↓), a representation of the hydrogen atom is then:

Electron in 1*s* orbital: ↑ Quantum number set
1*s* $n = 1, \ell = 0, m_\ell = 0, m_s = +1/2$

The choice of m_s (either $+1/2$ or $-1/2$) and the direction of the electron spin arrow are arbitrary; that is, we could choose either value, and the arrow may point in either direction. Diagrams such as these are called **orbital box diagrams.**



◀ **Examples of the periodicity of Group 1A and Group 7A elements.** Dmitri Mendeleev developed the first periodic table by listing elements in order of increasing atomic weight. Every so often, an element had properties similar to those of a lighter element, and these were placed in vertical columns or groups. We now recognize that the elements should be listed in order of increasing atomic number and that the periodic occurrence of similar properties is related to the electron configurations of the elements.

Orbitals Are Not Boxes Orbitals are not boxes in which electrons are placed. Thus, it is not conceptually correct to talk about electrons being in orbitals or occupying orbitals, although this is commonly done for the sake of simplicity.

A helium atom has two electrons. In the lowest energy (ground state) electronic configuration both electrons are assigned to the 1*s* orbital. So, the orbital box diagram is:

By having opposite or "paired" spins, the two electrons in the 1*s* orbital of an He atom have different sets of the four quantum numbers in accord with the Pauli exclusion principle.

Our understanding of orbitals and the knowledge that an orbital can accommodate no more than two electrons tell us the maximum number of electrons that can occupy each electron shell or subshell. For example, because two electrons can be assigned to each of the three orbitals in a *p* subshell, these subshells can hold a maximum of six electrons. By the same reasoning, the five orbitals of a *d* subshell can accommodate a total of 10 electrons, and the seven *f* orbitals can accommodate 14 electrons. Recall that there are *n* subshells in the *n*th shell, and that there are n^2 orbitals in that shell (Table 6.1). Thus, *the maximum number of electrons in any shell is* $2n^2$. The relationship among the quantum numbers and the numbers of electrons is shown in Table 7.1.

TABLE 7.1 Number of Electrons Accommodated in Electron Shells and Subshells with $n = 1$ to 6

Electron Shell (n)	Subshells Available	Orbitals Available ($2\ell + 1$)	Number of Electrons Possible in Subshell [$2(2\ell + 1)$]	Maximum Electrons Possible for nth Shell ($2n^2$)
1	*s*	1	2	2
2	*s*	1	2	8
	p	3	6	
3	*s*	1	2	18
	p	3	6	
	d	5	10	
4	*s*	1	2	32
	p	3	6	
	d	5	10	
	f	7	14	
5	*s*	1	2	50
	p	3	6	
	d	5	10	
	f	7	14	
	*g**	9	18	
6	*s*	1	2	72
	p	3	6	
	d	5	10	
	*f**	7	14	
	*g**	9	18	
	*h**	11	22	

*These orbitals are not occupied in the ground state of any known element.

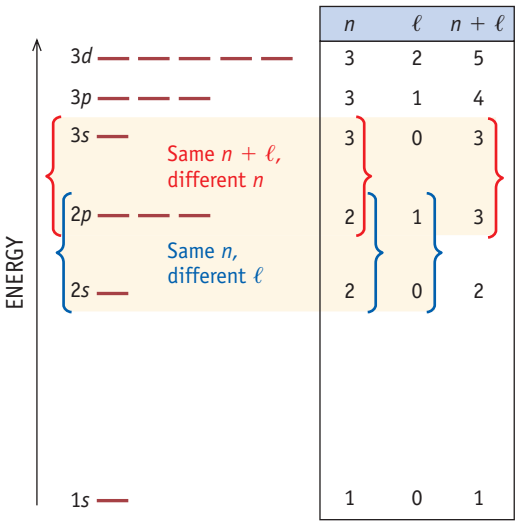
7.2 Atomic Subshell Energies and Electron Assignments

Goals for Section 7.2

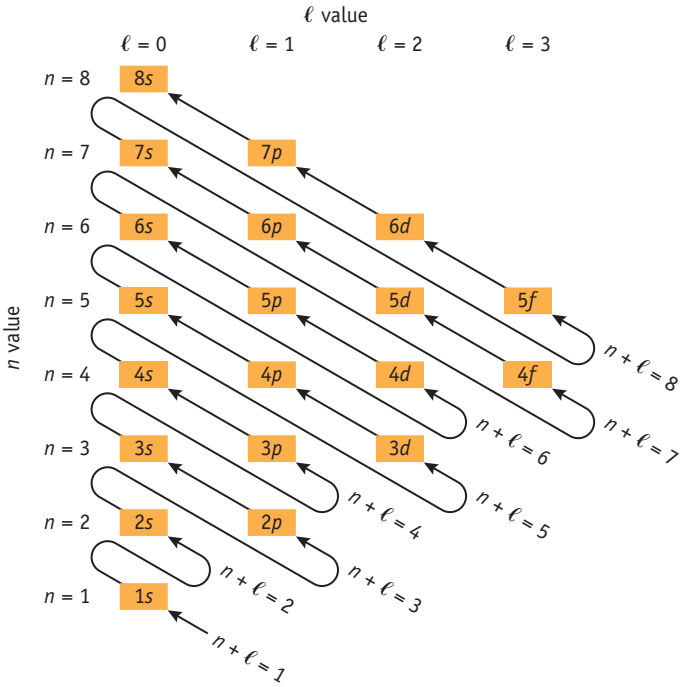
- Write the electron configuration for atoms.
- Recognize that electrons are assigned to the subshells of an atom in order of increasing energy (Aufbau principle). In the H atom, the energies increase with increasing n, but, in a many-electron atom, the energies depend on both n and ℓ.
- Understand the concept of effective nuclear charge, Z^*, and apply Z^* in determining orbital energy levels in atoms.

Our goal in this section is to understand and predict the distribution of electrons in atoms with many electrons. The procedure by which electrons are assigned to orbitals is known as the *Aufbau principle* (the German word *Aufbau* means "building up"). Electrons in an atom are assigned to shells (defined by the quantum number n) and subshells (defined by the quantum numbers n and ℓ) in order of increasingly higher energy. In this way, the total energy of the atom is as low as possible.



Order of Subshell Energies and Assignments

The Bohr model states that the energy of the H atom, with a single electron, depends only on the value of n (Equation 6.4, $E_n = -Rhc/n^2$). For atoms with more than one electron, however, the situation is more complex: the subshell energies in multielectron atoms depend on *both n and* ℓ (Figure 7.1a).



Based on theoretical and experimental studies of electron distributions in atoms, chemists have found there are two general rules that help predict these arrangements:

1. Electrons are assigned to subshells in order of increasing "$n + \ell$" value.
2. For two subshells with the same value of "$n + \ell$," electrons are assigned first to the subshell of lower n.

FIGURE 7.1 Subshell energies and filling order in a multielectron atom.

(a) Order of subshell energies in the first three shells in a multielectron atom. Energies of electron shells increase with increasing n, and, within a shell, subshell energies increase with increasing ℓ. (The energy axis is not to scale. The energy gaps between subshells of a given shell become smaller as n increases.)

(b) Subshell filling order. Subshells in atoms are filled in order of increasing $n + \ell$. When two subshells have the same $n + \ell$ value, the subshell of lower n is filled first. To use the diagram, begin at 1*s* and follow the arrows of increasing $n + \ell$. (Thus, the order of filling is $1s \Rightarrow 2s \Rightarrow 2p \Rightarrow 3s \Rightarrow 3p \Rightarrow 4s \Rightarrow 3d$ and so on.)

The following are examples of these rules:

- Electrons are assigned to the 2*s* subshell ($n + \ell = 2 + 0 = 2$) before the 2*p* subshell ($n + \ell = 2 + 1 = 3$).
- Electrons are assigned to 2*p* orbitals ($n + \ell = 2 + 1 = 3$) before the 3*s* subshell ($n + \ell = 3 + 0 = 3$) because n for the 2*p* electrons is less than n for the 3*s* electrons.
- Electrons are assigned to the 4*s* subshell ($n + \ell = 4 + 0 = 4$) before the 3*d* subshell ($n + \ell = 3 + 2 = 5$) because $n + \ell$ is less for 4*s* than for 3*d*.

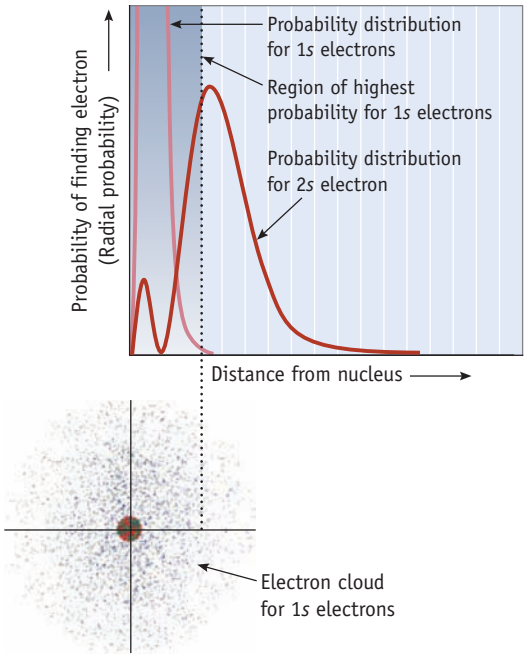

Figure 7.1b summarizes the assignment of electrons according to increasing $n + \ell$ values. The discussion that follows explores the basis for this assignment of electron configurations.

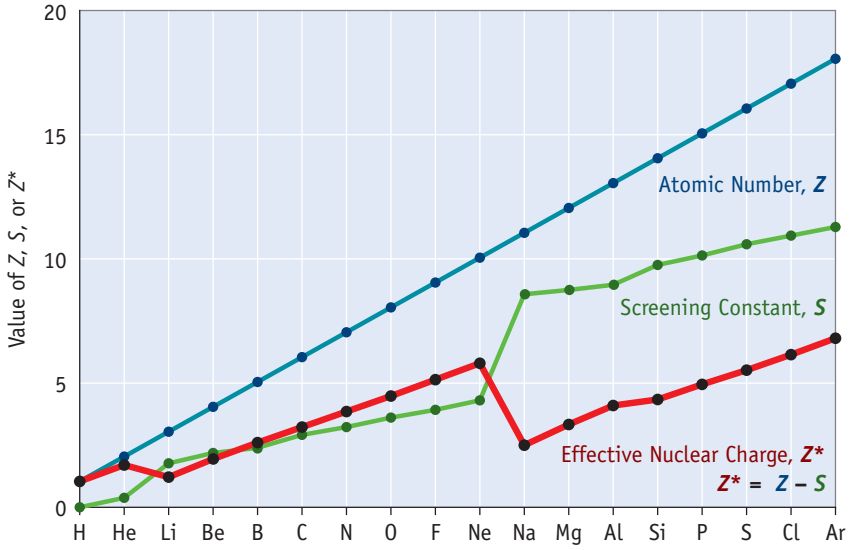
Effective Nuclear Charge, *Z**



The order of energies for electrons in shells and subshells in an atom can be rationalized by introducing the concept of **effective nuclear charge (*Z**)**. This is the *net charge experienced by a particular electron in a multielectron atom resulting from a balance of the attractive force of the nucleus and the repulsive forces of other electrons*.

The surface density plot ($4\pi r^2\psi^2$) for a 2*s* electron for a lithium atom is given in Figure 7.2. (Lithium has three protons in the nucleus, two 1*s* electrons in the first shell, and a 2*s* electron in the second shell.) The probability of finding the 2*s* electron (recorded on the vertical axis) varies depending on the distance from the nucleus (horizontal axis). The region in which the two 1*s* electrons have their highest probability is shaded in Figure 7.2. Notice that the 2*s* electron wave occurs partly within the region of space occupied by 1*s* electrons. Chemists say that the 2*s* orbital *penetrates* the region defining the 1*s* orbital.

At a large distance from the nucleus, the third electron in lithium will experience a +1 charge, the net effect of the two 1*s* electrons (total charge = −2) and the nucleus (+3 charge). The 1*s* electrons *screen* the 2*s* electron from experiencing the full nuclear charge. However, as the 2*s* electron wave penetrates the 1*s* electron region, it experiences the attraction of an increasingly higher net positive charge. When the 2*s* electron is

(left) The two 1*s* electrons of lithium have their highest probability in the shaded region, but this region is penetrated by the 2*s* electron (whose surface density plot is shown here). As the 2*s* electron penetrates the 1*s* region the 2*s* electron experiences a larger and larger positive charge, to a maximum of +3. On average, the 2*s* electron experiences a charge, called the effective nuclear charge *(Z*)*, which is smaller than +3 but greater than +1.

(right) The value of *Z** *for the highest occupied orbital* is given by ($Z - S$), where Z is the atomic number and S is the screening constant. (S reflects how much the inner electrons shield or screen the outermost electron from the nucleus.) Notice that S increases greatly on going from Ne in the second period to Na in the third period.

FIGURE 7.2 Effective nuclear charge, *Z.**

close to the nucleus, it is poorly screened from the nucleus by the 1*s* electrons, and the 2*s* electron experiences a charge close to +3. Thus, on average, a 2*s* electron experiences a positive charge greater than +1 but much smaller than +3. The *average* or *effective* charge, Z^*, experienced by the 2*s* electron in Li is 1.28 (Table 7.2).

In the hydrogen atom, with only one electron, the 2*s* and 2*p* subshells have the same energy. However, in atoms with two or more electrons, the energies of the 2*s* and 2*p* subshells are different. Why should this be true? The relative extent to which an outer electron penetrates inner orbitals occurs in the order $s > p > d > f$. Thus, the effective nuclear charge experienced by electrons in a multielectron atom is in the order $ns > np > nd > nf$. This is reflected in the values of Z^* for *s* and *p* electrons for the second-period elements (Table 7.2). In each case, Z^* is greater for *s* electrons than for *p* electrons. In a given shell, *s* electrons always have a lower energy than *p* electrons; *p* electrons have a lower energy than *d* electrons, and *d* electrons have a lower energy than *f* electrons. A consequence is that subshells within an electron shell are filled in the order *ns* before *np* before *nd* before *nf*. (*A Closer Look: Orbital Energies, Z*, and Electron Configurations*, page 322).

Another important thing to notice in Figure 7.2 is the trend across a period. From left to right across a period, the effective nuclear charge *increases*. The outer electrons in fluorine, for example, feel a greater attraction to the nucleus than do the outer electrons in oxygen. This greater effective nuclear charge plays a major role in determining various properties of the elements such as the relative sizes of the atoms (Section 7.6).

TABLE 7.2

Effective Nuclear Charges, Z^*, for $n = 2$ Elements

Atom	$Z^*(2s)$	$Z^*(2p)$
Li	1.28	
B	2.58	2.42
C	3.22	3.14
N	3.85	3.83
O	4.49	4.45
F	5.13	5.10

7.3 Electron Configurations of Atoms

Goals for Section 7.3

- Using the periodic table as a guide, describe electron configurations of neutral atoms using the orbital box, *spdf*, and noble gas notations.
- Apply the Pauli exclusion principle and Hund's rule when assigning electrons to atomic orbitals.

Arrangements of electrons in the elements up to 109—their *electron configurations*—are given in Table 7.3. Specifically, these are the *ground state electron configurations*, where electrons are found in the shells, subshells, and orbitals that result in the lowest energy for an isolated atom of the element. In general, electrons are assigned to orbitals in order of increasing $n + \ell$. The emphasis here, however, will be to connect the configurations of the elements with their positions in the periodic table (Figure 7.3).

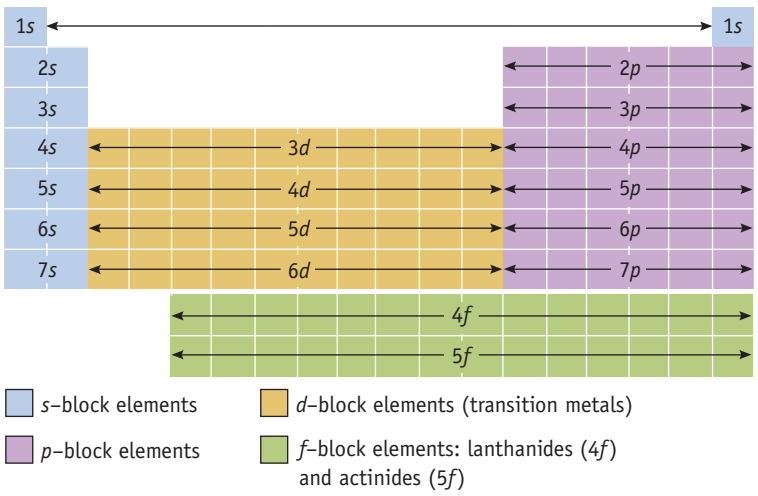

FIGURE 7.3 Electron configurations and the periodic table. The periodic table can serve as a guide in determining the order of filling of atomic orbitals (see Table 7.3).

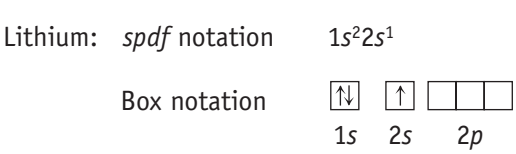
Electron Configurations of the Main Group Elements

Hydrogen, the first element in the periodic table, has one electron in a 1*s* orbital. One way to depict its electron configuration is with the orbital box diagram used earlier, but an alternative and more frequently used method is the *spdf* notation. Using this notation, the electron configuration of H is $1s^1$, read "one *s* one." This indicates that there is one electron (indicated by the superscript) in the 1*s* orbital.



Helium, the second element on the periodic table, has two electrons. The electron configuration is $1s^2$, with both electrons in the 1*s* orbital but having opposite spins. With helium, the first energy level is complete.

Lithium (Li) and Other Elements of Group 1A

Lithium, with three electrons, is the first element in the second period of the periodic table. In an atom of lithium, the first two electrons are in the 1*s* subshell, and the third electron is in the *s* subshell of the $n = 2$ shell. The *spdf* notation, $1s^22s^1$, is read "one *s* two, two *s* one."

Electron configurations are often written in abbreviated form by writing in brackets the symbol for the noble gas preceding the element (called the **noble gas notation**) and then indicating any electrons beyond those in the noble gas by using *spdf* or orbital box notation. In lithium, the arrangement preceding the 2*s* electron is the electron configuration of the noble gas helium. Instead of $1s^22s^1$ for lithium's configuration, it can be written as $[He]2s^1$.

The electrons included in the noble gas notation are often referred to as the **core electrons** of the atom. The core electrons can be ignored when considering the chemistry of an element. The electrons beyond the core electrons—the $2s^1$ electron in the case of lithium—are called **valence electrons**; these are the electrons that determine the chemical properties of an element.

All the elements of Group 1A have one electron assigned to an *s* orbital of the *n*th shell, for which *n* is the number of the period in which the element is found (Figure 7.3). For example, potassium is the first element in the $n = 4$ row (the fourth period), so potassium has the electron configuration of the element preceding it in the table (Ar) plus a single electron assigned to the 4*s* orbital: $[Ar]4s^1$.

Beryllium. Beryllium is one of the components of beryllium-copper alloy, which is used in the oil and gas industry and in electronics. All Group 2A elements like beryllium have an outer electron configuration of ns^2.

Verco Materials, LLC

Boron. Boron carbide, B_4C, is used in body armor. All Group 3A elements such as boron have an outer electron configuration of ns^2np^1.

Beryllium (Be) and Other Elements of Group 2A

All elements of Group 2A have electron configurations of [electrons of preceding noble gas]ns^2, where n is the period in which the element is found in the periodic table. An atom of beryllium, for example, has two electrons in the 1*s* orbital and two electrons in the 2*s* orbital.

Beryllium: *spdf* notation $1s^22s^2$ or $[He]2s^2$

Box notation ⇅ ⇅ □ □ □

1*s* 2*s* 2*p*

Because all the elements of Group 1A have the valence electron configuration ns^1, and those in Group 2A have ns^2, these elements are called ***s*-block elements**.

Boron (B) and Other Elements of Group 3A

Boron (Group 3A) is the first element in the block of elements on the right side of the periodic table. Because the 1*s* and 2*s* orbitals are filled in a boron atom, the fifth electron must be assigned to a 2*p* orbital.

Boron: *spdf* notation $1s^22s^22p^1$ or $[He]2s^22p^1$

Box notation ⇅ ⇅ ↑ □ □

1*s* 2*s* 2*p*

Elements from Group 3A through Group 8A are often called the ***p*-block elements**. All have the outer shell configuration ns^2np^x, where x varies from 1 to 6. The elements in Group 3A, for example, are in the first column of the *p*-block and have two *s* electrons and one *p* electron (ns^2np^1) in their outer shells.

Carbon (C) and Other Elements of Group 4A

Carbon (Group 4A) is in the second column of the *p*-block and thus an atom of carbon has two electrons assigned to the 2*p* orbitals. You can write the electron configuration of carbon by referring to the periodic table: Starting at H and moving from left to right across the successive periods, you write $1s^2$ to reach the end of period 1 and then $2s^2$ and finally $2p^2$ to bring the electron count to six. For carbon to be in its lowest energy (ground) state, these electrons must be assigned to different *p* orbitals, and both will have the same spin direction.

Carbon: *spdf* notation $1s^22s^22p^2$ or $[He]2s^22p^2$

Box notation ⇅ ⇅ ↑ ↑ □

1*s* 2*s* 2*p*

Hund's Rule and Exchange Energy
The reason a configuration with the maximum number of unpaired electrons is more stable is due to the *exchange energy*, a concept that comes out of quantum mechanics and goes beyond the level of general chemistry. Due to the exchange interaction, electrons with parallel spins result in a lower overall energy.

When assigning electrons to *p*, *d*, or *f* orbitals, each successive electron is assigned to a different orbital of the subshell, and each electron has the same spin as the previous one, until the subshell is half full. Additional electrons must then be assigned to half-filled orbitals. This procedure follows **Hund's rule,** which states that *the most stable arrangement of electrons in a subshell is that with the maximum number of unpaired electrons, all with the same spin direction.*

All elements in Group 4A have similar outer shell configurations, ns^2np^2, where n is the period in which the element is located in the periodic table.

Nitrogen (N) and Oxygen (O) and Elements of Groups 5A and 6A

An atom of nitrogen (Group 5A) has five valence electrons. Besides the two 2*s* electrons, it has three electrons, all with the same spin, in three different 2*p* orbitals.

Nitrogen: *spdf* notation $1s^2 2s^2 2p^3$ or $[He]2s^2 2p^3$

Box notation

An atom of oxygen (Group 6A) has six valence electrons. Two of these six electrons are assigned to the 2*s* orbital, and the other four electrons are assigned to 2*p* orbitals.

Oxygen: *spdf* notation $1s^2 2s^2 2p^4$ or $[He]2s^2 2p^4$

Box notation

The fourth 2*p* electron must pair up with one already present. It makes no difference to which orbital this electron is assigned (the 2*p* orbitals all have the same energy), but it must have a spin opposite to the other electron already assigned to that orbital so that each electron has a different set of quantum numbers.

All elements in Group 5A have an outer shell configuration of ns^2np^3, and all elements in Group 6A have an outer shell configuration of ns^2np^4, where *n* is the period in which the element is located in the periodic table.

Fluorine (F) and Neon (Ne) and Elements of Groups 7A and 8A

An atom of fluorine (Group 7A) has seven electrons in the $n = 2$ shell. Two of these electrons occupy the 2*s* subshell, and the remaining five electrons occupy the 2*p* subshell.

Fluorine: *spdf* notation $1s^2 2s^2 2p^5$ or $[He]2s^2 2p^5$

Box notation

All halogen atoms have similar outer shell configurations, ns^2np^5, where *n* is the period in which the element is located.

Like all the elements in Group 8A, neon is a noble gas. Atoms of Group 8A elements (except helium) have eight electrons in the shell of highest *n* value, and they have the outer shell configuration ns^2np^6, where *n* is the period in which the element is found. That is, all the noble gases have filled *ns* and *np* subshells. The nearly complete chemical inertness of the noble gases is associated with this electron configuration.

Neon: *spdf* notation $1s^2 2s^2 2p^6$ or $[He]2s^2 2p^6$

Box notation

© Cengage Learning/Charles D. Winters

Fluorine. Fluorine is found as the fluoride ion in the mineral fluorite (CaF_2), sometimes called *fluorspar*. The mineral, which is the state mineral of Illinois, comes in many colors. All Group 7A elements have an outer electron configuration of ns^2np^5.

Elements of Period 3

The elements of the third period have valence electron configurations similar to those of the second period, except that the preceding noble gas is neon and the valence shell is the third energy level. For example, silicon has four valence electrons

Sulfur. Sulfur is widely distributed on Earth. Like all Group 6A elements, it has the outer electron configuration ns^2np^4.

and a neon core. Because it is the second element in the *p* block, it has two electrons in 3*p* orbitals. Thus, its electron configuration is

Silicon: *spdf* notation $1s^2 2s^2 2p^6 3s^2 3p^2$ or $[Ne]3s^2 3p^2$

Box notation

EXAMPLE 7.1

Electron Configurations

Problem Give the electron configuration of sulfur, using the *spdf*, *spdf* with noble gas, and orbital box with noble gas notations.

What Do You Know? From the periodic table: sulfur, atomic number 16, is the sixth element in the third period ($n = 3$) and is in the fourth column of the *p*-block. You need to know the order of filling (Figure 7.1b).

Strategy

- For the *spdf* and orbital box notations: assign the 16 electrons for sulfur to orbitals based on the order of filling.
- For the noble gas notation: The first 10 electrons are identified by the symbol of the previous noble gas, Ne. The remaining 6 electrons are assigned to the 3*s* and 3*p* subshells. Make sure Hund's rule is followed in the box notation.

SOLUTION Sulfur, atomic number 16, is the sixth element in the third period ($n = 3$) and is in the *p*-block. The last six electrons assigned to the atom, therefore, have the configuration $3s^2 3p^4$. These are preceded by the completed shells $n = 1$ and $n = 2$, the electron arrangement for Ne.

Complete *spdf* notation: $1s^2 2s^2 2p^6 3s^2 3p^4$

spdf with noble gas notation: $[Ne]3s^2 3p^4$

Orbital box notation: [Ne]

Think about Your Answer The orbital box notation conveys information not found in the *spdf* notation, namely the number of unpaired electrons.

Check Your Understanding

(a) What element has the configuration $1s^2 2s^2 2p^6 3s^2 3p^5$?

(b) Using *spdf* notation and an orbital box diagram, show the electron configuration of phosphorus.

EXAMPLE 7.2

Electron Configurations and Quantum Numbers

Problem Write the electron configuration for Al using the *spdf* and orbital box notations with the noble gas notation, and give a set of quantum numbers for each of the electrons with $n = 3$ (the valence electrons).

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

What Do You Know? The periodic table informs you that Al (atomic number 13) is the third element after the noble gas neon.

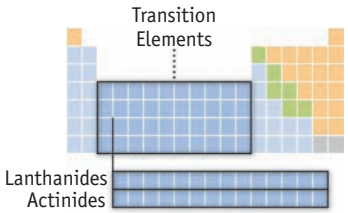
Strategy Because aluminum is the third element in the third period, it has three electrons with $n = 3$. Two of the electrons are assigned to 3*s*, and the remaining electron is assigned to 3*p*.

SOLUTION The element is preceded by the noble gas neon, so the electron configuration is $[Ne]3s^2 3p^1$. Using the box notation, the configuration is

Aluminum configuration: [Ne] ⇅ ↑ (3*s* 3*p*)

The possible sets of quantum numbers for the two 3*s* electrons are

	n	ℓ	m_ℓ	m_s
For ↑	3	0	0	$+\frac{1}{2}$
For ↓	3	0	0	$-\frac{1}{2}$



For the single 3*p* electron, one of six possible sets is $n = 3$, $\ell = 1$, $m_\ell = +1$, and $m_s = +\frac{1}{2}$.

Think about Your Answer Each set of four quantum numbers identifies a unique electron in an atom's electron configuration. No two sets of four quantum numbers can be the same.

Check Your Understanding

Write one possible set of quantum numbers for the valence electrons of calcium.

Electron Configurations of the Transition Elements

The elements of the fourth through the seventh periods use *d* and *f* subshells, in addition to *s* and *p* subshells, to accommodate electrons (see Figure 7.3 and Tables 7.3 and 7.4). Elements whose atoms have partially filled *d* subshells are called **transition elements.** Those elements for which atoms are filling *f* subshells are sometimes called the **inner transition elements** or, more often, the **lanthanides** (filling 4*f* orbitals, Ce through Lu) and **actinides** (filling 5*f* orbitals, Th through Lr).

In a given period in the periodic table, the transition elements are always preceded by two *s*-block elements. After filling the *ns* orbital in the period, we begin filling the $(n - 1)d$ orbitals. Scandium, the first transition element, has the configuration $[Ar]3d^1 4s^2$, and titanium follows with $[Ar]3d^2 4s^2$ (Table 7.4).

The general procedure for assigning electrons would suggest that the configuration of a chromium atom should be $[Ar]3d^4 4s^2$. The actual configuration, however, has one electron assigned to each of the six available 3*d* and 4*s* orbitals: $[Ar]3d^5 4s^1$. This configuration has a lower total energy (due to maximizing the number of unpaired electron spins) than the alternative configuration.

Following chromium, atoms of manganese, iron, and nickel have the configurations that would be expected from the order of orbital filling in Figure 7.1. Copper ($[Ar]3d^{10} 4s^1$) is the second "exception" in this series; it has a single electron in the 4*s* orbital, and the remaining 10 electrons beyond the argon core are assigned to the 3*d* orbitals. Zinc, with the configuration $[Ar]3d^{10} 4s^2$, ends the first transition series.

The fifth period transition elements follow the pattern of the fourth period but have more exceptions to the general rules of orbital filling.

Writing Configurations for Transition Metals We follow the convention of writing configurations with shells listed in order of increasing *n* and, within a given shell, writing subshells in order of increasing ℓ. However, some chemists reverse the order of the *ns* and $(n - 1)d$ orbitals to reflect the order of orbital filling.

Lanthanides and Actinides

The sixth period includes the lanthanide series. As the first element in the *d*-block, lanthanum has the configuration $[Xe]5d^1 6s^2$. The next element, cerium (Ce), is set

Agricultural Research Service/USDA

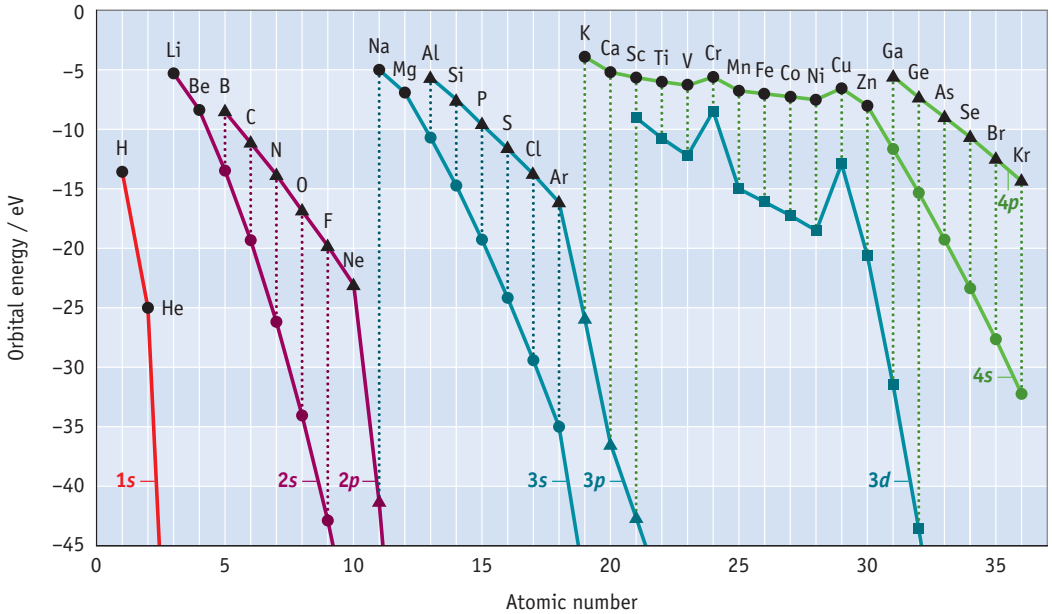
Lanthanides. These elements have many uses. Pictured are samples of lanthanide metal oxides.

out in a separate row at the bottom of the periodic table, and it is with the elements in this row (Ce through Lu) that electrons are first assigned to 4*f* orbitals. Thus, the configuration of cerium is $[Xe]4f^15d^16s^2$. Moving across the lanthanide series, the pattern continues (although with occasional variations in occupancy of the 5*d* and 4*f* orbitals). The lanthanide series ends with 14 electrons being assigned to the seven 4*f* orbitals in lutetium (Lu), whose electron configuration is $[Xe]4f^{14}5d^16s^2$.

The seventh period also includes an extended series of elements utilizing 5*f* orbitals, the actinides. Actinium (Ac) has the configuration $[Rn]6d^17s^2$. The next element is thorium (Th), which is followed by protactinium (Pa) and uranium (U). The electron configuration of uranium is $[Rn]5f^36d^17s^2$.

A CLOSER LOOK

Orbital Energies, *Z**, and Electron Configurations



The graph below shows how the energies of different atomic orbitals change on going from one element to the next in the periodic table. Here are some significant observations drawn from the graph.

(1) Generally, as one moves from left to right in any period, the energies of the atomic orbitals decrease. This trend correlates with the changes in *Z**, the effective charge experienced by an electron in a given orbital (Figure 7.2). As noted, *Z** is a parameter related to the nuclear charge and the shielding effect of all the other electrons. When moving from one element to the next across each period, the attractive effect of an additional proton in the nucleus outweighs the repulsive effect of an additional electron.

(2) Electrons are classified as either valence electrons or core electrons. We can now see from this graph the obvious distinction in these groups. Valence electrons are found in orbitals that have higher (less negative) energies. In contrast, the core electrons are in orbitals that have very low energy, because they experience a much higher *Z**. Furthermore, as one moves from one period to the next period (for example from Ar in period 3 to K in period 4) the energies of core orbitals plummet. The very low energy of electrons in these orbitals rules out the ability of these electrons to be involved in chemical reactions.

(3) Notice also the orbital energies of the first transition series. Each step going across the transition series involves adding a proton to the nucleus and a 3*d* electron to an inner shell. The 4*s* energy level decreases only slightly in this series of elements, reflecting the fact that the additional 3*d* electrons effectively shield a 4*s* electron from the higher charge resulting from addition of a proton. The additional nuclear charge has a greater effect on the 3*d* orbitals, and their energies decrease to a greater extent across the transition series. When the end of the transition series is reached the 3*d* electrons become part of the core and their energies plummet.

(4) Finally, note the exceptional behavior of Cr and Cu in this sequence. These elements have unexpected electron configurations (page 316) arising because another factor, exchange energy (page 318), is a contributor to the overall energy in the system.

Variation in orbital energies (derived from photoelectron spectroscopy data, page 333) with atomic number. The energies are in electron-volts (eV) where 1 eV = 1.602×10^{-19} J. (Figure redrawn from *Chemical Structure and Reactivity*, J. Keeler and P. Wothers, Oxford, 2008; used with permission.)

**A Closer Look: Questions about Transition Element Electron Configurations.*

EXAMPLE 7.3

Electron Configurations of the Transition Elements

Problem Using the *spdf* notation with the noble gas notation, give electron configurations for (a) technetium, Tc, and (b) osmium, Os.

What Do You Know? Base your answer on the positions of the elements in the periodic table. Technetium is the seventh element in period 5 and osmium is the 22nd element in the 6th period.

Strategy For each element, find the preceding noble gas, and then note the number of *s, p, d,* and *f* electrons that lead from the noble gas to the element.

SOLUTION

(a) Technetium, Tc: The noble gas that precedes Tc is krypton, Kr, at the end of the $n = 4$ row. After 36 electrons are assigned to the core as [Kr], seven electrons remain. Two of these electrons are in the 5*s* orbital, and the remaining five are in 4*d* orbitals. Therefore, the technetium configuration is $[Kr]4d^55s^2$.

(b) Osmium, Os: Osmium is a sixth-period element. Of the 22 electrons to be added after the Xe core, two are assigned to the 6*s* orbital and 14 to 4*f* orbitals. The remaining six are assigned to 5*d* orbitals. Thus, the osmium configuration is $[Xe]4f^{14}5d^66s^2$.

Think about Your Answer The periodic table is a useful guide when determining electron configurations. Keep in mind, however, that some exceptions exist, particularly in the heavier transition elements and the lanthanides and actinides.

Check Your Understanding

Using the periodic table and without looking at Table 7.3, write electron configurations for the following elements:

(a) P (c) Zr (e) Pb

(b) Zn (d) In (f) U

Use the *spdf* and noble gas notations. When you have finished, check your answers with Table 7.3.

7.4 Electron Configurations of Ions

Goals for Section 7.4

- Write electron configurations for ions of main group and transition metal elements.
- Understand the role magnetism plays in revealing electronic structure.

Anions and Cations

To form a monatomic anion, one or more electrons is added to the valence shell of a nonmetal atom so that the electron configuration of the ion is the same as the electron configuration of the next noble gas in the periodic table. Thus, a fluorine

A CLOSER LOOK

Questions about Transition Element Electron Configurations

Why don't all of the $n = 3$ subshells fill before beginning to fill the $n = 4$ subshells? Why is scandium's configuration $[Ar]3d^14s^2$ and not $[Ar]3d^3$? Why is chromium's configuration $[Ar]3d^54s^1$ and not $[Ar]3d^44s^2$? As we search for explanations keep in mind that the most stable configuration will be that with the lowest *total* energy.

From scandium to zinc the energies of the 3*d* orbitals are always lower than the energy of the 4*s* orbital, so for scandium the configuration $[Ar]3d^3$ would seem to be preferred. One way to understand why it is not is to consider the effect of electron–electron repulsion in 3*d* and 4*s* orbitals. The most stable configuration will be the one that most effectively minimizes electron–electron repulsions.

Plots of 3*d* and 4*s* orbitals (as was done for 1*s* and 2*s* in Figure 7.2) show the most probable distance of a 3*d* electron from the nucleus is less than that for a 4*s* electron. Being closer to the nucleus, the 3*d* orbitals are more compact than the 4*s* orbital. This means the 3*d* electrons are closer together, and so two 3*d* electrons would repel each other more strongly than two 4*s* electrons, for example. A consequence is that placing electrons in the slightly higher energy 4*s* orbital lessens the effect of electron–electron repulsions and lowers the overall energy of the atom.

For chromium the 4*s* and 3*d* orbital energies are closer together than other 4th period transition elements. Again, thinking in terms of total energy, it is the effect of exchange energy (page 318) that tips the balance and causes the configuration $[Ar]3d^54s^1$, in which all electron spins are the same, to be most stable.

For more on these questions, see the following papers in the *Journal of Chemical Education,* and Chapter 9 of the book *The Periodic Table* by E. Scerri.

atom gains one electron and becomes a fluoride ion with the same electron configuration as the noble gas neon.

$$F\ [1s^2 2s^2 2p^5]\ + e^- \longrightarrow F^-\ [1s^2 2s^2 2p^6]$$

Similarly, a sulfur atom gains two electrons to become the sulfide ion with the same electron configuration as the noble gas argon.

$$S\ [1s^2 2s^2 2p^6 3s^2 3p^4]\ + 2\ e^- \longrightarrow S^{2-}\ [1s^2 2s^2 2p^6 3s^2 3p^6]$$

To form a cation from a neutral atom, one or more of the valence electrons is removed. *Electrons are always removed first from the electron shell of highest n. If several subshells are present within the nth shell, the electron or electrons of maximum ℓ are removed.* Thus, a sodium ion is formed by removing the $3s^1$ electron from the Na atom,

$$Na\ [1s^2 2s^2 2p^6 3s^1] \longrightarrow Na^+\ [1s^2 2s^2 2p^6] + e^-$$

and Ge^{2+} is formed by removing two $4p$ electrons from a germanium atom,

$$Ge\ [Ar]3d^{10}4s^2 4p^2 \longrightarrow Ge^{2+}\ [Ar]3d^{10}4s^2 + 2\ e^-$$

The same general rule applies to transition metal atoms. This means, for example, that the titanium(II) cation has the configuration $[Ar]3d^2$

$$Ti\ [Ar]3d^2 4s^2 \longrightarrow Ti^{2+}\ [Ar]3d^2 + 2\ e^-$$

Iron(II) and iron(III) cations have the configurations $[Ar]3d^6$ and $[Ar]3d^5$, respectively:

$$Fe\ [Ar]3d^6 4s^2 \longrightarrow Fe^{2+}\ [Ar]3d^6 + 2\ e^-$$

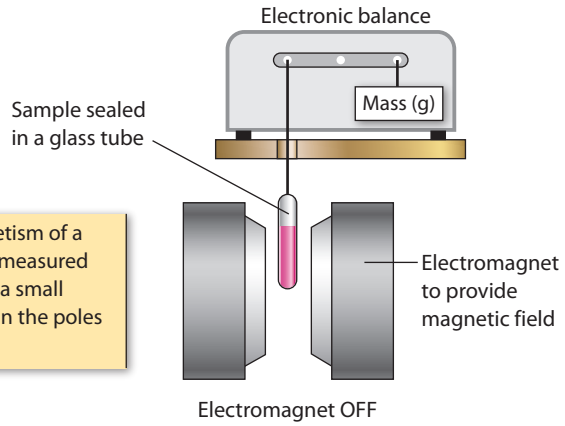
$$Fe^{2+}\ [Ar]3d^6 \longrightarrow Fe^{3+}\ [Ar]3d^5 + e^-$$

Note that in the ionization of transition metals the *ns* electrons are always lost before the $(n - 1)d$ electrons. The cations formed all have electron configurations of the general type [noble gas core]$(n - 1)d^x$. How do we know this is true? One important source of evidence is the study of the magnetic properties of matter.

Diamagnetism and Paramagnetism

If a hydrogen atom is placed in a magnetic field, the single electron will interact with the external field like the needle of a compass aligns with the magnetic lines of force on Earth. As a result the hydrogen atom is attracted by the magnet.

In contrast, helium atoms, each with two electrons, are not attracted to a magnet. In fact, they are slightly repelled by the magnet. To account for this observation, we assume, in line with the Pauli exclusion principle, that the two electrons of helium have different values of m_s, that is, they have *opposite* spin orientations. We say their spins are *paired*, and the result is that the magnetic field of one electron is canceled out by the magnetic field of the second electron with opposite spin.



Elements and compounds that have unpaired electrons are attracted to a magnet. Such species are said to be **paramagnetic.** Substances in which all electrons are paired (with the two electrons of each pair having opposite spins) experience a slight repulsion when subjected to a magnetic field; they are said to be **diamagnetic**. The magnetism of a substance can be determined by placing it in a magnetic field and observing the extent of attraction or repulsion (Figure 7.4).

By determining the magnetic behavior of a substance we can gain information about the electronic structure. For example, the Fe^{3+} ion is paramagnetic (Figure 7.4) to the extent of five unpaired electrons. This is consistent with two $4s$ electrons and one $3d$ electron being removed from an iron atom to form a Fe^{3+} ion, leaving behind five unpaired $3d$ electrons. If, instead, three $3d$ electrons had been removed, the Fe^{3+} ion would still be paramagnetic but only to the extent of three unpaired electrons.

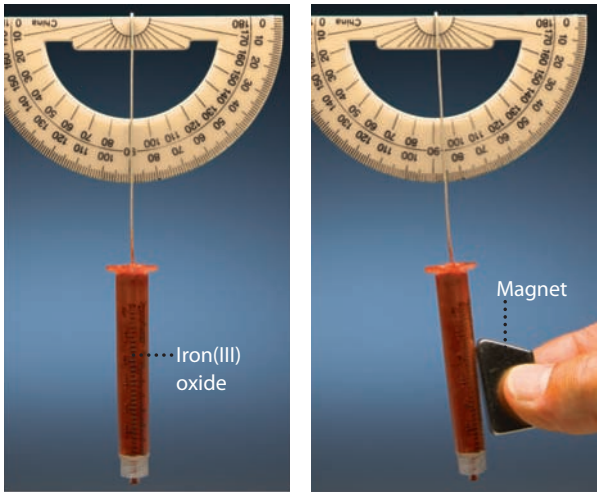
Laboratory measurement of paramagnetism



The paramagnetism of a sample can be measured by suspending a small sample between the poles of a magnet.

When the magnet is turned on, the paramagnetic sample is drawn into the magnetic field. The change in apparent mass can be related quantitatively to the degree of paramagnetism.

Observing the paramagnetism of iron(III) oxide.

Photos: © Cengage Learning/Charles D. Winters

To demonstrate paramagnetism, a sample of iron(III) oxide is packed into a plastic tube and suspended from a thin nylon filament.

When a powerful magnet is brought near the sample, the paramagnetic iron(III) ions in Fe_2O_3 cause the sample to be attracted to the magnet.

The magnet is made of neodymium, iron, and boron [$Nd_2Fe_{14}B$]. These powerful magnets are used in acoustic speakers.

Figure 7.4 **Measuring and observing paramagnetism of compounds.**

EXAMPLE 7.4

Configurations of Transition Metal Ions

Problem Give the electron configurations for Cu, Cu^+, and Cu^{2+}. Are any of these species paramagnetic? How many unpaired electrons does each have?

What Do You Know? You know the electron configuration of copper, which has one 4*s* electron and ten 3*d* electrons. When forming a transition metal ion, the outermost *ns* electrons are lost first, followed by the $(n - 1)d$ electrons.

Strategy Start with the electron configuration of copper (Table 7.4). It is always observed that the *ns* electron or electrons are ionized first followed by one or more $(n - 1)d$ electrons.

SOLUTION Copper has one electron in the 4*s* orbital and ten electrons in 3*d* orbitals:

Cu $[Ar]3d^{10}4s^1$ ↑↓ ↑↓ ↑↓ ↑↓ ↑↓ (3*d*) ↑ (4*s*)

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

When copper is oxidized to Cu^+, the 4*s* electron is lost.

Cu^+ $[Ar]3d^{10}$ ↑↓ ↑↓ ↑↓ ↑↓ ↑↓ □

3*d* 4*s*

The copper(II) ion is formed from copper(I) by removal of one of the 3*d* electrons.

Cu^{2+} $[Ar]3d^9$ ↑↓ ↑↓ ↑↓ ↑↓ ↑ □

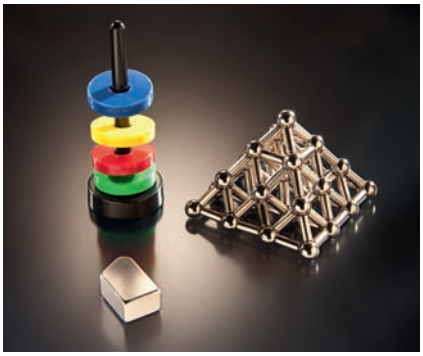
3*d* 4*s*

A copper atom and a copper(II) ion (Cu^{2+}) have one unpaired electron, so they are paramagnetic. In contrast, Cu^+ is diamagnetic.

Think about Your Answer Be sure to recall that the electron configuration for Cu is $[Ar]3d^{10}4s^1$ and not $[Ar]3d^94s^2$. Copper is one of two exceptions in the first transition series in the order of filling (Cr is the other).

Check Your Understanding

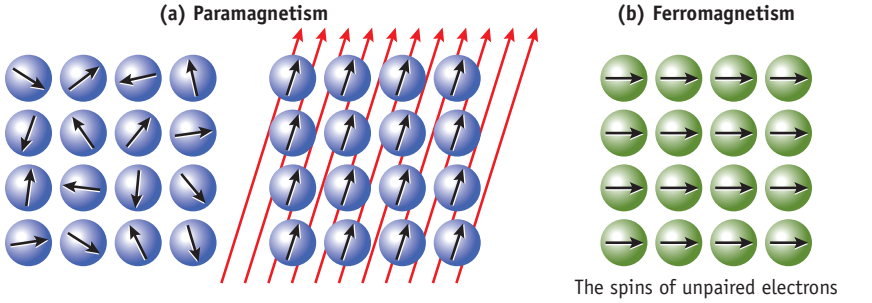
Depict the electron configurations for V^{2+}, V^{3+}, and Co^{3+}. Use orbital box diagrams and the noble gas notation. Are any of the ions paramagnetic? If so, give the number of unpaired electrons.



A CLOSER LOOK

Paramagnetism and Ferromagnetism

Magnetic materials are relatively common, and many are important in our economy. For example, a large magnet is at the heart of the magnetic resonance imaging (MRI) instruments used in medicine, and tiny magnets are found in stereo speakers and in telephone handsets. Magnetic oxides are used in recording tapes and computer disks.



The magnetic materials we use are **ferromagnetic**. The magnetic effect of ferromagnetic materials is much larger than that of paramagnetic materials. Ferromagnetism occurs when the spins of unpaired electrons in a cluster of atoms (called a *domain*) in the solid align themselves in the same direction. Only the metals of the iron, cobalt, and nickel subgroups, as well as a few other metals such as neodymium, exhibit this property. They are also unique in that, once the domains are aligned in a magnetic field, the metal is permanently magnetized.

Many alloys exhibit greater ferromagnetism than do the pure metals themselves. One example of such a material is Alnico, which is composed of aluminum, nickel, and cobalt as well as copper and iron. The strongest permanent magnet is an alloy of neodymium, iron, and boron ($Nd_2Fe_{14}B$).

© Cengage Learning/Charles D. Winters

Magnets. Many common consumer products such as loudspeakers contain permanent magnets.

Magnetism. (a) Paramagnetism: In the absence of an external magnetic field, the unpaired electrons in the atoms or ions of the substance are randomly oriented. If a magnetic field is imposed, however, these spins will tend to become aligned with the field. **(b)** Ferromagnetism: The spins of the unpaired electrons in a cluster of atoms or ions align themselves in the same direction even in the absence of a magnetic field.

7.5 Atomic Properties and Periodic Trends

Goal for Section 7.5

- Predict how properties of atoms—size, ionization energy (*IE*), and electron attachment enthalpy ($\Delta_{EA}H$)—vary within a group and across a period of the periodic table.

Once electron configurations were understood, chemists realized that *similarities in properties of the elements are the result of similar valence shell electron configurations*. An objective of this section is to describe how atomic electron configurations are related to some of the physical and chemical properties of the elements and why those properties change in a predictable manner when moving down groups and across periods.

Atomic Size

The sizes of atoms (Figure 7.5) influence many aspects of their properties and reactivity. Size can determine the number of atoms that may surround and be bound to a central atom and can be a determining factor in the shape of a molecule. As you will see in the next chapter the shapes of molecules are important in determining their properties.

Atom size is also geochemically and technologically important. For example, one atom may take the place of a similarly sized atom in an *alloy*, a solid solution of various elements in a metallic matrix (Section 12.5). Our technology-based industrial

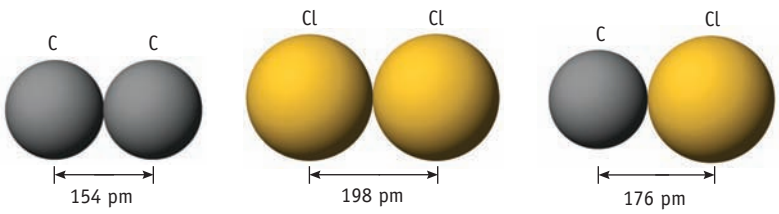
society depends on these materials. Substituting one element for another of similar size can often lead to alloys with different properties. But this is nothing new: humans made implements from iron meteorites (Figure 7.6) over 5000 years ago. Iron meteorites are an alloy composed of about 90% iron and 10% nickel, two elements of very similar size.

We know an orbital has no sharp boundary (Figure 6.12a), so how can we define the size of an atom? There are actually several ways, and they can give slightly different results.

One of the simplest and most useful ways to define atomic size is to relate it to the distance between atoms in a sample of the element. (Radii determined this way are often called *covalent radii*.) Let us consider a diatomic molecule such as Cl_2 (Figure 7.7a). The radius of a Cl atom is assumed to be half the experimentally determined distance between the centers of the two atoms (198 pm), so the radius of one Cl atom is 99 pm. Similarly, the C—C distance in diamond is 154 pm, so a radius of 77 pm can be assigned to carbon. To test these estimates, we can add them together to estimate the C—Cl distance in CCl_4. The predicted distance of 176 pm agrees with the experimentally measured C—Cl distance of 176 pm.

This approach to determining atomic radii applies only when covalently bonded species exist (and so it is largely limited to nonmetals and metalloids). For metals, atomic radii are estimated from measurements of the atom-to-atom distance in a crystal of the element (Figure 7.7b).

Some interesting periodic trends are seen immediately on looking at the table of radii (see Figure 7.5). *For the main group elements, atomic radii generally increase going down a group in the periodic table and decrease going across a period.* These trends reflect two important effects:



- The size of an atom is determined by the outermost electrons. In going from the top to the bottom of a group in the periodic table, the outermost electrons are assigned to orbitals with increasingly higher values of the principal quantum number, n. Because the underlying electrons require some space, these outer shell electrons are necessarily farther from the nucleus.
- For main group elements of a given period, the principal quantum number, n, of the valence electron orbitals is the same. In going from one element to the next across a period, the effective nuclear charge (Z^*) increases (see Figure 7.2). This results in an increased Coulombic force of attraction between the nucleus and the valence electrons, and the atomic radius decreases.

Figure 7.6 The Willamette iron meteorite. This 14150-kg meteorite is composed of 92.38% Fe and 7.62% Ni (with traces of Ga, Ge, and Ir). Iron and nickel atoms have nearly identical radii (124 pm and 125 pm, respectively), so one can substitute for the other in the solid. (The meteorite was discovered in Oregon in 1902, and it is now on display at the American Museum of Natural History.)

Atomic Radii—Caution Numerous tabulations of atomic and covalent radii exist, and the values quoted in them often differ somewhat. The variation comes about because several methods are used to determine the radii of atoms.

(a) The sum of the atomic radii of C and Cl provides a good estimate of the C-Cl distance in a molecule having such a bond.

(b) Pictured here is a tiny piece of an aluminum crystal. Each sphere represents an aluminum atom. Measuring the distance shown allows a scientist to estimate the radius of an aluminum atom.

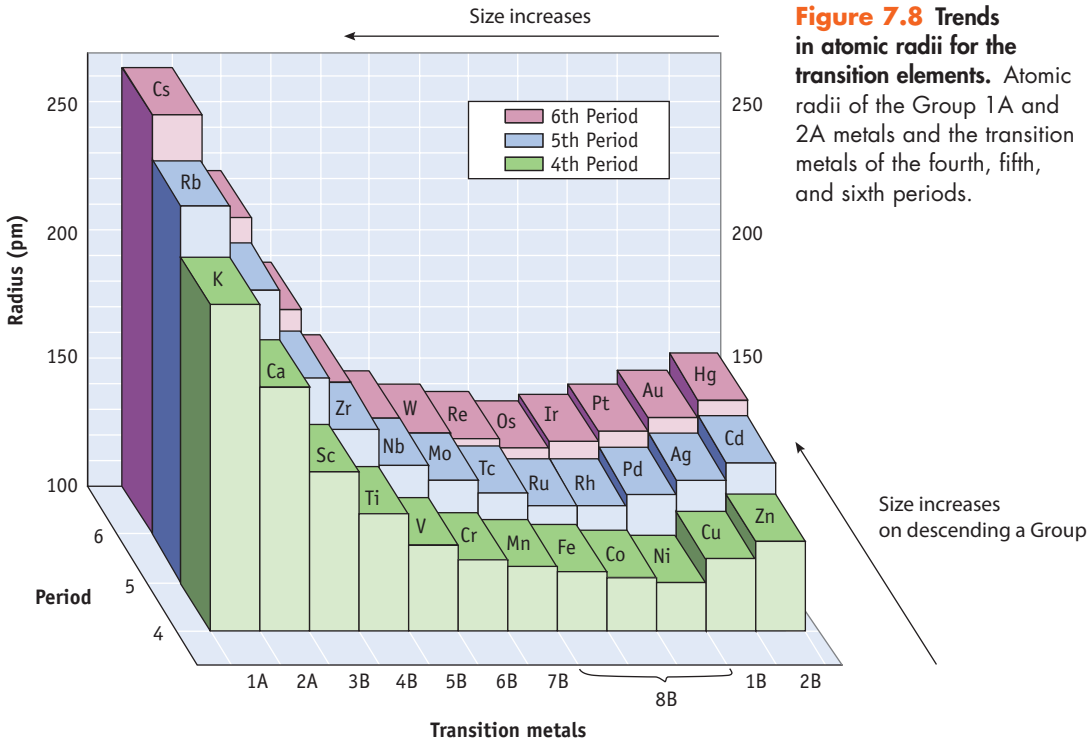

Figure 7.8 Trends in atomic radii for the transition elements. Atomic radii of the Group 1A and 2A metals and the transition metals of the fourth, fifth, and sixth periods.

The periodic trend in the atomic radii of transition metal atoms (Figure 7.8) across a period is somewhat different from that for main group elements. Going from left to right in a given period, the radii initially decrease. However, the sizes of the elements in the middle of a transition series change very little, and a small increase in size occurs at the end of the series. The size of transition metal atoms is determined largely by electrons in the outermost shell—that is, by the electrons of the *ns* subshell—but electrons are being added to the $(n - 1)d$ orbitals across the series. The increased nuclear charge on the atoms as one moves from left to right should cause the radius to decrease. This effect, however, is mostly canceled out by increased electron–electron repulsion as the atomic volume decreases. On reaching the Group 1B and 2B elements at the end of the series, the size increases slightly because the *d* subshell is filled and electron–electron repulsions dominate.

Ionization Energy

Ionization energy *(IE)* is the energy required to remove an electron from an atom in the gas phase.

$$\text{Atom in ground state(g)} \rightarrow \text{Atom}^+\text{(g)} + e^-$$

$$\Delta U \equiv \text{ionization energy, } IE$$

As predicted by Coulomb's law, energy must be supplied to overcome the attraction between an electron and the nucleus and to separate the electron from the atom. Thus, ionization energies always have positive values. An electron farther from the nucleus generally has a smaller ionization energy, and an electron closer to the nucleus has a larger ionization energy.

Atoms other than hydrogen have a series of ionization energies as electrons are removed sequentially. For example, the first three ionization energies of magnesium are

Measuring Ionization Energy Ionization energy values can be measured to a high level of accuracy. In contrast, atomic radii are approximate values.

First ionization energy, $IE_1 = 738$ kJ/mol

$$\underset{1s^2 2s^2 2p^6 3s^2}{\text{Mg(g)}} \rightarrow \underset{1s^2 2s^2 2p^6 3s^1}{\text{Mg}^+\text{(g)}} + e^-$$

Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Second ionization energy, $IE_2 = 1451$ kJ/mol

$$Mg^+(g) \rightarrow Mg^{2+}(g) + e^-$$
$$1s^2 2s^2 2p^6 3s^1 \qquad 1s^2 2s^2 2p^6$$

Third ionization energy, $IE_3 = 7732$ kJ/mol

$$Mg^{2+}(g) \rightarrow Mg^{3+}(g) + e^-$$
$$1s^2 2s^2 2p^6 \qquad 1s^2 2s^2 2p^5$$

Valence and Core Electrons Removal of core electrons requires much more energy than removal of a valence electron. Core electrons are not lost in chemical reactions.

Removing each subsequent electron requires more energy because the electron is removed from an increasingly positive ion (Table 7.5), but there is a particularly large increase in ionization energy for removing the third electron to give Mg^{3+}. The first two ionization steps are for the removal of electrons from the outermost or valence shell of electrons. The third electron, however, must come from the 2*p* subshell, which has a much lower energy than the 3*s* subshell (see Figure 7.1). This large increase is experimental evidence for the electron shell structure of atoms.

For main group (*s*- and *p*-block) elements, *first ionization energies generally increase across a period and decrease down a group* (Figure 7.9 and Appendix F). The trend across a period corresponds to the increase in effective nuclear charge, Z^*, with increasing atomic number (Figure 7.2). As Z^* increases across a period, the energy required to remove an electron increases. Going down a group, the ionization energy decreases. The electron removed is increasingly farther from the nucleus and thus is held less strongly.

Notice that the trends in atomic radius and ionization energy for a given period are both linked to Z^*, although they are inversely related. *Owing to an increase in effective nuclear charge across a period, the atomic radius generally decreases and the ionization energy increases.*

A closer look at ionization energies reveals exceptions to the general trend in a period. One exception occurs on going from *s*-block to *p*-block elements—from beryllium to boron, for example. The 2*p* electrons are slightly higher in energy than the 2*s* electrons, so the ionization energy for boron is slightly less than that for beryllium. Another dip to lower ionization energy occurs on going from nitrogen to oxygen. No change occurs in either n or ℓ, but electron–electron repulsions increase because in Groups 3A–5A, electrons are assigned to separate p orbitals (p_x, p_y, and p_z). Beginning in Group 6A, however, two electrons must be assigned to the

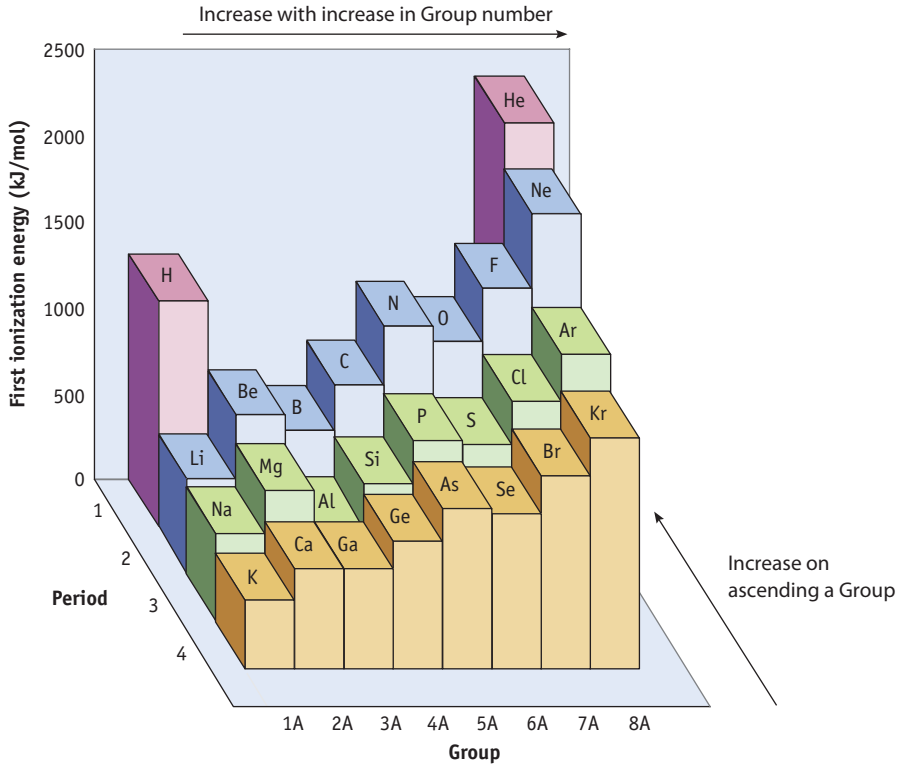

FIGURE 7.9 First ionization energies of the main group elements in the first four periods. (For specific values of the ionization energies for these elements see Table 7.5 and Appendix F.)

same *p* orbital. The fourth *p* electron is paired with another electron and thus experiences greater repulsion than it would if it had been assigned to an orbital of its own. Thus, less energy must be supplied for its removal.

$$\text{O (oxygen atom)} \xrightarrow{+1314\ \text{kJ/mol}} \text{O}^+\text{ (oxygen cation)} + e^-$$

The usual trend resumes on going from oxygen to fluorine to neon, reflecting the increase in Z^*.

Electron Attachment Enthalpy and Electron Affinity

The **electron attachment enthalpy**, $\Delta_{EA}H$, is defined as the enthalpy change occurring when a gaseous atom adds an electron, forming a gaseous anion.

$$A(g) + e^- \rightarrow A^-(g) \qquad \text{Electron attachment enthalpy} = \Delta_{EA}H$$

As illustrated in Figure 7.10, the value of $\Delta_{EA}H$ for many elements is negative, indicating that this process is exothermic and that energy is evolved. For example, $\Delta_{EA}H$ for fluorine is quite exothermic (-328 kJ/mol), whereas boron has a much less negative value of -26.7 kJ/mol. Values of $\Delta_{EA}H$ for a number of elements are given in Appendix F.

The **electron affinity**, EA, of an atom is closely related to $\Delta_{EA}H$. Electron affinity is equal in magnitude but opposite in sign to the internal energy change associated with a gaseous atom adding an electron.

$$A(g) + e^- \rightarrow A^-(g) \qquad \text{Electron affinity, } EA = -\Delta U$$

We expect EA and $\Delta_{EA}H$ to have nearly identical numerical values; however, current convention gives the two values opposite signs.

Electron Affinity, Electron Attachment Enthalpy, and Sign Conventions Changes in sign conventions for electron affinities over the years have caused confusion. For a useful discussion of electron affinity, see J. C. Wheeler: "Electron affinities of the alkaline earth metals and the sign convention for electron affinity," *Journal of Chemical Education*, Vol. 74, pp. 123–127, 1997. In this paper the electron affinity is taken as equivalent to the ionization energy of the anion (which is in fact the way electron affinities can be measured experimentally).

A CLOSER LOOK

Photoelectron Spectroscopy

Photoelectron spectroscopy (PES) is an experimental technique that provides information about the energies of electrons in atoms and molecules and yields evidence in favor of our modern orbital model of electrons in atoms. In this technique, sample atoms are bombarded with high-energy electromagnetic radiation. If a photon has sufficient energy, it can cause an electron in the sample to be ejected. In order to eject valence electrons, the energy required often corresponds to radiation in the ultraviolet region; to remove core electrons, however, higher-energy radiation, such as that in the x-ray region, is required.

The key to understanding PES is that all of the ejected electrons result from bombarding the atom with photons of the same energy ($h\nu$). Some of this energy goes into ejecting the electron from the atom, corresponding to the *ionization energy* (*IE*) of the electron, with the remainder going into kinetic energy of the electron [*KE*(electron)].

$$h\nu = IE + KE(\text{electron})$$

By analyzing the kinetic energies of the electrons emitted and knowing the energy of the original photons, it is possible to determine the ionization energy of each electron ejected.

Each peak in the PES spectrum corresponds to the energy of a subshell that contains electrons. In addition, the intensity of a peak in the spectrum corresponds to the number of electrons in that energy level. The spectrum of neon (Figure), for example, has three major peaks, corresponding to ejection of electrons from three different subshells with intensities corresponding to two, two, and six electrons, respectively, in line with the predicted ground state configuration of $1s^2 2s^2 2p^6$. In contrast, the spectrum for helium ($1s^2$) has only one peak, corresponding to two electrons in the 1*s* subshell, whereas krypton ($1s^2 2s^2 2p^6 3s^2 3p^6 3d^{10} 4s^2 4p^6$) has eight peaks corresponding to ejection of electrons from eight subshells of different energies.

Photoelectron spectra clearly show that electrons in subshells closer to the nucleus, and thus those experiencing higher values of Z^*, require more energy to be ejected (as predicted by Coulomb's law).

Just as PES provides evidence for the energies (and thus orbitals) of electrons in atoms, it also can be used to probe energies of electrons in molecules. (*Applying Chemical Principles, Probing Molecules with Photoelectron Spectroscopy*, p. 438.)

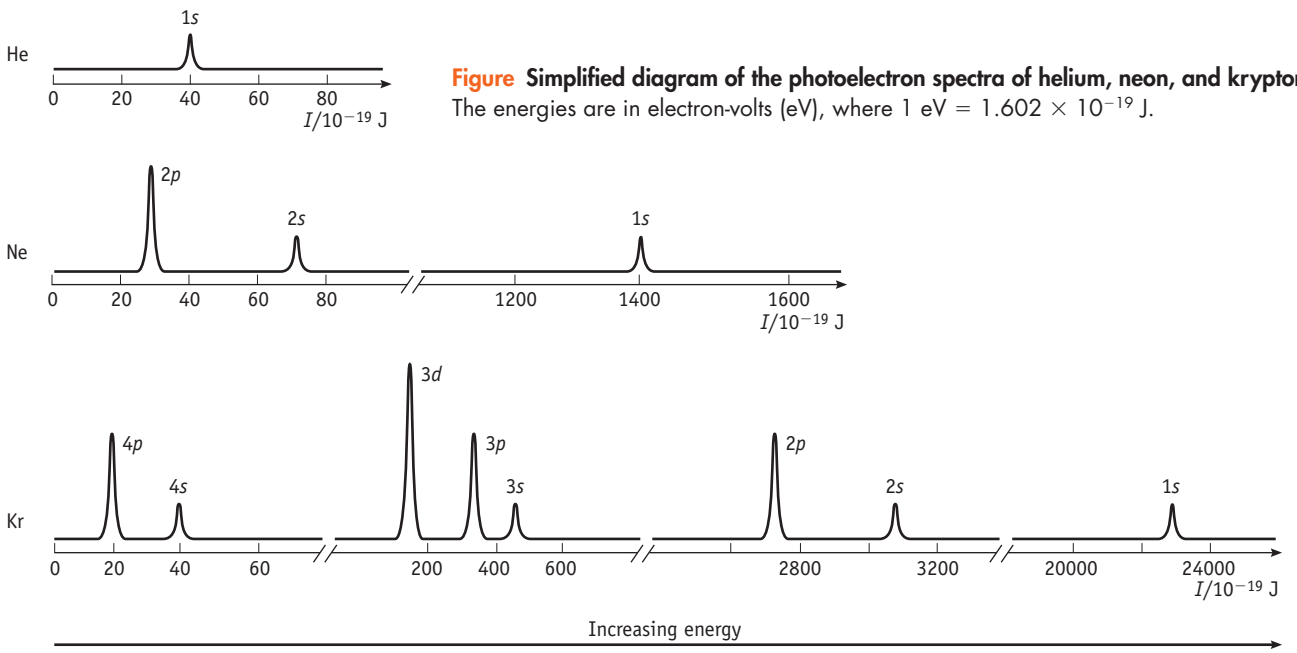

Figure Simplified diagram of the photoelectron spectra of helium, neon, and krypton. The energies are in electron-volts (eV), where 1 eV = 1.602×10^{-19} J.

Because electron attachment enthalpy and ionization energy represent the energy involved in the gain or loss of an electron by an atom, respectively, it makes sense that periodic trends in these properties are also related. The increase in effective nuclear charge of atoms across a period (Figure 7.2) makes it more difficult to ionize the atom, and it also increases the attraction of the atom for an additional electron. Thus, an element with a high ionization energy generally has a more negative value for its electron attachment enthalpy.

As seen in Figure 7.10, the values of $\Delta_{EA}H$ generally become more negative on moving across a period, but the trend is not smooth. The elements in Group 2A and 5A appear as exceptions to the general trend, corresponding to cases where the added electron would start a *p* subshell or would be paired with another electron in the *p* subshell, respectively.

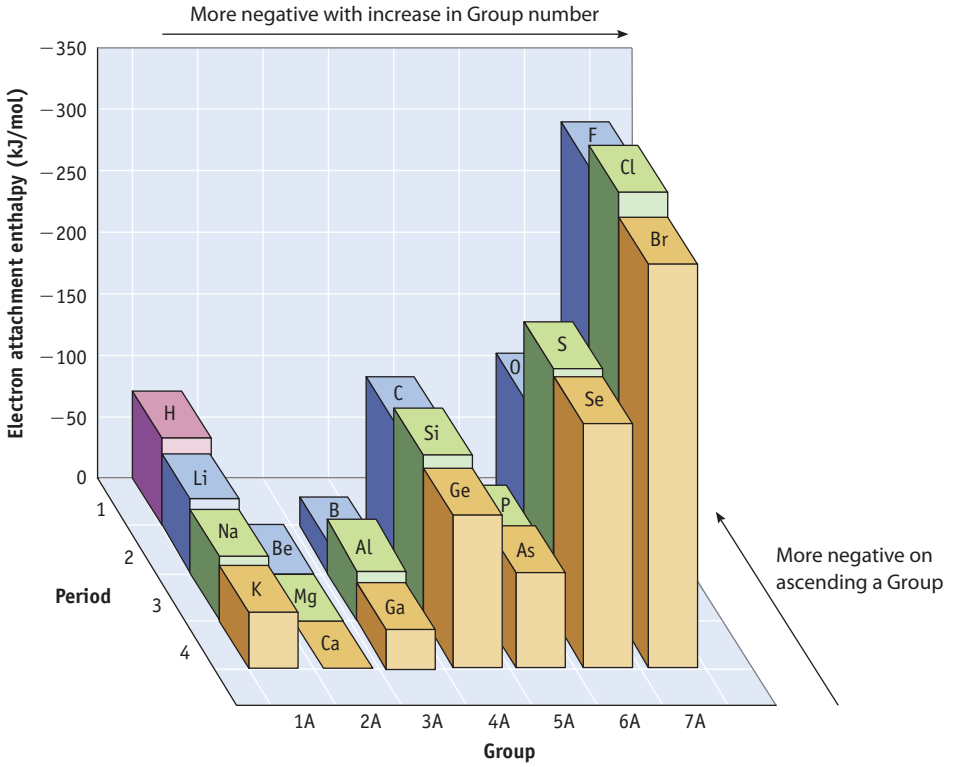

FIGURE 7.10 Electron attachment enthalpy. The greater the affinity of an atom for an electron, the more negative the value for $\Delta_{EA}H$. For numerical values, see Appendix F. (Data were taken from H. Hotop and W. C. Lineberger: "Binding energies of atomic negative ions," *Journal of Physical Chemistry*, Reference Data, Vol. 14, p. 731, 1985.)

The value of electron attachment enthalpy usually becomes less negative on moving down a group of the periodic table. Electrons are added increasingly farther from the nucleus, so the attractive force between the nucleus and electrons decreases. This general trend does not apply to second period elements, however. For example, the value of the electron attachment enthalpy of fluorine is less negative than the value for chlorine. The same phenomenon is observed in Groups 3A through 6A. One explanation is that significant electron–electron repulsions occur in small anions such as F^-. That is, adding an electron to the seven electrons already present in the $n = 2$ shell of the small F atom leads to considerable repulsion between electrons. Chlorine has a larger atomic volume than fluorine, so adding an electron leads to a lesser degree of electron–electron repulsions.

A few elements, such as nitrogen and the Group 2A elements, have no affinity for electrons and are listed as having a $\Delta_{EA}H$ value of zero. The noble gases are generally not listed in tables of $\Delta_{EA}H$ values. They have no affinity for electrons, because any additional electron must be added to the next higher electron shell with a considerably higher energy.

No atom has a negative $\Delta_{EA}H$ value for a second electron. So what accounts for the existence of ions such as O^{2-} that occur in many compounds? The answer is that doubly charged anions can be stabilized in crystalline environments by electrostatic attraction to neighboring positive ions.

Electron Attachment Enthalpy for the Halogens

Element	$\Delta_{EA}H$ (kJ/mol)	Atomic Radius (pm)
F	−328.0	71
Cl	−349.0	99
Br	−324.7	114
I	−295.2	133

EXAMPLE 7.5

Periodic Trends

Problem Compare the three elements C, O, and Si.

(a) Place them in order of increasing atomic radius.

(b) Which has the largest ionization energy?

(c) Which has the more negative electron attachment enthalpy, O or C?

What Do You Know? Carbon and silicon are the first and second elements in Group 4A and oxygen is the first element in Group 6A. You also know the trends in the periodic properties across periods and down groups.

Strategy Use the trends in atomic properties described in Figure 7.5, Figures 7.8–7.10, Table 7.5, and Appendix F.

SOLUTION

(a) *Atomic radii:* Atomic radii decrease on moving across a period, so oxygen has a smaller radius than carbon. However, the radius increases on moving down a periodic group. Because C and Si are in the same group (Group 4A), silicon must be larger than carbon. The trend is O < C < Si.

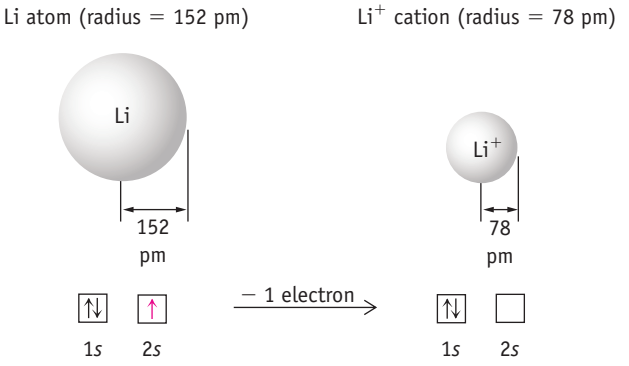
(b) *Ionization energy:* Ionization energies generally increase across a period and decrease down a group. Thus, the trend in ionization energies is Si (787 kJ/mol) < C (1086 kJ/mol) < O (1314 kJ/mol).

(c) *Electron attachment enthalpy:* Values generally become less negative down a group (except for the second period elements) and more negative across a period. Therefore, O (= −141.0 kJ/mol) has a more negative $\Delta_{EA}H$ than C (= −121.9 kJ/mol).

Think about Your Answer Notice the trends in atom size and ionization energy are in the opposite order as expected based on the values of Z^*.

Check Your Understanding

Without looking at the figures for the periodic properties, compare the three elements B, Al, and C.



(a) Place the three elements in order of increasing atomic radius.

(b) Rank the elements in order of increasing ionization energy.

(c) Which element, B or C, is expected to have the more negative electron attachment enthalpy value?

Trends in Ion Sizes

The trend in the sizes of ions down a periodic group is the same as that for neutral atoms: Positive and negative ions increase in size when descending the group (Figure 7.11). Pause for a moment, however, and compare the ionic radii with the atomic radii, as also illustrated in Figure 7.11. When an electron is removed from an atom to form a cation, the size shrinks considerably. The radius of a cation is *always* smaller than that of the atom from which it is derived. For example, the radius of Li is 152 pm, whereas the radius of Li^+ is only 78 pm. When an electron is removed from a Li atom, the attractive force of three protons is now exerted on only two electrons, so the remaining electrons are drawn closer to the nucleus. The decrease in ion size is especially great when the last electron of a particular shell is removed, as is the case for Li. The loss of the 2*s* electron from Li leaves Li^+ with no electrons in the $n = 2$ shell.

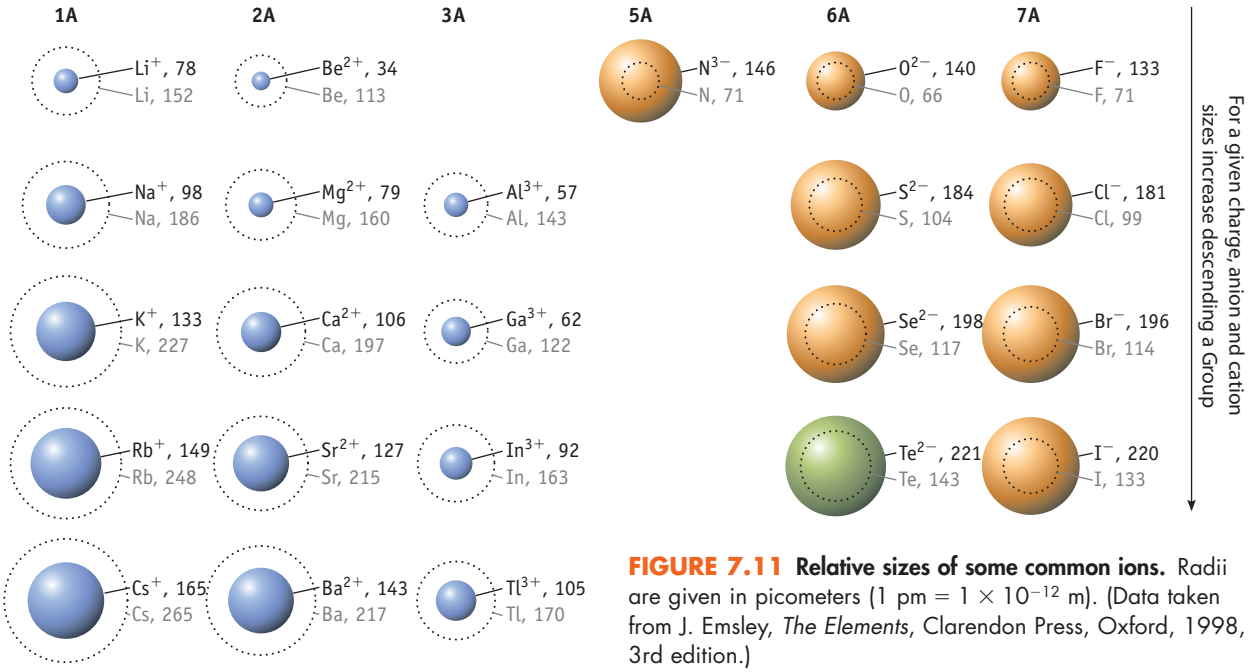

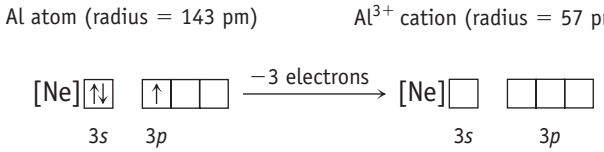

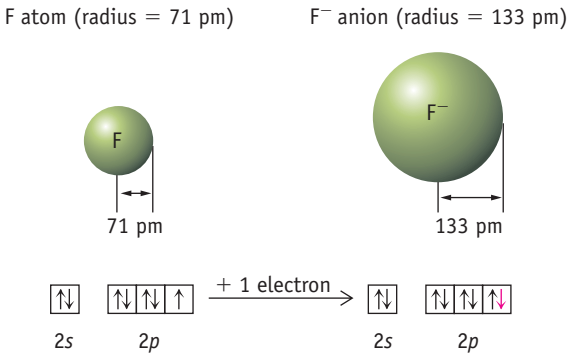

FIGURE 7.11 Relative sizes of some common ions. Radii are given in picometers (1 pm = 1×10^{-12} m). (Data taken from J. Emsley, *The Elements*, Clarendon Press, Oxford, 1998, 3rd edition.)

A large decrease in size is also expected if two or more electrons are removed from an atom. For example, an aluminum ion, Al^{3+}, has a radius of 57 pm, whereas the radius of an aluminum atom is 143 pm.

You can also see in Figure 7.11 that anions are *always* larger than the atoms from which they are derived. Here, the argument is the opposite of that used to explain positive ion radii. The F atom, for example, has nine protons and nine electrons. On forming the anion, the nuclear charge is still +9, but the anion has ten electrons. The F^- ion is larger than the F atom because of increased electron–electron repulsions.

Finally, it is useful to compare the sizes of isoelectronic ions across the periodic table. **Isoelectronic** ions have the same number of electrons but a different number of protons. One such series of ions is N^{3-}, O^{2-}, F^-, Na^+, and Mg^{2+}:

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Ion	N^{3-}	O^{2-}	F^-	Na^+	Mg^{2+}
Number of electrons	10	10	10	10	10
Number of nuclear protons	7	8	9	11	12
Ionic radius (pm)	146	140	133	98	79

All these ions have 10 electrons but they differ in the number of protons. As the number of protons increases in a series of isoelectronic ions, the balance between electron–proton attraction and electron–electron repulsion shifts in favor of attraction, and the radius decreases.

7.6 Periodic Trends and Chemical Properties

Goal for Section 7.6

- Recognize the role that ionization energy and electron attachment enthalpy play in forming ionic compounds.

Atomic and ionic radii, ionization energies, and electron attachment enthalpies are properties associated with atoms and their ions. Knowledge of these properties will be useful as we explore the chemistry involving formation of ionic compounds.

The periodic table was created by grouping elements having similar chemical properties. Alkali metals, for example, characteristically form compounds containing a 1+ ion, such as Li^+, Na^+, or K^+. Thus, the reaction between sodium and chlorine gives the ionic compound, NaCl (composed of $Na^+$and Cl^- ions) (Figure 1.2), and potassium and water react to form an aqueous solution of KOH, a solution containing the hydrated ions $K^+(aq)$ and $OH^-(aq)$.

$$2\ Na(s) + Cl_2(g) \rightarrow 2\ NaCl(s)$$

$$2\ K(s) + 2\ H_2O(\ell) \rightarrow 2\ K^+(aq) + 2\ OH^-(aq) + H_2(g)$$

The low ionization energies of alkali metals is the primary reason why Na^+ and K^+ are readily formed in chemical reactions.

Ionization energies also account for the fact that these reactions of sodium and potassium do not produce compounds such as $NaCl_2$ or $K(OH)_2$. The formation of an Na^{2+} or K^{2+} ion would be a very unfavorable process. Removing a second electron from these metals requires a great deal of energy because a core electron would have to be removed. The energetic barrier to this process is the underlying reason that *main group metals generally form cations with an electron configuration equivalent to that of the preceding noble gas.*

Why isn't Na_2Cl another possible product from the sodium and chlorine reaction? This formula would imply that the compound contains Na^+ and Cl^{2-} ions. Adding two electrons per atom to Cl means that the second electron must enter the next higher shell at much higher energy. Thus, anions such as Cl^{2-} are not known. This example also leads to a general statement: *nonmetals generally acquire enough electrons to form an anion with the electron configuration of the next noble gas.*

We can use similar logic to rationalize other observations. Ionization energies increase on going from left to right across a period. We have seen that elements from Groups 1A and 2A form ionic compounds, an observation directly related to the low ionization energies for these elements. Ionization energies for elements toward the right side of a period, however, are sufficiently large that cation formation is unfavorable. On the right side of the second period, oxygen and fluorine much prefer taking on electrons to giving them up; these elements have high ionization energies and relatively large, negative electron attachment enthalpies. Thus, oxygen and fluorine form anions and not cations when they react.

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Finally, let us think for a moment about carbon, the basis of thousands of chemical compounds. Its ionization energy is not favorable for cation formation, and it also does not generally form anions. Thus, we do not find many binary ionic compounds containing carbon; instead, we find carbon sharing electrons with other elements in compounds such as CO_2 and CCl_4. We will study those kinds of compounds in the next two chapters.

APPLYING CHEMICAL PRINCIPLES

7.1 The Not-So-Rare Earths

Lanthanum and the block of 14 elements stretching from cerium (element 58) through lutetium (element 71) are referred to as the lanthanides or, often, as the rare earth elements. The "rare earth" name is perhaps a misnomer because the elements are in fact not all that rare. With the exception of promethium, which is not found naturally, these elements are more abundant than gold. Cerium, for example, is the 26th most abundant element in the Earth's crust. Unfortunately, high concentrations of rare earth elements are rarely found in ore deposits. Furthermore, these elements are often mixed in the same deposits and their separation is difficult due to their similar chemical properties.

© Cengage Learning/Charles D. Winters

(a) Mixtures of lanthanides shoot showers of sparks when struck by iron.

© Cengage Learning/Charles D. Winters

(b) Most compact fluorescent bulbs use europium phosphors to produce a pleasing spectrum of light.

© Cengage Learning/Charles D. Winters

(c) Neodymium-iron-boron magnets.

Uses of lanthanides.

The rare earth elements possess electronic and optical properties that make them valuable in the production of electronics, lasers, magnets, superconductors, lighting devices, and even jewelry. Ferromagnetism is common among the rare earth elements, with neodymium and samarium used extensively in strong, permanent magnets (page 327). These magnets are commonly used in computer hard drives and electric motors. Neodymium is also used in high-powered scientific and industrial lasers, and yttrium is used in high-temperature superconductors. Europium and terbium are used to produce fluorescent phosphors for television displays and mercury-vapor lamps.

Questions:

1. The most common oxidation state of a rare earth element is +3.
   a. What is the ground state electron configuration of Sm^{3+}?
   b. Write a balanced chemical equation for the reaction of Sm(s) and O_2(g) to form samarium(III) oxide.
2. This textbook places lanthanum directly below yttrium in the periodic table. However, there is a minor controversy about this in the scientific community, and other periodic tables locate lanthanum at the front of the lanthanide series and place lutetium directly below yttrium. Does the electronic configuration argue for the placement of La or Lu below Y? Explain.
3. Gadolinium has eight unpaired electrons, the greatest number of any lanthanide element.
   a. Draw an orbital box diagram depicting the ground state electron configuration of Gd based upon its number of unpaired electrons.
   b. Predict the most common oxidation state for Gd. What is the ground state electron configuration of the most common oxidation state?
4. Use the atomic radii of scandium, yttrium, lanthanum, and lutetium to answer the questions below.

Element	Radii (pm)
Sc	160
Y	180
La	195
Lu	175

   a. Explain why lutetium has a smaller atomic radius than lanthanum, even though it has a greater number of electrons.
   b. Do the atomic radii argue for the placement of La or Lu below Y in the periodic table? Explain.
5. Europium oxide (Eu_2O_3) is used in the production of red phosphors for television displays. If the europium compound emits light with a wavelength of 612 nm, what is the frequency (s^{-1}) and energy (J/photon) of the light?
6. Neodymium is commonly used in magnets, usually as $Nd_2Fe_{14}B$. (Neodymium is combined with other elements to protect it from air oxidation.) Determine the mass percentage of neodymium in $Nd_2Fe_{14}B$.

7.2 Metals in Biochemistry and Medicine

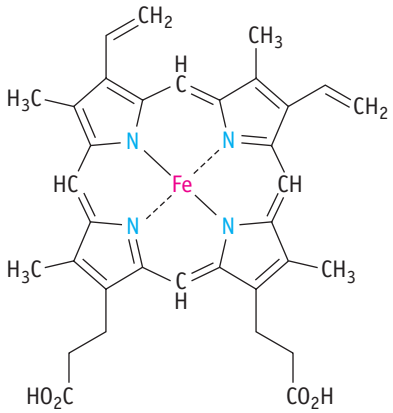
Many main group and transition metals play an important role in biochemistry and in medicine. Your body has low levels of the following metals in the form of various compounds: Ca, 1.5%; Na, 0.1%; Mg, 0.05%, as well as iron, cobalt, zinc, and copper, all less than about 0.05%. (Levels are percentages by mass.)

Much of the 3–4 g of iron in your body is found in hemoglobin, the substance responsible for carrying oxygen to cells. Iron deficiency is marked by fatigue, infections, and mouth inflammations.

Iron in your diet can come from eggs and brewer's yeast, which has a very high iron content. In addition, foods such as some breakfast cereals are "fortified" with metallic iron. (In an interesting experiment you can do at home, you can remove the iron by stirring the cereal with a strong magnet.) Vitamin pills often contain iron(II) compounds with anions such as sulfate and succinate ($C_4H_4O_4^{2-}$).

The average person has about 75 mg of copper, about one third of which is found in the muscles. Copper is involved in many biological functions, and a deficiency shows up in many ways: anemia, degeneration of the nervous system, and impaired immunity. Wilson's disease, a genetic disorder, leads to the over-accumulation of copper in the body and results in hepatic and neurological damage.

Copper ions have been found to act as a bacteriocide. Scientists from Britain and India recently investigated a long-held belief among people in India that storing water in brass pitchers can ward off illness. (Brass is an alloy of copper and zinc.) They filled brass pitchers with previously sterile water to which they had added *E. coli* (a bacterium that lives in the lower intestine of many warm-blooded animals and consequently is found in their feces). Other brass pitchers were filled with contaminated river water from India. In both cases, they found fecal bacteria counts dropped from as high as 1,000,000 bacteria per milliliter to zero in two days. In contrast, bacteria levels stayed high in plastic or earthenware pots. Apparently, enough copper ions are released by the brass to kill the bacteria but not enough to affect humans.



©Kailash K Soni/Shutterstock.com

Carrying drinking water in brass jugs in India. Copper ions released in tiny amounts from the brass kill bacteria in contaminated water.

Questions:

1. Give the electron configurations for iron and the iron(II) and iron(III) ions.
2. In hemoglobin, iron can be in the iron(II) or iron(III) state. Are either of these iron ions paramagnetic?
3. Why are copper atoms (radius = 128 pm) slightly larger than iron atoms (radius = 124 pm)?
4. In hemoglobin, the iron is enclosed by the porphyrin group (shown below), a flat grouping of carbon, hydrogen, and nitrogen atoms. (This is in turn encased in a protein.) When iron is in the form of the Fe^{3+} ion, it just fits into the space within the four N atoms, and the arrangement is flat. Speculate on what occurs to the structure when iron is reduced to the Fe^{2+} ion.

CHAPTER GOALS REVISITED

The goals for this chapter are keyed to specific Study Questions to help you organize your review.

7.1 The Pauli Exclusion Principle

- Recognize that each electron in an atom has a different set of the four quantum numbers, n, ℓ, m_ℓ, and m_s. **11, 12, 47.**
- Understand the Pauli exclusion principle: no atomic orbital can be assigned more than two electrons and the two electrons in an orbital must have opposite spins (different values of m_s). **13–16.**

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

7.2 Atomic Subshell Energies and Electron Assignments

- Write the electron configuration for atoms. **5–10.**
- Recognize that electrons are assigned to the subshells of an atom in order of increasing energy (Aufbau principle). In the H atom, the energies increase with increasing n, but, in a many-electron atom, the energies depend on both n and ℓ. **19, 20.**
- Understand the concept of effective nuclear charge, Z^*, and apply Z^* in determining orbital energy levels in atoms. **17, 18.**

7.3 Electron Configurations of Atoms

- Using the periodic table as a guide, describe electron configurations of neutral atoms using the orbital box, *spdf*, and noble gas notations. **5–10.**
- Apply the Pauli exclusion principle and Hund's rule when assigning electrons to atomic orbitals. **13–16, 71.**

7.4 Electron Configurations of Ions

- Write electron configurations for ions of main group and transition metal elements. **21, 22.**
- Understand the role magnetism plays in revealing electronic structure. **23–26, 62, 66.**

7.5 Atomic Properties and Periodic Trends

- Predict how properties of atoms—size, ionization energy (IE), and electron attachment enthalpy ($\Delta_{EA}H$)—vary within a group and across a period of the periodic table. **29–34.**

7.6 Periodic Trends and Chemical Properties

- Recognize the role that ionization energy and electron attachment enthalpy play in forming ionic compounds. **55, 68, 55, 84.**

STUDY QUESTIONS

▲ denotes challenging questions. **Blue-numbered questions** have answers in Appendix N and fully worked solutions in the *Student Solutions Manual*.

Practicing Skills

Writing Electron Configurations of Atoms

(See Section 7.3, Examples 7.1–7.3; Table 7.3.)

1. Write the electron configurations for P and Cl using both *spdf* notation and orbital box diagrams. Describe the relationship between each atom's electron configuration and its position in the periodic table.
2. Write the electron configurations for Mg and Ar using both *spdf* notation and orbital box diagrams. Describe the relationship of the atom's electron configuration to its position in the periodic table.
3. Using *spdf* notation, write the electron configurations for atoms of chromium and iron, two of the major components of stainless steel.
4. Using *spdf* notation, give the electron configuration of vanadium, V, an element found in some brown and red algae and some toadstools.
5. Depict the electron configuration for each of the following atoms using *spdf* and noble gas notations.
   (a) Arsenic, As. A deficiency of As can impair growth in animals, and larger amounts are poisonous.
   (b) Krypton, Kr. It ranks seventh in abundance of the gases in Earth's atmosphere.

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

6. Using *spdf* and noble gas notations, write electron configurations for atoms of the following elements. (Try to do this by looking at the periodic table but not at Table 7.3.)
   (a) Strontium, Sr. This element is named for a town in Scotland.
   (b) Zirconium, Zr. The metal is exceptionally resistant to corrosion and so has important industrial applications. Moon rocks show a surprisingly high zirconium content compared with rocks on Earth.
   (c) Rhodium, Rh. This metal is used in jewelry and in catalysts in industry.
   (d) Tin, Sn. The metal was used in the ancient world. Alloys of tin (solder, bronze, and pewter) are important.

7. Use noble gas and *spdf* notations to depict electron configurations for the following metals of the third transition series.
   (a) Tantalum, Ta. The metal and its alloys resist corrosion and are often used in surgical and dental tools.
   (b) Platinum, Pt. This metal was used by pre-Columbian Indians in jewelry. Now it is still used in jewelry but it is also the basis for anticancer drugs and catalysts (such as those in automobile exhaust systems).

8. The lanthanides, once called the rare earth elements, are really only "medium rare." Using noble gas and *spdf* notations, depict reasonable electron configurations for the following elements.
   (a) Samarium, Sm. This lanthanide is used in magnetic materials.
   (b) Ytterbium, Yb. This element was named for the village of Ytterby in Sweden, where a mineral source of the element was found.

9. Americium, Am, is a radioactive element isolated from spent fuel in nuclear reactors and used in home smoke detectors. Depict its electron configuration using noble gas and *spdf* notations.

10. Predict electron configurations for the following elements of the actinide series of elements. Use noble gas and *spdf* notations.
   (a) Plutonium, Pu. The element is best known as a by-product of nuclear power plant operations.
   (b) Curium, Cm. This actinide was named for Marie Curie (page 72).

Quantum Numbers and Electron Configurations

(See Section 7.3 and Example 7.2.)

11. What is the maximum number of electrons that can be identified with each of the following sets of quantum numbers? In some cases, the answer may be "none." In such cases, explain why "none" is the correct answer.
   (a) $n = 4$, $\ell = 3$, $m_\ell = 1$
   (b) $n = 6$, $\ell = 1$, $m_\ell = -1$, $m_s = -1/2$
   (c) $n = 3$, $\ell = 3$, $m_\ell = -3$

12. What is the maximum number of electrons that can be identified with each of the following sets of quantum numbers? In some cases, the answer may be "none." In such cases, explain why "none" is the correct answer.
   (a) $n = 3$
   (b) $n = 3$ and $\ell = 2$
   (c) $n = 4$, $\ell = 1$, $m_\ell = -1$, and $m_s = +1/2$
   (d) $n = 5$, $\ell = 0$, $m_\ell = -1$, $m_s = +1/2$

13. Depict the electron configuration for magnesium using an orbital box diagram and noble gas notation. Give a complete set of four quantum numbers for each of the electrons beyond those of the preceding noble gas.

14. Depict the electron configuration for phosphorus using an orbital box diagram and noble gas notation. Give one possible set of four quantum numbers for each of the electrons beyond those of the preceding noble gas.

15. Using an orbital box diagram and noble gas notation, show the electron configuration of gallium, Ga. Give one possible set of quantum numbers for the highest-energy electron.

16. Using an orbital box diagram and noble gas notation, show the electron configuration of titanium. Give one possible set of four quantum numbers for each of the electrons beyond those of the preceding noble gas.

Subshell Energies and Electron Assignments

(See Section 7.2.)

17. The effective nuclear charge, Z^*, is the net force of attraction experienced by the outermost electron in an atom. Which of the following statements best describes how Z^* varies among the elements of the second period (Li to F)?
   (a) regular increase from Li to F
   (b) regular decrease from Li to F
   (c) general increase from Li to F, but with exceptions

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

18. Which of the following statements correctly describes the value of the effective nuclear charge, Z^*, felt by

(a) the 2*s* electron at a large distance from a Li atom?
(i) Z^* equals 1.
(ii) Z^* is between 1 and 3.
(iii) Z^* equals 3.

(b) the 2*s* electron at its most probable distance from the nucleus of a Li atom?
(i) Z^* equals 1.
(ii) Z^* is between 1 and 3.
(iii) Z^* equals 3.

19. List the first five orbitals (the five orbitals in an atom at lowest energy) in order of filling, according to the Aufbau principle.

20. The values of n and ℓ are useful to determine the order of filling (Aufbau principle). Use n and ℓ to determine which orbital, 4*f*, 5*d*, or 6*s*, will fill first.

Electron Configurations of Atoms and Ions and Magnetic Behavior

(See Section 7.4 and Example 7.4.)

21. Using orbital box diagrams, depict an electron configuration for each of the following ions: (a) Mg^{2+}, (b) K^+, (c) Cl^-, and (d) O^{2-}.

22. Using orbital box diagrams, depict an electron configuration for each of the following ions: (a) Na^+, (b) Al^{3+}, (c) Ge^{2+}, and (d) F^-.

23. Using orbital box diagrams and noble gas notation, depict the electron configurations of (a) V, (b) V^{2+}, and (c) V^{5+}. Is the element or any of the ions paramagnetic?

24. Using orbital box diagrams and noble gas notation, depict the electron configurations of (a) Ti, (b) Ti^{2+}, and (c) Ti^{4+}. Is the element or any of the ions paramagnetic?

25. Manganese is found as MnO_2 in deep ocean deposits.

(a) Depict the electron configuration of this element using the noble gas notation and an orbital box diagram.

(b) Using an orbital box diagram, show the electrons beyond those of the preceding noble gas for Mn^{4+}.

(c) Is Mn^{4+} paramagnetic?

(d) How many unpaired electrons does the Mn^{4+} ion have?

26. One compound found in alkaline batteries is NiOOH, a compound containing Ni^{3+} ions. When the battery is discharged, the Ni^{3+} is reduced to Ni^{2+} ions [as in $Ni(OH)_2$]. Using orbital box diagrams and the noble gas notation, show electron configurations of these ions. Are either of these ions paramagnetic?

Periodic Properties

(See Section 7.5 and Example 7.5.)

27. Arrange the following elements in order of increasing size: Al, B, C, K, and Na. (Try doing it without looking at Figure 7.5; then check yourself by looking up the necessary atomic radii.)

28. Arrange the following elements in order of increasing size: Ca, Rb, P, Ge, and Sr. (Try doing it without looking at Figure 7.5; then check yourself by looking up the necessary atomic radii.)

29. Select the atom or ion in each pair that has the larger radius.

(a) Cl or Cl^- (b) Al or O (c) In or I

30. Select the atom or ion in each pair that has the larger radius.

(a) Cs or Rb (b) O^{2-} or O (c) Br or As

31. Which of the following groups of elements is arranged correctly in order of increasing ionization energy?

(a) C < Si < Li < Ne (c) Li < Si < C < Ne
(b) Ne < Si < C < Li (d) Ne < C < Si < Li

32. Arrange the following atoms in order of increasing ionization energy: Li, K, C, and N.

33. Compare the elements Na, Mg, O, and P.

(a) Which has the largest atomic radius?

(b) Which has the most negative electron attachment enthalpy?

(c) Place the elements in order of increasing ionization energy.

34. Compare the elements B, Al, C, and Si.

(a) Which has the most metallic character?

(b) Which has the largest atomic radius?

(c) Which has the most negative electron attachment enthalpy?

(d) Place the three elements B, Al, and C in order of increasing first ionization energy.

35. Explain each answer briefly.

(a) Place the following elements in order of increasing ionization energy: F, O, and S.

(b) Which has the largest ionization energy: O, S, or Se?

(c) Which has the most negative electron attachment enthalpy: Se, Cl, or Br?

(d) Which has the largest radius: O^{2-}, F^-, or F?

36. Explain each answer briefly.

(a) Rank the following in order of increasing atomic radius: O, S, and F.

(b) Which has the largest ionization energy: P, Si, S, or Se?

(c) Place the following in order of increasing radius: O^{2-}, N^{3-}, and F^{-}.

(d) Place the following in order of increasing ionization energy: Cs, Sr, and Ba.

37. Identify the element that corresponds to each of the simplified photoelectron spectral data given below. (Energy data taken from D. A. Shirley, R. L. Martin, S. P. Kowalczyk, F. R. McFeely, and L. Ley: "Core-electron binding energies of the first thirty elements," *Physical Review B*, Vol. 15, pp. 544–552, 1977.)

(a) There are peaks at energies of 64.8 and 5.4 eV, corresponding to 2 and 1 electrons, respectively.

(b) There are peaks at energies of 3614, 384, 301, 40.9, 24.7, and 4.34 eV, corresponding to 2, 2, 6, 2, 6, and 1 electrons, respectively.

(c) There are peaks at energies of 4494, 503, 404, 56.4, 33.6, 8.01, and 6.65 eV, corresponding to 2, 2, 6, 2, 6, 1, and 2 electrons, respectively.

38. Identify the element that corresponds to each of the simplified photoelectron spectral data given below. (Energy data taken from D. A. Shirley, R. L. Martin, S. P. Kowalczyk, F. R. McFeely, and L. Ley: "Core-electron binding energies of the first thirty elements," *Physical Review B*, Vol. 15, pp. 544–552, 1977.)

(a) There are peaks at energies corresponding to 1079, 70.8, 38.0, 5.14 eV, corresponding to 2, 2, 6, and 1 electrons, respectively.

(b) There are peaks at energies corresponding to 4043, 443, 351, 48.4, 30.1, and 6.11 eV, corresponding to 2, 2, 6, 2, 6, and 2 electrons, respectively.

(c) There are peaks at energies corresponding to 5475, 638, 524, 77, 47, 12, and 7.3 eV, corresponding to 2, 2, 6, 2, 6, 3, and 2 electrons, respectively.

39. Explain why the photoelectron spectra of hydrogen and helium each has one peak whereas that for lithium has two peaks. What would be the relative intensity of each of the peaks in these spectra?

40. Sketch the major features (number of peaks and relative intensities for the peaks) of the expected photoelectron spectrum for atoms of nitrogen.

General Questions

These questions are not designated as to type or location in the chapter. They may combine several concepts.

41. The red color of rubies is the result of the substitution of some Cr^{3+} ions for Al^{3+} ions in solid Al_2O_3.

(a) Using *spdf* notation with the noble gas notation, write the electron configuration for the Cr atom and for the Cr^{3+} ion?

(b) Is Cr^{2+} paramagnetic? Is Cr^{3+}?

(c) The radius of the Cr^{3+} ion is 64 pm. How does this compare with the radius of the Al^{3+} ion?

42. The deep blue color of sapphires comes from the presence of Fe^{2+} and Ti^{4+} in solid Al_2O_3. Using *spdf* notation with the noble gas notation, write the electron configuration for each of these ions.

43. Using an orbital box diagram and noble gas notation, show the electron configurations of uranium and of the uranium(IV) ion. Is either of these paramagnetic?

44. The rare earth elements, or lanthanides, commonly exist as 3+ ions. Using an orbital box diagram and noble gas notation, show the electron configurations of the following elements and ions.

(a) Ce and Ce^{3+} (cerium)

(b) Ho and Ho^{3+} (holmium)

45. A neutral atom has two electrons with $n = 1$, eight electrons with $n = 2$, eight electrons with $n = 3$, and two electrons with $n = 4$. Assuming this element is in its ground state, supply the following information:

(a) atomic number

(b) total number of *s* electrons

(c) total number of *p* electrons

(d) total number of *d* electrons

(e) Is the element a metal, metalloid, or nonmetal?

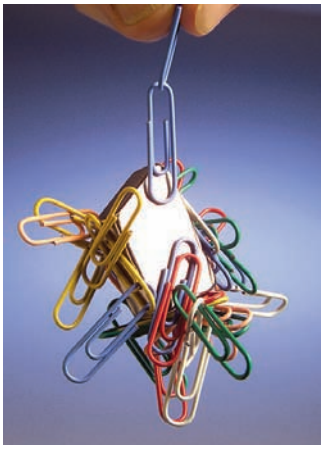
46. Element 109, now named meitnerium (in honor of the Austrian–Swedish physicist, Lise Meitner [1878–1968]), was produced in August 1982 by a team at Germany's Institute for Heavy Ion Research. Depict its electron configuration using *spdf* and noble gas notations. Name another element found in the same group as meitnerium.

PF-(bygone1)/Alamy Stock Photo



Lise Meitner (1878–1968) and Otto Hahn (1879–1968). Element 109 (Mt) was named after Meitner. She earned her Ph.D. in physics under Ludwig Boltzmann at the University of Vienna, and she was the first woman to earn a Ph.D. at that university.

47. Which of the following is *not* an allowable set of quantum numbers? Explain your answer briefly. For those sets that are valid, identify an element in which an outermost valence electron could have that set of quantum numbers.

	n	ℓ	m_ℓ	m_s
(a)	2	0	0	$-\frac{1}{2}$
(b)	1	1	0	$+\frac{1}{2}$
(c)	2	1	−1	$-\frac{1}{2}$
(d)	4	2	+2	$-\frac{1}{2}$

48. A possible excited state for the H atom has an electron in a 4*p* orbital. List all possible sets of quantum numbers (n, ℓ, m_ℓ, m_s) for this electron.

49. The magnet in the following photo is made from neodymium, iron, and boron.

© Cengage Learning/Charles D. Winters

A magnet made of an alloy containing the elements Nd, Fe, and B.

(a) Write the electron configuration of each of these elements using an orbital box diagram and noble gas notation.

(b) Are these elements paramagnetic or diamagnetic?

(c) Write the electron configurations of Nd^{3+} and Fe^{3+} using orbital box diagrams and noble gas notation. Are these ions paramagnetic or diamagnetic?

50. Name the element corresponding to each characteristic below.

(a) the element with the electron configuration $1s^2 2s^2 2p^6 3s^2 3p^3$

(b) the alkaline earth element with the smallest atomic radius

(c) the element with the largest ionization energy in Group 5A

(d) the element whose 2+ ion has the configuration [Kr]$4d^5$

(e) the element with the most negative electron attachment enthalpy in Group 7A

(f) the element whose electron configuration is [Ar]$3d^{10}4s^2$

51. Arrange the following atoms in order of increasing ionization energy: Si, K, P, and Ca.

52. Rank the following in order of increasing ionization energy: Cl, Ca^{2+}, and Cl^-. Briefly explain your answer.

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

53. Answer the questions below about the elements A and B, which have the electron configurations shown.

$$A = [Kr]5s^1 \qquad B = [Ar]3d^{10}4s^24p^4$$

(a) Is element A a metal, nonmetal, or metalloid?

(b) Which element has the greater ionization energy?

(c) Which element has the less negative electron attachment enthalpy?

(d) Which element has the larger atomic radius?

(e) What is the formula for a compound formed between A and B?

54. Answer the following questions about the elements with the electron configurations shown here:

$$A = [Ar]4s^2 \qquad B = [Ar]3d^{10}4s^24p^5$$

(a) Is element A a metal, metalloid, or nonmetal?

(b) Is element B a metal, metalloid, or nonmetal?

(c) Which element is expected to have the larger ionization energy?

(d) Which element has the smaller atomic radius?

55. Which of the following ions are unlikely to be found in a chemical compound: Cs^+, In^{4+}, Fe^{6+}, Te^{2-}, Sn^{5+}, and I^-? Explain briefly.

56. Place the following ions in order of decreasing size: K^+, Cl^-, S^{2-}, and Ca^{2+}.

57. Answer each of the following questions:

(a) Of the elements S, Se, and Cl, which has the largest atomic radius?

(b) Which has the larger radius, Br or Br^-?

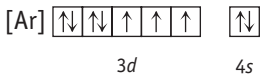
(c) Which should have the largest difference between the first and second ionization energy: Si, Na, P, or Mg?

(d) Which has the largest ionization energy: N, P, or As?

(e) Which of the following has the largest radius: O^{2-}, N^{3-}, or F^-?

58. ▲ The following are isoelectronic species: Cl^-, K^+, and Ca^{2+}. Rank them in order of increasing (a) size, (b) ionization energy, and (c) electron attachment enthalpy.

59. Compare the elements Na, B, Al, and C with regard to the following properties:



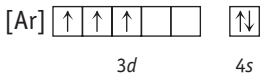
(a) Which has the largest atomic radius?

(b) Which has the most negative electron attachment enthalpy?

(c) Place the elements in order of increasing ionization energy.

60. ▲ Two elements in the second transition series (Y through Cd) have four unpaired electrons in their 3+ ions. What elements fit this description?

61. The configuration for an element is given here.



(a) What is the identity of the element with this configuration?

(b) Is a sample of the element paramagnetic or diamagnetic?

(c) How many unpaired electrons does a 3+ ion of this element have?

62. The configuration of an element is given here.

(a) What is the identity of the element?

(b) In what group and period is the element found?

(c) Is the element a nonmetal, a main group element, a transition metal, a lanthanide, or an actinide?

(d) Is the element diamagnetic or paramagnetic? If paramagnetic, how many unpaired electrons are there?

(e) Write a complete set of quantum numbers (n, ℓ, m_ℓ, m_s) for each of the valence electrons.

(f) What is the configuration of the 2+ ion formed from this element? Is the ion diamagnetic or paramagnetic?

63. Answer the questions below about the elements A and B, which have the ground state electron configurations shown.

$$A = [Kr]5s^2 \qquad B = [Kr]4d^{10}5s^25p^5$$

(a) Is element A a metal, nonmetal, or metalloid?

(b) Which element has the greater ionization energy?

(c) Which element has a larger atomic radius?

(d) Which element has the more negative electron attachment enthalpy?

(e) Which is more likely to form a cation?

(f) What is a likely formula for a compound formed between A and B?

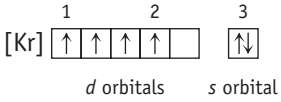
64. Answer the questions below concerning ground state electron configurations.

(a) What element has the electron configuration $[Ar]3d^6 4s^2$?

(b) What element has a 2+ ion with the configuration $[Ar]3d^5$? Is the ion paramagnetic or diamagnetic?



(c) How many unpaired electrons are in a Ni^{2+} ion?

(d) The configuration for an element is given here.

What is the identity of the element? Is a sample of the element paramagnetic or diamagnetic? How many unpaired electrons does a 3− ion of this element have?

(e) What element has the following electron configuration? Write a complete set of quantum numbers for electrons 1-3.

Electron	n	ℓ	m_ℓ	m_s
1	_____	_____	_____	_____
2	_____	_____	_____	_____
3	_____	_____	_____	_____

In the Laboratory

65. Nickel(II) formate [$Ni(HCO_2)_2$] is widely used as a catalyst precursor and to make metallic nickel. It can be prepared in the general chemistry laboratory by treating nickel(II) acetate with formic acid (HCO_2H).

$$Ni(CH_3CO_2)_2(aq) + 2\ HCO_2H(aq) \rightarrow Ni(HCO_2)_2(aq) + 2\ CH_3CO_2H(aq)$$

Green crystalline $Ni(HCO_2)_2$ is precipitated after adding ethanol to the solution.

(a) What is the theoretical yield of nickel(II) formate from 0.500 g of nickel(II) acetate and excess formic acid?

(b) Is nickel(II) formate paramagnetic or diamagnetic? If it is paramagnetic, how many unpaired electrons would you expect?

(c) If nickel(II) formate is heated to 300 °C in the absence of air for 30 minutes, the salt decomposes to form pure nickel powder. What mass of nickel powder should be produced by heating 253 mg of nickel(II) formate? Are nickel atoms paramagnetic?

66. ▲ Spinels are solids with the general formula $M^{2+}(M'^{3+})_2O_4$ (where M^{2+} and M'^{3+} are metal cations of the same or different metals). The best-known example is common magnetite, Fe_3O_4 [which you can formulate as $(Fe^{2+})(Fe^{3+})_2O_4$].

© Cengage Learning/Charles D. Winters

A crystal of a spinel

(a) Given its name, it is evident that magnetite is ferromagnetic. How many unpaired electrons are in iron(II) and in iron(III) ions?

(b) Two other spinels are $CoAl_2O_4$ and $SnCo_2O_4$. What metal ions are involved in each? What are their electron configurations? Are the metal ions paramagnetic, and if so, how many unpaired electrons are involved?

Summary and Conceptual Questions

The following questions use concepts from this and previous chapters.

67. Why is the radius of Li^+ so much smaller than the radius of Li? Why is the radius of F^- so much larger than the radius of F?

68. Which ions in the following list are not likely to be found in chemical compounds: K^{2+}, Cs^+, Al^{4+}, F^{2-}, and Se^{2-}? Explain briefly.

69. Answer the following questions about first ionization energies.

(a) Generally ionization energies increase on proceeding across a period, but this is not true for magnesium (738 kJ/mol) and aluminum (578 kJ/mol). Explain this observation.

(b) Explain why the ionization energy of phosphorus (1012 kJ/mol) is greater than that of sulfur (1000 kJ/mol) when the general trend in ionization energies in a period would predict the opposite.

70. ▲ The ionization of the hydrogen atom can be calculated from Bohr's equation for the electron energy.

$$E = -(N_A Rhc)(Z^2/n^2)$$

where $N_A Rhc = 1312$ kJ/mol and Z is the atomic number. Let us use this approach to calculate a possible ionization energy for helium. First, assume the electrons of the He experience the full 2+

nuclear charge. This gives us the upper limit for the ionization energy. Next, assume one electron of He completely screens the nuclear charge from the other electrons, so $Z = 1$. This gives us a lower limit to the ionization energy. Compare these calculated values for the upper and lower limits to the experimental value of 2372.3 kJ/mol. What does this tell us about the ability of one electron to screen the nuclear charge?

71. Compare the configurations below with two electrons located in *p* orbitals. Which would be the most stable (have the lowest energy)? Which would be the least stable? Explain your answers.

(a) 

(b) 

(c) 

(d) 

72. The bond lengths in Cl_2, Br_2, and I_2 are 200, 228, and 266 pm, respectively. Knowing that the tin radius is 141 pm, estimate the bond distances in Sn—Cl, Sn—Br, and Sn—I. Compare the estimated values with the experimental values of 233, 250, and 270 pm, respectively.

73. Write electron configurations to show the first two ionization processes for potassium. Explain why the second ionization energy is much greater than the first.

74. What is the trend in ionization energy when proceeding down a group in the periodic table. Rationalize this trend.

75. (a) Explain why the sizes of atoms change when proceeding across a period of the periodic table.

(b) Explain why the sizes of transition metal atoms change very little across a period.

76. Which of the following elements has the greatest difference between its first and second ionization energies: C, Li, N, Be? Explain your answer.

77. ▲ What arguments would you use to convince another student in general chemistry that MgO consists of the ions Mg^{2+} and O^{2-} and not the ions Mg^{+} and O^{-}? What experiments could be done to provide some evidence that the correct formulation of magnesium oxide is $Mg^{2+}O^{2-}$?

78. Explain why the first ionization energy of Ca is greater than that of K, whereas the second ionization energy of Ca is lower than the second ionization energy of K.

79. The energies of the orbitals in many elements have been determined. For the first two periods they have the following values:

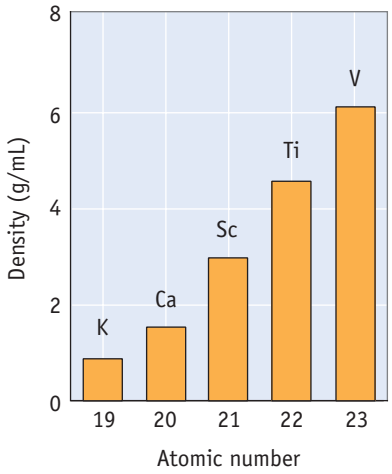
Element	1*s* (kJ/mol)	2*s* (kJ/mol)	2*p* (kJ/mol)
H	−1313		
He	−2373		
Li		−520.0	
Be		−899.3	
B		−1356	−800.8
C		−1875	−1029
N		−2466	−1272
O		−3124	−1526
F		−3876	−1799
Ne		−4677	−2083

(a) ▲ Why do the orbital energies generally become more negative on proceeding across the second period?

(b) How are these values related to the ionization energy and electron attachment enthalpy of the elements?

(c) Use these energy values to explain the observation that the ionization energies of the first four second-period elements are in the order Li < Be > B < C.

(Data from J. B. Mann, T. L. Meek, and L. C. Allen: *Journal of the American Chemical Society*, Vol. 122, p. 2780, 2000.)



80. ▲ The ionization energies for the removal of the first electron in Si, P, S, and Cl are as listed in the table below. Briefly rationalize this trend.

Element	First Ionization Energy (kJ/mol)
Si	787
P	1012
S	1000
Cl	1251

81. Using your knowledge of the trends in element sizes on going across the periodic table, explain briefly why the density of the elements increases from K through V.

82. The densities (in g/cm^3) of elements in Groups 6B, 8B, and 1B are given in the table below.

Period 4	Cr, 7.19	Co, 8.90	Cu, 8.96
Period 5	Mo, 10.22	Rh, 12.41	Ag, 10.50
Period 6	W, 19.30	Ir, 22.56	Au, 19.32

Transition metals in the sixth period all have much greater densities than the elements in the same groups in the fourth and fifth periods. Refer to Figure 7.8, and explain this observation.

83. The discovery of two new elements (atomic numbers 113 and 115) was announced in February 2004.

(a) Use *spdf* and noble gas notations to give the electron configurations of these two elements.

(b) For each of these elements, name another element in the same periodic group.

(c) Element 113 was made by firing the nucleus of a light atom at a heavy americium atom. The two nuclei combine to give a nucleus with 113 protons. What light atom was used as a projectile?

84. Explain why the reaction of calcium and fluorine does not form CaF_3.

85. ▲ Thionyl chloride, $SOCl_2$, is an important chlorinating and oxidizing agent in organic chemistry. It is prepared industrially by oxygen atom transfer from SO_3 to SCl_2.

$$SO_3(g) + SCl_2(g) \rightarrow SO_2(g) + SOCl_2(g)$$

(a) Give the electron configuration for an atom of sulfur using an orbital box diagram. Do not use the noble gas notation.

(b) Using the configuration given in part (a), write a set of quantum numbers for the highest-energy electron in a sulfur atom.

(c) What element involved in this reaction (O, S, Cl) should have the smallest ionization energy? The smallest radius?

(d) Which should be smaller: the sulfide ion, S^{2-}, or a sulfur atom, S?

(e) If you want to make 675 g of $SOCl_2$, what mass of SCl_2 is required?

(f) If you use 10.0 g of SO_3 and 10.0 g of SCl_2, what is the theoretical yield of $SOCl_2$?

(g) $\Delta_r H°$ for the reaction of SO_3 and SCl_2 is -96.0 kJ/mol $SOCl_2$ produced. Using data in Appendix L, calculate the standard molar enthalpy of formation of SCl_2.

86. Sodium metal reacts readily with chlorine gas to give sodium chloride.

$$Na(s) + {}^1/_2\, Cl_2(g) \rightarrow NaCl(s)$$

(a) What is the reducing agent in this reaction? What property of the element contributes to its ability to act as a reducing agent?

(b) What is the oxidizing agent in this reaction? What property of the element contributes to its ability to act as an oxidizing agent?

(c) Why does the reaction produce NaCl and not a compound such as Na_2Cl or $NaCl_2$?

87. ▲ Slater's rules are a way to estimate the effective nuclear charge experienced by an electron. In this approach, the "shielding constant," *S*, is calculated. The effective nuclear charge is then the difference between *S* and the atomic number, *Z*. (Note that the results in Table 7.2 and Figure 7.2 were calculated in a slightly different way.)

$$Z^* = Z - S$$

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

The shielding constant, S, is calculated using the following rules:

(1) The electrons of an atom are grouped as follows: (1*s*) (2*s*, 2*p*) (3*s*, 3*p*) (3*d*) (4*s*, 4*p*) (4*d*), and so on.

(2) Electrons in higher groups (to the right) do not shield those in the lower groups.

(3) For *ns* and *np* valence electrons
   a) Electrons in the same *ns*, *np* group contribute 0.35 (for 1*s* 0.30 works better).
   b) Electrons in $n - 1$ groups contribute 0.85.
   c) Electrons in $n - 2$ groups (and lower) contribute 1.00.

(4) For *nd* and *nf* electrons, electrons in the same *nd* or *nf* group contribute 0.35, and those in groups to the left contribute 1.00.

As an example, let us calculate Z^* for the outermost electron of oxygen:

$$S = (2 \times 0.85) + (5 \times 0.35) = 3.45$$

$$Z^* = 8 - 3.45 = 4.55$$

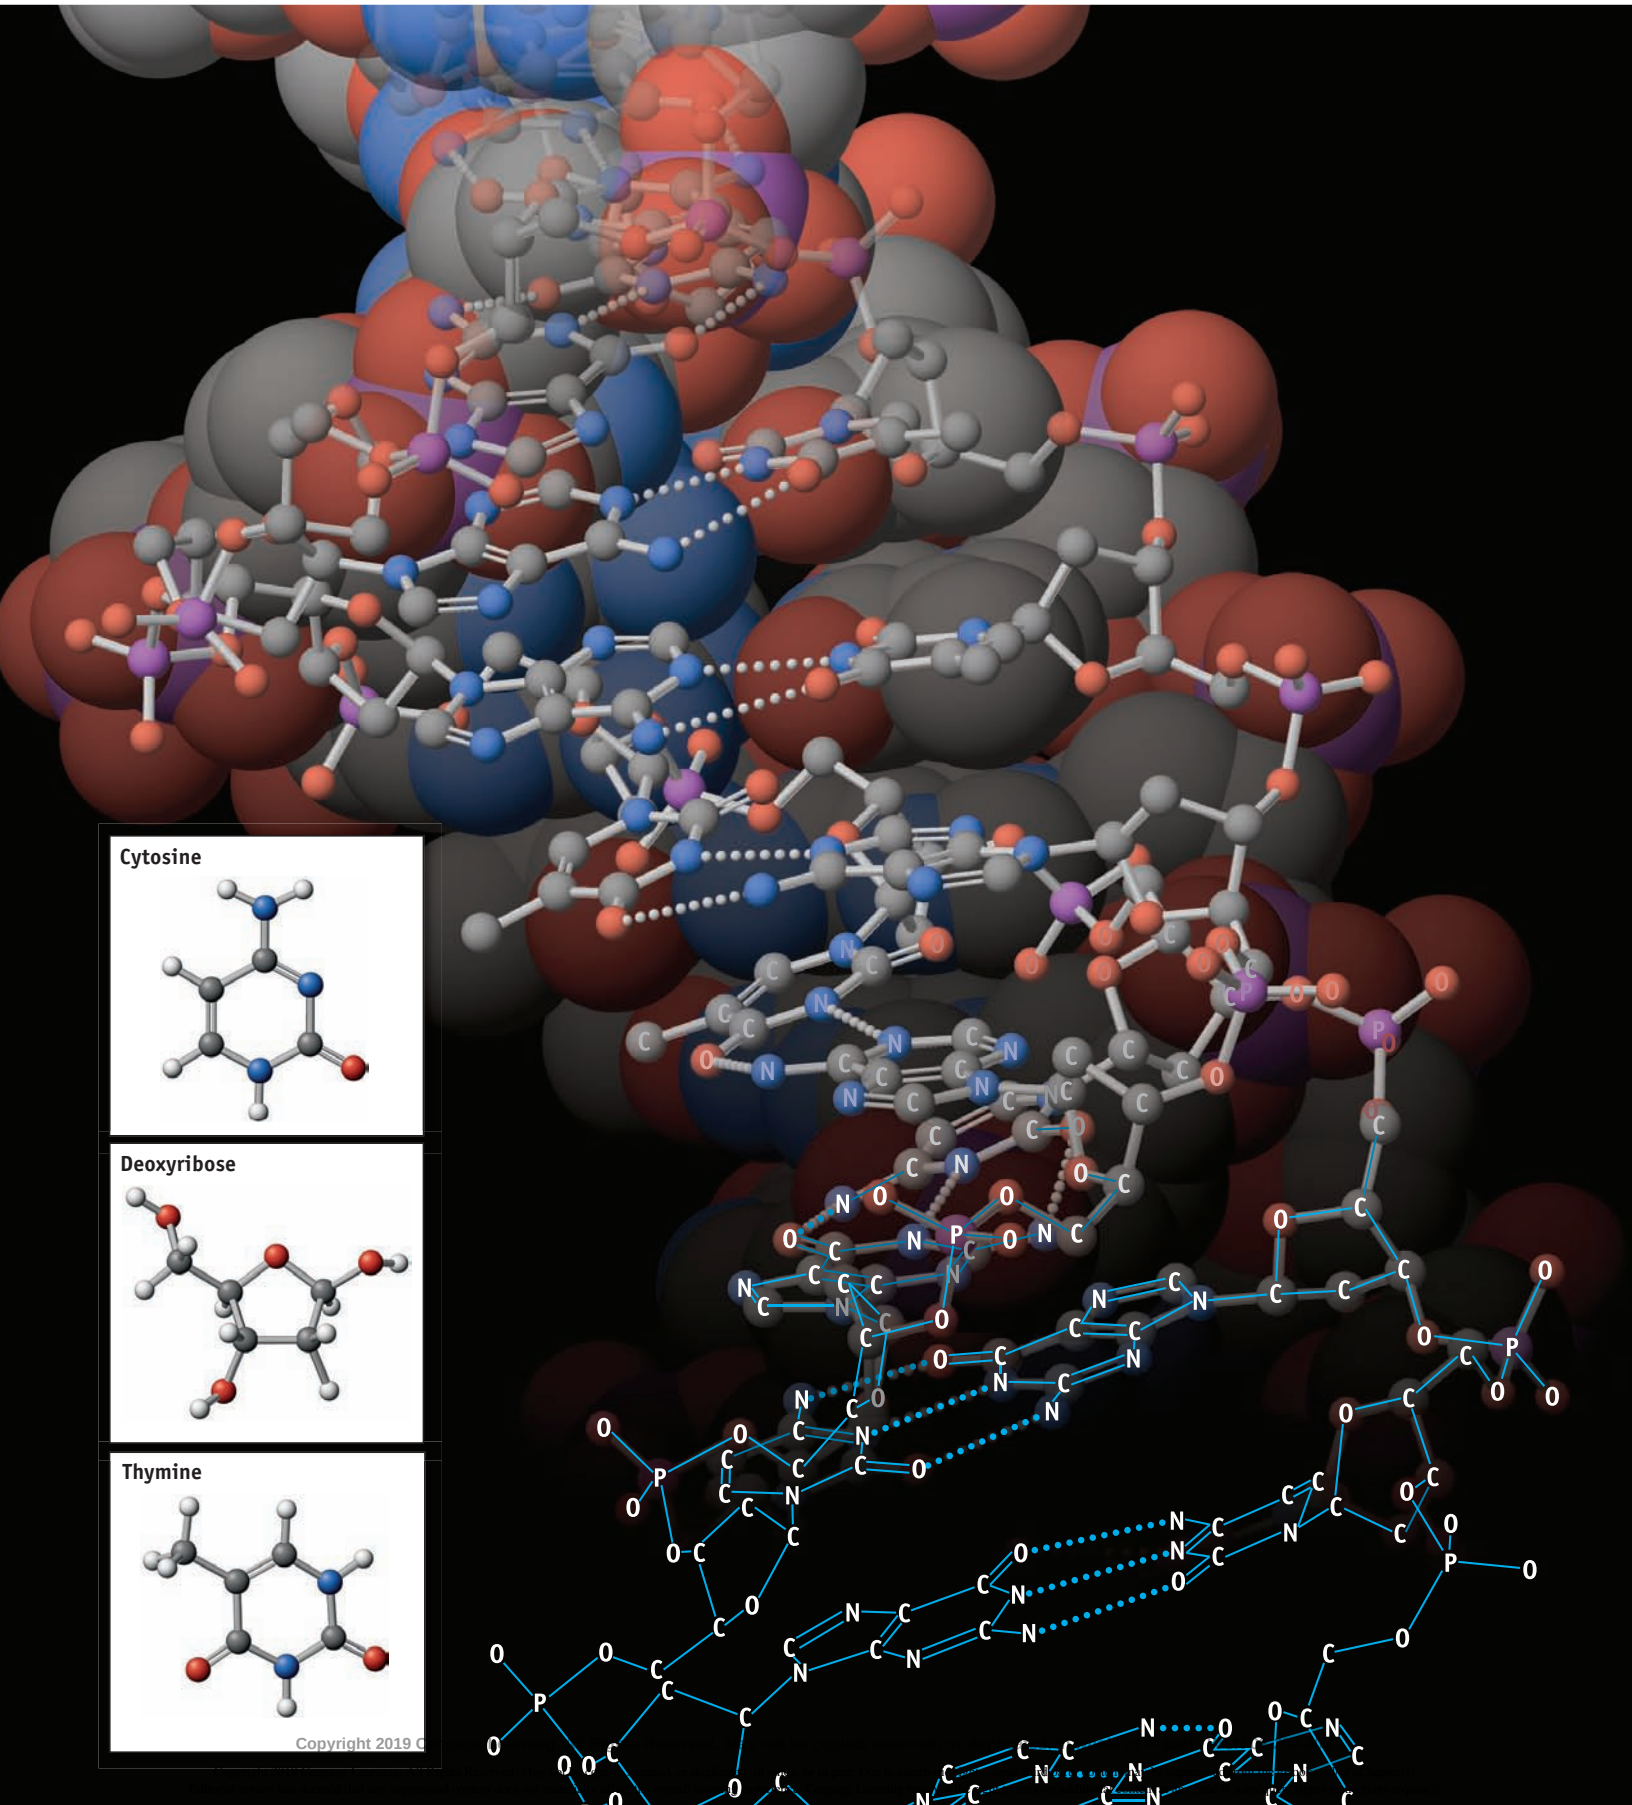
Here is a calculation for a *d* electron in Ni:

$$Z^* = 28 - [18 \times 1.00] - [7 \times 0.35] = 7.55$$

and for an *s* electron in Ni:

$$Z^* = 28 - [10 \times 1.00] - [16 \times 0.85] - [1 \times 0.35] = 4.05$$

(Here 3*s*, 3*p*, and 3*d* electrons are in the $(n - 1)$ groups.)



a) Calculate Z^* for F and Ne. Relate the Z^* values for O, F, and Ne to their relative atomic radii and ionization energies.

b) Calculate Z^* for one of the 3*d* electrons of Mn, and compare this with Z^* for one of the 4*s* electrons of the element. Do the Z^* values give us some insight into the ionization of Mn to give the cation?

8 Bonding and Molecular Structure

CHAPTER OUTLINE

8.1 Chemical Bond Formation and Lewis Electron Dot Structures

8.2 Covalent Bonding and Lewis Structures

8.3 Atom Formal Charges in Covalent Molecules and Ions

8.4 Resonance

8.5 Exceptions to the Octet Rule

8.6 Molecular Shapes

8.7 Electronegativity and Bond Polarity

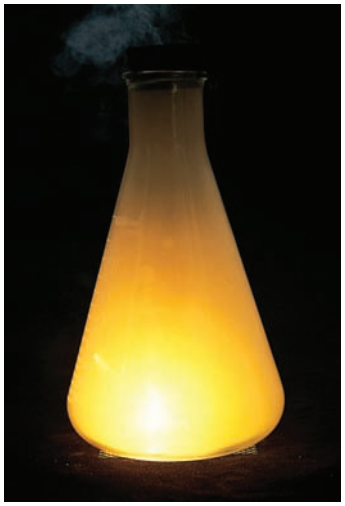
8.8 Molecular Polarity

8.9 Bond Properties: Order, Length, and Dissociation Enthalpy

8.10 DNA, Revisited

8.1 Chemical Bond Formation and Lewis Electron Dot Symbols

Goal for Section 8.1



- Draw Lewis electron dot structures for atoms and ions.

Our discussion of structure and bonding begins with small molecules and polyatomic ions and then progresses to larger molecules. From compound to compound, atoms of the same element participate in structure and bonding in predictable ways. This allows us to develop principles that apply to many different chemical compounds, from a simple molecule like water to such complex molecules as DNA.

◀ **Structure and Bonding in DNA. Structure** refers to the way atoms are arranged in space and **bonding** describes the forces that hold adjacent atoms together. These topics are illustrated by a portion of a DNA molecule, a large molecule composed of atoms of C, H, N, O, and P. Each line between two atoms represents a chemical bond and each bond is associated with a pair of electrons shared between the two atoms. The overall DNA structure is a helical coil of two chains constructed from phosphate (PO_4) and deoxyribose groups. Organic bases (such as thymine and cytosine) attached to the deoxyribose on one chain interact with complementary bases on the second chain to link the two chains.

Formation of an ionic compound. The reaction of Na and Cl_2 is quite exothermic. $\Delta_f H°$ [NaCl(s)] = −411.12 kJ/mol.

When a chemical reaction occurs between two atoms, some of their electrons are reorganized, resulting in a net attractive force—a **chemical bond**—between the atoms. Chemists generally think of bonds as falling into three broad categories—metallic, covalent, and ionic, but the boundaries between them can be indistinct. This chapter is devoted largely to covalent bonds, whereas ionic and metallic bonds are described in Chapter 12.

Covalent bonding *involves a sharing of electrons from each atom's outermost shell* (valence electrons) *between atoms.* Two chlorine atoms, for example, share a pair of electrons, one electron from each atom, to form a covalent bond.

Ions form when *one or more electrons from an atom's outermost shell are transferred from one atom to another*, creating positive and negative ions. When elemental sodium and chlorine gas (Cl_2) react, we might imagine the reaction occurs by the transfer of an electron from a sodium atom to a chlorine atom to form Na^+ and Cl^- ions.

Sodium [$1s^2 2s^2 2p^6 3s^1$] has a low ionization energy and readily loses an electron to form Na^+ [$1s^2 2s^2 2p^6$]. Chlorine [$1s^2 2s^2 2p^6 3s^2 3p^5$] has a high electron affinity and readily gains an electron to form Cl^- [$1s^2 2s^2 2p^6 3s^2 3p^6$]. The resulting Na^+ and Cl^- ions are attracted to each other by electrostatic forces, and it is this attraction between oppositely charged ions that constitutes the **ionic bond.** The ions arrange themselves into a crystal lattice (Figure 2.23) in which the attractions between the oppositely charged ions are maximized, and the repulsions between ions of the same charge are minimized.

The melting point of most metals is quite high, so we know there must be substantial bonding forces holding them together. The classic description of these **metallic bonding forces** is that the atoms in an extended lattice are immersed in a sea of delocalized electrons (Chapter 12). Bonding is the result of coulombic forces of attraction between the electrons and the charged nuclei. This model readily explains the electrical conductivity of metals, which results because the electrons are free to move with little resistance through the lattice under the influence of an electric potential.

As we describe bonding in greater detail, you will discover that equal sharing of electrons (covalent bonds), complete electron transfer (ionic bonds), and delocalization of electrons around positive nuclei (metallic bonds) are extreme cases.

That there is a continuum of bonding descriptions from purely ionic to purely covalent to metallic is illustrated by the van Arkel–Ketelaar bonding triangle (Figure 8.1). The limiting forms of bonding are at the corners of the triangle. Depending on the atoms involved, the bonding can be described as ionic (CsF), covalent (F_2), or metallic (Cs). Other combinations of atoms are a blend of these forms and so are found within the confines of the triangle. For example, the bonding in CO_2 is more covalent than ionic whereas NaCl is largely ionic. A semiconductor like AlAs tends toward metallic bonding with some properties of ionic and covalent bonding. And $AlCl_3$ is on the borderline between ionic and covalent whereas bonding in solid Si is partially metallic and partially covalent.

Although we will treat molecular bonding as purely covalent in this chapter, *do not lose sight of the fact that bonding in virtually all materials is a blend of the three limiting forms.*

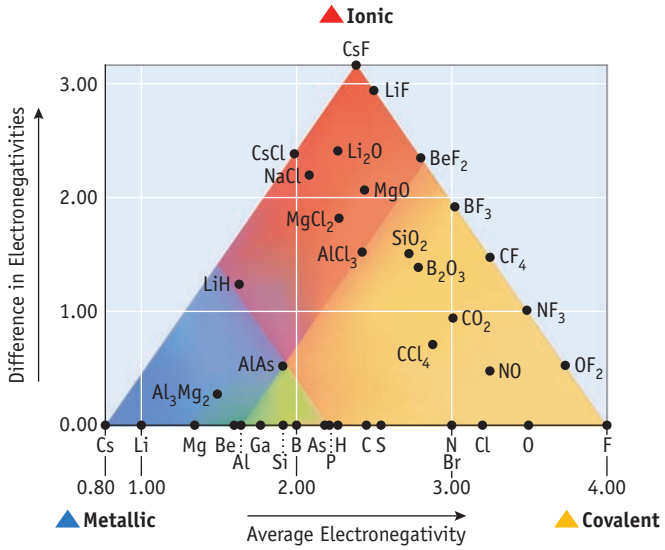

Figure 8.1 A van Arkel–Ketelaar diagram. The four regions of this triangle represent the locations of metallic (blue), semiconducting (green), ionic (red), and covalent (orange) compounds. Electronegativity, which is a measure of the ability of an atom in a molecule to attract electrons, is used in this figure and is discussed more fully in Section 8.7. Van Arkel triangles are discussed further in *Applying Chemical Principles, 8.2, van Arkel Triangles and Bonding*, page 397.

Valence Electrons and Lewis Symbols for Atoms

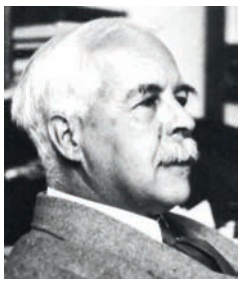
The electrons in an atom may be categorized as either **valence electrons** or **core electrons.** Chemical reactions result in the loss, gain, or rearrangement of valence electrons. The core electrons are not involved in bonding or in chemical reactions.

For main group elements (elements of the A groups in the periodic table), the valence electrons are the *s* and *p* electrons in the outermost shell. All electrons in inner shells are core electrons. For example,

Na, Group 1A Core electrons = $1s^2 2s^2 2p^6$ = [Ne] Valence electron = $3s^1$

As, Group 5A Core electrons = $1s^2 2s^2 2p^6 3s^2 3p^6 3d^{10}$ = [Ar]$3d^{10}$ Valence electrons = $4s^2 4p^3$

For *main group elements the number of valence electrons is equal to the group number*. The fact that all elements in a periodic group have the same number of valence electrons accounts for the similarity of chemical properties among members of the group.



Valence electrons for transition elements include the electrons in the *ns* and $(n-1)d$ orbitals. The remaining electrons are core electrons. As with main group elements, the valence electrons for transition metals determine the chemical properties of these elements.

Ti, Group 4B Core electrons = $1s^2 2s^2 2p^6 3s^2 3p^6$ = [Ar] Valence electrons = $3d^2 4s^2$

A useful way to represent electrons in the valence shell of an atom was introduced by Gilbert Newton Lewis (1875–1946). The element's symbol represents the atomic nucleus together with the core electrons. Up to four valence electrons, represented by dots, are placed one at a time around the symbol; then, if any valence electrons remain, they are paired with ones already there. Chemists now refer to these pictures as **Lewis electron dot symbols.** Lewis dot symbols for main group elements of the second and third periods are shown in Table 8.1.

TABLE 8.1 Lewis Electron Dot Symbols for Main Group Atoms

Oesper Collection in the History of Chemistry/University of Cincinnati

Gilbert Newton Lewis (1875–1946) Lewis introduced the theory of shared electron-pair chemical bonds in a paper published in the *Journal of the American Chemical Society* in 1916. Lewis also made major contributions in acid–base chemistry, thermodynamics, and the interaction of light with substances.

Lewis was born in Massachusetts but raised in Nebraska. After earning his B.A. and Ph.D. at Harvard, he began his career in 1912 at the University of California at Berkeley. He was not only a productive researcher but was also an influential teacher. Among his ideas was the use of problem sets in teaching, a practice still in use today.

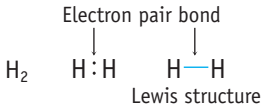
Arranging the valence electrons of a main group element around an atom in four groups is meant to convey the idea that the valence shell can accommodate four pairs of electrons. Because this represents eight electrons in all, this is referred to as an **octet** of electrons. The noble gases, with the exception of helium, already have an octet of valence electrons and demonstrate a notable lack of reactivity. (Helium and neon do not undergo any chemical reactions, and the other noble gases have very limited chemical reactivity.) Because chemical reactions involve changes in the valence electron shell, the limited reactivity of the noble gases is taken as evidence of the stability of their noble gas (ns^2np^6) electron configuration. Many elements gain, lose, or share electrons to achieve an octet of valence electrons, a noble gas configuration. This is sometimes referred to as the **octet rule**. Hydrogen, which in its compounds has two electrons in its valence shell, obeys the spirit of this rule by matching the electron configuration of the helium atom.

8.2 Covalent Bonding and Lewis Structures

Goal for Section 8.2

- Apply the octet rule when drawing Lewis electron dot structures for simple molecules and polyatomic ions.

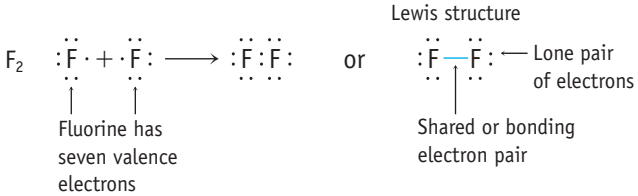
There are many examples of compounds having covalent bonds, including the gases in our atmosphere (O_2, N_2, H_2O, and CO_2), common fuels (CH_4), and most of the compounds in your body. Covalent bonds are also responsible for the atom-to-atom connections in polyatomic ions such as CO_3^{2-}, CN^-, NH_4^+, NO_3^-, and PO_4^{3-}. We will develop the basic principles of structure and bonding using these and other small molecules and ions, but the same principles apply to larger molecules from aspirin to proteins and DNA with many thousands of atoms.



Importance of Lone Pairs As you will see later in this chapter, lone pairs can be important in a structure. Because they are in the same valence electron shell as the bonding electrons, they can influence molecular shape (Section 8.6).

The molecules and ions just mentioned are composed entirely of *nonmetal* atoms. A point that needs special emphasis is that, *in molecules or polyatomic ions made up only of nonmetal atoms, the atoms are attached by covalent bonds*. Conversely, the presence of a metal in a formula is a signal that the compound is likely to be ionic.

In a simple description of covalent bonding, a bond results when one or more electron pairs are shared between two atoms.



The electron pair bond between the two atoms of an H_2 molecule is represented by a pair of dots or, alternatively, a line.

The representation of a molecule in this fashion is called a **Lewis electron dot structure** or just a **Lewis structure**.

Simple Lewis structures, such as that for F_2, can be drawn starting with Lewis dot symbols for atoms and arranging the valence electrons to form bonds. Fluorine, an element in Group 7A, has seven valence electrons. The Lewis symbol shows that an F atom has a single unpaired electron along with three electron pairs. In F_2, the single electrons, one on each F atom, pair up in the covalent bond.

In the Lewis structure for F_2 the pair of electrons in the F—F bond is the bonding pair, or **bond pair.** The other six pairs reside on single atoms and are called **lone pairs.** Because they are not involved in bonding, they are also called **nonbonding electrons.**

Carbon dioxide, CO_2, and dinitrogen, N_2, are examples of molecules in which two atoms share more than one electron pair.

In carbon dioxide, the carbon atom shares two pairs of electrons with each oxygen and so is linked to each O atom by a **double bond**. The valence shell of each oxygen atom in CO_2 has two bonding pairs and two lone pairs.

In dinitrogen, the two nitrogen atoms share three pairs of electrons, so they are linked by a **triple bond**. In addition, each N atom has a single lone pair.

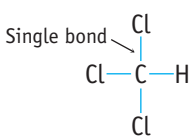
An important observation can be made about the molecules you have seen so far: *Each atom in the Lewis structures is surrounded by four pairs of electrons, that is, an octet of electrons.* (The exception is hydrogen, which typically forms a bond to only one other atom, resulting in two electrons in its valence shell.) *The tendency of molecules and polyatomic ions to have structures in which eight electrons surround each atom is the basis for the* ***octet rule****.* As an example, given the number of valence electrons on nitrogen, a triple bond is necessary in N_2 in order to have an octet around each nitrogen atom. The carbon atom and both oxygen atoms in CO_2 achieve the octet configuration by forming double bonds.

The octet rule is extremely useful, but it is more a *guideline* than a rule. Particularly for the second period elements C, N, O, and F, a Lewis structure in which each atom achieves an octet is likely to be a good representation of the bonding.

Exceptions to the Octet Rule
If you find a Lewis structure does not follow the octet rule, you should first question the structure's validity. It is possible an incorrect formula has been assigned to the compound or the atoms have been assembled in an incorrect way. However, as described in Section 8.5, there are valid exceptions. Fortunately, many will be obvious, such as when there are more than four bonds to an element or when the compound contains an odd number of electrons.

Drawing Lewis Electron Dot Structures

A systematic approach to constructing Lewis structures is illustrated with chloroform, $CHCl_3$, a compound once used as an anesthetic.

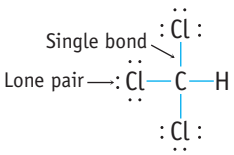


Step 1 *Determine the arrangement of atoms within a molecule.* The central atom is *usually* the one with the lowest affinity for electrons (least negative electron attachment enthalpy, Section 7.5). (In Section 8.7 we will introduce the concept of electronegativity, which can also be used to determine the central atom in a molecule: the central atom is usually the one with the lowest electronegativity.)

$CHCl_3$
Central atom

Step 2 *Determine the total number of valence electrons in the molecule or ion.* In a neutral molecule, this number will be the sum of the valence electrons for each atom. The number of valence electron *pairs* will be half the total number of valence electrons.

$CHCl_3$ valence electrons
C = 4
H = 1
Cl = 3 × 7 = 21
Total = 26 electrons or 13 pairs



Step 3 *Place one pair of electrons between each pair of bonded atoms to form a single bond.* Here, four electron pairs are used to make four single bonds (which are represented by single lines). Nine pairs of electrons, of the original 13, remain to be used.

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

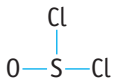
Step 4 *Use remaining pairs as lone pairs around each terminal atom (except H) so that each terminal atom is surrounded by eight electrons.* If, after this is done, there are electrons left over, assign them to the central atom. All 13 pairs have now been assigned in $CHCl_3$. The H atom has a share in two electrons, as it normally does, and all other atoms have a share in an octet of electrons. The Lewis structure for $CHCl_3$ is complete.

Step 5 If no valence electron pairs remain after forming single bonds and completing the octets of terminal atoms, and the central atom does not have an octet of electrons, then multiple bonds can be created by sharing one or more pairs of electrons between terminal atoms and the central atom. (See the case of CH_2O following Example 8.1.)

This step is not required for $CHCl_3$.

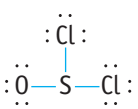
EXAMPLE 8.1

Drawing Lewis Electron Dot Structures



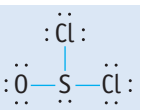
Problem Draw the Lewis electron dot structure for thionyl chloride, $SOCl_2$, a reagent widely used in organic chemistry.

What Do You Know? The formula of the compound is given so you can determine the number of valence electrons. Further, you can expect that each atom will achieve an octet configuration.



Strategy Follow the steps outlined for $CHCl_3$ in the preceding text.

SOLUTION FOR $SOCl_2$



1. Sulfur is the central atom. The electron affinity of sulfur is lower than that of both oxygen and chlorine. (The electron attachment enthalpy of S is less negative than that of O or Cl.)
2. Valence electrons = 26 (13 pairs) = 6 (for S) + 6 (for O) + 2 × 7 (for each Cl)
3. Three electron pairs form single bonds from the sulfur to oxygen and chlorine:

4. Distribute nine pairs of electrons around the O and Cl terminal atoms.

5. One pair of electrons remains. The central S atom as yet has only three electron pairs surrounding it, so the last of the pairs is placed there. Each atom now has a share in four electron pairs.

Think about Your Answer Here a pair of electrons remained after forming bonds and completing the octet around the terminal atoms. The pair was then placed on the central atom.

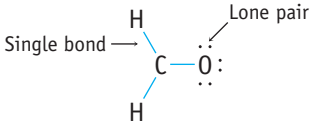
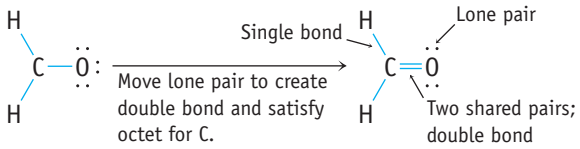
Check Your Understanding

Draw Lewis electron dot structures for CH_3Cl (methyl chloride, a topical anesthetic), H_2O_2 (hydrogen peroxide, with an O—O bond), and NH_2OH (with an N—O bond).



There are many molecules that have two or even three bonds between a pair of atoms, and a simple example of this is the formaldehyde molecule, CH_2O. Here carbon is the central atom, and there is a total of 12 valence electrons.

$$\text{Valence electrons for } CH_2O = 12 \text{ electrons (or 6 electron pairs)}$$
$$= 4 \text{ (for C)} + 2 \times 1 \text{ (for two H atoms)} + 6 \text{ (for O)}$$



To build the Lewis structure we begin by placing one pair of electrons between each pair of bonded atoms to form a single bond,

and then we place the three remaining pairs as lone pairs around the terminal O atom.

Now all six pairs have been assigned, but the C atom still has a share in only three pairs. *If the central atom has fewer than eight electrons at this point, change one or more of the lone pairs on a terminal atom into a bonding pair between the central and terminal atom to form a multiple bond.*

As a general rule, double or triple bonds are most often encountered when *both* atoms are C, N, or O. That is, bonds such as C═C, C═N, and C═O will be observed frequently.

EXAMPLE 8.2

Drawing Lewis Electron Dot Structures with a Multiple Bond

Problem Draw the Lewis electron dot structure for CO_2, carbon dioxide.

What Do You Know? The formula is given so you can determine the number of valence electrons. Further, you can expect that each atom will achieve an octet configuration.

Strategy Follow the steps outlined for CH_2O in the preceding text.

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

SOLUTION

1. Designate C as the central atom.
2. Valence electrons = 16 (8 pairs) = 4 (for C) + 2 × 6 (for O)
3. Two electron pairs form single bonds between C and O.

Distribute three lone pairs on the terminal O atoms to complete their octets.

4. None of the original 8 electron pairs remain to be used, but the C atom does not yet have an octet of electrons. Therefore, we use lone pairs of electrons on the O atoms to form additional CO bonds, one on each side of the molecule.

Think about Your Answer Why do we not take two lone pairs from one side and none from the other (to give a CO triple bond and a CO single bond, respectively)? We shall discuss that possibility after describing charge distribution in molecules and ions (Section 8.7).

Check Your Understanding

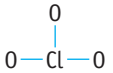
Draw the Lewis electron dot structure for CO.

To complete our examples of building electron dot structures, let's look at polyatomic ions. You encounter many of these in chemistry, as both cations and anions.

EXAMPLE 8.3

Drawing Lewis Electron Dot Structures for Polyatomic Ions

Problem Draw Lewis structures for the chlorate ion (ClO_3^-) and the nitronium ion (NO_2^+).

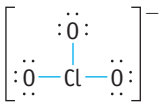


What Do You Know? The formula of each ion is given so you can determine the number of valence electrons. Further, you can expect that each atom will achieve an octet configuration.

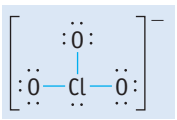
Strategy Follow the steps outlined in the preceding examples with the added step of accounting for the ion charge.

- For an *anion, add* the number of electrons equal to the negative charge.
- For a *cation, subtract* the number of electrons equal to the ion charge.

SOLUTION FOR CHLORATE ION, ClO_3^-



1. Cl is the central atom, and the O atoms are terminal atoms.
2. Valence electrons = 26 (13 pairs)
   = 7 (for Cl) + 18 (six for each O) + 1 (for the negative charge)
3. Three electron pairs form single bonds from Cl to the O terminal atoms.



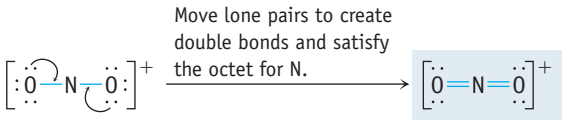
Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

4. Distribute three lone pairs on each of the terminal O atoms to complete the octet of electrons around each of these atoms.

5. One pair of electrons remains, and it is placed on the central Cl atom to complete its octet.

SOLUTION FOR NITRONIUM ION, NO_2^+



1. Nitrogen is the central atom.
2. Valence electrons = 16 (8 pairs)
   = 5 (for N) + 12 (six for each O) − 1 (for the positive charge)
3. Two electron pairs form single bonds from the nitrogen to each oxygen:

   O—N—O

4. Distribute the remaining six pairs of electrons on the terminal O atoms:

5. The central nitrogen atom is two electron pairs short of an octet. As in CO_2, a lone pair of electrons on each oxygen atom is converted to a bonding electron pair to give two N═O double bonds. Each atom in the ion now has four electron pairs. Nitrogen has four bonding pairs, and each oxygen atom has two lone pairs and shares two bond pairs.

Think about Your Answer Notice that the dot structure of ClO_3^- and NO_2^+ resemble those of $SOCl_2$ (Example 8.1) and CO_2 (Example 8.2), respectively. Both ClO_3^- and $SOCl_2$ have the same number of valence electron pairs, the same number of bond and lone pairs, and both have a lone pair on the central atom. Similarly, CO_2 and NO_2^+ have the same number of valence electrons, and both have two double bonds.

Check Your Understanding

Draw Lewis structures for NH_4^+, NO^+, and SO_4^{2-}.

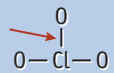
Strategy Map 8.3

PROBLEM

Draw the **Lewis electron dot structure** for **ClO_3^-**.

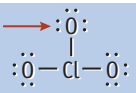
DATA/INFORMATION

- **Formula** of the ion



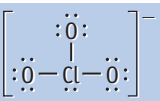
STEP 1. Decide on **central atom**

Cl is central atom, surrounded by three **O** atoms.



STEP 2. Calculate number of **valence electrons**

ClO_3^- has **26** valence electrons or **13 pairs.**



STEP 3. Form **single bonds** between ***central atom*** and ***terminal atoms***

Single bonds 

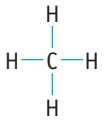
STEP 4. Place **electron pairs** on ***terminal atoms*** so each has an **octet** of electrons.

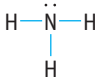
Electron pairs 

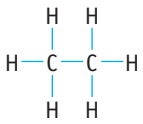
STEP 5. Place **remaining electron pairs** on the ***central atom*** to achieve octet.

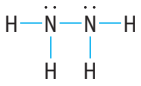
Complete 

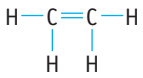
Problem Solving Tip 8.1 Choosing the Central Atom in a Dot Structure

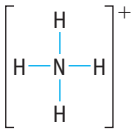


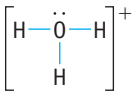












The first step in building a Lewis electron dot structure is to choose the central atom.

1. Generally the central atom is the one of lowest electronegativity. Electronegativity is discussed in Section 8.7.
2. For simple compounds and ions, the first atom in a formula is often the central atom (e.g., SO_2, NH_4^+, NO_3^-). This is not always a reliable predictor, however. Notable exceptions include water (H_2O) and most common acids (HNO_3, H_2SO_4), in which the acidic hydrogen is usually written first but where another atom (such as N or S) is the central atom.
3. Certain elements often appear as the central atom, among them C, N, P, and S.
4. Halogens are often terminal atoms forming a single bond to one other atom, but they can be the central atom when combined with O in oxoacids (such as in $HClO_4$).
5. Oxygen is the central atom in water, but in combination with nitrogen, phosphorus, and the halogens it is usually a terminal atom.
6. With rare exceptions, hydrogen is a terminal atom because it typically bonds to only one other atom.

TABLE 8.2 Lewis Structures of Common Hydrogen-Containing Molecules and Ions of Second-Period Elements

Group 4A	Group 5A	Group 6A	Group 7A
CH_4 methane 	NH_3 ammonia 	H_2O water 	HF hydrogen fluoride 
C_2H_6 ethane 	N_2H_4 hydrazine 	H_2O_2 hydrogen peroxide 	
C_2H_4 ethylene 	NH_4^+ ammonium ion 	H_3O^+ hydronium ion 	
C_2H_2 acetylene 	NH_2^- amide ion 	OH^- hydroxide ion 	

Predicting Lewis Structures

The guidelines for drawing Lewis structures are helpful, but you will find you can also rely on patterns of bonding in related molecules.

Hydrogen-Containing Compounds

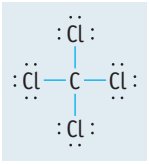
The Lewis symbol for an element is a useful guide in determining the number of bonds formed by the element. For example, nitrogen has five valence electrons. Two electrons occur as a lone pair; the other three occur as unpaired electrons. To reach an octet, it is necessary to pair each of the unpaired electrons with an electron from another atom. Thus, N is predicted to form three bonds in *uncharged* molecules. Similarly, for *uncharged* compounds, carbon is expected to form four bonds, oxygen two, and fluorine one. See Table 8.2 for examples of common hydrogen-containing molecules and ions based on C, N, O, and F.

The elements C, N, and O are often a central atom in polyatomic ions, for example the ammonium and hydronium ions. Here we could think of NH_4^+ as based on N^+, a cation formed by taking away one electron from N. The N^+ ion has four unpaired valence electrons (analogous to C) and so is capable of forming four single bonds to hydrogen atoms. The amide anion, NH_2^-, can be broken down similarly. In this anion N^- has 6 electrons, two pairs of electrons and two unpaired electrons (analogous to O) and is capable of forming two single bonds.

EXAMPLE 8.4

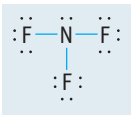
Predicting Lewis Electron Dot Structures

Problem Draw Lewis electron dot structures for CCl_4 and NF_3.



What Do You Know? Carbon tetrachloride (CCl_4) and NF_3 have stoichiometries similar to CH_4 and NH_3 (Table 8.2), so you might reasonably expect similar Lewis structures.

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203



Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Strategy Recall that carbon is expected to form four bonds and nitrogen three bonds to achieve an octet of electrons. In addition, halogen atoms have seven valence electrons, so both Cl and F can attain an octet by forming one covalent bond.

SOLUTION

carbon tetrachloride

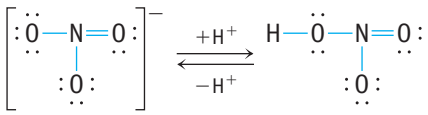
nitrogen trifluoride

Think about Your Answer As a check, count the number of valence electrons for each molecule, and verify that all are shown in the Lewis structure.

CCl_4: Valence electrons = 4 (for C) + 4 × 7 (for Cl) = 32 electrons (16 pairs)

The Lewis structure for CCl_4 shows 8 electrons in single bonds and 24 electrons as lone pair electrons, for a total of 32 electrons. The structure is correct.

NF_3: Valence electrons = 5 (for N) + 3 × 7 (for F) = 26 electrons (13 pairs)



The Lewis structure for NF_3 shows 6 electrons in single bonds and 20 electrons as lone pair electrons, for a total of 26 electrons. The structure is correct.

Check Your Understanding

Predict Lewis structures for methanol, CH_3OH, and hydroxylamine, H_2NOH. (In each molecule the central C or N atom is bonded to H atoms and one O atom.)

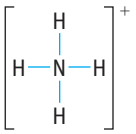
Oxoacids and Their Anions

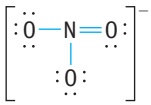
Oxoacids such as HNO_3, H_2SO_4, H_3PO_4, and $HClO_4$ are covalently bonded molecular compounds. In each of these one or more H atoms is attached to an O atom (and not the central N, S, P, or Cl atom), and it is the H atoms that are dissociated to give a hydronium ion and the appropriate anion. A Lewis structure for the nitrate ion, for example, can be created using the guidelines in the preceding examples, and the result is a structure with two N—O single bonds and one N═O double bond. To form nitric acid from the nitrate ion, a hydrogen ion is attached utilizing a lone pair on one of the O atoms.

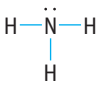
nitrate ion nitric acid

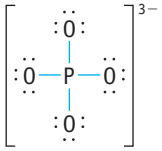
Isoelectronic Species

The species NO^+, N_2, CO, and CN^- are similar in that they each have two atoms and the same total number of valence electrons, 10, which leads to a similar Lewis structure for each molecule or ion. The two atoms in each are linked with a triple bond. With three bonding pairs and one lone pair, each atom thus has an octet of electrons.









Molecules and ions having the *same number of valence electrons and similar Lewis structures* are said to be **isoelectronic** (Table 8.3).

Isoelectronic Structures There are similarities and important differences in chemical properties of isoelectronic species. For example, both carbon monoxide, CO, and cyanide ion, CN^-, are very toxic, which results from the fact that they can interfere with hemoglobin in blood and block the uptake of oxygen. They are different, though, in their acid–base chemistry. In aqueous solution, cyanide ion readily adds H^+ to form hydrogen cyanide, whereas CO is not protonated.

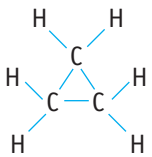
Carbon-Based Organic Compounds

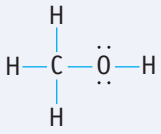


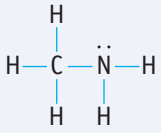
The vast majority of the molecules in our world and within our bodies are carbon-based organic molecules that consist of C and H with N, O, and, occasionally, other elements such as S and P. You can often draw Lewis structures of organic molecules quickly by following a few guidelines.

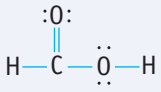
- All organic molecules follow the octet rule.
- Carbon forms four bonds. (Possible arrangements include four single bonds; two single bonds and one double bond; two double bonds; or one single bond and one triple bond.)
- In uncharged species, nitrogen forms three bonds and oxygen forms two bonds.
- Hydrogen forms only one bond to another atom.
- When multiple bonds are formed, both atoms involved are usually one of the following: C, N, and O. Oxygen has the ability to form multiple bonds with a variety of elements. Carbon forms many compounds having multiple bonds to another carbon or to N or O.
- When drawing a Lewis structure, always account for single bonds and lone pairs before determining whether multiple bonds are present.

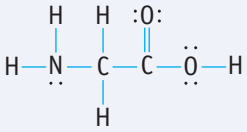
Let us take the hydrocarbon C_3H_6 (with 18 valence electrons) as an example. There are only two ways to arrange three C atoms: in a triangle or in line. If we draw a bond between the C atoms in those structures, we have:

Next, attach H atoms to the C atoms. In the C_3 triangle arrangement each C atom can accommodate two H atoms. Each C atom has an octet of electrons, and the structure is complete.









The situation is different for the "linear" structure. Each C atom must have four bonds. If the C atoms are connected by single bonds and each C atom has H atoms

TABLE 8.4 Lewis Structures for Simple Organic Molecules Based on C, H, N, and O

CH_4O	14 valence electrons		methyl alcohol
CH_5N	14 valence electrons		methyl amine
CH_2O_2	18 valence electrons		formic acid (methanoic acid)
$C_2H_5NO_2$	30 valence electrons		glycine

attached, we would need eight H atoms. As the molecule has only six H atoms, the structure can only be that below, a structure with one C═C double bond.

You have already seen another example of the Lewis structure of a simple organic molecule (CH_2O, page 357). See Table 8.4 for several more examples of Lewis structures of common organic molecules.

8.3 Atom Formal Charges in Covalent Molecules and Ions

Goal for Section 8.3

- Understand the meaning of atom formal charge and calculate the formal charge on each atom in a molecule or polyatomic ion.

You have seen that Lewis structures show how electron pairs are placed in a covalently bonded species, whether it is a neutral molecule or a polyatomic ion. Now we turn to one of the consequences of the placement of electron pairs in this way: Individual atoms can have a small negative or positive charge or have no electric charge. The location of a positive or negative charge in a molecule or ion will influence, among other things, the atom at which a reaction occurs. For example, does a positive H^+ ion attach itself to the Cl or the O of the ion ClO^- to form hypochlorous acid? It is reasonable to expect H^+ to attach to the more negatively charged atom, and we can predict this by evaluating atom formal charges in molecules and ions.

The **formal charge** is the electrostatic charge that would reside on an atom in a molecule or polyatomic ion if all bonding electrons are shared equally between pairs of atoms. The formal charge for an atom in a molecule or ion is calculated based on the Lewis structure of the molecule or ion, using Equation 8.1,

$$\text{Formal charge of an atom in a molecule or ion} = \text{NVE} - [\text{LPE} + \tfrac{1}{2}(\text{BE})] \qquad (8.1)$$

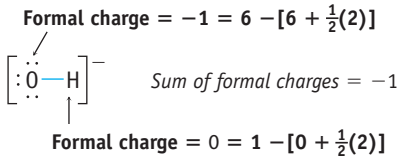
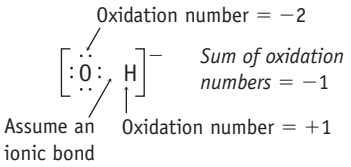
where NVE = number of valence electrons in the uncombined atom (and, for main group elements, is equal to its group number in the periodic table), LPE = number of lone pair electrons on an atom, and BE = number of bonding electrons around an atom. The term in square brackets is the number of electrons assigned by the Lewis structure to an atom in a molecule or ion. *The difference between this term and the number of valence electrons on the uncombined atom is the formal charge.* A positive formal charge means that an atom in a molecule or ion "contributed" more electrons to bonding than it "got back." The atom's formal charge will be negative if the reverse is true.

There are two important assumptions in Equation 8.1. First, lone pairs are assumed to "belong" to the atom on which they reside in the Lewis structure. Second, bond pairs are assumed to be divided *equally* between the bonded atoms (and is the reason BE is multiplied by $^1/_2$).



The sum of the formal charges on the atoms in a molecule must be zero, whereas the sum for atoms in an ion equals the charge on the ion. Consider the hypochlorite ion, ClO^-. Oxygen is in Group 6A and so has six valence electrons. However, the oxygen atom in OCl^- can lay claim to seven electrons (six lone pair electrons and one bonding electron), so the atom has a formal charge of −1. The O atom has formally gained an electron by bonding to chlorine.



The formal charge on the Cl atom in ClO^- is zero. So we have −1 for oxygen and 0 for chlorine, and the sum of these equals the net charge of −1 for the ion. An important conclusion we can draw from the formal charges in ClO^- is that, if an H^+ ion approaches the ion, it should attach itself to the negatively charged O atom to give hypochlorous acid, HOCl.

A CLOSER LOOK — Comparing Oxidation Number and Formal Charge

In Section 3.8 you learned to calculate the oxidation number of an atom as a way to tell if a reaction involves oxidation and reduction. Are an atom's oxidation number and its formal charge related? To answer this question, let us look at the hydroxide ion. The formal charges are −1 on the O atom and 0 on the H atom. Recall that these formal charges are calculated assuming the O—H bond electrons are shared equally in an O—H covalent bond.

In contrast, in Section 3.8, you learned that O has an oxidation number of −2 and H has an oxidation number of +1. *Oxidation numbers are determined by assuming that the bond between a pair of atoms is ionic*, not covalent. For OH^- this means the pair of electrons between O and H is located *fully* on O. Thus, the O atom now has eight valence electrons instead of six and a charge of −2. The H atom now has no valence electrons and a charge of +1.

Formal charges and oxidation numbers are calculated for different purposes. Oxidation numbers allow us to follow changes in redox reactions. Formal charges provide insight into the distribution of charges in molecules and polyatomic ions.

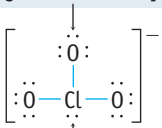
EXAMPLE 8.5

Calculating Formal Charges



Problem Calculate formal charges for the atoms of the ClO_3^- ion.

What Do You Know? You know the Lewis structure of ClO_3^-, which was developed in Example 8.3.

Strategy The first step is always to write the Lewis structure for the molecule or ion. Then Equation 8.1 can be used to calculate the formal charges.

SOLUTION

$$\text{Formal charge} = -1 = 6 - [6 + \tfrac{1}{2}(2)]$$

$$\text{Formal charge} = +2 = 7 - [2 + \tfrac{1}{2}(6)]$$

The formal charge on each O atom is -1, whereas for the Cl atom it is $+2$.

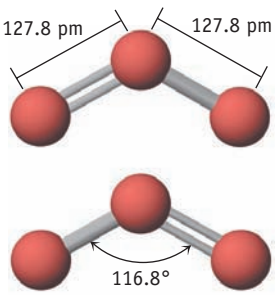
Think about Your Answer Notice that the sum of the formal charges on all the atoms equals the charge on the ion.

Check Your Understanding

Calculate formal charges on each atom in (a) CN^- and (b) SO_3^{2-}.

8.4 Resonance

Goal for Section 8.4



- Draw resonance structures for simple molecules and polyatomic ions, understand what resonance means, and know how and when to use resonance to represent bonding.

Ozone, O_3, an unstable, blue, diamagnetic gas with a characteristic pungent odor, protects Earth and its inhabitants from intense ultraviolet radiation from the Sun. To understand the bonding in the molecule, it is important to notice the two oxygen–oxygen bonds are the same length. Equal O—O bond lengths imply an equal number of bond pairs in each O—O bond. Using the guidelines for drawing Lewis structures, however, you might come to a different conclusion. There are two possible ways of writing the Lewis structure for the molecule:

Double bond on the left: 

Double bond on the right: 

These structures seem the same in that each has a double bond on one side of the central oxygen atom and a single bond on the other side. If either were the actual structure of ozone, one bond (O═O) should be shorter than the other (O—O). The actual structure of ozone shows this is not the case. The inescapable conclusion is that neither Lewis structure correctly represents the bonding in ozone.

Ozone, O_3, is a bent molecule with oxygen–oxygen bonds of the same length.

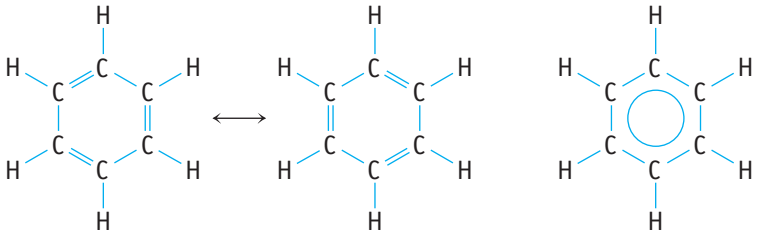
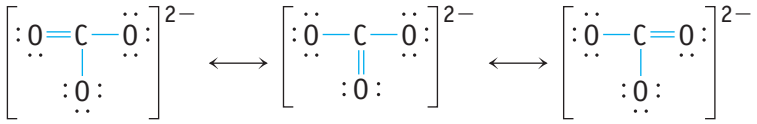
Depicting Resonance Structures
The use of a double-headed arrow (⟷) as a symbol to link resonance structures and the term *resonance* are somewhat unfortunate. An arrow might seem to imply that a change is occurring, and the term *resonance* has the connotation of vibrating or alternating back and forth between different forms. Neither view is correct. Electron pairs are not actually moving from one atom to another.

Linus Pauling (1901–1994) proposed the concept of **resonance** to solve the problem. *Resonance structures are used to represent bonding in a molecule or ion when a single Lewis structure fails to describe accurately the actual electronic structure*. The alternative structures shown for ozone are called **resonance structures.** They have identical patterns of bonding and equal energy. The actual structure of this molecule is a *composite*, or "hybrid," of the equivalent resonance structures (and the term *resonance hybrid* is often used). In the O_3 resonance hybrid, the bonds between the oxygens are between a single bond and a double bond in length, in this case corresponding to one and a half bonds between each pair of O atoms. This is a reasonable conclusion because we see that the O—O bonds in ozone both have a length of 127.8 pm, intermediate between the average length of an O=O double bond (121 pm) and an O—O single bond (132 pm). Because a single Lewis structure cannot represent fractions of a bond, chemists draw the resonance structures and connect them with double-headed arrows (⟷) to indicate that the true structure is a composite of these extreme structures.



J. R. Eyerman/The LIFE Picture Collection/Getty Images

Linus Pauling (1901–1994). Linus Pauling was born in Portland, Oregon. He earned a B.Sc. degree in chemical engineering from Oregon State College in 1922 and a Ph.D. in chemistry at the California Institute of Technology in 1925. He is well known for his book *The Nature of the Chemical Bond*, a seminal work in chemistry. In the words of Francis Crick, Pauling was also "one of the founders of molecular biology." It was this and his study of chemical bonding that were cited in the award of the Nobel Prize in Chemistry in 1954. Finally, he also received the Nobel Peace Prize in 1962 for the role he and his wife played in advocating for the nuclear test ban treaty.



Benzene, C_6H_6, is the classic example of the use of resonance to describe a structure. The benzene molecule is a six-member ring of carbon atoms with six equivalent carbon–carbon bonds (and a hydrogen atom attached to each carbon atom). The carbon–carbon bonds are 139 pm long, intermediate between the average length of a C=C double bond (134 pm) and a C—C single bond (154 pm). Two resonance structures that differ only in double bond placement can be written for the molecule. A hybrid of these two structures, however, will lead to a molecule with six equivalent carbon–carbon bonds.

resonance structures of benzene, C_6H_6

abbreviated representation of resonance structures

Let us use resonance to describe bonding in the carbonate ion, CO_3^{2-}, an anion with 24 valence electrons (12 pairs).

Three equivalent structures can be drawn for this ion, differing only in the location of the C=O double bond, but no single structure correctly describes this ion. Instead, the actual structure is a composite of the three structures, in good agreement with experimental results. In the CO_3^{2-} ion, all three carbon–oxygen bond lengths are 129 pm, intermediate between the lengths of C—O single bonds (143 pm) and C=O double bonds (122 pm).

Formal charges can be calculated for each atom in the resonance structure for a molecule or ion. For example, using one of the resonance structures for the nitrate ion, we find that the central N atom has a formal charge of +1, and the singly

A CLOSER LOOK

Resonance

- Resonance is a means of representing the bonding in a molecule or polyatomic ion when a single Lewis structure fails to give an accurate picture.
- The atoms must have the same arrangement in each resonance structure. Do not attach the atoms in a different fashion as this creates a different compound.
- Resonance structures differ only in the assignment of electron-pair positions, never atom positions.
- Resonance structures differ in the number of bond pairs between a given pair of atoms.
- Resonance is not meant to indicate the motion of electrons.
- The actual structure of a molecule is a composite or hybrid of the resonance structures.
- There will always be at least one multiple bond (double or triple) in each resonance structure.

bonded O atoms are both -1. The doubly bonded O atom has no charge. The net charge for the ion is thus -1.

Is this a reasonable charge distribution for the nitrate ion? The answer is no. The actual structure of the nitrate ion is a hybrid of three equivalent resonance structures. Because the three oxygen atoms in NO_3^- are equivalent, the charge on one oxygen atom should not be different from the other two. This can be resolved if the formal charges are averaged to give a formal charge of $-{}^2/_3$ on each of the three oxygen atoms. Summing the charges on the three oxygen atoms and the $+1$ charge on the nitrogen atom then gives -1, the charge on the ion.

In the resonance structures for O_3, CO_3^{2-}, and NO_3^- all the possible resonance structures are equally likely; they are "equivalent" structures. Therefore, the molecule or ion has a symmetrical distribution of electrons over all the atoms involved—that is, its electronic structure consists of an equal mixture of the resonance structures. However, there are also many examples in which reasonable resonance structures can be drawn that are not equivalent. For example there are three possible resonance structures for the thiocyanate ion, SCN^-.

All obey the octet rule, and the electronic structure of this ion can be described as a hybrid of these structures. However, because the structures are not equivalent, there will be unequal mixing in the resonance hybrid, and the actual electronic structure will resemble one of these structures more than the other two. We will discuss this later in Section 8.7 and describe a way to decide which resonance structure is more important than another.

EXAMPLE 8.6

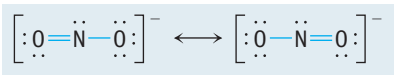
Drawing Resonance Structures

Problem Draw resonance structures for the nitrite ion, NO_2^-. Are the N—O bonds single, double, or intermediate in value? What are the formal charges on the N and O atoms?

What Do You Know? The N atom is the central atom, bonded to two terminal oxygen atoms.

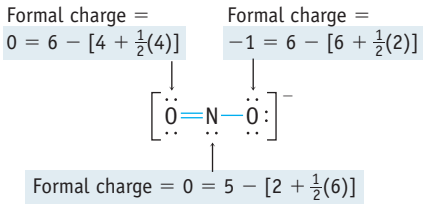
Strategy

- Using the guidelines for drawing Lewis structures, determine whether there is more than one way to achieve an octet of electrons around each atom.
- Use one of the Lewis structures to determine the formal charges on the atoms.
- If the formal charges on the two oxygen atoms are different, then the formal charge on oxygen will be an average of the two values.



SOLUTION Nitrogen is the central atom in the nitrite ion, which has a total of 18 valence electrons.

Valence electrons = 5 (for the N atom) + 12 (6 for each O atom) + 1 (for negative charge)



After forming N—O single bonds and distributing lone pairs on the terminal O atoms, one electron pair remains, which is placed on the central N atom.

To complete the octet of electrons about the N atom, form a N═O double bond. Because there are two ways to do this, two equivalent structures can be drawn, and the actual structure must be a composite or resonance hybrid of these two structures. The nitrogen–oxygen bonds are neither single nor double bonds but have an intermediate value.

Taking one of the resonance structures, you should find the formal charge for the N atom is 0. The charge on one O atom is 0 and –1 for the other O atom. Because the two resonance structures are of equal importance, however, the net formal charge on each O atom is –1/2.

Think about Your Answer The NO bonds in NO_2^- are equivalent, each being intermediate between a single N—O bond and a double N═O bond.

Check Your Understanding

Draw resonance structures for the bicarbonate ion, HCO_3^-.

(a) Does HCO_3^- have the same number of resonance structures as the CO_3^{2-} ion? Are any less likely than others?

(b) What are the formal charges on the O and C atoms in HCO_3^-? What is the average formal charge on the O atoms? Compare this with the O atoms in CO_3^{2-}.

(c) Protonation of HCO_3^- gives H_2CO_3. How do formal charges predict where the H^+ ion will be attached?

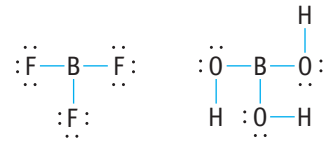
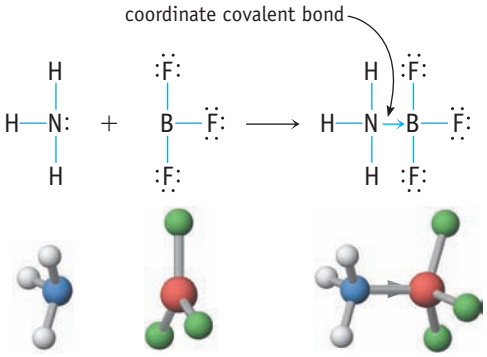
8.5 Exceptions to the Octet Rule



Goal for Section 8.5

- Recognize molecules and polyatomic ions that do not obey the octet rule and draw reasonable Lewis electron dot structures for them.

Although the vast majority of molecular compounds and ions obey the octet rule, there are exceptions. These include molecules and ions that have fewer than four pairs of electrons on a central atom, those that have more than four pairs, and those that have an odd number of electrons.



Compounds in Which an Atom Has Fewer Than Eight Valence Electrons

Boron, a metalloid in Group 3A, has three valence electrons and so is expected to form three covalent bonds with other nonmetallic elements. This results in a valence shell for boron in its compounds with only six electrons, two short of an octet. Many boron compounds of this type are known, including such common compounds as boric acid ($B(OH)_3$), borax ($Na_2B_4O_5(OH)_4 \cdot 8\ H_2O$) (Figure 8.2), and the boron trihalides (BF_3, BCl_3, BBr_3, and BI_3).

boron trifluoride boric acid

Boron compounds such as BF_3 that are two electrons short of an octet are quite reactive. The boron atom can accommodate a fourth electron pair when that pair is provided by another atom, and molecules or ions with lone pairs can fulfill this role. Ammonia, for example, reacts with BF_3 to form $H_3N{\rightarrow}BF_3$.

If a bonding pair of electrons originates on one of the bonded atoms, the bond is called a **coordinate covalent bond.** In Lewis structures, a coordinate covalent bond is often symbolized by an arrow that points away from the atom donating the electron pair.

Compounds in Which an Atom Has More Than Eight Valence Electrons

Elements in the third or higher periods form compounds and ions in which the central element can be surrounded by more than four electron pairs (such as those illustrated in Table 8.5). Such compounds are often referred to as **hypervalent**, and in most cases the central atom is bonded to fluorine, chlorine, or oxygen.

It is often obvious from the formula of a compound that an octet around an atom has been exceeded. Sulfur hexafluoride, SF_6, a relatively inert gas used to fill

A CLOSER LOOK

A Scientific Controversy—Resonance, Formal Charges, and the Question of Double Bonds in Sulfate and Phosphate Ions

With some background about Lewis structures, resonance, and formal charge, we want to discuss a current scientific controversy: the disagreement among chemists about drawing Lewis structures for such simple species as sulfate ion and phosphate ion. For example, two different Lewis structures have been proposed for the sulfate ion:

1

2

When drawing Lewis structures, *the most important step is first to satisfy the octet rule for each atom in a molecule or ion*. If a single Lewis structure does not accurately represent a species, resonance can be introduced. [If two resonance structures are different (as with ions such as SCN^- or a compound like N_2O), a decision can be made among the possible choices by giving preference to structures that minimize formal charges and place negative charges on the most electronegative atoms (page 381).] In the large majority of cases, Lewis structures created by this approach can then be used to determine molecular structure and provide a qualitative picture of bonding.

In this book, we choose to represent the sulfate ion with Lewis structure 1 in which all of the atoms achieve an octet of electrons. The S—O bond order is 1, the sulfur atom has a formal charge of +2, and each oxygen has a formal charge of −1. (As you shall see in Chapter 9, the S atom uses the 3*s* and 3*p* orbitals in bond formation.) Some chemists, however, choose to represent sulfate by a different Lewis structure (structure 2, one of six equivalent resonance structures with an average sulfur–oxygen bond order of 1.5). This structure is attractive because it minimizes formal charges: sulfur has a formal charge of 0, two of the oxygen atoms have a formal charge of zero, and the other two have formal charges of −1. However, as described in more detail in Chapter 9, for sulfur to form six bonds requires that S have six valence orbitals available. This implies that, in addition to 3*s* and 3*p* orbitals, 3*d* orbitals on sulfur must also be involved in the bonding description.

A similar situation is encountered with the phosphate ion and a number of other related species. Several resonance structures can be drawn with double bonds.

The question is which is the better representation of bonding in SO_4^{2-}, 1 or 2? Here we find a controversy. A paper in the *Journal of Chemical Education*[1] presents arguments supporting the description of sulfate by structure 2. Among data offered to support multiple bonding between sulfur and oxygen is the observation that the sulfate ion has shorter SO bonds (149 pm) than the known S—O single bond length (about 170 pm) but longer than the double bond in sulfur monoxide (128 pm).

Support for structure 1 comes from a theoretical study also reported in the *Journal of Chemical Education*.[2] The authors of this paper conclude that structure 1 for sulfate is more reasonable and that structure 2 "should be given no weight at all." The basic argument is that the energy of the 3*d* orbitals is too high to allow any significant involvement of these orbitals in bonding. In keeping with this the authors determined that ". . . the calculated *d*-orbital occupancies . . . are quite small . . . and inconsistent with any significant valence shell expansion."

We give more credence to the theoretical study in reference 2 and believe that structure 1 better represents the sulfate ion (and related species) than 2.

There are two important conclusions:

- In this book our interest is in drawing Lewis structures that adhere to the octet rule, even if this occasionally leads to higher formal charges.
- Finally, you should recognize that *Lewis structures represent only an approximation when representing structure and bonding*.

high voltage transformers, is one such example. Sulfur is the central atom in this compound, and fluorine typically bonds to only one other atom with a single electron pair bond (as in HF and CF_4). A Lewis structure for SF_6 with six S—F bonds will require six electron pairs around the sulfur atom.

More than four atoms or groups bonded to a central atom is a reliable signal that there are more than four electron pairs around a central atom. But be careful—the central atom octet can also be exceeded with four or fewer atoms bonded to the central atom. Consider three examples from Table 8.5: The central atom in SF_4, ClF_3, and XeF_2 has five electron pairs around the central atom.

A useful observation is that *only elements of the third and higher periods in the periodic table form compounds and ions in which an octet is exceeded by the central atom*. Second-period elements (B, C, N, O, F) are restricted to a maximum of eight electrons in their compounds. For example, nitrogen forms compounds and ions such as NH_3, NH_4^+, and NF_3, but NF_5 is unknown. Phosphorus, the third-period element just below nitrogen in the periodic table, forms many compounds similar to

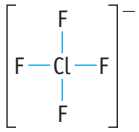
SiF_6^{2-}	PF_6^-	SF_6	BrF_5	XeF_4

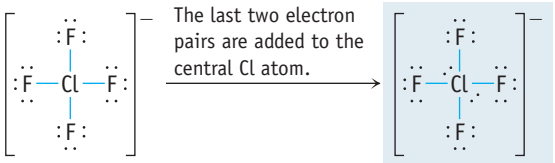
nitrogen (PH_3, PH_4^+, PF_3), but it also readily forms compounds such as PF_5 or ions such as PF_6^-. Arsenic, antimony, and bismuth, the elements below phosphorus in Group 5A, resemble phosphorus in their behavior.

EXAMPLE 8.7



Lewis Structures in Which the Central Atom Has More Than Eight Electrons

Problem Sketch the Lewis structure of the ClF_4^- ion.



What Do You Know? Chlorine is the central atom, bonded to four fluorine atoms. The ion has 36 valence electrons (18 pairs) [7 (for Cl) + 4 × 7 (for F) + 1 (for ion charge) = 36].

Strategy Use the guidelines in Example 8.3 to complete the structure.

SOLUTION Draw the ion with four single covalent Cl—F bonds.

Place lone pairs on the terminal atoms. Because two electron pairs remain after placing lone pairs on the four F atoms and because we know that Cl can accommodate more than four pairs, these two pairs are placed on the central Cl atom.

Think about Your Answer The central atom, chlorine, has more than 8 electrons (4 bond pairs and 2 lone pairs). Because chlorine is in the third period of the periodic table, this is not unreasonable.

Check Your Understanding

Sketch the Lewis structures for ClF_2^+ and ClF_2^-. How many lone pairs and bond pairs surround the Cl atom in each ion?

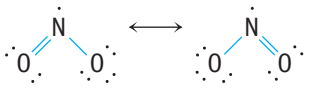
A CLOSER LOOK

Structure and Bonding for Hypervalent Molecules



The usual explanation for why third-period elements can form hypervalent molecules whereas second-period elements cannot centers on the number of orbitals in the valence shell of an atom. Second-period elements have four valence orbitals (one 2*s* and three 2*p* orbitals). Two electrons per orbital means a total of eight electrons can be accommodated around an atom. For elements in the third and higher periods, the *d* orbitals in the outer shell have been included among the valence orbitals for the elements. Thus, for phosphorus, up to two 3*d* orbitals are included with the 3*s* and 3*p* orbitals as orbitals involved in bonding. The extra orbitals allow the element to accommodate up to 12 electrons and thus form six bonds. Recent research, however, has shown that *d* orbitals are involved to a very small extent if at all. Bonding in species such as SF_4, XeF_2, and SiF_6^{2-} can be adequately explained using only *s* and *p* orbitals (page 437).

In this chapter our focus is on predicting and understanding the structure of molecules and ions. Knowing the number of electron pairs around an atom allows us to predict its structure and have insight into its properties. Detailed knowledge of the bonding in the molecule is not needed for this purpose.

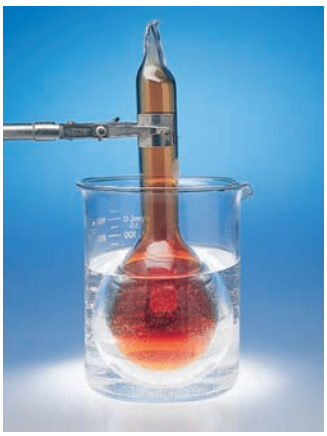
Molecules with an Odd Number of Electrons

Two nitrogen oxides—NO, with 11 valence electrons, and NO_2, with 17 valence electrons—are among a very small group of stable molecules with an odd number of electrons. Because they have an odd number of electrons, it is impossible to draw a structure obeying the octet rule; at least one atom must have an odd number of electrons.

Even though NO_2 does not obey the octet rule, an electron dot structure can be written that approximates the bonding in the molecule. This Lewis structure places the unpaired electron on nitrogen, and two resonance structures show that the nitrogen-oxygen bonds are expected to be equivalent, as is observed.

Experimental evidence for NO indicates that the bonding between N and O is intermediate between a double and a triple bond. It is not possible to write a Lewis structure for NO that reflects this property, so a different theory is needed to understand bonding in this molecule. (We shall return to compounds of this type when molecular orbital theory is introduced in Section 9.2.)

Bonding in NO_2—A Comment
Evidence for the NO_2 structure in the text includes the fact that the N—O bond length is intermediate between a single and a double bond as well as the observation that two NO_2 molecules come together to give N_2O_4 with an N—N bond.



The two nitrogen oxides, NO and NO_2, are members of a class of chemical substances called free radicals. A **free radical** is a chemical species with an unpaired electron, and this makes them generally quite reactive. Atoms such as H and Cl, for example, are free radicals and readily combine with each other to give molecules such as H_2, Cl_2, and HCl.

Free radicals are involved in many reactions in the environment. For example, small amounts of NO are released from vehicle exhausts. The NO rapidly forms NO_2, which is even more harmful to human health and to plants. Exposure to NO_2 at concentrations of 50–100 parts per million can lead to significant inflammation of lung tissue. Nitrogen dioxide is also generated by natural processes. For example, when hay, corn, or silage, which have a high level of nitrates, is stored in silos on farms, NO_2 can be generated as the organic material ferments, and there have been reports of farm workers dying from exposure to this gas in the silo (because NO_2 reacts with water in the lungs to produce nitric acid).

The two nitrogen oxides, NO and NO_2, are unique in that they can be isolated, and neither has the extreme reactivity of most free radicals. When cooled, however, two NO_2 molecules join or "dimerize" to form colorless N_2O_4; the unpaired electrons combine to form an N—N bond in N_2O_4 (Figure 8.3).

A flask of brown NO_2 gas in warm water

When cooled, NO_2 free radicals couple to form N_2O_4 molecules.

N_2O_4 gas is colorless.

A flask of NO_2 gas in ice water

Figure 8.3 Free radical chemistry. When cooled, the concentration of the brown gas NO_2 drops dramatically. Nitrogen dioxide is a free radical, and two NO_2 molecules couple to form colorless N_2O_4, a molecule with an N—N single bond. (N_2O_4 has a boiling point of about 21 °C, so it is liquid at 0 °C. This photo shows some NO_2 remains at this temperature.)

8.6 Molecular Shapes

Goal for Section 8.6

- Use the valence shell electron-pair repulsion (VSEPR) theory to predict the shapes of simple molecules and polyatomic ions and to understand the structures of more complex molecules.

Lewis structures show how atoms are connected in molecules and polyatomic ions. However, they do not show three-dimensional geometry, which is often crucial to molecular function. For that reason we want to take the next step: Use Lewis structures to predict three-dimensional structures.

The **valence shell electron-pair repulsion (VSEPR)** theory is a method for predicting the shapes of covalent molecules and polyatomic ions. It is based on the idea that *bond and lone electron pairs in the valence shell of an element repel each other and seek to be as far apart as possible*. The positions assumed by the bond and lone electron pairs thus define the angles between bonds to surrounding atoms. VSEPR is remarkably successful in predicting structures of molecules and polyatomic ions of main group elements.

To have a sense of how valence shell electron pairs determine structure, blow up several balloons to a similar size. Imagine that each balloon represents an electron cloud. When two, three, four, five, or six balloons are tied together at a central point (representing the nucleus and core electrons of a central atom), the balloons naturally form the shapes shown in Figure 8.4. These geometric arrangements minimize interactions between the balloons and are the same as the arrangements of electron pairs observed in molecules.

© Cengage Learning/Charles D. Winters

Linear | Trigonal planar | Tetrahedral | Trigonal bipyramidal | Octahedral

Figure 8.4 Balloon models of electron-pair geometries for two to six electron pairs. If two to six balloons of similar size and shape are tied together, they will naturally assume the arrangements shown. These pictures illustrate the predictions of VSEPR.

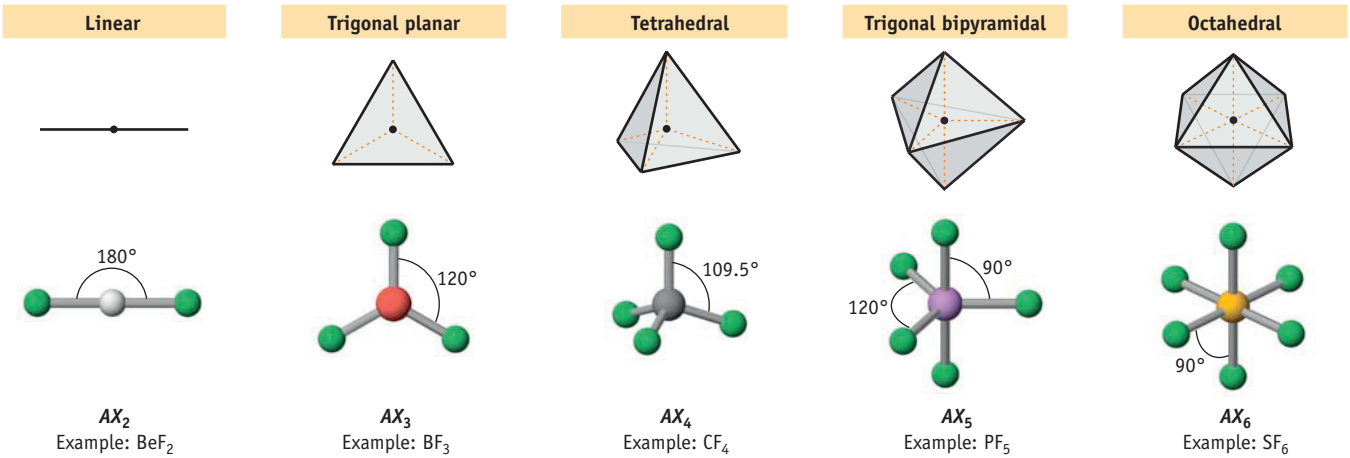

Figure 8.5 Geometries predicted by VSEPR. Geometries predicted by VSEPR for molecules of the type AX_n, where A is the central atom and n is the number of X groups covalently bonded to it.

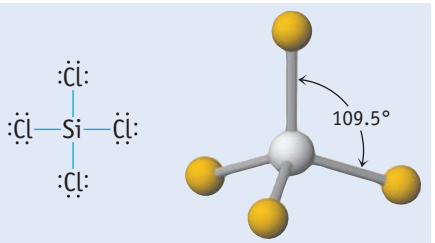
Central Atoms Surrounded Only by Single-Bond Pairs

Figure 8.5 illustrates the geometries predicted for molecules or polyatomic ions based on a central atom with two to six bonded atoms. For molecules with two pairs of electrons around the central atom, a *linear geometry* is expected, with a bond angle of 180°. Three electron pairs around a central atom leads to a *trigonal planar geometry* with 120° bond angles. Molecules with four electron pairs assume a *tetrahedral geometry* and bond angles of 109.5°. (Pay attention particularly to the three dimensionality of the tetrahedral arrangement; the importance of this geometry will become especially evident when we look at the wide range of carbon-based organic compounds.) Molecules with five electron pairs around a central atom assume a trigonal bipyramidal configuration, with angles of 120° or 90°. Octahedral geometry with 90° bond angles is adopted if there are six electron pairs surrounding a central atom.

EXAMPLE 8.8

Predicting Molecular Shapes



Problem Predict the shape of silicon tetrachloride, $SiCl_4$.

What Do You Know? You know the compound's formula and the number of valence electrons. In $SiCl_4$ there are 32 valence electrons or 16 pairs, and Si is the central atom.

Strategy The first step is to draw the Lewis structure. Don't worry about drawing it in any particular way because its purpose is only to describe the number of bonds around an atom and to determine if there are any lone pairs, particularly on the central atom. The shape of the molecule is dictated by the positions of the bond and lone electron pairs on the central atom.

SOLUTION The Lewis structure of $SiCl_4$ has four electron pairs, all of them bond pairs, around the central Si atom. Therefore, a tetrahedral structure is predicted for the $SiCl_4$ molecule, with Cl—Si—Cl bond angles of 109.5°. This agrees with the actual structure for $SiCl_4$.

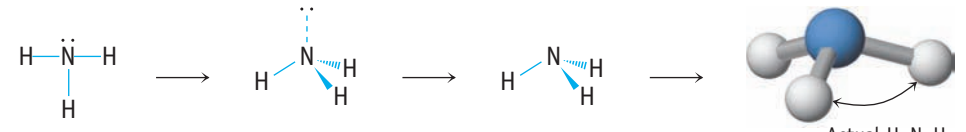
Think about Your Answer Be sure to recognize that all four positions in a tetrahedral geometry are equivalent.



Check Your Understanding

What is the shape of the dichloromethane (CH_2Cl_2) molecule? Predict the Cl—C—Cl bond angle.

Central Atoms with Single-Bond Pairs and Lone Pairs

To see how lone pairs affect the geometry of a molecule or polyatomic ion, return to the balloon models in Figure 8.4. If you assume the balloons represent *all* the electron pairs in the valence shell of the central atom, the model predicts the "electron-pair geometry" of the molecule or ion. The **electron-pair geometry** is the geometry assumed by *all* the valence electron pairs around a central atom (both bond and lone pairs). This is different than the **molecular geometry**, which describes only the geometry of the central atom and the atoms directly attached to it. It is important to recognize that *lone pairs of electrons on the central atom occupy spatial positions, but their location is not included in the verbal description of the shape of the molecule or ion.*

Let us use the VSEPR model to predict the molecular geometry and bond angles in the NH_3 molecule. On drawing the Lewis structure, we see there are four pairs of electrons surrounding the central nitrogen atom: three bond pairs and one lone pair. Thus, the predicted *electron-pair geometry* is *tetrahedral*. The *molecular geometry,* however, is said to be *trigonal pyramidal* because that describes the location of the atoms. The nitrogen atom is at the apex of the pyramid, and the three hydrogen atoms form the trigonal base.

Lewis structure | electron-pair geometry, tetrahedral | molecular geometry | Actual H–N–H angle = 107.5° | molecular geometry, trigonal pyramidal

Effect of Lone Pairs on Bond Angles

Because the electron-pair geometry in NH_3 is tetrahedral, we would expect the H—N—H bond angle to be 109.5°. However, the experimentally determined bond angles in NH_3 are 107.5°, and the H—O—H angle in water is smaller still (104.5°) (Figure 8.6). These angles are close to the tetrahedral angle but not exactly that value. This highlights the fact that VSEPR theory can only predict approximate geometries. Small variations in geometry are quite common and arise because there is a difference between the spatial requirements of lone pairs and bond pairs. Lone pairs of electrons seem to occupy a larger volume than bonding pairs, and the increased volume of lone pairs causes bond pairs to squeeze closer together. In general, the relative strengths of repulsions that determine the overall structure and the bond angles are in the order

Lone pair–lone pair > lone pair–bond pair > bond pair–bond pair

This is clearly seen in the decrease in bond angles in the series CH_4, NH_3, and H_2O as the number of lone pairs on the central atom increases (Figure 8.6).

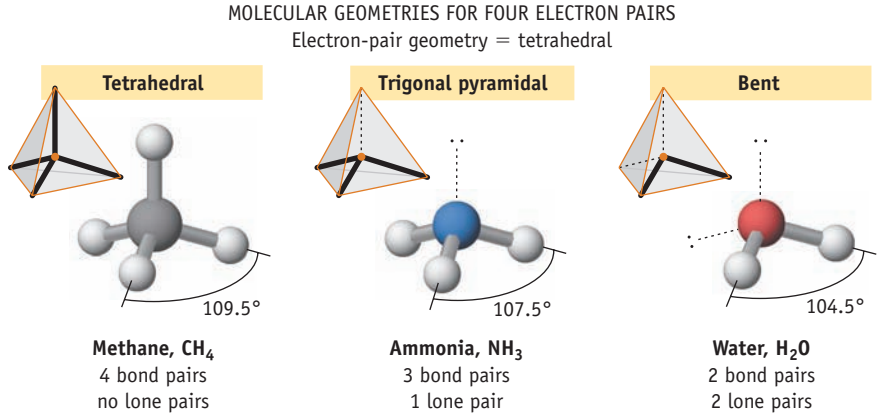

Figure 8.6 The molecular geometries of methane, ammonia, and water. All have four electron pairs around the central atom and have a tetrahedral electron-pair geometry. The decrease in bond angles in the series can be explained by the fact that the lone pairs have a larger spatial requirement than the bond pairs.

EXAMPLE 8.9

Predicting the Shapes of Molecules and Polyatomic Ions

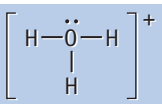
Problem What are the shapes of the ions H_3O^+ and ClF_2^+?

What Do You Know? Knowing the formulas of the ions will allow you to draw the Lewis structures.

Strategy

- Draw the Lewis structure for each ion.
- Count the number of lone and bond pairs around the central atom.
- Use Figure 8.5 to decide on the electron-pair geometry. The location of the atoms in the ion gives the molecular geometry of the ion.

Strategy Map 8.9

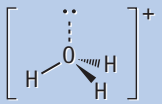


PROBLEM

Determine the **molecular geometry** of H_3O^+.

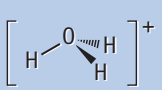
DATA/INFORMATION

- **Formula** of the ion (H_3O^+).



STEP 1. Draw the **Lewis electron dot structure.**

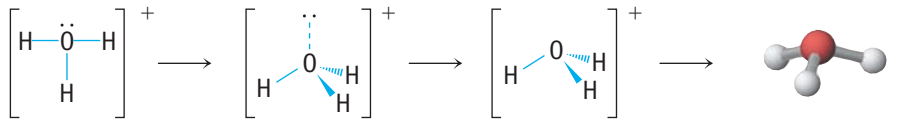
Lewis structure 



STEP 2. Count the number of **bond** and **lone pairs** on the ***central atom***.

In this ion there are ***three*** **bond pairs** and ***one*** **lone pair.**

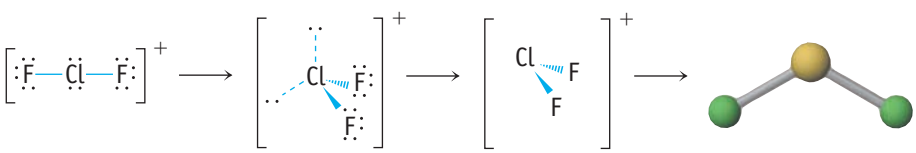
STEP 3. Decide on the **electron-pair geometry.**



Four pairs = **tetrahedral** electron-pair geometry 

STEP 4. Decide on the **molecular geometry.**

The molecular geometry is **trigonal pyramidal.** 



SOLUTION

(a) The Lewis structure for H_3O^+ shows the oxygen atom is surrounded by four electron pairs, so the electron-pair geometry is tetrahedral. Because three of the four pairs are used to bond terminal atoms, the central O atom and the three H atoms form a trigonal-pyramidal molecular shape like that of NH_3.

Lewis structure | electron-pair geometry, tetrahedral | molecular geometry | molecular geometry, trigonal pyramidal

(b) Chlorine, the central atom in ClF_2^+ is surrounded by four electron pairs, so the electron-pair geometry around chlorine is tetrahedral. Because only two of the four pairs are bonding pairs, the ion has a bent geometry.

Lewis structure | electron-pair geometry, tetrahedral | molecular geometry | molecular geometry, bent or angular

Think about Your Answer In each of these ions the occurrence of lone pairs on the central atom influences the molecular geometry. In both ions the angle (H–O–H or F–Cl–F) is likely to be slightly less than 109.5°.

Check Your Understanding

Give the electron-pair geometry and molecular shape for BF_3 and BF_4^-. What is the effect on the molecular geometry of adding an F^- ion to BF_3 to give BF_4^-?

Central Atoms with More Than Four Valence Electron Pairs

What structures are observed if the central atom has five or six electron pairs, some of which are lone pairs? A trigonal-bipyramidal structure (Figures 8.5 and 8.7) has two sets of positions that are not equivalent. The positions in the trigonal plane lie in the equator of an imaginary sphere around the central atom and are called *equatorial* positions. The north and south poles in this representation are called *axial* positions. Each equatorial atom has two neighboring groups (the axial atoms) at 90°, and each axial atom has three groups (the equatorial atoms) at 90°. If lone pairs are present in the valence shell, they require more space than bonding pairs and so prefer to occupy equatorial positions rather than axial positions.

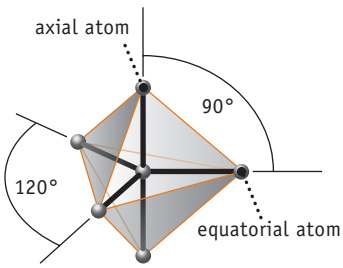

Figure 8.7 The trigonal bipyramid showing the axial and equatorial atoms. The angles between atoms in the equator are 120°. The angles between equatorial and axial atoms are 90°. If there are lone pairs they are found in the equatorial positions.

The entries in the top row of Figure 8.8 show species having a total of five valence electron pairs, with zero, one, two, and three lone pairs. In SF_4, with one lone pair, the molecule assumes a "*seesaw*" shape with the lone pair in one of the equatorial positions. The ClF_3 molecule has three bond pairs and two lone pairs. The two lone pairs in ClF_3 are in equatorial positions; two bond pairs are axial, and the third is in the equatorial plane, so the molecular geometry is *T-shaped*. The third molecule shown is XeF_2. Here, all three equatorial positions are occupied by lone pairs, so the molecular geometry is *linear*.

The geometry assumed by six electron pairs is *octahedral* (Figure 8.8), and all the angles at adjacent positions are 90°. Unlike the trigonal bipyramid, all positions in

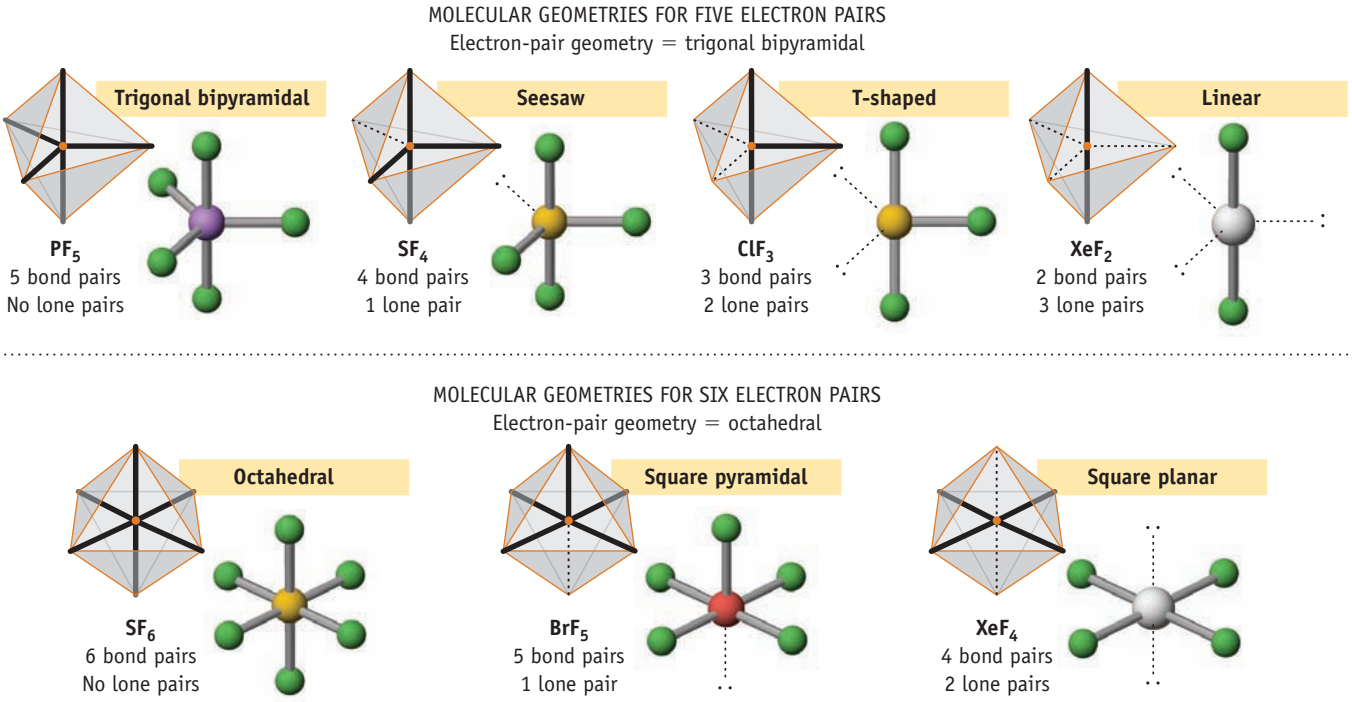

Figure 8.8 Electron-pair and molecular geometries for molecules and ions with five or six electron pairs around the central atom.

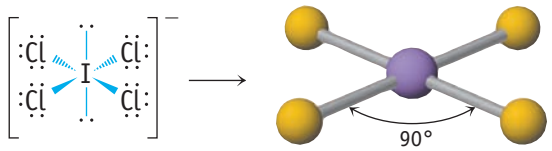
the octahedron are the same. Therefore, if the molecule has one lone pair, as in BrF_5, it makes no difference which position it occupies. The lone pair is often drawn in the top or bottom position to make it easier to visualize the molecular geometry, which in this case is *square pyramidal*. If two pairs of electrons in an octahedral arrangement are lone pairs, they seek to be as far apart as possible. The result is a *square planar* molecule, as illustrated by XeF_4.

EXAMPLE 8.10



Predicting Molecular Shape

Problem What is the shape of the ICl_4^- ion?

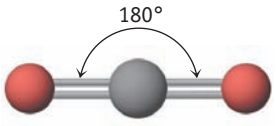
What Do You Know? You know the number of valence electrons, so you can draw the Lewis electron dot structure.

Strategy Draw the Lewis structure, and then decide on the electron-pair geometry. The position of the atoms gives the molecular geometry of the ion (see Example 8.7 and Figure 8.8).

SOLUTION A Lewis structure for the ICl_4^- ion shows that the central iodine atom has six electron pairs in its valence shell. Two of these are lone pairs. Placing the lone pairs on opposite sides leaves the four chlorine atoms in a square-planar geometry.

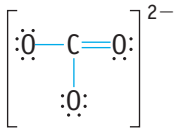
electron-pair geometry, octahedral

molecular geometry, square planar

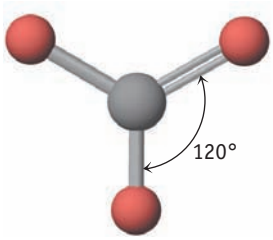


Think about Your Answer Square-planar geometry allows the two lone pairs on the central atom to be as far apart as possible.

Check Your Understanding



Draw the Lewis structure for ICl_2^-, and then decide on the geometry of the ion.



Lewis structure, electron-pair geometry = linear

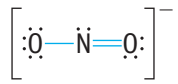
molecular structure, linear

Lewis structure, one resonance structure, electron-pair geometry = trigonal planar

molecular structure, trigonal planar

Multiple Bonds and Molecular Geometry

Double and triple bonds involve more electron pairs than single bonds, but this has little effect on the overall molecular shape. *All the electron pairs in a multiple bond are shared between the same two nuclei and occupy the same region of space.* Therefore, all electron pairs in a multiple bond count as one bonding group and affect the molecular geometry the same as a single bond does. For example, the carbon atom in CO_2 has no lone pairs and participates in two double bonds. Each double bond is a region of electron density and effectively counts as one bond for the purpose of predicting geometry; the structure of CO_2 is *linear*.



When resonance structures are possible, the geometry can be predicted from any of the Lewis resonance structures or from the resonance hybrid structure. For example, the geometry of the CO_3^{2-} ion is predicted to be *trigonal planar* because the carbon atom has three sets of bonds and no lone pairs.

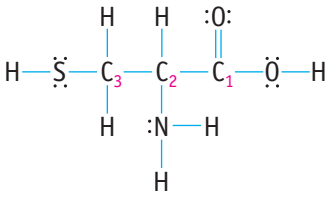
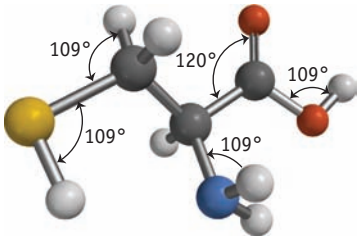
The NO_2^- ion also has a trigonal-planar electron-pair geometry. Because there is a lone pair on the central nitrogen atom, and bonds in the other two positions, the geometry of the ion is *angular or bent*.



The techniques just outlined can be used to find the geometries around the atoms in more complicated molecules. Consider cysteine, one of the natural amino acids. Four pairs of electrons occur around the S, N, C_2, and C_3 atoms, and around the oxygen attached to the hydrogen, so the electron-pair geometry around each is tetrahedral. Thus, all of the angles in the molecule are predicted to be approximately 109° except for the angles around C_1, which are 120° because the electron-pair geometry around C_1 is trigonal planar.



Lewis structure, one resonance structure, electron-pair geometry = trigonal planar

molecular structure, angular or bent

Cysteine, $HSCH_2CH(NH_2)CO_2H$

8.7 Electronegativity and Bond Polarity

Goals for Section 8.7

- Understand electronegativity and use it to determine the polarity of bonds.
- Use electronegativity and formal charge to predict the charge distribution in molecules and polyatomic ions.

"Pure" covalent bonding, in which atoms share an electron pair *equally*, occurs *only* when two identical atoms are bonded. When two dissimilar atoms form a covalent bond, the electron pair will be unequally shared. The result is a **polar covalent bond,** a bond in which the two atoms have partial electrostatic charges (Figure 8.9).

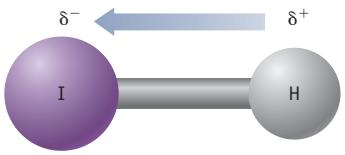


Figure 8.9 A polar covalent bond. In hydrogen iodide, iodine has a larger share of the bonding electrons, and hydrogen has a smaller share. The result is that I has a partial negative charge (δ^-), and H has an equal partial positive charge (δ^+). Sometimes bond polarity is shown by an arrow pointing from + to −.

Bonds are polar because not all atoms hold on to their valence electrons with the same force or take on additional electrons with equal ease. Recall from the discussion of atom properties that different elements have different values of ionization energy and electron affinity (electron attachment enthalpy) (Section 7.5). These differences in behavior for free atoms carry over to atoms in molecules.

If a bond pair is not equally shared between atoms, the bonding electrons are on average nearer to one of the atoms. The atom toward which the pair is displaced has a larger share of the electron pair and so has a partial negative charge. At the same time, the atom at the other end of the bond is depleted in electrons and has a partial positive charge. The bond between the two atoms is **polar**; that is, it has a positive end and a negative end.

In ionic compounds, displacement of the bonding pair to one of the two atoms is complete, and + and − symbols are written alongside the atom symbols in the Lewis drawings. For a polar covalent bond, the polarity is indicated by writing the symbols δ^+ and δ^- alongside the atom symbols, where δ (the Greek lowercase letter "delta") stands for a *partial* charge. With so many atoms to use in covalent bond formation, it is not surprising that bonds between atoms can fall anywhere in a continuum from completely covalent to completely ionic (Figures 8.1 and 8.10)

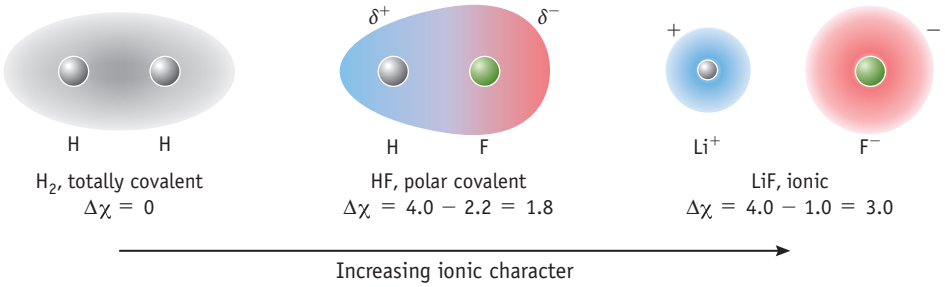

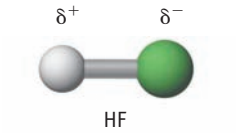

Figure 8.10 Covalent to ionic bonding. As the electronegativity difference increases between the atoms of a bond, the bond becomes increasingly ionic.

HF, A Polar Molecule. The difference in electronegativity between H and F is 1.8, making H-F very polar.

In the 1930s, Linus Pauling proposed a parameter called *atom electronegativity* that allows us to decide if a bond is polar, which atom of the bond is partially negative and which is partially positive, and if one bond is more polar than another. The **electronegativity,** χ, of an atom is defined as a measure of *the ability of an atom in a molecule to attract electrons to itself.*

Looking at the values of electronegativity in Figure 8.11 you will notice several important features:

- Fluorine has the largest value of electronegativity; it is assigned a value of $\chi = 4.0$. The element with the smallest value is the alkali metal cesium.
- Electronegativities generally increase from left to right across a period and decrease down a group. This is the opposite of the trend observed for metallic character.
- Metals typically have low values of electronegativity, ranging from slightly less than 1 to about 2.
- Electronegativity values for the metalloids are around 2, whereas nonmetals have values greater than 2.

Notice that there is a large *difference* in electronegativity for atoms from the left and right sides of the periodic table. For cesium fluoride, for example, the difference in electronegativity values, $\Delta\chi$, is 3.2 [= 4.0 (for F) − 0.8 (for Cs)]. (See the bonding

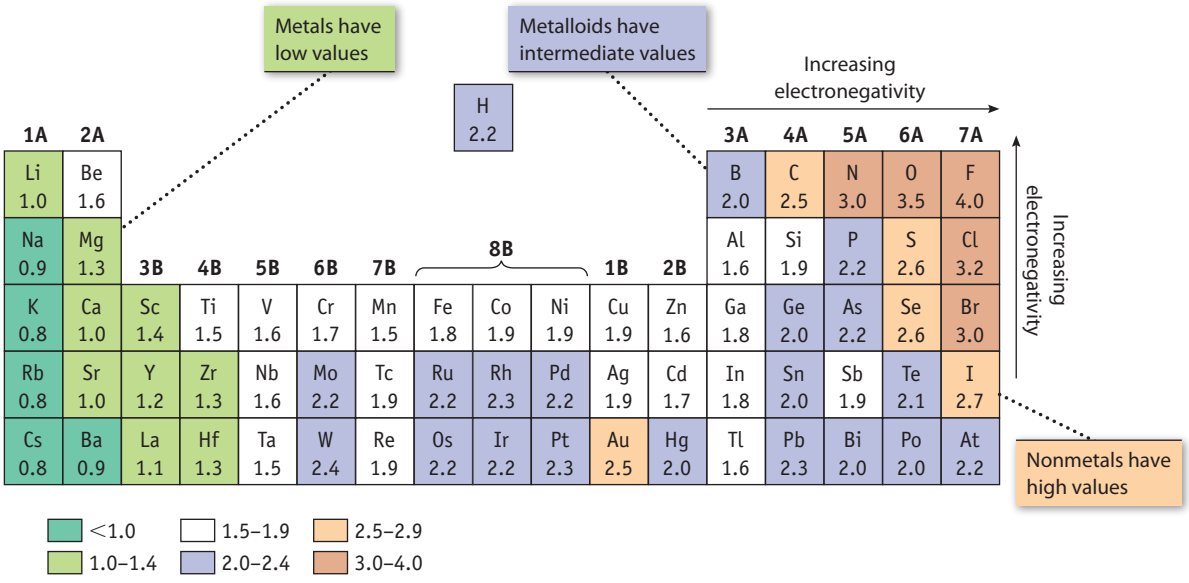

Figure 8.11 Pauling electronegativity values for the elements. Values are also available for the noble gases and the lanthanides and actinides. The values in this table are from J. Emsley, *The Elements*, 3rd ed., Clarendon Press, Oxford, 1998.

triangle in Figure 8.1.) Bonding in CsF is decidedly ionic, with Cs the cation (Cs^+) and F the anion (F^-). In contrast, the electronegativity difference between H and F in HF is only 1.8 [= 4.0 (for F) − 2.2 (for H)], and bonding in HF is more covalent. However, because the electronegativities of hydrogen and fluorine are different, the H—F bond is polar. In a polar bond, the more electronegative atom takes on the partial negative charge, and the less electronegative atom takes on the partial positive charge. Thus, hydrogen is the positive end of this molecule and fluorine is the negative end ($H^{\delta+}$—$F^{\delta-}$).

EXAMPLE 8.11

Estimating Bond Polarities

Problem For each of the following bond pairs, decide which bond is more polar and indicate the negative and positive poles.

(a) B—F and B—Cl (b) Si—O and P—P

What Do You Know? You know the general trends in electronegativity and can look up the actual values in Figure 8.11.

Strategy Locate the elements in the periodic table and try to answer the questions based on general trends in electronegativity. Recall that electronegativity generally increases across a period and up a group.

SOLUTION

(a) B and F lie relatively far apart in the periodic table. B is a metalloid, and F is a nonmetal. Here, χ for B = 2.0, and χ for F = 4.0. Similarly, B and Cl are relatively far apart in the periodic table, but Cl is below F in the periodic table (χ for Cl = 3.2) and is therefore less electronegative than F. The difference in electronegativity for B—F is 2.0, and for B—Cl it is 1.2. Both B—F and B—Cl bonds are expected to be polar, with B positive and the halide atom negative, but a B—F bond is more polar than a B—Cl bond.

(b) The P—P bond is nonpolar because the bond is between two atoms of the same kind. In the case of Si—O, the O atom has a greater electronegativity (3.5) than Si (1.9), and the bond is highly polar ($\Delta\chi = 1.6$), with O the more negative atom.

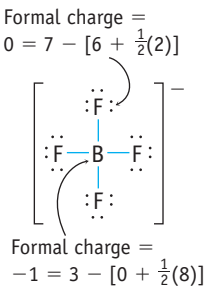
Think about Your Answer When F is one of the bonded atoms, a highly polar bond usually results. Bonds involving identical elements, as in the P—P bond in this example, will be nonpolar.

Check Your Understanding

For each of the following pairs of bonds, decide which is more polar. For each polar bond, indicate the positive and negative poles. After making your prediction from the relative atom positions in the periodic table, check your prediction by calculating $\Delta\chi$ from electronegativity values in Figure 8.11.

(a) H—F and H—I (b) B—C and B—F (c) C—Si and C—S

Charge Distribution: Combining Formal Charge and Electronegativity



The way electrons are distributed in a molecule or ion is called its **charge distribution.** Charge distribution can profoundly affect the properties of a molecule. Examples include physical properties such as melting and boiling points, and chemical

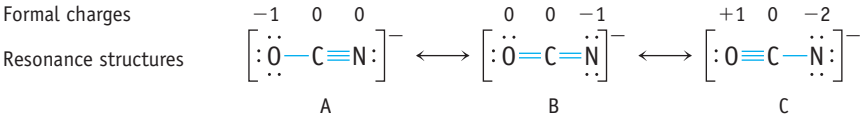
properties such as susceptibility to attack by an anion or cation or whether the molecule is an acid or a base.

The site of a charge in a molecule or an ion can often be learned from a formal charge calculation (Section 8.3). However, it is possible to get an incorrect result from this determination because formal charge calculations assume there is equal sharing of electrons in all bonds. The BF_4^- ion illustrates this point. Boron has a formal charge of -1 in this ion, and the formal charge calculated for the fluorine atoms is 0. Based on the electronegativity difference between fluorine and boron ($\Delta\chi = 2.0$), the B—F bonds are expected to be polar with the fluorine atom the negative end of the bond ($B^{\delta+}$—$F^{\delta-}$). So, in this instance, predictions based on electronegativity and formal charge work in opposite directions.

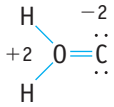


According to Linus Pauling, there are two guidelines to use when describing charge distributions in molecules and ions. The first is the **principle of electroneutrality:** Electrons will be distributed in such a way that the charges on all atoms are as close to zero as possible. Second, if a negative charge is present, it should reside on the most electronegative atoms. Similarly, positive charges are expected on the least electronegative atoms. The effect of these principles is clearly seen in the case of BF_4^-, where it turns out that the negative charge is indeed distributed over the four fluorine atoms, as predicted by the atoms' electronegativities, rather than residing on boron, as would be predicted by formal charge calculations.

Considering the concepts of electronegativity and formal charge together can help to decide which of several resonance structures is the more important. For example, Lewis structure A for CO_2 is the logical one to draw. But what is wrong with B, in which each atom also has an octet of electrons?

For structure A, each atom has a formal charge of 0, a favorable situation. In B, however, one oxygen atom has a formal charge of $+1$, and the other has -1. This is contrary to the principle of electroneutrality. In addition, B places a positive charge on an O atom, which is also unsatisfactory. Because carbon is less electronegative than oxygen, any positive charge in this molecule should be on carbon. The best description for CO_2 is structure A. At the same time, because the electronegativity of O is greater than C, the bond is polar ($C^{\delta+}$—$O^{\delta-}$).

Now use the same logic to decide which of the three possible resonance structures for the OCN^- ion is the most reasonable. Formal charges for each atom are given above each element's symbol.



Structure C is not expected to contribute significantly to the overall electronic structure of the ion. It has a -2 formal charge on the N atom and a $+1$ formal charge on the O atom. Not only is the charge on the N atom high, but O is more electronegative than N and would be expected to take on a more negative charge than N. Structure A is more significant than structure B because the negative charge in A is placed on the most electronegative atom (O). We predict, therefore, that the resonance hybrid will reflect most strongly structure A and that the carbon–nitrogen bond will most resemble a triple bond. The result for OCN^- also allows us to predict that protonation of the ion will lead to HOCN and not HNCO. That is, an H^+ ion will add to the more negative oxygen atom.

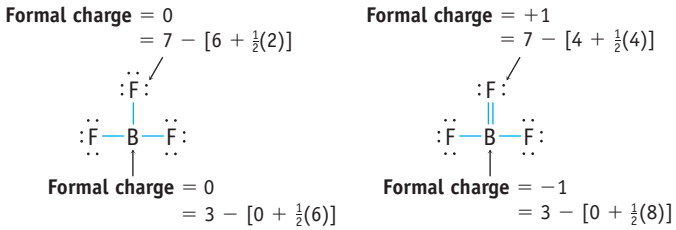
When we began to discuss drawing Lewis structures we said that the central atom is usually the atom of lowest electronegativity. Let's look at a case where we assign the wrong atom as the central atom. For example, suppose the Lewis structure for CH_2O has the more electronegative O atom as the central atom.

On calculating the formal charge, you would find that the very electronegative O atom has a charge of +2, and the C atom has a charge of −2. Not only does the more electronegative atom have a positive formal charge, but large formal charges (±2) result from the requirement of having an octet around carbon and oxygen.

EXAMPLE 8.12

Calculating and Using Formal Charges



Problem Boron-containing compounds often have a boron atom with only three bonds (and no lone pairs). Why not form a double bond with a terminal atom to complete the boron octet? To answer this, consider possible resonance structures of BF_3, and calculate the formal charges of the B and F atoms. Are the bonds polar in BF_3? If so, which is the more negative atom?

What Do You Know? Boron trihalides are good examples of stable compounds that do not obey the octet rule. The most common Lewis structure given for BF_3, for example, shows the boron atom with only three bond pairs of electrons.

Strategy

- Draw the Lewis structure for BF_3. Then draw a resonance structure (one of three possible) in which boron achieves an octet structure, using one of the electron pairs for fluorine to create a double bond between boron and fluorine.
- Determine the formal charges on each atom in the two structures.
- Decide the importance of the different resonance structures based on the positions of charges in the molecule.

SOLUTION The two possible structures for BF_3 are illustrated here with the calculated formal charges on the B and F atoms.

The structure on the left is preferred because all atoms have a zero formal charge and the very electronegative F atom does not have a charge of +1. Fluorine ($\chi = 4.0$) is much more electronegative than B ($\chi = 2.0$), so the B—F bond is highly polar, the F atom being partially negative and the B atom partially positive.

Think about Your Answer We can clearly say that the BF_3 structure with three single bonds is preferred. However, there is experimental evidence that the B—F bonds in BF_3 do have a slight amount of double bond character in spite of an unfavorable charge distribution.

Check Your Understanding

Draw the resonance structures for SCN^-. What are the formal charges on each atom in each resonance structure? What are the bond polarities? Do they agree with the formal charges?

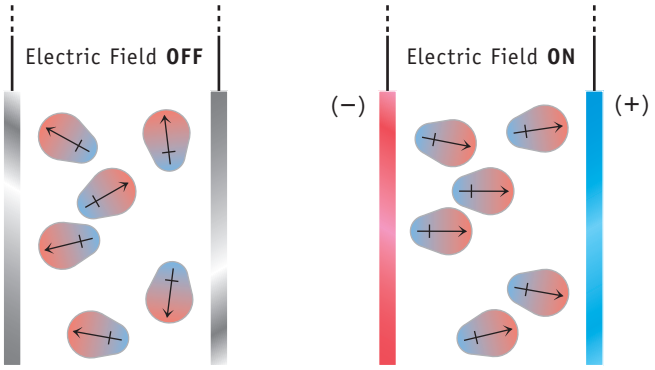
8.8 Molecular Polarity

Goal for Section 8.8

- Predict the polarity of molecules and understand why some molecules are polar whereas others are nonpolar.

The term "polar" describes a bond in which one atom has a partial positive charge and the other a partial negative charge. Because most molecules have polar bonds, molecules as a whole can also be polar. In a polar molecule, electron density accumulates toward one side of the molecule, giving that side a partial negative charge (δ^-), and leaving the other side with an equal but positive partial charge (δ^+).

To predict if a molecule is polar, we need to consider how the atoms are positioned relative to one another. The polarity of the bonds is a secondary consideration.



Diatomic molecules composed of two atoms with different electronegativities are always polar (Table 8.6); there is one bond, and the molecule has a positive and a negative end.

But what happens with a molecule composed of three or more atoms? Consider a linear triatomic molecule such as carbon dioxide, CO_2. Here, each C═O bond is polar, with the oxygen atom the negative end of the bond dipole. The terminal O atoms are at the same distance from the C atom, they both have the same δ^- charge,

A CLOSER LOOK

Measuring Molecular Polarity

How is the polarity of a molecule measured? When polar molecules are placed in an electric field created by a pair of oppositely charged plates, the molecules experience a force that tends to align them with the field. The positive end of each molecule is attracted to the negative plate, and the negative end is attracted to the positive plate. The orientation of the polar molecule affects the electrical capacitance of the plates (their ability to hold a charge), and this provides a way to experimentally measure the magnitude of the dipole moment.

The extent to which the molecules line up with the field depends on their **dipole moment,** μ. In a molecule with partial charges equal to $+q$ and $-q$ and in which these charges are separated by a distance, d, in the molecule, the magnitude of the dipole moment is given by the equation $\mu = q \times d$. The SI unit of the dipole moment is the coulomb-meter, but dipole moments have traditionally been given using a derived unit called the *debye* (D; 1 D = 3.34×10^{-30} C·m). Experimental values of some dipole moments are listed in Table 8.6.

The commonly used unit of dipole moments is named in honor of Peter Debye (1884–1966). Debye was born in the Netherlands and educated in Germany. He received the Nobel Prize in Chemistry in 1936 and was later a professor at Cornell University in Ithaca, NY.

TABLE 8.6 Dipole Moments (μ) of Selected Molecules (in debye units)

Molecule (AX)	Moment (μ, D)	Geometry	Molecule (AX_2)	Moment (μ, D)	Geometry
HF	1.78	Linear	H_2O	1.85	Bent
HCl	1.07	Linear	H_2S	0.95	Bent
HBr	0.79	Linear	SO_2	1.62	Bent
HI	0.38	Linear	CO_2	0	Linear
H_2	0	Linear			
Molecule (AX_3)	**Moment (μ, D)**	**Geometry**	**Molecule (AX_4)**	**Moment (μ, D)**	**Geometry**
NH_3	1.47	Trigonal pyramidal	CH_4	0	Tetrahedral
NF_3	0.23	Trigonal pyramidal	CH_3Cl	1.92	Tetrahedral
BF_3	0	Trigonal planar	CH_2Cl_2	1.60	Tetrahedral
			$CHCl_3$	1.04	Tetrahedral
			CCl_4	0	Tetrahedral

and they are symmetrically arranged around the central C atom. Therefore, CO_2 has no molecular dipole, even though each bond is polar. This is analogous to a tug-of-war in which the people at opposite ends of a rope are pulling with equal force.

In contrast, water is a bent triatomic molecule. Because O has a larger electronegativity ($\chi = 3.5$) than H ($\chi = 2.2$), each of the O—H bonds is polar, with the H atoms having the same δ^+ charge and oxygen having a negative charge (δ^-). Electron density accumulates on the O side of the molecule, making the molecule electrically "lopsided" and therefore polar ($\mu = 1.85$ D).

In trigonal-planar BF_3, the B—F bonds are quite polar because F is much more electronegative than B (χ of B = 2.0 and χ of F = 4.0) (Figure 8.12). The molecule is nonpolar, however, because the three terminal F atoms have the same δ^- charge, are the same distance from the boron atom, and are arranged symmetrically around the central boron atom. In contrast, the trigonal-planar molecule phosgene is polar (Cl_2CO, $\mu = 1.17$ D) (Figure 8.12). Here, the angles are all about 120°, so the O and Cl atoms are symmetrically arranged around the C atom. The electronegativities of the three types of atoms in the molecule differ, however: $\chi(O) > \chi(Cl) > \chi(C)$. There is therefore a net displacement of electron density away from the center of the molecule, more toward the O atom than the Cl atoms.

Ammonia, like BF_3, has AX_3 stoichiometry and polar bonds. In contrast to BF_3, however, NH_3 is a trigonal-pyramidal molecule. The positive H atoms are located in the base of the pyramid, and the negative N atom is on the apex of the pyramid. As a consequence, NH_3 is polar (Figure 8.12). Indeed, trigonal-pyramidal molecules are generally polar.

Molecules like carbon tetrachloride, CCl_4, and methane, CH_4, are nonpolar, owing to their symmetrical, tetrahedral structures. The four atoms bonded to C have the same partial charge and are the same distance from the C atom. Tetrahedral molecules with both Cl and H atoms ($CHCl_3$, CH_2Cl_2, and CH_3Cl) are polar, however (Figure 8.13). The electronegativity for H atoms (2.2) is less than that of Cl atoms (3.2), and the carbon–hydrogen distance is different from the carbon–chlorine distances. Because Cl is more electronegative than H, the Cl atoms are on

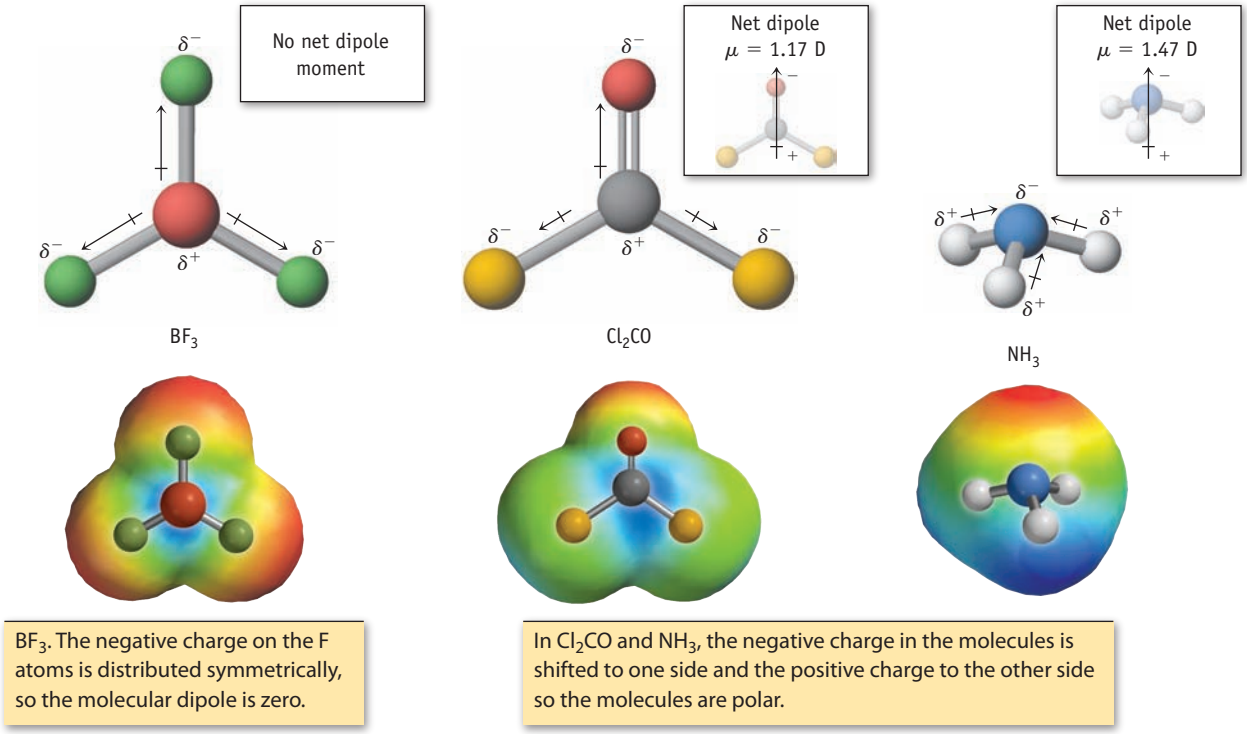

Figure 8.12 Polar and nonpolar molecules of the type AX_3. Charge distributions are reflected in the electrostatic potential surfaces (where a red color indicates a negative charge and blue a positive charge). (See *A Closer Look: Visualizing Charge Distributions and Molecular Polarity—Electrostatic Potential Surfaces and Partial Charge*.)

the more negative side of the molecule. This means the positive end of the molecular dipole is toward the H atom.

To summarize this discussion of molecular polarity, look again at Figure 8.5. These are sketches of molecules of the type AX_n where A is the central atom and X is a terminal atom. You can predict that a molecule AX_n will *not* be polar, regardless of whether the A—X bonds are polar, if

- all the terminal atoms (or groups), X, are identical, and
- all the X atoms (or groups) are arranged symmetrically around the central atom, A.

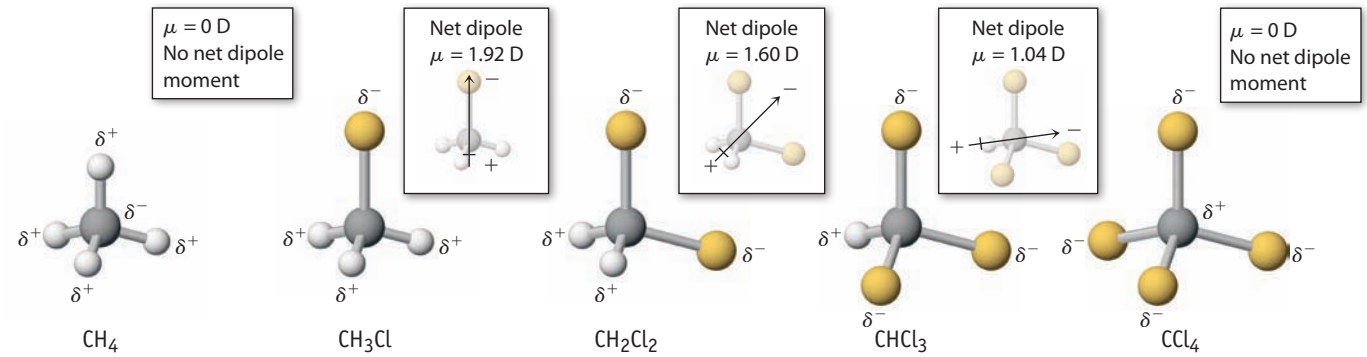

Figure 8.13 Polarity of tetrahedral molecules. The electronegativities of the atoms involved are in the order Cl (3.2) > C (2.5) > H (2.2). This means the C—H and C—Cl bonds are polar with a net displacement of electron density away from the H atoms and toward the Cl atoms [$H^{\delta+}$—$C^{\delta-}$ and $C^{\delta+}$—$Cl^{\delta-}$]. Although the electron-pair geometry around the C atom in each molecule is tetrahedral, only in CH_4 and CCl_4 are the polar bonds totally symmetrical in their arrangement. In contrast, CH_3Cl, CH_2Cl_2, and $CHCl_3$ are polar molecules, with the negative end toward the Cl atoms and the positive end toward the H atoms.

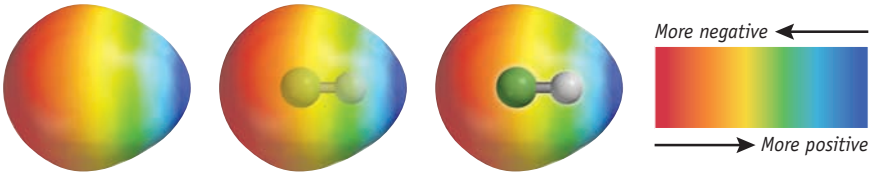
A CLOSER LOOK

Visualizing Charge Distributions and Molecular Polarity—Electrostatic Potential Surfaces and Partial Charge

In Chapter 6, you learned about atomic orbitals. The boundary surface of these orbitals was created in such a way that the electron wave amplitude at all points of the surface was the same value. When we use advanced molecular modeling software, we can generate the same type of pictures for molecules, and in Figure A you see a surface defining the electron density in the HF molecule. The electron density surface, calculated using Spartan software from Wavefunction, Inc., is made up of all of the points in space around the HF molecule where the electron density is 0.002 $e^-/Å^3$ (where 1 Å = 0.1 nm). You can see that the surface bulges toward the F end of the molecule, an indication of the larger size of the F atom. The larger size of the F atom here is mainly related to the fact that it has more valence electrons than H, and to a lesser extent to the fact that the H—F bond is polar and electron density in that bond is shifted toward the F atom.

We can add another layer of information to our picture. The electron density surface can be colored according to the *electrostatic potential*. (Hence, this figure is called an *electrostatic potential surface*.) The computer program calculates the electrostatic potential that would be observed by a proton (H^+) at every point on the surface. This is the sum of the attractive and repulsive forces on that proton due to the nuclei and the electrons in the molecule. Regions of the molecule in which there is an attractive potential are colored red. That is, this is a region of negative charge on the molecule. Repulsive potentials occur in regions where the molecule is positively charged; these regions are colored blue. As might be expected, the net electrostatic potential will change continuously as one moves from a negative portion of a molecule to a positive portion, and this is indicated by a progression of colors from red to blue (from negative to positive).



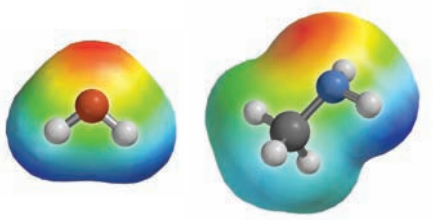


Figure A Three views of the electrostatic potential surface for HF. (*left*) The electron density surface around HF. The F atom is at the left. The surface is made up of all of the points in space around the HF molecule where the electron density is 0.002 $e^-/Å^3$ (where 1 Å = 0.1 nm). (*middle*) The surface is made more transparent, so you can see the HF atom nuclei inside the surface. (*right*) The front of the electron density surface has been "peeled away" for a view of the HF molecule inside. **Color scheme:** The colors on the electron density surface reflect the charge in the different regions of the molecule. Colors toward the blue end of the spectrum indicate a positive charge, whereas colors to the red end of the spectrum indicate a negative charge.

The electrostatic potential surface for HF shows the H atom is positive (the H atom end of the molecule is blue), and the F atom is negative (the F atom end is red). This is, of course, what we would predict based on electronegativity.

The program also calculated that the F atom has a charge of −0.3 and H has a charge of +0.3. Finally, the calculated dipole moment for the molecule is about 1.7 D, in good agreement with the experimental value in Table 8.6.

Other examples of electrostatic potential surfaces illustrate the polarity of water and methylamine, CH_3NH_2.

The surface for water shows the O atom of the molecule bears a partial negative charge and the H atoms are positive. The surface for the amine shows the molecule is polar and that the region around the N atom is negative. Indeed, we know from experiment that an H^+ ion will attack the N atom to give the cation $CH_3NH_3^+$.

water methylamine, CH_3NH_2

You will see many examples in this book in which electrostatic potential diagrams are used to illustrate important features of other molecules.

On the other hand, if one of the *X* atoms (or groups) is different in the structures in Figure 8.5 (as in Figures 8.12 and 8.13), or if one of the *X* positions is occupied by a lone pair, the molecule will be polar.

EXAMPLE 8.13

Molecular Polarity

Problem Are sulfur tetrafluoride (SF_4) and nitrogen trifluoride (NF_3) polar or nonpolar? If polar, indicate the negative and positive sides of the molecule.

What Do You Know? Based on the discussion in this chapter, you know how to derive the molecular geometry of molecules and how to decide which bonds are polar. Based on this information you can decide if the molecule is polar.

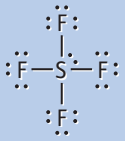
Strategy Map 8.13

PROBLEM



Is a molecule **polar**?

DATA/INFORMATION

- **Formula** of the molecule (SF_4)

STEP 1. Draw the **Lewis electron dot structure.**

Lewis structure

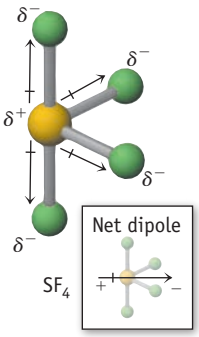
STEP 2. Decide on the **electron-pair geometry.**

Trigonal bipyramidal

STEP 3. Decide on the **molecular geometry.**

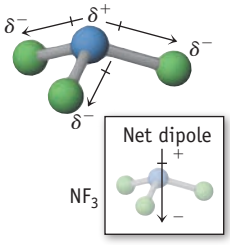
"Seesaw"

STEP 4. Decide if the molecule is **symmetrical.**



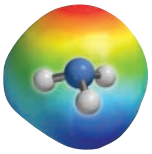
Yes → **Not** polar

No → SF_4 is **polar**

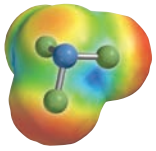


Strategy Draw the Lewis structure, decide on the electron-pair geometry, and determine the molecular geometry. Determine if the molecule is completely symmetrical. If it is, then it is nonpolar; if it is not, the molecule is polar.

SOLUTION



(a) The S—F bonds in sulfur tetrafluoride, SF_4, are polar, with F as the negative end (χ for S is 2.6 and χ for F is 4.0). The molecule has a trigonal bipyramidal electron-pair geometry (Figure 8.7). Because the lone pair occupies one of the positions, the S—F bonds are not arranged symmetrically. The axial S—F bond dipoles cancel each other because they point in opposite directions. The equatorial S—F bonds, however, both point to one side of the molecule, so SF_4 is polar.



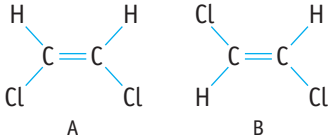
(b) NF_3 has the same trigonal-pyramidal structure as NH_3. Because F is more electronegative than N, each bond is polar, the more negative end being the F atom. Because this molecule contains polar bonds and because the geometry is not symmetrical (three positions of the tetrahedron occupied by bonding groups and one by a lone pair), the NF_3 molecule as a whole is expected to be polar.

Think about Your Answer It is interesting to compare NF_3 and NH_3. The effect of the F atoms is to make the N atom slightly positive in NF_3, whereas it is slightly negative in NH_3 when the less electronegative H atoms are attached.

NH_3

NF_3

Ammonia, $\mu = 1.47$ D Nitrogen trifluoride, $\mu = 0.23$ D



Check Your Understanding

For each of the following molecules, decide whether the molecule is polar and which side is positive and which negative: $BFCl_2$, NH_2Cl, and SCl_2.

EXAMPLE 8.14

Molecular Polarity

Problem 1,2-Dichloroethylene can exist in two forms. Is either of these planar molecules polar?

A B

What Do You Know? The structures for the two molecules are given. Note that these are planar molecules.

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

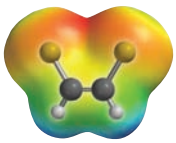
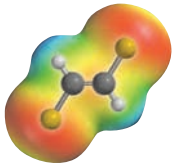
Strategy

- Use electronegativity values to decide on the bond polarity.
- Decide if the electron density in the bonds is distributed symmetrically or if it is shifted to one side of the molecule.

SOLUTION The H and Cl atoms are arranged around the C═C double bonds with all bond angles 120° (and all the atoms lie in one plane). The electronegativities of the atoms involved are in the order Cl (3.2) > C (2.5) > H (2.2). This means the C—H and C—Cl bonds are polar with a net displacement of electron density away from the H atoms and toward the Cl atoms [$H^{\delta+}$—$C^{\delta-}$ and $C^{\delta+}$—$Cl^{\delta-}$]. In structure A, the Cl atoms are located on one side of the molecule, so electrons in the H—C and C—Cl bonds are displaced toward the side of the molecule with Cl atoms and away from the side with the H atoms. Molecule A is polar. In molecule B, the displacement of electron density toward the Cl atom on one end of the molecule is counterbalanced by an opposing displacement on the other end. Molecule B is not polar.

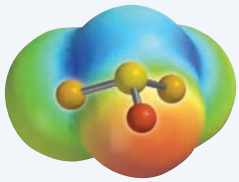


A, polar, displacement of bonding electrons to one side of the molecule



B, not polar, no net displacement of bonding electrons to one side of the molecule

Think about Your Answer The electrostatic potential surfaces reflect the fact that molecule A is polar because the electron density is shifted to one side of the molecule. Molecule B is not polar because the electron density is distributed symmetrically.



A = *cis*-1,2-dichloroethylene

B = *trans*-1,2-dichloroethylene

Check Your Understanding

The electrostatic potential surface for $SOCl_2$ is pictured here.

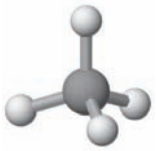
(a) Draw a Lewis electron dot picture for the molecule, and give the formal charge of each atom.

(b) What is the molecular geometry of $SOCl_2$? Is it polar?

8.9 Bond Properties: Order, Length, and Dissociation Enthalpy

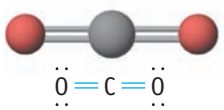
Goal for Section 8.9

- Understand the properties of covalent bonds (bond order, bond length, and bond dissociation enthalpy) and their influence on molecular structure and properties.



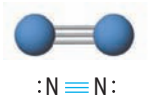
Bond Order

The **order of a bond** is the number of bonding electron pairs shared by two atoms in a molecule. You will encounter bond orders of 1, 2, and 3, as well as fractional bond orders.



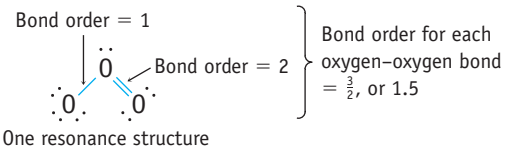
Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.



When the bond order is 1, there is only a single covalent bond between a pair of atoms. Examples are the bonds in molecules such as H_2, NH_3, and CH_4. The bond order is 2 when two electron pairs are shared between atoms, such as the C═O bonds in CO_2 and the C═C bond in ethylene, $H_2C{=}CH_2$. The bond order is 3 when two atoms are connected by three bonds. Examples include the carbon–oxygen bond in carbon monoxide, CO, and the nitrogen–nitrogen bond in N_2.

B.O. for CH = 1



B.O. for CO = 2

B.O. for NN = 3

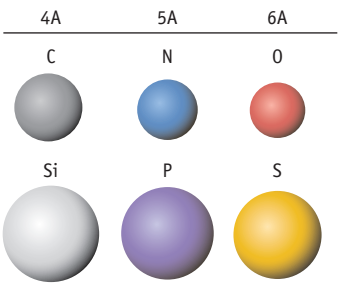
Fractional bond orders occur in molecules and ions having resonance structures. For example, what is the bond order for each oxygen–oxygen bond in O_3? Each resonance structure of O_3 has one O—O single bond and one O═O double bond, for a total of three shared bonding pairs accounting for two oxygen–oxygen links.

We can define the bond order between any bonded pair of atoms X and Y as

$$\text{Bond order} = \frac{\text{number of shared pairs in all X—Y bonds}}{\text{number of X—Y links in the molecule or ion}} \qquad (8.2)$$

For ozone, there are three bond pairs involved in two oxygen–oxygen links, so the bond order for each oxygen–oxygen bond is $^3/_2$, or 1.5.

Bond Length



Bond length, the distance between the nuclei of two bonded atoms, is clearly related to the sizes of the atoms (Section 7.5). In addition, for a given pair of atoms, the order of the bond plays a role.

Table 8.7 lists average bond lengths for a number of common chemical bonds. It is important to recognize that these are *average* values. Neighboring parts of a molecule can affect the length of a particular bond, so there can be a range of values for a particular bond type. For example, Table 8.7 gives the average C—H bond as 110 pm. However, in methane, CH_4, the measured bond length is 109.4 pm, whereas the C—H bond is only 105.9 pm long in acetylene, H—C≡C—H. Variations as great as 10% from the average values listed in Table 8.7 are possible.

Because atom sizes vary in a regular fashion with the position of the element in the periodic table (Figure 7.5), we can predict trends in bond lengths. For example, the H—X distance in the hydrogen halides increases in the order predicted by the relative sizes of the halogens: H—F < H—Cl < H—Br < H—I. Likewise, bonds between carbon and another element in a given period decrease going from left to right, in a predictable fashion; for example, C—C > C—N > C—O. Trends for multiple bonds are similar. A C═O bond is shorter than a C═S bond, and a C═N bond is shorter than a C═C bond.

The relationship between bond length and bond order is evident when bonds between the same two atoms are compared. For example, the bonds become shorter as the bond order increases in the series C—O, C═O, and C≡O:

Bond	C—O	C═O	C≡O
Bond order	1	2	3
Average bond length (pm)	143	122	113

Relative sizes of some atoms of Groups 4A, 5A, and 6A.

Bond lengths are related to atom sizes.

C—H	N—H	O—H
110	98	94 pm
Si—H	**P—H**	**S—H**
145	138	132 pm

TABLE 8.7 Some Average Single- and Multiple-Bond Lengths in Picometers (pm)*

Single Bond Lengths											
	Group										
	1A	4A	5A	6A	7A	4A	5A	6A	7A	7A	7A
	H	C	N	O	F	Si	P	S	Cl	Br	I
H	74	110	98	94	92	145	138	132	127	142	161
C		154	147	143	141	194	187	181	176	191	210
N			140	136	134	187	180	174	169	184	203
O				132	130	183	176	170	165	180	199
F					128	181	174	168	163	178	197
Si						234	227	221	216	231	250
P							220	214	209	224	243
S								208	203	218	237
Cl									200	213	232
Br										228	247
I											266

Multiple Bond Lengths			
C═C	134	C≡C	121
C═N	127	C≡N	115
C═O	122	C≡O	113
N═O	115	N≡O	108

*1 pm = 10^{-12} m.

The carbonate ion, CO_3^{2-}, has three equivalent resonance structures. Each CO bond has a bond order of 1.33 (or $^4/_3$) because four electron pairs are used to form three carbon–oxygen links. The CO bond distance (129 pm) is intermediate between a C—O single bond (143 pm) and a C═O double bond (122 pm).

Bond Dissociation Enthalpy

Bond energy, or more correctly the **bond dissociation enthalpy,** is the enthalpy change when breaking a bond in a molecule with the reactants and products *in the gas phase*. *The process of breaking bonds in a molecule is always endothermic,* so $\Delta_r H$ for bond breaking is always positive.

$$\text{Molecule (g)} \underset{\text{Energy released, } \Delta H < 0}{\overset{\text{Energy supplied, } \Delta H > 0}{\rightleftharpoons}} \text{Molecular fragments (g)}$$

Suppose you wish to break the carbon–carbon bonds in ethane ($H_3C—CH_3$), ethylene ($H_2C═CH_2$), and acetylene (HC≡CH). The carbon–carbon bond orders

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

in these molecules are 1, 2, and 3, respectively, and these bond orders are reflected in the bond dissociation enthalpies. Breaking the single C—C bond in ethane requires the least energy in this group, whereas breaking the C≡C triple bond in acetylene requires the most energy.

Variability in Bond Dissociation Enthalpies The values of $\Delta_r H$ for ethane, ethylene, and acetylene shown in the text are for the reactions of those molecules in particular. The bond dissociation enthalpies in Table 8.8 are average values for a range of molecules containing the indicated bond.

$$H_3C{-}CH_3(g) \rightarrow H_3C{\cdot}(g) + {\cdot}CH_3(g) \qquad \Delta_r H = +368 \text{ kJ/mol-rxn}$$

$$H_2C{=}CH_2(g) \rightarrow H_2C{\cdot}(g) + {\cdot}CH_2(g) \qquad \Delta_r H = +682 \text{ kJ/mol-rxn}$$

$$HC{\equiv}CH(g) \rightarrow HC{\cdot}(g) + {\cdot}CH(g) \qquad \Delta_r H = +962 \text{ kJ/mol-rxn}$$

The energy supplied to break carbon–carbon bonds must be the same as the energy released when the same bonds form. *The formation of bonds from atoms or radicals in the gas phase is always exothermic.* This means, for example, that $\Delta_r H$ for the formation of $H_3C{-}CH_3$ from two ${\cdot}CH_3(g)$ radicals is −368 kJ/mol-rxn.

$$H_3C{\cdot}\,(g) + {\cdot}CH_3(g) \rightarrow H_3C{-}CH_3(g) \qquad \Delta_r H = -368 \text{ kJ/mol-rxn}$$

Generally, the bond dissociation enthalpy for a given type of bond (a C—C bond, for example) varies somewhat, depending on the compound, just as bond lengths vary from one molecule to another. Thus, data provided in tables are *average bond dissociation enthalpies* (Table 8.8). The values in such tables may be used to *estimate* the enthalpy change for a reaction, as described below.

TABLE 8.8 Some Average Bond Dissociation Enthalpies (kJ/mol)*

Single Bonds

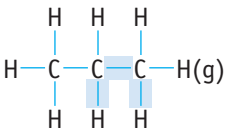
In reactions between molecules, bonds in reactants are broken, and new bonds are formed as products form. If the total energy released when new bonds form exceeds the energy required to break the original bonds, the overall reaction is predicted to be exothermic. If the opposite is true, then the overall reaction is endothermic.

Let us use bond dissociation enthalpies to estimate the enthalpy change for the hydrogenation of propene to propane:



The first step is to identify which bonds are broken and which bonds are formed. In this case, the C═C bond in propene and the H—H bond in hydrogen are broken. One C—C bond and two C—H bonds are formed.

Bonds broken: 1 mol of C═C bonds and 1 mol of H—H bonds

Energy required = 610 kJ for C═C bonds + 436 kJ for H—H bonds
= 1046 kJ/mol-rxn

Bonds formed: 1 mol of C—C bonds and 2 mol of C—H bonds

Energy evolved = 346 kJ for C—C bonds + 2 mol × 413 kJ/mol for C—H bonds
= 1172 kJ/mol-rxn

By combining the enthalpy changes for breaking bonds and for making bonds, we can estimate $\Delta_r H$ for the hydrogenation of propene and predict that the reaction will be exothermic.

$$\Delta_r H = 1046 \text{ kJ/mol-rxn} - 1172 \text{ kJ/mol-rxn} = -126 \text{ kJ/mol-rxn}$$

In general, the enthalpy change for any reaction can be estimated using Equation 8.3,

$$\Delta_r H = \Sigma \Delta H(\text{bonds broken}) - \Sigma \Delta H(\text{bonds formed}) \qquad (8.3)$$

Such calculations can give acceptable results in many cases.

$\Delta_r H$ from Enthalpies of Formation
Using $\Delta_f H°$ values for propane and propene, we calculate $\Delta_r H° = -125.1$ kJ/mol–rxn. The bond dissociation enthalpy calculation is in excellent agreement with that from enthalpies of formation in this case.

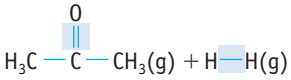
EXAMPLE 8.15

Using Bond Dissociation Enthalpies

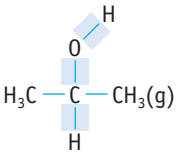
Problem Acetone, a common industrial solvent, can be converted to 2-propanol (rubbing alcohol) by hydrogenation. Calculate the enthalpy change for this reaction using bond enthalpies.

acetone 2-propanol



What Do You Know? You know the molecular structures of the reactants and the product as well as relevant bond dissociation enthalpies.

Strategy Determine which bonds are broken and which are formed. Add up the enthalpy changes for breaking bonds in the reactants and for forming bonds in the product. The difference in the sums of bond dissociation enthalpies can be used as an estimate of the enthalpy change of the reaction (Equation 8.3).



SOLUTION

Bonds broken: 1 mol of C═O bonds and 1 mol of H—H bonds

$$\Sigma\Delta H(\text{bonds broken}) = 745 \text{ kJ for C=O bonds} + 436 \text{ kJ for H—H bonds}$$
$$= 1181 \text{ kJ/mol-rxn}$$

Bonds formed: 1 mol of C—H bonds, 1 mol of C—O bonds, and 1 mol of O—H bonds

$$\Sigma\Delta H(\text{bonds formed}) = 413 \text{ kJ for C—H} + 358 \text{ kJ for C—O} + 463 \text{ kJ for O—H}$$
$$= 1234 \text{ kJ/mol-rxn}$$

$$\Delta_r H = \Sigma\Delta H(\text{bonds broken}) - \Sigma\Delta H(\text{bonds formed})$$

$$\Delta_r H = 1181 \text{ kJ} - 1234 \text{ kJ} = -53 \text{ kJ/mol-rxn}$$

Think about Your Answer The overall reaction is predicted to be exothermic by 53 kJ per mol of product formed. This is in good agreement with the value calculated from $\Delta_f H°$ values (−55.8 kJ/mol-rxn).

Check Your Understanding

Using the bond dissociation enthalpies in Table 8.8, estimate the enthalpy of combustion of gaseous methane, CH_4, to give water vapor and carbon dioxide gas.

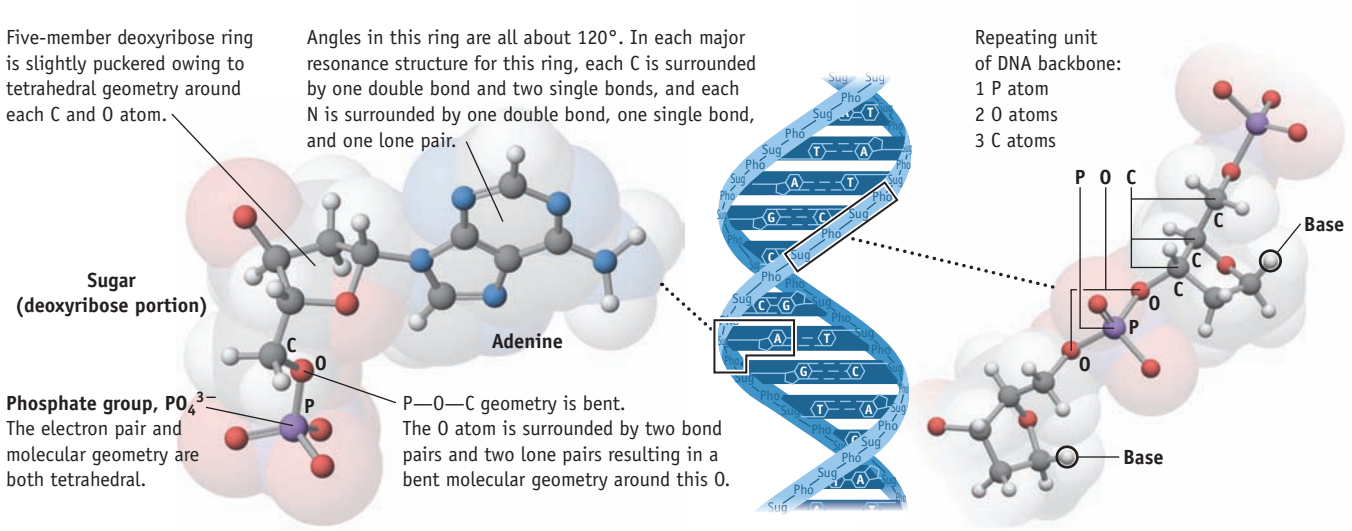
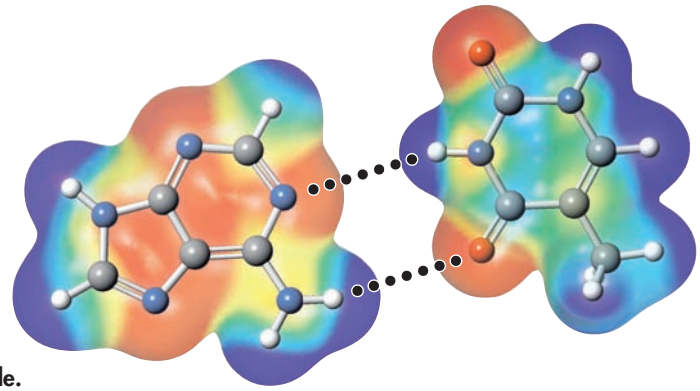
8.10 DNA, Revisited



Goal for Section 8.10

- To better understand the structure of DNA.

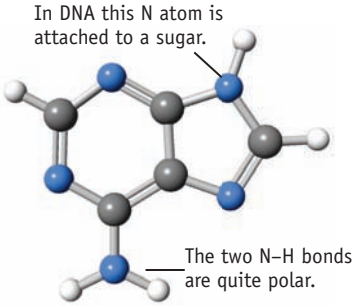


Each strand of the double-stranded DNA molecule consists of three repeating parts (Figure 8.14): a phosphate, a deoxyribose molecule (a sugar molecule with a five-member ring), and a nitrogen-containing base. (The bases in DNA can be one of four molecules: adenine, guanine, cytosine, and thymine; in Figure 8.14, the base is adenine.) Two units of the backbone (without the adenine on the deoxyribose ring) are also illustrated in Figure 8.14a.

One important point here is that the repeating unit in the backbone of DNA consists of the atoms O—P—O—C—C—C. Each atom has a tetrahedral electron-pair geometry. Therefore, the chain cannot be linear. In fact, the chain twists as one moves along the backbone, and it is this twisting that gives DNA its helical shape.

Why are there two strands in DNA with the O—P—O—C—C—C backbone on the outside of the helix and the nitrogen-containing bases on the inside? This structure arises from the polarity of the bonds in the base molecules attached to the backbone. For example, the N–H bonds in the adenine molecule are very polar, which leads to a special type of intermolecular force—hydrogen bonding—binding the adenine to thymine in the neighboring chain (Figure 8.14b). You will learn more about this in Chapter 11 when we explore intermolecular forces and also in Chapter 24, *Biochemistry*.

(a) A repeating unit consists of a phosphate portion, a deoxyribose portion (a sugar molecule with a five-member ring), and a nitrogen-containing base (here adenine) attached to the deoxyribose ring.



(b) Two of the four bases in DNA, adenine (left) and thymine (right). The electrostatic potential surfaces help to visualize where the partially charged atoms are in these molecules and how they can interact.

Figure 8.14 **Bonding in the DNA molecule.**

Adenine. All the C and N atoms of the five- and six-member rings have trigonal-planar electron pair geometry. The indicated N atom of the five-member ring is attached to a sugar in DNA.

The rings in the nitrogen-containing bases are all flat with trigonal-planar electron-pair geometry around each atom in the rings. For example, look at the electron-pair geometries in one of the bases, adenine. There are two major resonance structures for this ring system. In these, each carbon atom is surrounded by one double bond and two single bonds, leading to a trigonal-planar electron-pair geometry. Each nitrogen atom in the rings, except the one attached to the sugar, is surrounded by a double bond, a single bond, and a lone pair, likewise leading to trigonal-planar electron-pair geometries around these atoms. The nitrogen attached to the sugar, however, is different from what we would normally predict. It is surrounded by three single bonds and one lone pair. We would normally expect it to have a tetrahedral electron-pair geometry (and trigonal-pyramidal molecular geometry), but it does not. Instead, the bonding groups assume a trigonal-planar geometry, and the lone pair is in a plane perpendicular to the bonds. After studying Chapter 9, you will understand how this allows the electrons in this lone pair to interact with the electrons in the rings' double bonds in a favorable way.

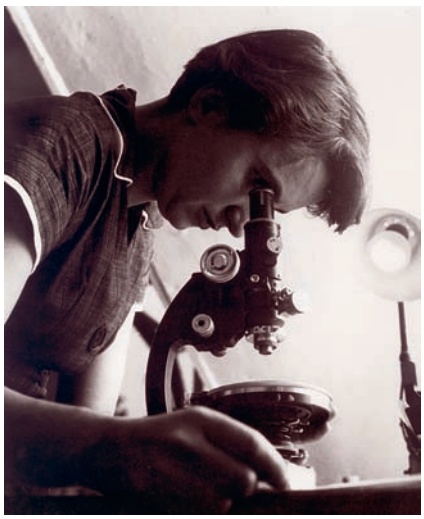
A CLOSER LOOK

DNA—Watson, Crick, Wilkins, and Franklin

DNA is the substance in every plant and animal that carries the exact blueprint of that plant or animal. The structure of this molecule, the cornerstone of life, was uncovered in 1953, and James D. Watson, Francis Crick, and Maurice Wilkins shared the 1962 Nobel Prize in Medicine and Physiology for the work. It was one of the most important scientific discoveries of the 20th century, and the story has been told by Watson in his book *The Double Helix*.

When Watson was a graduate student at Indiana University, he had an interest in the gene and said he hoped that its biological role might be solved "without my learning any chemistry." Later, however, he and Crick found out just how useful chemistry can be when they began to unravel the structure of DNA.

Watson went to Cambridge in 1951. There he met Crick, who, Watson said, talked louder and faster than anyone else. Crick shared Watson's belief in the fundamental importance of DNA, and the pair soon learned that Maurice Wilkins and Rosalind Franklin at King's College in London were using a technique called *x-ray crystallography* to learn more about DNA's structure. Watson and Crick believed that understanding this structure was crucial to understanding genetics. To solve the structural problem, however, they needed experimental data of the type that could come from the experiments at King's College.



The King's College group was initially reluctant to share their data, and, what is more, they did not seem to share Watson and Crick's sense of urgency. There was also an ethical dilemma: Could Watson and Crick work on a problem that others had claimed as theirs? "The English sense of fair play would not allow Francis to move in on Maurice's problem," said Watson.

Watson and Crick approached the problem through a technique chemists now use frequently—model building. They built models of the pieces of the DNA chain, and they tried various chemically reasonable ways of fitting them together. Finally, they discovered that one arrangement was "too pretty not to be true." Ultimately, the experimental evidence of Wilkins and Franklin confirmed the "pretty structure" to be the real DNA structure.

A. Barrington Brown/Science Source

James D. Watson (1928–) and Francis Crick (1918–2004). Watson *(right)* and Crick (*left*), together with Maurice Wilkins, received the Nobel Prize in Medicine and Physiology in 1962.

Henry Grant Collection/Museum of London

Rosalind Franklin (1920–1958). King's College, London. She died at the age of 37. Because Nobel Prizes are never awarded posthumously, she did not share in this honor with Watson, Crick, and Wilkins. See *Rosalind Franklin: The Dark Lady of DNA,* by Brenda Maddox.

8.1 Ibuprofen, A Study in Green Chemistry

Ibuprofen, $C_{13}H_{18}O_2$, (Figure A) is now one of the world's most common, over-the-counter drugs. It is an effective anti-inflammatory drug and is used to treat arthritis and similar conditions. Unlike aspirin it does not decompose in solution, so ibuprofen can be applied to the skin as a topical gel and avoid the gastrointestinal problems sometimes associated with aspirin. This question explores its structure and synthesis.

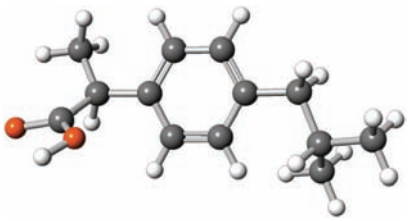

Figure A Ibuprofen, $C_{13}H_{18}O_2$

Ibuprofen was first synthesized in the 1960s by the Boots Company in England, and millions of kilograms are now sold every year. Unfortunately, the original method of making ibuprofen took six steps, wasted chemicals, and produced byproducts that required disposal. Many of the atoms of the reagents used to make the drug did not end up in the drug itself, that is, the method had a very poor atom economy (page 207). Recognizing this, chemists looked for new approaches for the synthesis of ibuprofen. A method was soon found that uses only three steps, severely reduces waste, and uses reagents that can be recovered and reused. A plant in Texas now makes more than 3 million kilograms of ibuprofen annually by the new method, enough to make over 6 billion tablets.

Questions:

1. The third and final step in the synthesis involves the transformation of an OH group with CO to a carboxylic acid group ($-CO_2H$) (Figure B). Using bond enthalpy data, is this an endothermic or exothermic step?

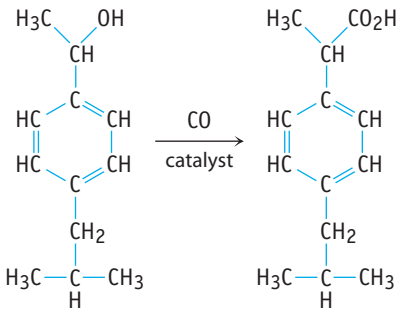

Figure B The final step in the synthesis of ibuprofen.

2. Do any of the atoms in an ibuprofen molecule have a nonzero formal charge?
3. What is the most polar bond in the molecule?
4. Is the molecule polar?
5. What is the shortest bond in the molecule?
6. What bond or bonds have the highest bond order?
7. Are there any 120° bond angles in ibuprofen? Any 180° angles?
8. If you were to titrate 200. mg of ibuprofen to the equivalence point with 0.0259 M NaOH, what volume of NaOH would be required? (Ibuprofen supplies one H^+ ion per molecule in its reaction with a base.)

8.2 van Arkel Triangles and Bonding

Two types of bonding, covalent and ionic, involve localized electrons. On one extreme are nonpolar covalent bonds, where electrons are equally shared between two atoms. On the other extreme are ionic bonds, where no sharing of electrons occurs. However, there are many bonds that fall between these extremes, and predictions of the extent of the polarity of a bond can be made using the electronegativity of the individual atoms. And finally, there is a third bonding type: metallic bonding. This raises the question of whether it is possible to develop an integrated picture wherein all three types of bonding, and their variations, can be represented. The answer is that it is possible, at least for binary compounds.

The first efforts in this direction were made by A. E. van Arkel in 1941 and modified later by J. A. A. Ketelaar. They summarized their findings in diagrams such as that shown in the Figure. Referred to now as van Arkel–Ketelaar triangles, the current version of this diagram portrays a wide variety of compounds composed of two different atoms within the boundary of an equilateral triangle. The corners represent the three types of bonding: metallic bonding at the lower left, covalent bonding on the lower right, and ionic bonding at the top. The least electronegative element (Cs), the most electronegative element (F), and the ionic compound formed from these elements are located at the corners of the triangle. All other binary compounds can be positioned inside the triangle.

Different versions of the van Arkel triangle have been developed, each using different scales on the axes. The one chosen for the Figure uses electronegativity values. Here, the *x*-axis is defined as the average of the electronegativities of the two atoms; as such, the x-axis is a measure of the localization of

Figure A van Arkel–Ketelaar diagram. The four regions of this triangle represent the locations of metallic (blue), semiconducting (green), ionic (red), and covalent (orange) compounds.

bonding electrons. The bonding electrons are completely delocalized in cesium, whereas the bonding electrons are completely localized in fluorine. The *y*-axis is defined as the difference in electronegativities. The greater the value in the *y*-axis, the greater the ionic character of the compound. With these parameters, the position of each binary compound can be assigned, associating the bond between elements with the degree of ionic/covalent/metallic character.

Questions:

1. Use electronegativity values (Figure 8.11) to place the compounds GaAs, SBr_2, Mg_3N_2, BP, C_3N_4, CuZn, and $SrBr_2$ on the van Arkel diagram and use the results to answer the following questions:
   a. Which of the compounds are metallic?
   b. Which of the compounds are semiconductors? Are either (or both) element(s) in these compounds metalloid(s)?
   c. Which of the compounds are ionic? Are the compounds composed of a metal and a nonmetal?
   d. Carbon nitride (C_3N_4) is predicted to be harder than diamond (which is currently the hardest known substance), but too little has been synthesized to enable a comparison. What type of bonding is predicted for C_3N_4?
   e. Which of the compounds are covalent? Are both elements in these compounds nonmetallic?
2. High boiling points are one characteristic of ionic compounds. For example, magnesium chloride boils at 1412 °C. Beryllium chloride, on the other hand, vaporizes at 520 °C. The boiling point of $BeCl_2$ is far lower than expected for an ionic compound, yet large for a covalent one. Determine where $BeCl_2$ lies on the van Arkel diagram.

8.3 Linus Pauling and the Origin of the Concept of Electronegativity

Linus Pauling noticed that, when he compared the bond dissociation enthalpies ($\Delta_{diss}H$) between identical atoms, say A—A or B—B, with the bond dissociation enthalpies for different atoms, A—B, the energy for the A—B bond was always larger than the average of the A—A and B—B energies.

$$\Delta_{diss}H(\text{A—B}) > 1/2\ [\Delta_{diss}H(\text{A—A}) + \Delta_{diss}H(\text{B—B})]$$

Why should this be true, and what useful information can be derived from it?

When a bond forms between two identical atoms, the bonding electrons are shared equally between the two atoms. In a bond between dissimilar atoms, the atoms do not share the electrons equally. When this is the case, one atom incurs a slightly positive charge and the other a slightly negative one. A coulombic attraction between the oppositely charged atoms increases the strength of the bond. Pauling said that this difference in energy is related to the electronegativities of the atoms involved and defined electronegativity (χ) as "the ability of an atom in a molecule to attract electrons to itself." More specifically, he said the difference he observed is mathematically related to the difference in electronegativities by

$$\chi_A - \chi_B = 0.102\sqrt{\Delta_{diss}H(AB) - \frac{\Delta_{diss}H(AA) + \Delta_{diss}H(BB)}{2}}$$

Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Using bond dissociation enthalpies, Pauling calculated electronegativity values for many elements by assigning fluorine a value of 4.0. Because they are so useful, Pauling's values have been continually refined since Pauling's 1932 publication, but Pauling's calculated electronegativity values are close to those computed today.

A variety of methods for quantifying electronegativity values have been developed since Pauling's initial work. One notable method, developed by Robert Mulliken (1896–1986) in 1934, calculates electronegativity values for individual elements using ionization energy (IE) and the electron attachment enthalpy ($\Delta_{EA}H$). The electronegativity of an element may be calculated from the following equation,

$$\chi_A = 1.97 \times 10^{-3} (IE - \Delta_{EA}H) + 0.19$$

where the ionization energy and $\Delta_{EA}H$ have units of kJ/mol.

Questions:

1. Calculate the difference in electronegativity between hydrogen and chlorine ($\chi_{Cl} - \chi_H$) in hydrogen chloride using average bond dissociation enthalpy values (Table 8.8). Compare your results with those calculated using electronegativity values from Figure 8.11.
2. Predict the bond dissociation enthalpy for a nitrogen–iodine bond in NI_3 using bond dissociation enthalpy values (Table 8.8) and electronegativity values (Figure 8.11).
3. Calculate the electronegativity of sulfur atoms using ionization energy and electron attachment enthalpy values (Appendix F). Compare the value with the one in Figure 8.11.

CHAPTER GOALS REVISITED

The goals for this chapter are keyed to specific Study Questions to help you organize your review.

8.1 Chemical Bond Formation and Lewis Electron Dot Structures

- Draw Lewis electron dot structures for atoms and ions. 1

8.2 Covalent Bonding and Lewis Structures

- Apply the octet rule when drawing Lewis electron dot structures for simple molecules and polyatomic ions. 5–8, 59, 60.

8.3 Atom Formal Charges in Covalent Molecules and Ions

- Understand the meaning of atom formal charge and calculate the formal charge on each atom in a molecule or polyatomic ion. 1, 13–16, 38.

8.4 Resonance

- Draw resonance structures for simple molecules and polyatomic ions, understand what resonance means, and know how and when to use resonance to represent bonding. 9, 10, 33, 37, 64, 66.

8.5 Exceptions to the Octet Rule

- Recognize molecules and polyatomic ions that do not obey the octet rule and draw reasonable Lewis electron dot structures for them. 59, 60.

8.6 Molecular Shapes

- Use the valence shell electron-pair repulsion (VSEPR) theory to predict the shapes of simple molecules and polyatomic ions and to understand the structures of more complex molecules. (Table 8.9 is a summary of the relation between valence electron pairs, electron-pair and molecular geometry, and molecular polarity.) 17–24.

TABLE 8.9 Summary of Molecular Shapes and Molecular Polarity

Pairs of Valence Electrons	Electron-Pair Geometry	Number of Bond Pairs	Number of Lone Pairs	Molecular Geometry	Molecular Dipole?*	Examples
2	Linear	2	0	Linear	No	$BeCl_2$
3	Trigonal planar	3	0	Trigonal planar	No	BF_3, BCl_3
		2	1	Bent	Yes	$SnCl_2(g)$
4	Tetrahedral	4	0	Tetrahedral	No	CH_4, BF_4^-
		3	1	Trigonal pyramidal	Yes	NH_3, PF_3
		2	2	Bent	Yes	H_2O, SCl_2
5	Trigonal bipyramidal	5	0	Trigonal bipyramidal	No	PF_5
		4	1	Seesaw	Yes	SF_4
		3	2	T-shaped	Yes	ClF_3
		2	3	Linear	No	XeF_2, I_3^-
6	Octahedral	6	0	Octahedral	No	SF_6, PF_6^-
		5	1	Square pyramidal	Yes	ClF_5
		4	2	Square planar	No	XeF_4

*For molecules of AX_n, where the X atoms are identical.

8.7 Electronegativity and Bond Polarity

- Understand electronegativity and use it to determine the polarity of bonds. **27, 29.**
- Use electronegativity and formal charge to predict the charge distribution in molecules and polyatomic ions. **31–38, 79, 80.**

8.8 Molecular Polarity

- Predict the polarity of molecules and understand why some molecules are polar whereas others are nonpolar. **39–42, 82, 83b, 86.**

8.9 Bond Properties: Order, Length, and Dissociation Enthalpy

- Understand the properties of covalent bonds (bond order, bond length, and bond dissociation enthalpy) and their influence on molecular structure and properties. **43–46, 49–52, 62, 73, 85.**

8.10 DNA, Revisited

- To better understand the structure of DNA. **92–94.**

KEY EQUATION

Equation 8.1 (page 363) Used to calculate the formal charge on an atom in a molecule.

$$\text{Formal charge of an atom in a molecule or ion} = \text{NVE} - [\text{LPE} + \tfrac{1}{2}(\text{BE})]$$

Equation 8.2 (page 390) Used to calculate bond order.

$$\text{Bond order} = \frac{\text{number of shared pairs in all X—Y bonds}}{\text{number of X—Y links in the molecule or ion}}$$

Equation 8.3 (page 393) Used to estimate the enthalpy change for a reaction using bond dissociation enthalpies.

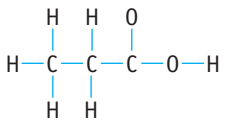
$$\Delta_r H = \Sigma \Delta H(\text{bonds broken}) - \Sigma \Delta H(\text{bonds formed})$$

STUDY QUESTIONS

▲ denotes challenging questions. **Blue-numbered questions** have answers in Appendix N and fully worked solutions in the *Student Solutions Manual*.

Practicing Skills

Valence Electrons and the Octet Rule



(See Section 8.1.)

1. Give the periodic group number and number of valence electrons for each of the following atoms.
   (a) O (d) Mg
   (b) B (e) F
   (c) Na (f) S
2. Give the periodic group number and number of valence electrons for each of the following atoms.
   (a) C (d) Si
   (b) Cl (e) Se
   (c) Ne (f) Al
3. For elements in Groups 4A–7A of the periodic table, give the number of bonds an element is expected to form (in an uncharged molecule) if it obeys the octet rule.
4. Which of the following elements are capable of forming hypervalent compounds?
   (a) C (e) Cl
   (b) P (f) B
   (c) O (g) Se
   (d) F (h) Sn

Lewis Electron Dot Structures

(See Sections 8.2, 8.4, and 8.5; Examples 8.1–8.4 and 8.6–8.7.)

5. Draw a Lewis structure for each of the following molecules or ions.
   (a) NF_3 (c) HOBr
   (b) ClO_3^- (d) SO_3^{2-}
6. Draw a Lewis structure for each of the following molecules or ions:
   (a) CS_2
   (b) BF_4^-
   (c) HNO_2 (where the arrangement of atoms is HONO)
   (d) $OSCl_2$ (where S is the central atom)
7. Draw a Lewis structure for each of the following molecules:
   (a) chlorodifluoromethane, $CHClF_2$
   (b) propanoic acid, $C_2H_5CO_2H$ (basic structure pictured below)

   (c) acetonitrile, CH_3CN (the framework is $H_3C—C—N$)
   (d) allene, H_2CCCH_2

8. Draw a Lewis structure for each of the following molecules:
   (a) methanol, CH_3OH
   (b) vinyl chloride, $H_2C{=}CHCl$, the molecule from which PVC plastics are made
   (c) acrylonitrile, $H_2C{=}CHCN$, the molecule from which materials such as Orlon are made

9. Show all possible resonance structures for each of the following molecules:
   (a) sulfur dioxide, SO_2
   (b) nitrous acid, HNO_2
   (c) thiocyanic acid, HSCN

10. Show all possible resonance structures for each of the following molecules or ions:
   (a) nitrate ion, NO_3^-
   (b) nitric acid, HNO_3
   (c) dinitrogen monoxide (nitrous oxide, laughing gas), N_2O (where the bonding is in the order N—N—O)

11. Draw a Lewis structure for each of the following molecules or ions:
   (a) BrF_3
   (b) I_3^-
   (c) XeO_2F_2
   (d) XeF_3^+

12. Draw a Lewis structure for each of the following molecules or ions:
   (a) BrF_5
   (b) IF_3
   (c) IBr_2^-
   (d) BrF_2^+

Formal Charge

(See Section 8.3 and Example 8.5.)

13. Determine the formal charge on each atom in the following molecules or ions:
   (a) N_2H_4
   (b) PO_4^{3-}
   (c) BH_4^-
   (d) NH_2OH

14. Determine the formal charge on each atom in the following molecules or ions:
   (a) SCO
   (b) HCO_2^- (formate ion)
   (c) CO_3^{2-}
   (d) HCO_2H (formic acid)

15. Determine the formal charge on each atom in the following molecules and ions:
   (a) NO_2^+
   (b) NO_2^-
   (c) NF_3
   (d) HNO_3

16. Determine the formal charge on each atom in the following molecules and ions:
   (a) SO_2
   (b) $OSCl_2$
   (c) O_2SCl_2
   (d) FSO_3^-

Molecular Geometry

(See Section 8.6 and Examples 8.8–8.10.)

17. Draw a Lewis structure for each of the following molecules or ions. Describe the electron-pair geometry and molecular geometry around the central atom.
   (a) NH_2Cl
   (b) Cl_2O (O is the central atom)
   (c) SCN^-
   (d) HOF

18. Draw a Lewis structure for each of the following molecules or ions. Describe the electron-pair geometry and molecular geometry around the central atom.
   (a) ClF_2^+
   (b) $SnCl_3^-$
   (c) PO_4^{3-}
   (d) CS_2

19. The following molecules or ions all have two oxygen atoms attached to a central atom. Draw a Lewis structure for each one, and then describe the electron-pair geometry and molecular geometry around the central atom. Comment on similarities and differences in the series.
   (a) CO_2
   (b) NO_2^-
   (c) O_3
   (d) ClO_2^-

20. The following molecules or ions all have three oxygen atoms attached to a central atom. Draw a Lewis structure for each one, and then describe the electron-pair geometry and molecular geometry around the central atom. Comment on similarities and differences in the series.
   (a) CO_3^{2-}
   (b) NO_3^-
   (c) SO_3^{2-}
   (d) ClO_3^-

21. Draw a Lewis structure for each of the following molecules or ions. Describe the electron-pair geometry and molecular geometry around the central atom.
   (a) ClF_2^-
   (b) ClF_3
   (c) ClF_4^-
   (d) ClF_5

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

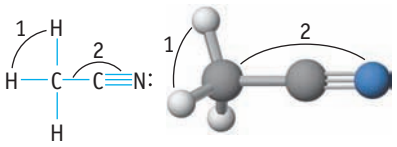
22. Draw a Lewis structure for each of the following molecules or ions. Describe the electron-pair geometry and molecular geometry around the central atom.

(a) SiF_6^{2-} (c) SF_4

(b) PF_5 (d) XeF_4



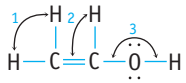
23. Give approximate values for the indicated bond angles.

(a) O—S—O angle in SO_2

(b) F—B—F angle in BF_3

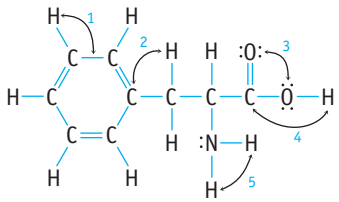
(c) Cl—C—Cl angle in Cl_2CO

(d) H—C—H (angle 1) and C—C≡N (angle 2) in acetonitrile



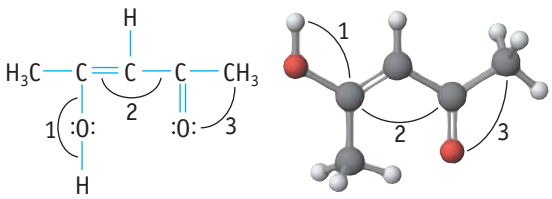
Acetonitrile

24. Give approximate values for the indicated bond angles:



(a) Cl—S—Cl in SCl_2

(b) N—N—O in N_2O



(c) Bond angles 1, 2, and 3 in vinyl alcohol (a component of polymers and a molecule found in outer space)

25. Phenylalanine is one of the natural amino acids and is a "breakdown" product of the artificial sweetener aspartame. Estimate the values of the indicated angles in the amino acid. Explain why the $—CH_2—CH(NH_2)—CO_2H$ chain is not linear.

26. Acetylacetone has the structure shown here. Estimate the values of the indicated angles.

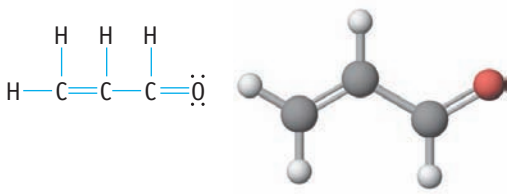
Acetylacetone

Bond Polarity, Electronegativity, and Formal Charge

(See Section 8.7 and Examples 8.11 and 8.12.)

27. For each pair of bonds, indicate the more polar bond, and use an arrow to show the direction of polarity in each bond.

(a) C—O and C—N (c) B—O and B—S



(b) P—Br and P—Cl (d) B—F and B—I

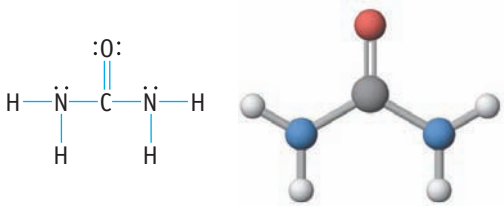
28. For each of the bonds listed below, tell which atom is the more negatively charged.

(a) C—N (c) C—Br

(b) C—H (d) S—O

29. Acrolein, C_3H_4O, is the starting material for certain plastics.

Acrolein



(a) Which bonds in the molecule are polar, and which are nonpolar?

(b) Which is the most polar bond in the molecule? Which is the more negative atom of this bond?

30. Urea, $(NH_2)_2CO$, is used in plastics and fertilizers. It is also the primary nitrogen-containing substance excreted by humans.

(a) Which bonds in the molecule are polar, and which are nonpolar?

(b) Which is the most polar bond in the molecule? Which atom is the negative end of the bond dipole?

Urea

31. Considering both formal charges and bond polarities, predict on which atom or atoms the negative charge resides in the following anions:

(a) OH^-

(b) BH_4^-

(c) $CH_3CO_2^-$

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

32. Considering both formal charge and bond polarities, predict on which atom or atoms the positive charge resides in the following cations:

(a) H_3O^+ (c) NO_2^+

(b) NH_4^+ (d) NF_4^+

33. Three resonance structures are possible for dinitrogen monoxide, N_2O.

(a) Draw the three resonance structures.

(b) Calculate the formal charge on each atom in each resonance structure.

(c) Based on formal charges and electronegativity, predict which resonance structure is the most reasonable.

34. Three resonance structures are possible for the thiocyanate ion, SCN^-.

(a) Draw the three resonance structures.

(b) Calculate the formal charge on each atom in each resonance structure.

(c) Based on formal charges and electronegativity, predict which resonance structure most closely approximates the bonding in this ion?

(d) What are the similarities and differences of bonding in SCN^- compared to the bonding in OCN^- (page 382).

35. Compare the electron dot structures of the hydrogen carbonate ion and nitric acid.

(a) Are these species isoelectronic?

(b) How many resonance structures does each species have?

(c) What are the formal charges of each atom in these species?

(d) Compare the two species with respect to their acid-base behavior. (Can either or both species behave as a base and form a bond to H^+?)

36. Compare the electron dot structures of the carbonate (CO_3^{2-}) and borate (BO_3^{3-}) ions.

(a) Are these ions isoelectronic?

(b) How many resonance structures does each ion have?

(c) What are the formal charges of each atom in these ions?

(d) If an H^+ ion attaches to CO_3^{2-} to form the bicarbonate ion, HCO_3^-, does it attach to an O atom or to the C atom?

37. The chemistry of the nitrite ion and HNO_2:

(a) Two resonance structures are possible for NO_2^-. Draw these structures, and then find the formal charge on each atom in each resonance structure.

(b) In forming the acid HNO_2 an H^+ ion attaches to the O atom and not the N atom of NO_2^-. Explain why you would predict this result.

(c) Two resonance structures are possible for HNO_2. Draw these structures, and then find the formal charge on each atom in each resonance structure. Is either of these structures strongly preferred over the other?

38. Draw the resonance structures for the formate ion, HCO_2^-, and find the formal charge on each atom. If an H^+ ion is attached to HCO_2^- (to form formic acid), does it attach to C or O?

Molecular Polarity

(See Section 8.8 and Examples 8.13 and 8.14.)

39. Consider the following molecules:

(a) H_2O (c) CO_2 (e) CCl_4

(b) NH_3 (d) ClF

(i) In which compound are the bonds most polar?

(ii) Which compounds in the list are *not* polar?

(iii) Which atom in ClF is more negatively charged?

40. Consider the following molecules:

(a) CH_4 (c) BF_3

(b) NH_2Cl (d) CS_2

(i) In which compound are the bonds most polar?

(ii) Which compounds are *not* polar?

(iii) Are the H atoms in NH_2Cl negative or positive?

41. Which of the following molecules is(are) polar? For each polar molecule, indicate the direction of polarity—that is, which is the negative end, and which is the positive end of the molecule.

(a) $BeCl_2$ (c) CH_3Cl

(b) HBF_2 (d) SO_3

42. Which of the following molecules is(are) not polar? For each polar molecule, indicate the direction of polarity—that is, which is the negative end and which is the positive end.

(a) BCl_3 (c) PCl_3

(b) CF_4 (d) GeH_4

Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Bond Order and Bond Length

(See Section 8.9.)

43. Give the bond order for each bond in the following molecules or ions:

(a) CH_2O (c) NO_2^+

(b) SO_3^{2-} (d) NOCl

44. Give the bond order for each bond in the following molecules or ions:

(a) CN^- (c) SO_3

(b) CH_3CN (d) $CH_3CH{=}CH_2$

45. In each pair of bonds, predict which is shorter.

(a) B—Cl or Ga—Cl (c) P—S or P—O

(b) Sn—O or C—O (d) C═O or C═N

46. In each pair of bonds, predict which is shorter.

(a) Si—N or Si—O

(b) Si—O or C—O

(c) C—F or C—Br

(d) The C—N bond or the C≡N bond in $H_2NCH_2C{\equiv}N$

47. Consider the nitrogen–oxygen bond lengths in NO_2^+, NO_2^-, and NO_3^-. In which ion is the bond predicted to be longest? In which is it predicted to be the shortest? Explain briefly.

48. Compare the carbon–oxygen bond lengths in the formate ion (HCO_2^-), in methanol (CH_3OH), and in the carbonate ion (CO_3^{2-}). In which species is the carbon–oxygen bond predicted to be longest? In which is it predicted to be shortest? Explain briefly.

Bond Strength and Bond Dissociation Enthalpy

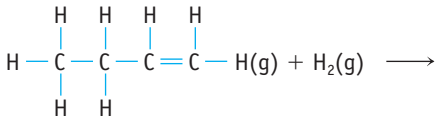
(See Section 8.9, Table 8.8, and Example 8.15.)

49. Consider the carbon–oxygen bond in formaldehyde (CH_2O) and carbon monoxide (CO). In which molecule is the CO bond shorter? In which molecule is the CO bond stronger?

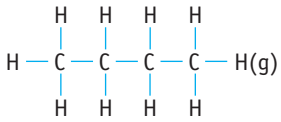
50. Compare the nitrogen–nitrogen bond in hydrazine, H_2NNH_2, with that in "laughing gas," N_2O. In which molecule is the nitrogen–nitrogen bond shorter? In which is the bond stronger?

51. Ethanol can be made by the reaction of ethylene and water:

$$H_2C{=}CH_2(g) + H_2O(g) \rightarrow CH_3CH_2OH(g)$$



Use bond dissociation enthalpies to estimate the enthalpy change in this reaction. Compare the value obtained to the value calculated from enthalpies of formation.



52. Methanol can be made by partial oxidation of methane using O_2 in the presence of a catalyst:

$$2\ CH_4(g) + O_2(g) \rightarrow 2\ CH_3OH(\ell)$$

Use bond dissociation enthalpies to estimate the enthalpy change for this reaction. Compare the value obtained to the value calculated using standard enthalpies of formation.

53. Hydrogenation reactions, which involve the addition of H_2 to a molecule, are widely used in industry to transform one compound into another. For example, 1-butene (C_4H_8) is converted to butane (C_4H_{10}) by addition of H_2.

Use the bond dissociation enthalpies in Table 8.8 to estimate the enthalpy change for this hydrogenation reaction.

54. Phosgene, Cl_2CO, is a highly toxic gas that was used as a weapon in World War I. Using the bond dissociation enthalpies in Table 8.8, estimate the enthalpy change for the reaction of carbon monoxide and chlorine to produce phosgene.

$$CO(g) + Cl_2(g) \rightarrow Cl_2CO(g)$$

55. The compound oxygen difluoride is quite reactive, giving oxygen and HF when treated with water:

$$OF_2(g) + H_2O(g) \rightarrow O_2(g) + 2\ HF(g)$$

$$\Delta_r H^\circ = -318\ \text{kJ/mol-rxn}$$

Using bond dissociation enthalpies, calculate the bond dissociation enthalpy of the O—F bond in OF_2.

56. Oxygen atoms can combine with ozone to form oxygen:

$$O_3(g) + O(g) \rightarrow 2\ O_2(g)$$

$$\Delta_r H^\circ = -392\ \text{kJ/mol-rxn}$$

Using $\Delta_r H^\circ$ and the bond dissociation enthalpy data in Table 8.8, estimate the bond dissociation enthalpy for the oxygen–oxygen bond in ozone, O_3. How does your estimate compare with the energies of an O—O single bond and an O═O double bond? Does the oxygen–oxygen bond dissociation enthalpy in ozone correlate with its bond order?

General Questions

These questions are not designated as to type or location in the chapter. They may combine several concepts.

57. Specify the number of valence electrons for Li, Ti, Zn, Si, and Cl.

58. In boron compounds, the B atom often is not surrounded by four valence electron pairs. Illustrate this with BCl_3. Show how the molecule can achieve an octet configuration by forming a coordinate covalent bond with ammonia (NH_3).

59. Which of the following compounds or ions do *not* have an octet of electrons surrounding the central atom: BF_4^-, SiF_4, SeF_4, BrF_4^-, XeF_4?

60. In which of the following does the central atom obey the octet rule: NO_2, SF_4, NH_3, SO_3, ClO_2, and ClO_2^-? Are any of these species odd-electron molecules or ions?

61. Draw resonance structures for the formate ion, HCO_2^- and then determine the C—O bond order in the ion.

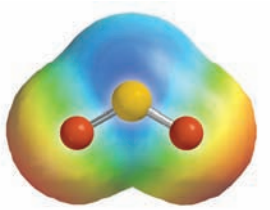
62. Consider a series of molecules in which carbon is attached by single covalent bonds to atoms of second-period elements: C—O, C—F, C—N, C—C, and C—B. Place these bonds in order of increasing bond length.

63. To estimate the enthalpy change for the reaction

$$O_2(g) + 2\ H_2(g) \rightarrow 2\ H_2O(g)$$

what bond dissociation enthalpies do you need? Outline the calculation, being careful to show correct algebraic signs.

64. What is the principle of electroneutrality? Use this rule to exclude a possible resonance structure of CO_2.



65. Draw Lewis structures (and resonance structures where appropriate) for the following molecules and ions. What similarities and differences are there in this series?

(a) CO_2

(b) N_3^-

(c) OCN^-

66. Draw resonance structures for the SO_2 molecule, and determine the formal charges on the S and O atoms. Are the S—O bonds polar, and is the molecule as a whole polar? If so, what is the direction of the net dipole in SO_2? Is your prediction confirmed by the electrostatic potential surface? Explain briefly.

Electrostatic potential surface for sulfur dioxide

67. What are the orders of the N—O bonds in NO_2^- and NO_2^+? The nitrogen–oxygen bond length in one of these ions is 110 pm and 124 pm in the other. Which bond length corresponds to which ion? Explain briefly.

68. Which has the greater O—N—O bond angle, NO_2^- or NO_2^+? Explain briefly.

69. Compare the F—Cl—F angles in ClF_2^+ and ClF_2^-. Using Lewis structures, determine the approximate bond angle in each ion. Which ion has the greater bond angle?

70. Draw an electron dot structure for the cyanide ion, CN^-. In aqueous solution, this ion interacts with H^+ to form the acid. Should the acid formula be written as HCN or CNH?

71. Draw the electron dot structure for the sulfite ion, SO_3^{2-}. In aqueous solution, the ion interacts with H^+. Predict whether a H^+ ion will attach to the S atom or the O atom of SO_3^{2-}.

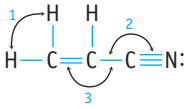
72. Dinitrogen monoxide, N_2O, can decompose to nitrogen and oxygen gas:

$$2\ N_2O(g) \rightarrow 2\ N_2(g) + O_2(g)$$

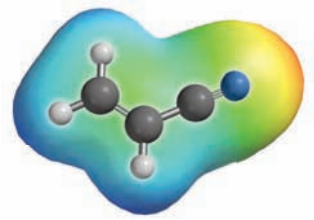
Use bond dissociation enthalpies to estimate the enthalpy change for this reaction.

73. ▲ The equation for the combustion of gaseous methanol is

$$2\ CH_3OH(g) + 3\ O_2(g) \rightarrow 2\ CO_2(g) + 4\ H_2O(g)$$



(a) Using the bond dissociation enthalpies in Table 8.8, estimate the enthalpy change for this reaction. What is the enthalpy of combustion of one mole of gaseous methanol?



(b) Compare your answer in part (a) with the value of $\Delta_f H°$ calculated using enthalpies of formation data.

Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

74. ▲ Acrylonitrile, C_3H_3N, is the building block of the synthetic fiber Orlon.

Electrostatic potential surface for acrylonitrile

(a) Give the approximate values of angles 1, 2, and 3.

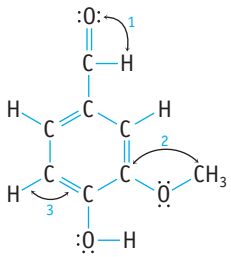
(b) Which is the shorter carbon–carbon bond?

(c) Which is the stronger carbon–carbon bond?

(d) Based on the electrostatic potential surface, where are the positive and negative charges located in the molecule?

(e) Which is the most polar bond?

(f) Is the molecule polar?



75. ▲ The cyanate ion, OCN^-, has the least electronegative atom, C, in the center. The unstable fulminate ion, CNO^-, has the same molecular formula, but the N atom is in the center.

(a) Draw the three possible resonance structures of CNO^-.

(b) On the basis of formal charges, decide on the resonance structure with the most reasonable distribution of charge.

(c) Mercury fulminate is so unstable it is used in blasting caps for dynamite. Can you offer an explanation for this instability? (*Hint:* Are the formal charges in any resonance structure reasonable in view of the relative electronegativities of the atoms?)

76. Vanillin is the flavoring agent in vanilla extract and in vanilla ice cream. Its structure is shown here:

(a) Give values for the three bond angles indicated.

(b) Indicate the shortest carbon–oxygen bond in the molecule.

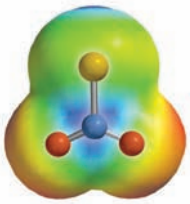
(c) Indicate the most polar bond in the molecule.

77. ▲ Explain why

(a) XeF_2 has a linear molecular structure and not a bent one.

(b) ClF_3 has a T-shaped structure and not a trigonal-planar one.

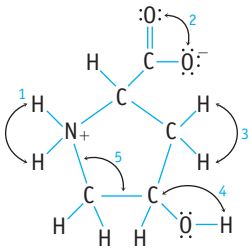
78. The formula for nitryl chloride is $ClNO_2$ (in which N is the central atom).



(a) Draw the Lewis structure for the molecule, including all resonance structures.

(b) What is the N—O bond order?

(c) Describe the electron-pair and molecular geometries, and give values for all bond angles.

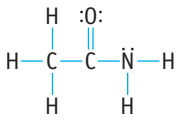


(d) What is the most polar bond in the molecule? Is the molecule polar?

(e) ▲ The computer program used to calculate electrostatic potential surfaces gave the following charges on atoms in the molecule: A = −0.03, B = −0.26, and C = +0.56. Identify the atoms A, B, and C. Are these calculated charges in accord with your predictions?

Electrostatic potential surface for $ClNO_2$

79. Hydroxyproline is a less-common amino acid.



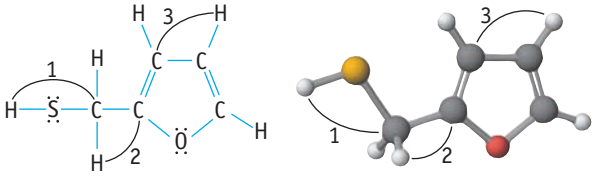
(a) Give approximate values for the indicated bond angles.

(b) Which are the most polar bonds in the molecule?

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

80. Amides are an important class of organic molecules. They are usually drawn as sketched here, but another resonance structure is possible.



(a) Draw a second resonance structure of the structure above. Do you think that this should be a significant contributor to the bonding? Explain your answer.

(b) The H—N—H angle is close to 120° in this molecule. Does this fact influence your thoughts on the importance of this structure?

81. Use the bond dissociation enthalpies in Table 8.8 to estimate the enthalpy change for the decomposition of urea (Question 30) to hydrazine, $H_2N—NH_2$, and carbon monoxide. (Assume all compounds are in the gas phase.)

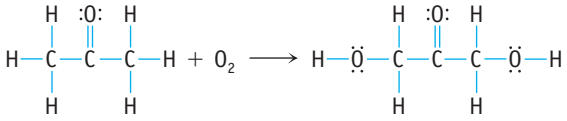
82. The molecule shown here, 2-furylmethanethiol, is responsible for the aroma of coffee:

2-Furylmethanethiol

(a) What are the formal charges on the S and O atoms?

(b) Give approximate values of angles 1, 2, and 3.

(c) Which are the shorter carbon–carbon bonds in the molecule?



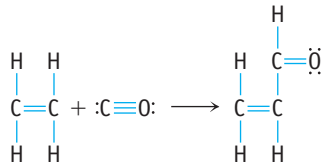
(d) Which bond in this molecule is the most polar?

(e) Is the molecule polar or nonpolar?

(f) The four C atoms of the ring are all in a plane. Is the O atom in that same plane (making the five-member ring planar), or is the O atom bent above or below the plane?

83. ▲ Dihydroxyacetone is a component of quick-tanning lotions. (It reacts with the amino acids in the upper layer of skin and colors them brown in a reaction similar to that occurring when food is browned as it cooks.)

(a) Use bond dissociation enthalpies to estimate the enthalpy change for the following reaction. Is the reaction exothermic or endothermic?



Acetone **Dihydroxyacetone**

(b) Are dihydroxyacetone and acetone polar molecules?

(c) A proton (H^+) can be removed from a molecule of dihydroxyacetone with strong bases (which is in part what happens in the tanning reaction). Which H atoms are the most positive in dihydroxyacetone?

84. It is possible to draw three resonance structures for HNO_3, one of which contributes much less to the resonance hybrid than the other two. Sketch the three resonance structures, and assign a formal charge to each atom. Which one of your structures is the least important?

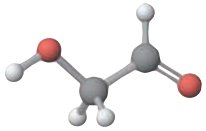
85. ▲ Acrolein is used to make plastics. Suppose this compound can be prepared by inserting a carbon monoxide molecule into the C—H bond of ethylene.

Ethylene **Acrolein**

(a) Which is the stronger carbon–carbon bond in acrolein?

(b) Which is the longer carbon–carbon bond in acrolein?

(c) Is ethylene or acrolein polar?



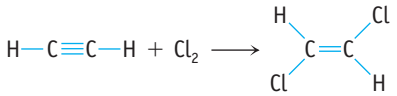
(d) Use bond dissociation enthalpies to predict whether the reaction of CO with C_2H_4 to give acrolein is endothermic or exothermic.

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

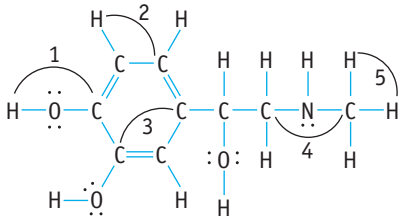
86. Molecules in space:

(a) In addition to molecules such as CO, HCl, H_2O, and NH_3, glycolaldehyde has been detected in outer space. Is the molecule polar?

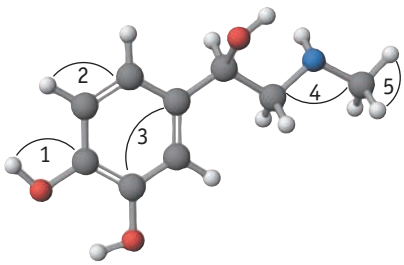


$HOCH_2CHO$, glycolaldehyde

(b) Where do the positive and negative charges lie in the molecule?



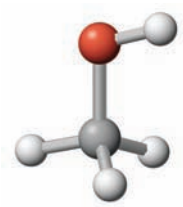
(c) One molecule found in the 1995 Hale-Bopp comet is HC_3N. Suggest a structure for this molecule.



87. 1,2-Dichloroethylene can be synthesized by adding Cl_2 to the carbon–carbon triple bond of acetylene.

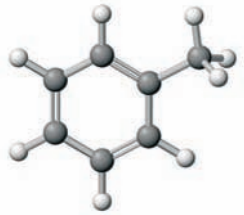
Using bond dissociation enthalpies, estimate the enthalpy change for this reaction in the gas phase.

88. The molecule pictured below is epinephrine, a compound used as a bronchodilator and antiglaucoma agent.



Epinephrine

(a) Give a value for each of the indicated bond angles.

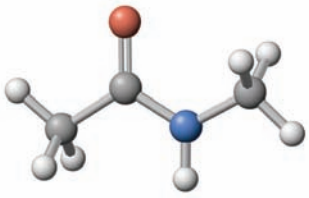


(b) What are the most polar bonds in the molecule?

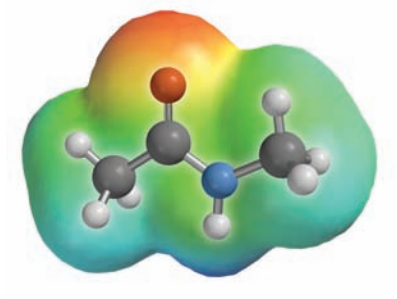
In the Laboratory

89. You are doing an experiment in the laboratory and want to prepare a solution in a polar solvent. Which solvent would you choose, methanol (CH_3OH) or toluene ($C_6H_5CH_3$)? Explain your choice.

Methanol



Toluene



90. Methylacetamide, $CH_3CONHCH_3$, is a small molecule with an amide link (CO—NH), the group that binds one amino acid to another in proteins.

(a) Is this molecule polar?

(b) Where do you expect the positive and negative charges to lie in this molecule? Does the electrostatic potential surface confirm your predictions?

Methylacetamide
Ball-and-stick model

Electrostatic potential surface

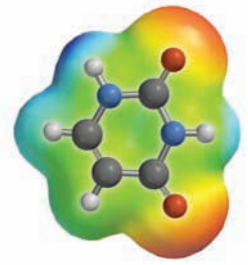
91. ▲ A paper published in the research journal *Science* in 2007 (S. Vallina and R. Simo, *Science*, Vol. 315, p. 506, January 26, 2007) reported studies of dimethylsulfide (DMS), an important greenhouse gas that is released by marine phytoplankton. This gas "represents the largest natural source of atmospheric sulfur and a major precursor of hygroscopic (i.e., cloud-forming) particles in clean air over the remote oceans, thereby acting to reduce the amount of solar radiation that crosses the atmosphere and is absorbed by the ocean."

(a) Sketch the Lewis structure of dimethylsulfide, CH_3SCH_3, and list the bond angles in the molecule.



(b) Use electronegativities to decide where the positive and negative charges lie in the molecule. Is the molecule polar?

(c) The mean seawater concentration of DMS in the ocean in the region between 15° north latitude and 15° south latitude is 2.7 nM (nanomolar). How many molecules of DMS are present in 1.0 m^3 of seawater?

92. Uracil is one of the bases in RNA, a close relative of DNA.

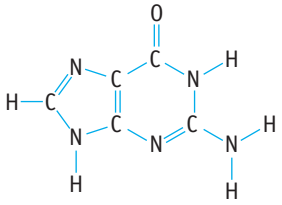
Uracil, $C_4H_4N_2O_2$

Electrostatic potential surface for uracil

(a) What are the values of the O—C—N and C—N—H angles?

(b) There are two carbon–carbon bonds in the molecule. Which is predicted to be shorter?

(c) If a proton (H+) attacks the molecule, decide on the basis of the electrostatic potential surface to which atom or atoms it could be attached.

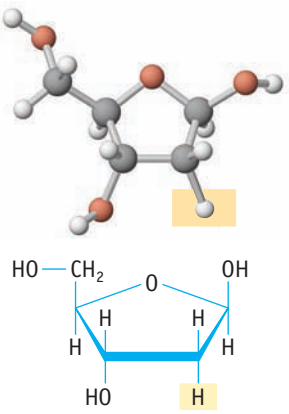


93. Guanine is present in both DNA and RNA.

(a) What is the most polar bond in the molecule?

(b) What is the N–C=N angle in the 6-member ring?

(c) What is the N–C=N angle in the 5-member ring?



(d) What is the bond angle around the N atom of the NH_2 group?

Guanine

Guanine

94. The backbone of both DNA and RNA consists of alternating deoxyribose and phophate groups (Figure 8.14).

2-Deoxyribose

(a) Rank the types of bonds (such as C–C, C–O) in 2-deoxyribose in terms of increasing polarity.

(b) What are the expected C–O–C, O–C–C, and C–C–C bond angles in the C_4O ring?

Summary and Conceptual Questions

The following questions may use concepts from this and previous chapters.

95. White phosphorus exists as P_4 molecules with phosphorus atoms at the corners of a tetrahedron.

White phosphorus, P_4

(a) Elemental phosphorus reacts with Cl_2 to form PCl_3. Write a balanced chemical equation for this reaction.

(b) The standard enthalpy of formation ($\Delta_f H°$) of $P_4(g)$ is +58.9 kJ/mol; for $PCl_3(g)$ it is −287.0 kJ/mol. Use these numbers to calculate the enthalpy change for the reaction of $P_4(g)$ and $Cl_2(g)$ to give $PCl_3(g)$.

(c) Based on the equation in (a), determine what bonds are broken and what bonds are formed. Then, use this information along with the value of $\Delta_r H°$ calculated in (b) and the bond dissociation enthalpies for the P—P and Cl—Cl bonds from Table 8.8 to estimate the bond dissociation enthalpy for the P—Cl bonds. How does your estimate compare with the value in Table 8.8?

96. The answer in Study Question 95 does not exactly match the value for the bond dissociation enthalpy of P—Cl in Table 8.8. The reason is that the numbers in the table are averages, derived from data on a number of different compounds. Values calculated from different compounds do vary, sometimes widely. To illustrate this, let's do another calculation. Next look at the following reaction:

$$PCl_3(g) + Cl_2(g) \rightarrow PCl_5(g)$$

The enthalpy of formation of $PCl_5(g)$ is −374.9 kJ/mol. Use this and $\Delta_f H°$ of $PCl_3(g)$ to determine the enthalpy change for this reaction. Then, use that value of $\Delta_r H°$, along with the bond dissociation enthalpy of Cl_2, to calculate the enthalpy change for the formation of a P—Cl bond in this reaction.

97. Bromine-containing species play a role in environmental chemistry. For example, they are evolved in volcanic eruptions.

(a) The following molecules are important in bromine environmental chemistry: HBr, BrO, and HOBr. Which is an odd-electron molecule?

(b) Use bond dissociation enthalpies to estimate $\Delta_r H$ for three reactions of bromine:

$$Br_2(g) \rightarrow 2\ Br(g)$$

$$2\ Br(g) + O_2(g) \rightarrow 2\ BrO(g)$$

$$BrO(g) + H_2O(g) \rightarrow HOBr(g) + OH(g)$$

(c) Using bond dissociation enthalpies, estimate the standard enthalpy of formation of HOBr(g) from $H_2(g)$, $O_2(g)$, and $Br_2(g)$.

(d) Are the reactions in parts (b) and (c) exothermic or endothermic?

98. Acrylamide, $H_2C{=}CHCONH_2$, is a known neurotoxin and possible carcinogen. It was a shock to all consumers of potato chips and french fries a few years ago when it was found to occur in those products.

(a) Sketch the molecular structure of acrylamide and identify all bond angles.

(b) Indicate which carbon–carbon bond is the stronger of the two.

(c) Is the molecule polar or nonpolar?

(d) The amount of acrylamide found in potato chips is 1.7 mg/kg. If a serving of potato chips is 28 g, how many moles of acrylamide are you consuming?

CHAPTER OUTLINE

9.1 Valence Bond Theory

9.2 Molecular Orbital Theory

9.3 Theories of Chemical Bonding: A Summary

9.1 Valence Bond Theory

Goals for Section 9.1

- Understand how sigma (σ) and pi (π) bonds arise through orbital overlap.
- Identify the hybrid orbitals used to match the electron-pair geometry of the central atom.

In Chapter 6, the electronic structure of atoms was successfully described by an orbital model. It seems reasonable, then, that an orbital model should also be used to describe electrons in molecules, and there are two widely used bonding theories: **valence bond (VB) theory** and **molecular orbital (MO) theory**. The former was largely developed by Linus Pauling (page 366) and the latter by another American scientist, Robert S. Mulliken (1896–1986). The valence bond approach, which is described in this section, is closely tied to Lewis's idea that there are electron pairs between bonded atoms and lone pairs of electrons localized on a particular atom. In contrast, Mulliken's approach, described in Section 9.2, was to derive molecular orbitals that are "spread out," or delocalized, over the molecule. Orbitals from the atoms of the molecule are combined to form a new set of orbitals, molecular orbitals, and valence electrons populate those orbitals similar to the way electrons fill atomic orbitals.

Bonds Are a "Figment of Our Own Imagination" C. A. Coulson, a prominent theoretical chemist at the University of Oxford, England, has said that "Sometimes it seems to me that a bond between atoms has become so real, so tangible, so friendly, that I can almost see it. Then I awake with a little shock, for a chemical bond is not a real thing. It does not exist. No one has ever seen one. No one ever can. It is a figment of our own imagination" (*Chemical and Engineering News*, January 29, 2007, page 37). Nonetheless, bonds are a useful figment, and this chapter presents some of these ideas.

The Orbital Overlap Model of Bonding

What happens if two hydrogen atoms at an infinite distance apart are brought together to form a bond? Widely separated, the two atoms do not interact. If the atoms move closer together, however, the electron on one atom is attracted to the positive charge of the nucleus of the other atom. As illustrated in Figure 9.1, this distorts the electron clouds of the two atoms, drawing the electrons toward the region of space between the atoms where the two orbitals overlap. Because of the attractive forces between the nuclei and electrons, the potential energy of the system decreases. Calculations predict that at a distance of 74 pm between the H atoms the potential energy reaches a minimum. Decreasing the distance between the H atoms further, however, results in a rapid increase in the potential energy due to repulsions between the nuclei of the two atoms and between the electrons of the atoms.

◀ **Liquid oxygen is attracted to a magnet.** This occurs because oxygen is paramagnetic, a property that can best be reconciled using molecular orbital theory, one of the topics of this chapter.

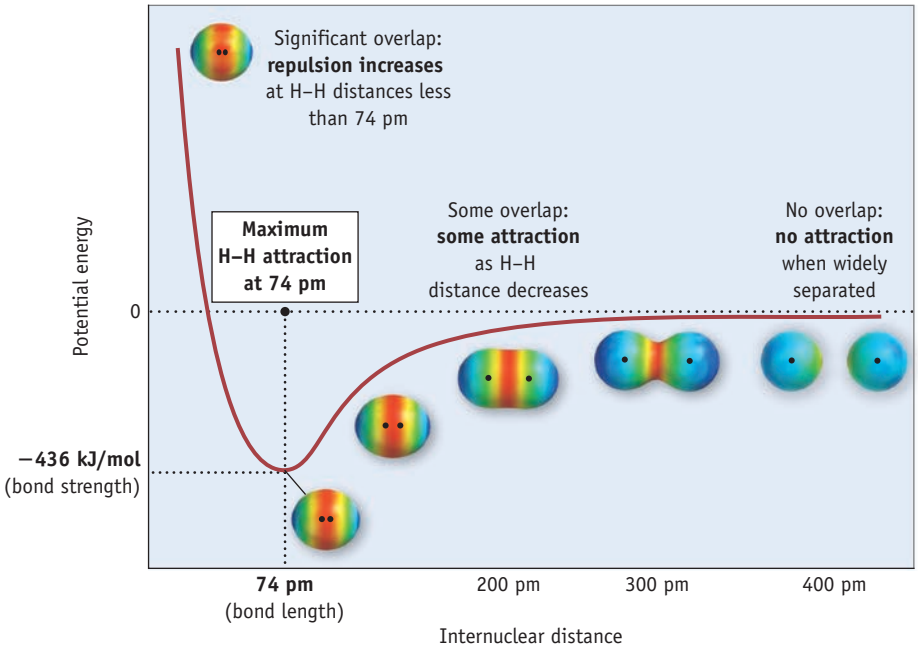

Figure 9.1 Potential energy change during H—H bond formation from isolated hydrogen atoms. The red color in the orbital pictures reflects the increase in electron density between the H atoms as the distance decreases.

A system is most stable when the potential energy is lowest. For the H_2 molecule this is predicted to occur when the two hydrogen atoms are 74 pm apart. Significantly, 74 pm also corresponds to the experimentally measured bond distance in the H_2 molecule.

In the H_2 molecule, the two electrons, one from each atom and with opposite spins, pair up to form the bond. There is a net stabilization, representing the extent to which the energies of the two electrons are lowered from their value in the free atoms. The calculated net stabilization matches the experimentally determined bond energy, and this agreement between theory and experiment on both bond distance and energy is evidence that this theoretical approach has merit.

The idea that bonds are formed by the overlap of atomic orbitals is the basis for valence bond theory. This is usually illustrated as in Figures 9.1 and 9.2, where the electron clouds on the two atoms are seen to interpenetrate or overlap. This orbital overlap increases the probability of finding the bonding electrons in the region of space between the two nuclei.

The covalent bond in H_2 that arises from the overlap of two *s* orbitals, one from each of two H atoms, is called a **sigma (σ) bond** (Figure 9.2a). *A sigma bond is a bond in which electron density is greatest along the axis of the bond.*

In summary, the main points of the valence bond theory of bonding are that

- orbitals overlap to form a covalent bond between two atoms.
- two electrons, *of opposite spin*, can be accommodated in the overlapping orbitals. (Usually, one electron is supplied by each of the two bonded atoms.)
- the bonding electrons have a higher probability of being found within a region of space influenced by both nuclei. Both electrons are thus simultaneously attracted to both nuclei.

How does this picture apply to elements beyond hydrogen? In the Lewis structure of HF, for example, a bonding electron pair is placed between H and F, and three lone pairs of electrons are depicted as localized on the F atom (Figure 9.2b). To use an orbital approach, look at the valence shell electrons and orbitals for each atom that can overlap. The hydrogen atom will use its 1*s* orbital in bond formation. The electron configuration of fluorine is $1s^2 2s^2 2p^5$, and the unpaired electron for this atom is assigned to one of the 2*p* orbitals. A sigma bond results from overlap of the hydrogen 1*s* and this fluorine 2*p* orbital. There is an optimum distance (92 pm) at

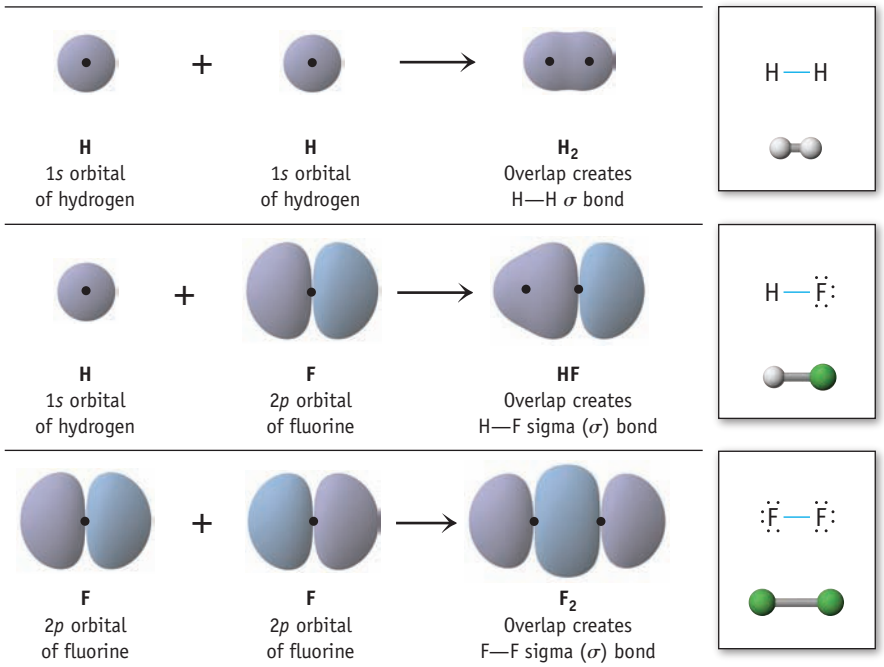

Figure 9.2 **Covalent (sigma) bond formation in H_2, HF, and F_2.**

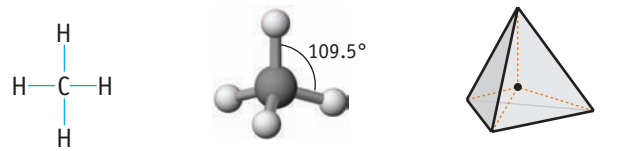


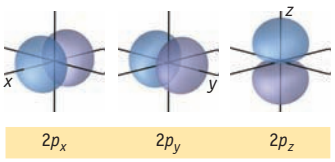
which the energy is lowest, and this corresponds to the bond distance in HF. The net stabilization achieved in this process is the energy for the H—F bond.

The remaining valence electrons on the fluorine atom in HF (a pair of electrons in the 2*s* orbital and two pairs of electrons in the other two 2*p* orbitals) are not involved in bonding. They are nonbonding electrons, the lone pairs associated with this element in the Lewis structure.

This model can be extended to a description of bonding in F_2. The 2*p* orbitals on the two atoms overlap, and the single electron from each atom is paired in the resulting σ bond (Figure 9.2c). The 2*s* and the 2*p* electrons not involved in the bond are the lone pairs on each atom.

Hybridization Using *s* and *p* Atomic Orbitals

The simple picture using orbital overlap to describe bonding works well for molecules such as H_2, HF, and F_2, but we run into difficulty when molecules with more atoms are considered. For example, a Lewis dot structure of methane, CH_4, shows four C—H covalent bonds. Valence shell electron pair repulsion (VSEPR) theory predicts, and experiments confirm, that the electron-pair geometry of the C atom in CH_4 is tetrahedral, with an angle of 109.5° between the bond pairs. The hydrogen atoms are identical in this structure. This means that there are four equivalent bonding electron pairs around the C atom. An orbital picture of bonding should rationalize both the geometry of the bonds and the fact that all C—H bonds are the same.



If we apply the orbital overlap model used for H_2 and F_2 without modification to describe the bonding in CH_4, we can immediately see a problem. Although the spherical 2*s* orbital could form a bond in any direction, the three *p*-orbitals for the

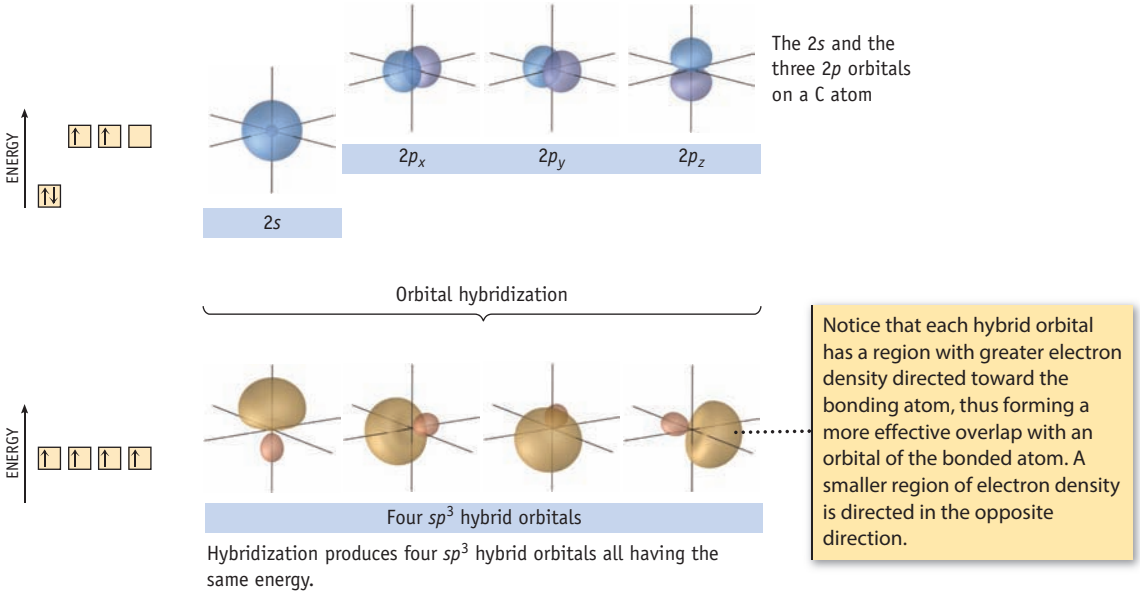
valence electrons of carbon ($2p_x$, $2p_y$, $2p_z$) are at right angles (90°) and do not match the tetrahedral angle of 109.5°.

Furthermore, a carbon atom in its ground state ($1s^2 2s^2 2p^2$) has only two unpaired electrons (in the $2p$ orbitals). Because a bond involves a carbon orbital with one electron, and a hydrogen $1s$ orbital with one electron, this might lead us to expect carbon could form only two bonds.

Carbon in CH_4 clearly forms four, two-electron bonds at the corners of a tetrahedron, and to explain this Linus Pauling proposed the theory of **orbital hybridization**. He suggested that a new set of orbitals, called **hybrid orbitals**, could be created by mixing the s and p orbitals on an atom and that these orbitals would be directed to the corners of a tetrahedron.

In methane, four orbitals directed to the corners of a tetrahedron are needed to match the electron-pair geometry on the central carbon atom. By combining the four valence shell orbitals, the $2s$ and all three of the $2p$ orbitals on carbon, a new set of four hybrid orbitals is created that has tetrahedral geometry (Figure 9.3). Each of the four hybrid orbitals is labeled sp^3 to indicate the atomic orbital combination (an s orbital and three p orbitals) from which it is derived. All four sp^3 orbitals have an identical shape, and the angle between them is 109.5°, the tetrahedral angle. One electron can be assigned to each hybrid orbital. Then, each C—H bond is formed by overlap of one of the carbon sp^3 hybrid orbitals with the $1s$ orbital from a hydrogen atom; one electron from the C atom is paired with an electron from an H atom.



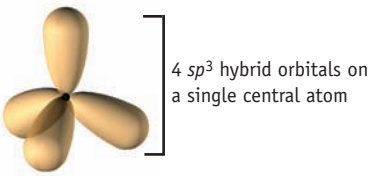


Figure 9.3 **(a) sp^3 hybrid orbitals for methane.** The formation of sp^3 hybrid orbitals from an s and three p orbitals in a molecule with tetrahedral electron-pair geometry. The electron distribution here is for carbon.

(b) Simplified version of sp^3 hybrid orbitals. Because it is difficult to accurately depict a group of hybrid orbitals on a single atom, we often use simplified drawings such as that shown here and in other figures.

Methane is the usual example of a molecule with sp^3 hybridization, but ammonia and water also have tetrahedral electron-pair geometries and are also examples of molecules in which valence bond theory assigns sp^3 hybridization to the central atom (Figures 9.3 and 9.4).

The Lewis structure for ammonia has four electron pairs in the valence shell of nitrogen: three bond pairs and a lone pair. VSEPR theory predicts a tetrahedral electron-pair geometry and a trigonal-pyramidal molecular geometry. The actual structure is a close match to the predicted structure; the H—N—H bond angles are 107.5° in this molecule.

Based on the electron-pair geometry of NH_3, we predict sp^3 hybridization to accommodate the four electron pairs on the N atom. The lone pair is assigned to one of the hybrid orbitals, and each of the other three hybrid orbitals is occupied by a single electron. Overlap of each of the singly occupied, sp^3 hybrid orbitals with a 1*s* orbital from a hydrogen atom, and pairing of the electrons in these orbitals, create the N—H bonds.

The oxygen atom of water has two bonding pairs and two lone pairs in its valence shell, and the H—O—H angle is 104.5°. Four sp^3 hybrid orbitals are created from the 2*s* and 2*p* atomic orbitals of oxygen. Two of these sp^3 orbitals are occupied by unpaired electrons and are used to form O—H bonds. Lone pairs occupy the other two hybrid orbitals.

Example 9.1 looks at the use of hybrid orbitals in more complex molecules.

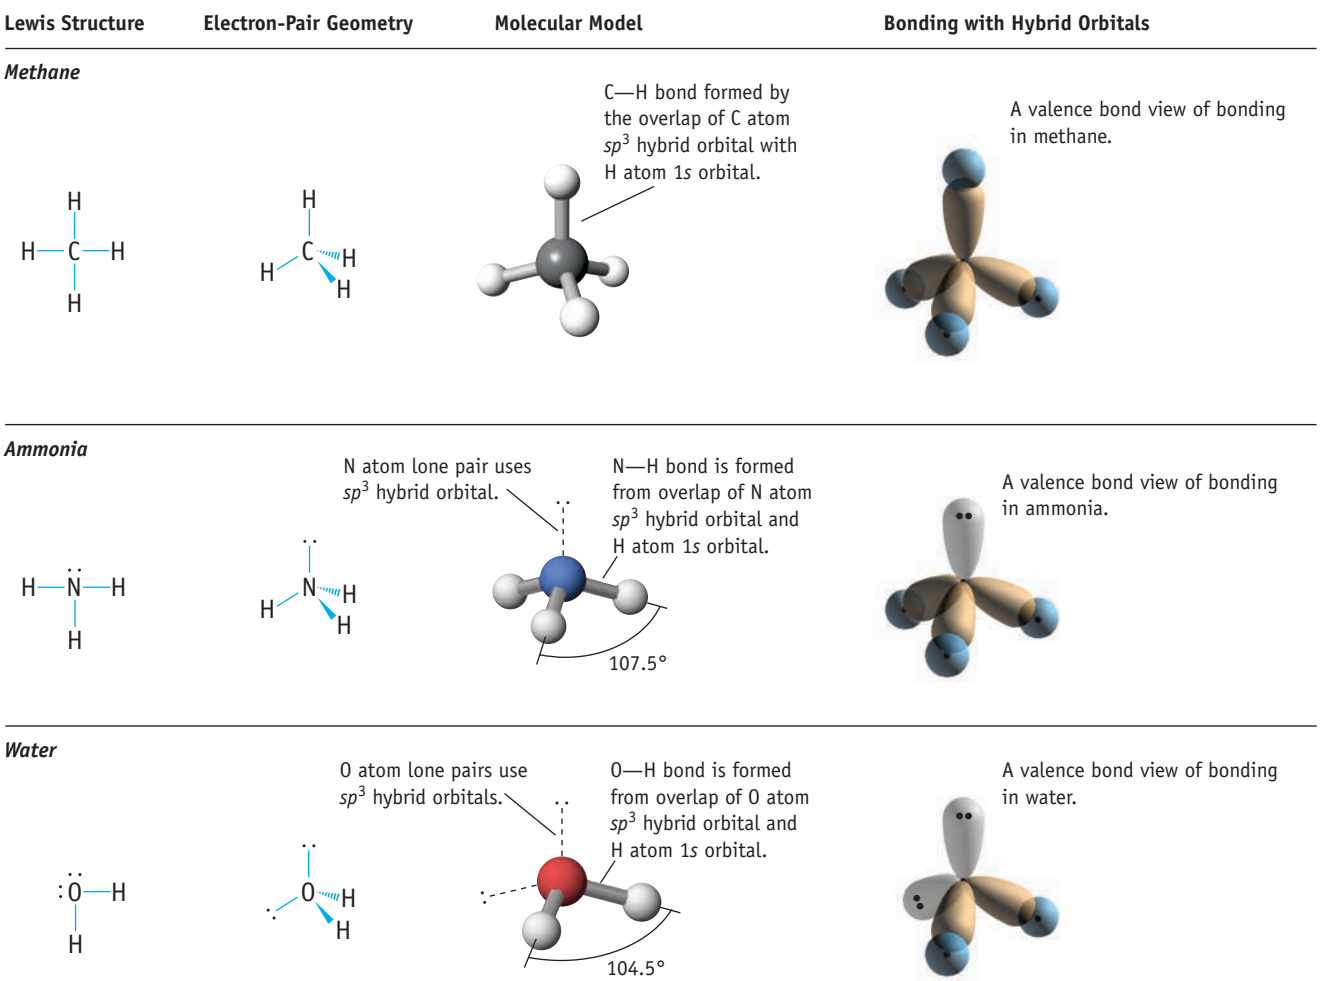

Figure 9.4 **Bonding in molecules with tetrahedral electron-pair geometry.**

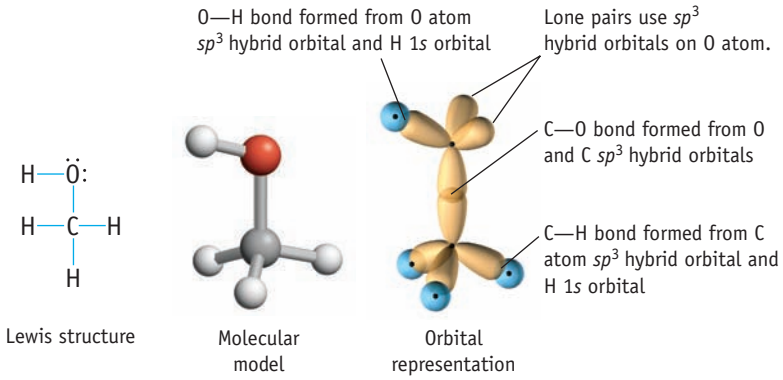
EXAMPLE 9.1

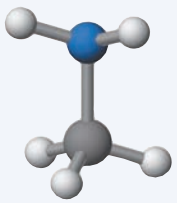


Valence Bond Description of Bonding in Methanol

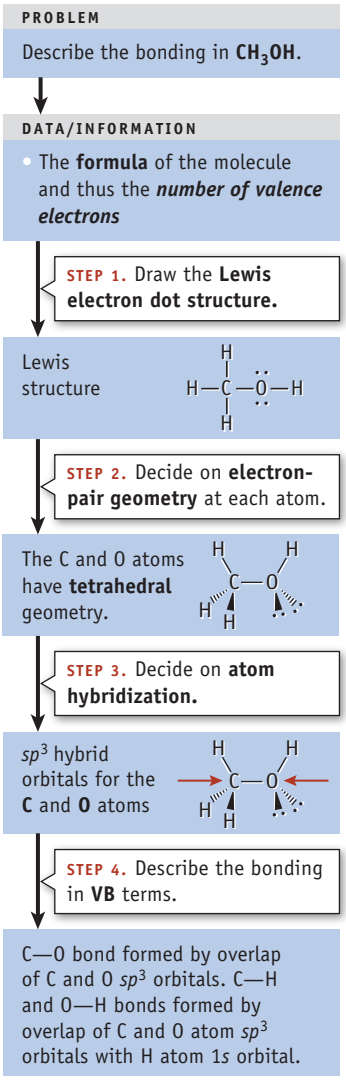
Problem Describe the bonding in the methanol molecule, CH_3OH, using valence bond theory.

What Do You Know? The formula, CH_3OH, helps to define how atoms are linked together. Three hydrogen atoms are linked to carbon. The fourth bond from carbon is to oxygen, and oxygen is attached to the remaining hydrogen.

Strategy First, construct the Lewis structure for the molecule. The electron-pair geometry around each atom determines the hybrid orbital set used by that atom.



SOLUTION The electron-pair geometry around both the C and O atoms in CH_3OH is tetrahedral. Thus, we assign sp^3 hybridization to each atom, and the C—O bond is formed by overlap of sp^3 orbitals on these atoms. Each C—H bond is formed by overlap of a carbon sp^3 orbital with a hydrogen 1*s* orbital, and the O—H bond is formed by overlap of an oxygen sp^3 orbital with the hydrogen 1*s* orbital. Two lone pairs on oxygen occupy the remaining sp^3 orbitals on the atom.



Think about Your Answer Notice that one end of the CH_3OH molecule (the CH_3 or methyl group) is just like the CH_3 group in the methane molecule, and the OH group resembles the OH group in water. This example shows how to predict the structure and bonding in a complicated molecule by looking at each part separately.

Check Your Understanding

Use valence bond theory to describe the bonding in methylamine, CH_3NH_2.

methylamine, CH_3NH_2

Strategy Map 9.1

Hybrid Orbitals for Molecules and Ions with Trigonal-Planar and Linear Electron-Pair Geometries

Species such as BF_3, O_3, NO_3^-, and CO_3^{2-} all have a trigonal-planar electron-pair geometry, which requires a central atom with three hybrid orbitals in a plane, 120° apart. Three hybrid orbitals mean three atomic orbitals must be combined. Assuming the *s*, p_x, and p_y orbitals are used in hybrid orbital formation, the three hybrid sp^2

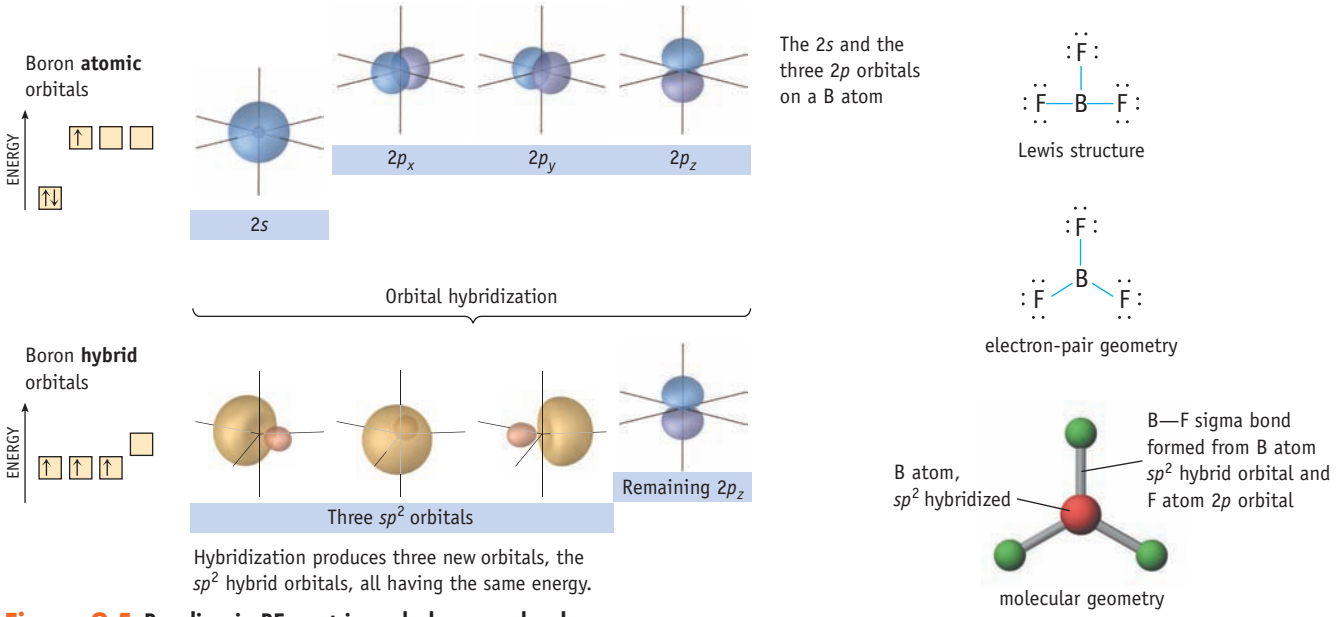

Figure 9.5 Bonding in BF_3, a trigonal-planar molecule.

orbitals will lie in the *xy*-plane. The p_z orbital not used to form these hybrid orbitals is perpendicular to the plane containing the three sp^2 orbitals.

Boron trifluoride has a trigonal-planar electron-pair and molecular geometry (Figure 9.5). Each boron–fluorine bond in this compound results from overlap of an sp^2 orbital on boron with a *p* orbital on fluorine. Notice that one *p* orbital on boron, which is not used to form the sp^2 hybrid orbitals, is not occupied by electrons.

For molecules in which the central atom has a linear electron-pair geometry, two hybrid orbitals, 180° apart, are required. One *s* and one *p* orbital can be hybridized to form two *sp* hybrid orbitals (Figure 9.6). If the p_z orbital is used in hybrid orbital formation, then the *sp* orbitals are oriented along the *z*-axis. The p_x and p_y orbitals are perpendicular to this axis.

Beryllium dichloride, $BeCl_2$, is a solid under ordinary conditions. When it is heated to over 520 °C, however, it vaporizes to give $BeCl_2$ vapor. In the gas phase,

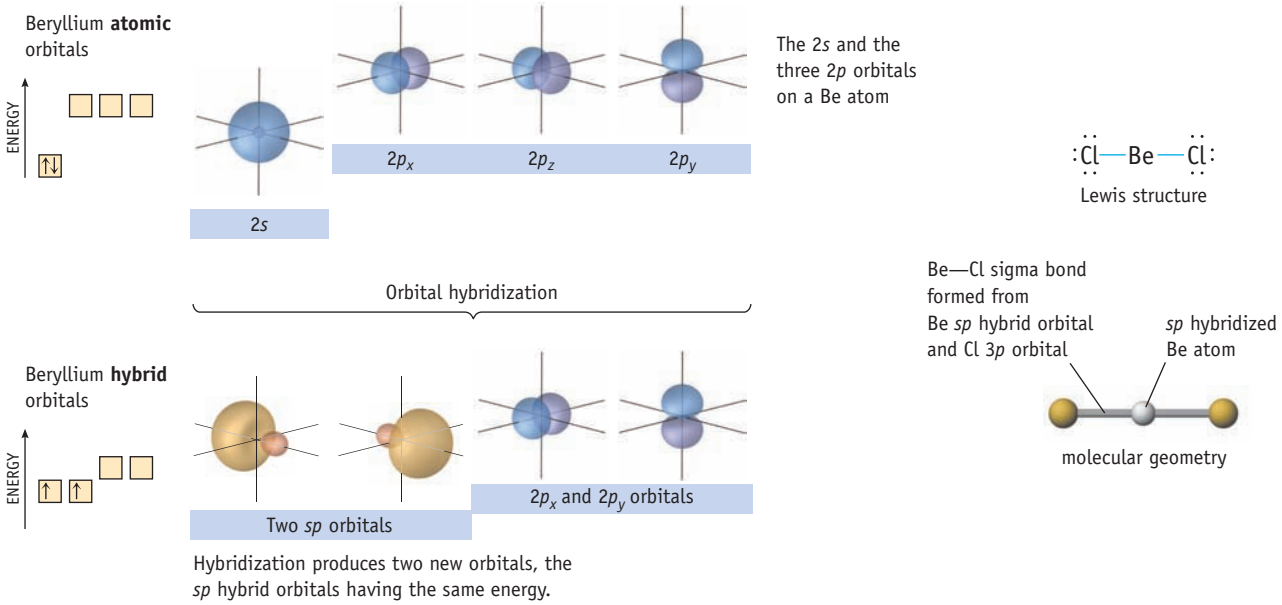

Figure 9.6 Bonding in a linear molecule. Because only one *p* orbital is incorporated in the hybrid orbital, two *p* orbitals remain unhybridized. These orbitals are perpendicular to each other and to the axis along which the two *sp* hybrid orbitals lie.

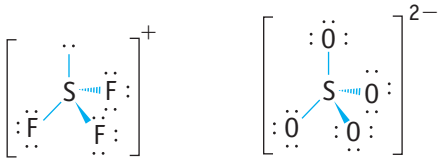
$BeCl_2$ is a linear molecule, so *sp* hybridization for the beryllium atom is appropriate. Combining beryllium's 2*s* and $2p_z$ orbitals gives the two *sp* hybrid orbitals that lie along the *z*-axis. Each Be—Cl bond arises by overlap of an *sp* hybrid orbital on beryllium with a 3*p* orbital on chlorine. In this molecule, there are only two electron pairs around the beryllium atom, so the p_x and p_y orbitals (perpendicular to the Cl—Be—Cl axis) are not occupied (Figure 9.6).

Hybrid Orbitals for Molecules and Ions with Trigonal-Bipyramidal or Octahedral Electron-Pair Geometries: Possible *d*-Orbital Participation

In Chapter 8 you learned that elements beyond the second period could form *hypervalent* molecules such as PF_5 and SF_6. Because this implies there are five or six bonds around the central element, chemists might assume the element must utilize five or six atomic orbitals to form a hybrid orbital set. In the original Pauling theory of hybridization, one or two *d* orbitals were combined with *s* and *p* orbitals in the same valence shell to create the hybrid orbital sets $\boldsymbol{sp^3d}$ and $\boldsymbol{sp^3d^2}$. These could be utilized by the central atom of a molecule or ion with a trigonal-bipyramidal or octahedral electron-pair geometry, respectively. This view is no longer in favor, however. While it is a convenient representation of bonding in these species, current research indicates there is little evidence for *d* orbital participation in bonding in hypervalent molecules. Other ways to represent bonding in these compounds that do not involve *d* orbitals have been developed and are now preferred (page 437).

EXAMPLE 9.2

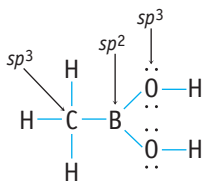
Recognizing Hybridization



Problem Identify the hybridization of each underlined atom in the following compounds and ions:

(a) $\underline{S}F_3^+$ (b) $\underline{S}O_4^{2-}$ (c) $\underline{C}H_3\underline{B}(\underline{O}H)_2$

What Do You Know? To determine hybridization, you need to know the electron-pair geometry.



Strategy The strategy here is the same as in Example 9.1: Formula → Lewis structure → electron-pair geometry → hybridization.

SOLUTION The structures for SF_3^+, and SO_4^{2-} are written as follows:

Four electron pairs surround the central atom in each of these ions, and the electron-pair geometry for these atoms is tetrahedral. Thus, sp^3 hybridization for the central atom is used to describe the bonding.

The Lewis structure for $CH_3B(OH)_2$ is drawn below. The carbon and oxygen atoms have tetrahedral geometry and are assigned sp^3 hybridization. The boron atom has trigonal-planar geometry and is assigned sp^2 hybridization.

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

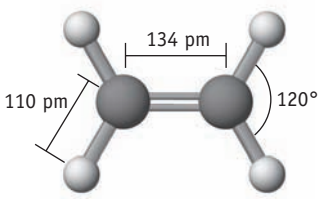
Think about Your Answer You can describe the bonding in molecules like $CH_3B(OH)_2$ by thinking in terms of small pieces of the molecule. There is a CH_3— group like the one in CH_3OH. The two —OH groups are like the ones in CH_3OH or in water, and the central B is trigonal planar like the B atom in BF_3 .

Check Your Understanding

Identify the hybridization of each underlined atom in the following compounds and ions:



(a) $\underline{B}H_4^-$ (b) $H_2\underline{C}{=}\underline{C}H{-}\underline{C}H_3$ (c) $\underline{B}Cl_3$

Valence Bond Theory and Multiple Bonds

Many molecules have double or triple bonds, that is, there are two or three bonds, respectively, between pairs of atoms. According to valence bond theory, bond formation requires that two orbitals on adjacent atoms overlap, so a double bond requires *two* sets of overlapping orbitals and *two* electron pairs. For a triple bond, *three* sets of atomic orbitals are required, each set accommodating a pair of electrons.

Double Bonds

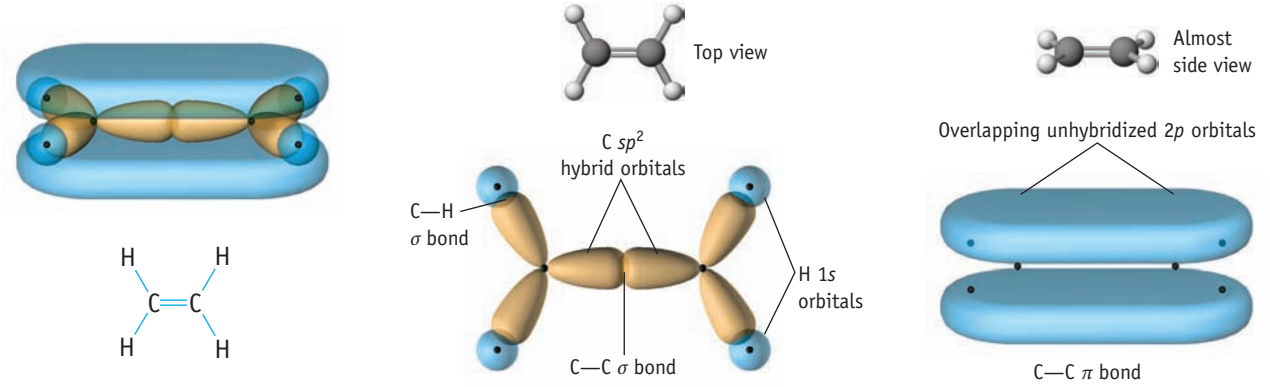
Consider ethylene, $H_2C{=}CH_2$, a common molecule with a double bond. The molecular structure of ethylene places all six atoms in a plane, with H—C—H and H—C—C angles of approximately 120°. Each carbon atom has trigonal-planar geometry, so sp^2 hybridization is assumed for these atoms.

ethylene, C_2H_4

The valence bond description of bonding in ethylene starts with each carbon atom having three sp^2 hybrid orbitals in the molecular plane and an unhybridized p orbital perpendicular to that plane (Figure 9.5). Because each carbon atom is involved in four bonds, a single unpaired electron is placed in each of these orbitals.

Unhybridized p orbital perpendicular to molecular plane. Used for π bonding in C_2H_4.

Three sp^2 hybrid orbitals in molecular plane. Used for C—H and C—C σ bonding in C_2H_4.



The C—H bonds of C_2H_4 arise from overlap of sp^2 orbitals on carbon with hydrogen 1s orbitals. After accounting for these bonds, one sp^2 orbital on each carbon atom remains. These hybrid orbitals point toward each other and overlap to form one of the bonds linking the carbon atoms (Figure 9.7). This leaves one other orbital unaccounted for on each carbon, an unhybridized p orbital, and these orbitals are used to create the second bond between carbon atoms in C_2H_4. If they are aligned correctly, the unhybridized p orbitals on the two carbons can overlap, allowing the electrons in these orbitals to be paired. The overlap does not occur directly along the C—C axis, however. Instead, the arrangement compels these orbitals to overlap sideways, and the electron pair forms a bond with electron density above and below the plane containing the six atoms.

This description results in two types of bonds in C_2H_4. The C—H and C—C σ bonds arise from the overlap of atomic orbitals that lie along the bond axes. The other is the bond formed by sideways overlap of p atomic orbitals, called a **pi (π) bond**. In a π bond, the overlap region is above and below the internuclear axis, and the electron density of the π bond is above and below the bond axis.

A π bond can form *only* if (a) there are unhybridized p orbitals on adjacent atoms and (b) the p orbitals are perpendicular to the plane of the molecule and parallel to one another as in C_2H_4. This happens only if the sp^2 orbitals of both carbon atoms are in the same plane.

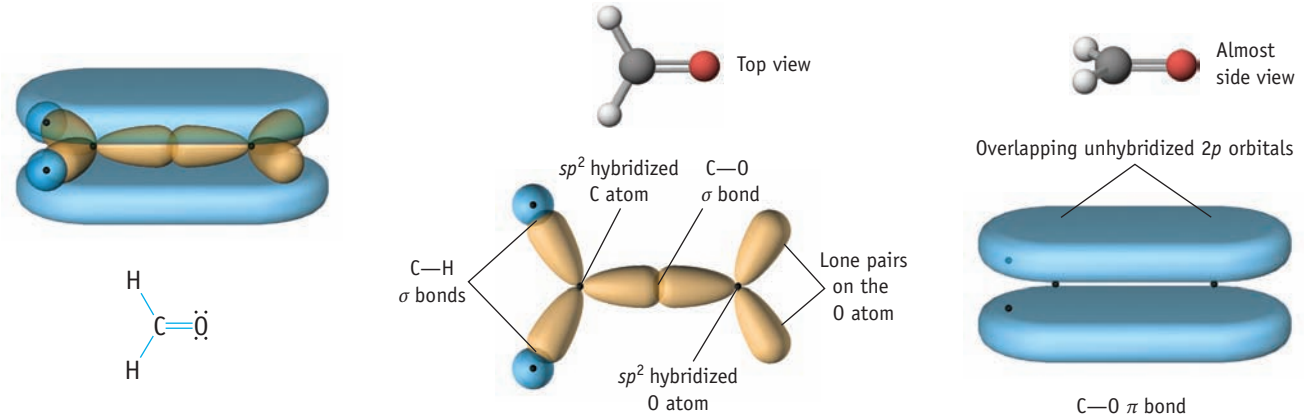
(a) Lewis structure and bonding of ethylene, C_2H_4.



(b) The C—H σ bonds are formed by overlap of C atom sp^2 hybrid orbitals with H atom 1s orbitals. The σ bond between C atoms arises from overlap of sp^2 orbitals.

(c) The carbon–carbon π bond is formed by overlap of an unhybridized 2p orbital on each atom. Note the lack of electron density along the C—C bond axis from this bond.

Figure 9.7 The valence bond model of bonding in ethylene, C_2H_4. Each C atom is assumed to be sp^2 hybridized.

Double bonds between carbon and oxygen, sulfur, or nitrogen are quite common. Consider formaldehyde, CH_2O, in which a carbon–oxygen π bond occurs (Figure 9.8). A trigonal-planar electron-pair geometry indicates sp^2 hybridization for the C atom. The σ bonds from carbon to the O atom and the two H atoms form by overlap of sp^2 hybrid orbitals with half-filled orbitals from the oxygen and two hydrogen atoms. An unhybridized p orbital on carbon is oriented perpendicular to the molecular plane (just as for the carbon atoms of C_2H_4). This p orbital is available for π bonding, this time with an oxygen orbital.

What orbitals on oxygen are used in this model? The approach in Figure 9.8 assumes sp^2 hybridization for oxygen. This uses one O atom sp^2 orbital in σ bond formation, leaving two sp^2 orbitals to accommodate lone pairs. The remaining p orbital on the O atom participates in the π bond.

(a) Lewis structure and bonding of formaldehyde, CH_2O.

(b) The C—H σ bonds are formed by overlap of C atom sp^2 hybrid orbitals with H atom 1s orbitals. The σ bond between C and O atoms arises from overlap of sp^2 orbitals.

(c) The C—O π bond comes from the side-by-side overlap of p orbitals on the two atoms.

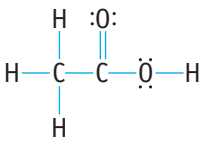
EXAMPLE 9.3

Bonding in Acetic Acid

Problem Using valence bond theory, describe the bonding in acetic acid, CH_3CO_2H, the important ingredient in vinegar.

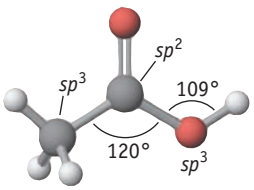
What Do You Know? Acetic acid is an organic acid and so contains the CO_2H group in which both oxygen atoms are attached to the carbon. A $—CH_3$ group is also part of the molecule.

Strategy Write a Lewis electron dot structure, and determine the geometry around each atom using VSEPR theory. Use this geometry to decide what hybrid orbitals are used in σ bonding. If unhybridized p orbitals are available on adjacent C and O or C and C atoms, then π bonding can occur.



SOLUTION

The carbon atom of the CH_3 group has tetrahedral electron-pair geometry and so is assumed to be sp^3 hybridized. Three sp^3 orbitals are used to form the C—H bonds. The fourth sp^3 orbital is used to bond to the carbon atom of the CO_2H group.



The C atom of the CO_2H group has a trigonal-planar electron-pair geometry; it must be sp^2 hybridized. A bond to the $—CH_3$ group is formed using one of these hybrid orbitals, and the other two sp^2 orbitals are used to form the σ bonds to the two oxygen atoms.

The oxygen of the O—H group has four valence electron pairs; it must be tetrahedral and sp^3 hybridized. Thus, this O atom uses two sp^3 orbitals to bond to the adjacent carbon and the hydrogen atoms, and two sp^3 orbitals accommodate the two lone pairs.

The carbon–oxygen double bond can be described by assuming the C and O atoms are both sp^2 hybridized (like the C—O π bond in formaldehyde, Figure 9.8). The unhybridized p orbital remaining on each atom is used to form the carbon–oxygen π bond, and the lone pairs on the O atom are accommodated in sp^2 hybrid orbitals.

Think about Your Answer Notice that the hybridization for each atom is determined by its electron-pair geometry.

Check Your Understanding

Use valence bond theory to describe the bonding in acetone, CH_3COCH_3.

acetone

Triple Bonds

Acetylene, H—C≡C—H, has a carbon-carbon triple bond. VSEPR theory predicts that the four atoms lie in a straight line with H—C—C angles of 180°, which implies that the carbon atom is sp hybridized (Figure 9.9). For each carbon atom, there are two sp orbitals, one directed toward hydrogen and used to create the C—H σ bond and the second directed toward the other carbon and used to create a σ bond between the two carbon atoms. Two unhybridized p orbitals remain on

each carbon, and they are oriented so that it is possible to form *two* π bonds in HC≡CH.

↑|↑ Two unhybridized *p* orbitals. Used for π bonding in C_2H_2.

↑|↑ Two *sp* hybrid orbitals. Used for C—H and C—C σ bonding in C_2H_2.

These π bonds are perpendicular to the molecular axis and perpendicular to each other. Three electrons on each carbon atom are used to form the triple bond consisting of a σ bond and two π bonds.

Cis-Trans Isomerism: A Consequence of π Bonding

Ethylene, C_2H_4, is a planar molecule, a geometry that allows the unhybridized *p* orbitals on the two carbon atoms to line up and form a π bond (Figure 9.7). But what would happen if one end of the ethylene molecule were twisted relative to the other end (Figure 9.10)? This would distort the molecule away from planarity, and the *p* orbitals would rotate out of alignment. Rotation would diminish the extent of overlap of these orbitals, and, if a twist of 90° were achieved, the two *p* orbitals would no longer overlap at all; the π bond would be broken. However, so much energy is required to break this bond (about 260 kJ/mol) that rotation around a C═C bond is not expected to occur at room temperature.

A consequence of restricted rotation is that isomers occur for many compounds containing a C═C bond. **Isomers** are compounds that have the same formula but different structures. In this case, the two isomeric compounds differ with respect to the orientation of the groups attached to the carbons of the double bond. Two isomers of $C_2H_2Cl_2$ are *cis*- and *trans*-1,2-dichloroethylene. Their structures resemble ethylene, except that two hydrogen atoms have been replaced by chlorine atoms. Because a large amount of energy is required to break the π bond, the *cis* compound

Figure 9.10
Rotation around bonds.

(a) In ethane nearly free rotation can occur around the axis of a single (σ) bond.

(b) Rotation is severely restricted around the double bond in ethylene because doing so would break the π bond, a process requiring a great deal of energy.

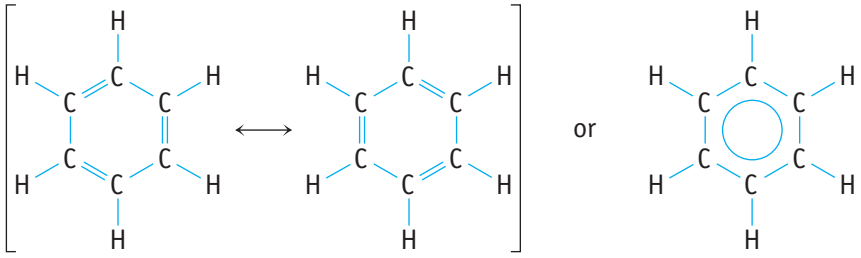
Problem Solving Tip 9.1 Multiple Bond Formation

Let us summarize several important points regarding double and triple bond formation:

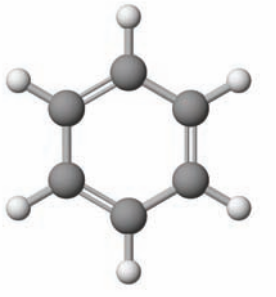
- In valence bond theory a double bond *always* consists of a σ bond and a π bond, and a triple bond *always* consists of a σ bond and *two* π bonds.
- A π bond may form *only* if unhybridized *p* orbitals remain on the bonded atoms.
- If a Lewis structure shows multiple bonds, the atoms involved must be either sp^2 or *sp* hybridized. With these hybridizations, unhybridized *p* orbitals will be available to form one or two π bonds, respectively.

cannot rearrange to the *trans* compound under ordinary conditions. Each compound can be obtained separately, and each has unique physical properties. [*Cis*-1,2-dichloroethylene boils at 60.3 °C, whereas *trans*-1,2-dichloroethylene boils at 47.5 °C.]



cis-1,2-dichloroethylene *trans*-1,2-dichloroethylene

Although *cis* and *trans* isomers do not interconvert at ordinary temperatures, they will do so at higher temperatures. If the temperature is sufficiently high, the molecular motions can become sufficiently energetic that rotation around the C═C bond can occur. Interconversion of isomers may also occur under other special conditions, such as when the molecule absorbs light energy.



Benzene: A Special Case of π Bonding

Benzene, C_6H_6, is the simplest member of a large group of substances known as *aromatic* compounds, a historical reference to their odor. The compound occupies a pivotal place in the history and practice of chemistry.

To 19th-century chemists, benzene was a perplexing substance with an unknown structure. Based on its chemical reactions, however, August Kekulé (1829–1896) suggested that the molecule has a planar, symmetrical ring structure. We know now he was correct. The ring is flat, and all the carbon–carbon bonds are the same length, 139 pm, a distance intermediate between the average single bond (154 pm) and double bond (134 pm) lengths. Assuming the molecule has two resonance structures with alternating double bonds, the observed structure is rationalized. The C—C bond order in C_6H_6 (1.5) is the average of a single and a double bond.

The C atoms of the ring are bonded to each other through σ bonds using C atom sp^2 hybrid orbitals. The C—H bonds also use C atom sp^2 hybrid orbitals.

The π framework of the molecule arises from overlap of C atom *p* orbitals not used in hybrid orbital formation. Because these orbitals are perpendicular to the ring, π electron density is above and below the plane of the ring.

A composite of σ and π bonding in benzene.

Figure 9.11 **Bonding in benzene, C_6H_6.**

Understanding the bonding in benzene (Figure 9.11) is important because the benzene ring structure occurs in an enormous number of chemical compounds. We begin by assuming that the trigonal-planar carbon atoms have sp^2 hybridization. Each C—H bond is formed by overlap of an sp^2 orbital of a carbon atom with a 1*s* orbital of hydrogen, and the C—C σ bonds in the ring arise by overlap of sp^2 orbitals on adjacent carbon atoms. After accounting for the σ bonding, an unhybridized *p* orbital remains on each C atom, and each is occupied by a single electron. These six orbitals and six electrons form three π bonds. Because all carbon–carbon bond lengths are the same, each *p* orbital overlaps equally well with the *p* orbitals of both adjacent carbons, and the π interaction is unbroken around the six-member ring.

Hybridization: A Summary

Hybridization and Geometry
Hybridization reconciles the electron-pair geometry with the orbital overlap criterion of bonding. A statement such as "the atom is tetrahedral because it is sp^3 hybridized" is backward. That the electron-pair geometry around the atom is tetrahedral is a fact. Hybridization is one way to describe the bonding that can occur in this geometry.

- The number of hybrid orbitals on an atom is always equal to the number of atomic orbitals that are mixed to create the hybrid orbital set.
- Hybrid orbital sets are always built by combining an *s* orbital with as many *p* orbitals as needed to have enough hybrid orbitals to accommodate the sigma bonding and lone electron pairs on the central atom.
- The hybrid orbitals are directed toward the terminal atoms, leading to better orbital overlap and a stronger bond between the central and terminal atoms.
- The hybrid orbitals required by an atom in a molecule or ion are chosen to match the electron-pair geometry of the atom because a hybrid orbital is required for each sigma bond electron pair and each lone pair.
- The following types of hybridization are important:

  sp*:** If the valence shell *s* orbital on the central atom in a molecule or ion is mixed with a valence shell *p* orbital on that same atom, two ***sp hybrid orbitals are created. They are separated by 180°.

  ***sp*²:** If an *s* orbital is combined with two *p* orbitals, all in the same valence shell, three ***sp*²** hybrid orbitals are created. They are in the same plane and are separated by 120°.

  ***sp*³:** When the *s* orbital is combined with three *p* orbitals in the same valence shell, the result is four hybrid orbitals, each labeled ***sp*³**. The hybrid orbitals are separated by 109.5°, the tetrahedral angle.

9.2 Molecular Orbital Theory

Goal for Section 9.2

- Write molecular orbital configurations for simple diatomic molecules or ions, determine the bond order of each species, and predict its magnetic behavior.

Molecular orbital (MO) theory is an alternative way to view orbitals in molecules. According to MO theory, pure atomic orbitals of the atoms in the molecule are combined to produce **molecular orbitals** that are spread out, or delocalized, over some or all the atoms in the molecule. Population of these MOs with valence electrons leads to chemical bonding.

One reason for learning about the MO concept is that it correctly predicts the electronic structures of molecules such as O_2 that do not follow the electron-pairing assumptions of the Lewis approach. The rules of Section 8.2 would guide you to draw the electron dot structure of O_2 with all the electrons paired, which fails to explain its paramagnetism (page 325). The molecular orbital approach can account for this property, but valence bond theory cannot. To see how MO theory can be used to describe the bonding in O_2 and other diatomic molecules, let us first describe four principles of the theory.

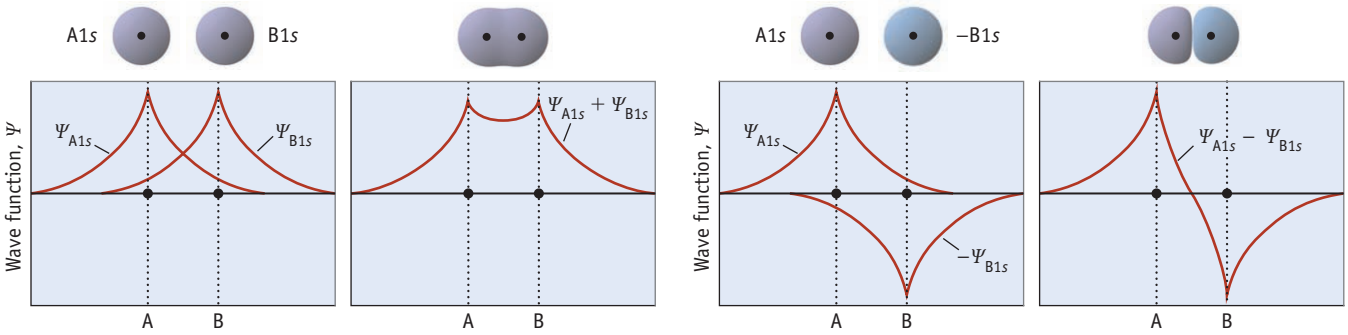
Principles of Molecular Orbital Theory

In MO theory, we begin with a given arrangement of atoms in the molecule at the known bond distances and then determine the atomic orbitals that combine to produce *sets* of molecular orbitals. One way to do this is to combine available orbitals on all the constituent atoms. The resulting molecular orbitals more or less encompass all the atoms of the molecule, and the valence electrons for all the atoms in the molecule occupy the molecular orbitals. Just as with orbitals in atoms, electrons are assigned in order of increasing orbital energy and according to the Pauli principle and Hund's rule (Sections 7.1 and 7.3).

Molecular Orbitals for H_2

The **first principle of molecular orbital theory** is that *the total number of molecular orbitals is always equal to the total number of atomic orbitals contributed by the combining atoms.* To illustrate this orbital conservation principle, let us consider the H_2 molecule.

Molecular orbital theory specifies that when the 1*s* orbitals of two hydrogen atoms overlap, *two* molecular orbitals result. One molecular orbital results from the *addition* of the 1*s* atomic orbital wave functions, leading to an increased probability that electrons will reside in the bond region between the two nuclei (Figures 9.12 and 9.13). This is called a **bonding molecular orbital**. It is also a σ orbital because the region of electron probability lies directly along the bond axis. This molecular orbital is labeled σ_{1s}, the subscript 1*s* indicating that 1*s* atomic orbitals were used to create the molecular orbital.



Combining Atomic Orbitals
MOs are created by combining atomic orbitals. If the orbitals have the same sign of the wave function, the effect is additive. If they have opposite signs, the effect is subtractive. See Figure 9.12, and recall the discussion on page 298 where we introduced the fact that wave functions have an algebraic sign.

The other molecular orbital is constructed by *subtracting* one atomic orbital wave function from the other (Figures 9.12 and 9.13). When this happens, the probability of finding an electron between the nuclei in the molecular orbital is reduced, and the probability of finding the electron in other regions is higher. Without significant electron density between the nuclei, the two atoms repel one another. This an **antibonding molecular orbital**. Because it is also a σ orbital, derived from 1*s* atomic orbitals, it is labeled σ^*_{1s} (the * denotes it as antibonding) and is referred to as a "sigma-star" orbital. *Antibonding orbitals have no counterpart in valence bond theory.*

A **second principle of molecular orbital theory** is that *the bonding molecular orbital is lower in energy than the parent orbitals, and the antibonding orbital is higher in*

Uncombined 1s atomic orbitals with the same wave function signs.

Bonding molecular orbital (σ_{1s}). The MO is created by adding the two 1s wave functions; this results in an enhancement of the wave and an increased probability of finding the electrons between the nuclei.

Uncombined 1s atomic orbitals with opposite wave function signs.

Antibonding molecular orbital (σ^*_{1s}). This MO created by combining two 1s orbitals of opposite sign. There is now a node between the nuclei.

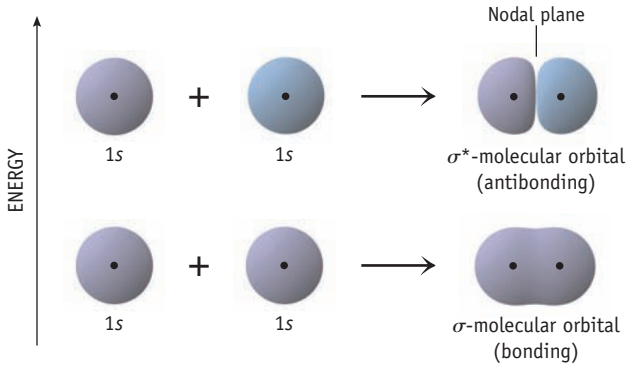

Figure 9.12 Molecular orbitals in H_2. The matter waves for the 1s electrons overlap along the bond axis to create bonding and antibonding molecular orbitals. The interference can be constructive, giving a bonding MO, or destructive, giving an antibonding MO.

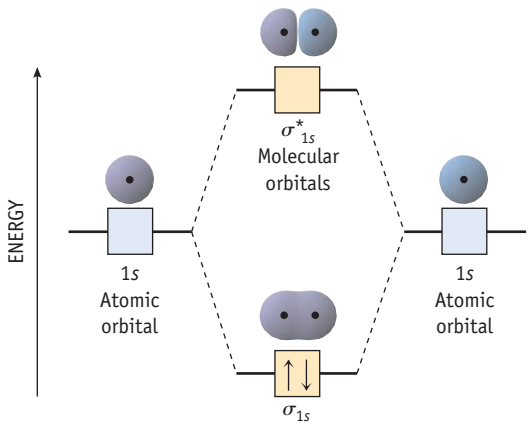
Phases of Atomic and Molecular Orbitals. Recall that electron wave functions have positive and negative phases (page 298), here depicted in purple and blue. A bonding MO results if the combining atomic orbitals overlap in phase (Figure 9.12a), or an antibonding MO results if they have opposite phases (Figure 9.12b). Other figures in this chapter follow the same scheme.

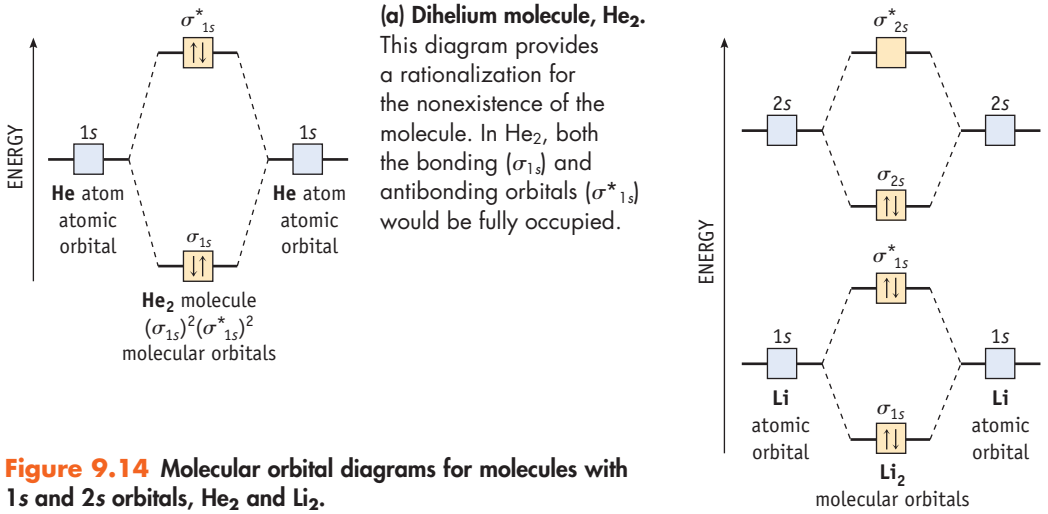


energy (Figure 9.13). This means that the energy of a group of atoms is lower than the energy of the separated atoms when electrons occupy bonding molecular orbitals. Chemists say the system is "stabilized" by chemical bond formation. Conversely, the system is "destabilized" when electrons occupy antibonding orbitals because the energy of the system is higher than that of the atoms themselves.

A **third principle of molecular orbital theory** is that the *electrons of the molecule are assigned to orbitals of successively higher energy*, just as they are in atoms and according to the Pauli exclusion principle and Hund's rule. Thus, electrons occupy the lowest energy orbitals available, and, when two electrons are assigned to an orbital, their spins must be paired.

Energy level diagrams are commonly used in describing bonding using MO theory. These diagrams show the relative energies of the atomic orbitals for the individual atoms and the derived molecular orbitals. In the energy level diagram for H_2 (Figure 9.13) you see the energy of the electrons in the bonding orbital is lower than the energy of either parent 1s electron. The antibonding orbital has a higher energy. In the H_2 molecule, the two electrons are assigned to the bonding orbital. We write the molecular electron configuration of H_2 as $(\sigma_{1s})^2$.

(a) Bonding and antibonding σ-molecular orbitals are formed from two 1s atomic orbitals on adjacent atoms. Notice the presence of a node between the nuclei in the antibonding orbital. (The node is a plane on which there is zero probability of finding an electron.)



(b) A molecular orbital energy diagram for H_2. The two electrons are placed in the σ_{1s} orbital. This bonding molecular orbital is lower in energy than the parent 1s orbitals.

(a) Dihelium molecule, He_2. This diagram provides a rationalization for the nonexistence of the molecule. In He_2, both the bonding (σ_{1s}) and antibonding orbitals (σ^*_{1s}) would be fully occupied.

(b) Dilithium molecule, Li_2. The molecular orbitals are created by combining orbitals of similar energies (1*s* on one Li with 1*s* on the other Li and 2*s* on one Li with 2*s* on the other Li).

Figure 9.14 Molecular orbital diagrams for molecules with 1*s* and 2*s* orbitals, He_2 and Li_2.

What would happen if we tried to combine two helium atoms to form dihelium, He_2? Both He atoms have a 1*s* valence orbital that can produce the same kind of molecular orbitals as in H_2. However, four electrons now need to be assigned to these orbitals (Figure 9.14a). The pair of electrons in the σ_{1s} orbital stabilizes He_2 whereas the two electrons in σ^*_{1s} destabilize the molecule. The energy decrease from the electrons in the σ_{1s} bonding molecular orbital is fully offset by the energy increase due to the electrons in the σ^*_{1s} antibonding molecular orbital. Thus, molecular orbital theory predicts that He_2 has no net stability; that is, two He atoms should have no tendency to combine. This explains what we already know: elemental helium exists in the form of single atoms and not as a diatomic molecule.

Bond Order

Bond order was defined in Section 8.9 as the net number of bonding electron pairs linking a pair of atoms. This same concept can be applied directly to molecular orbital theory, but now bond order is defined as

$$\text{Bond order} = 1/2\ (\text{number of electrons in bonding MOs} - \text{number of electrons in antibonding MOs}) \quad (9.1)$$

In the H_2 molecule, there are two electrons in a bonding orbital and none in an antibonding orbital, so H_2 has a bond order of 1 [$\frac{1}{2}(2 - 0) = 1$]. In contrast, in the hypothetical molecule He_2 the stabilizing effect of the σ_{1s} pair would be canceled by the destabilizing effect of the σ^*_{1s} pair, and so the bond order would be 0.

Fractional bond orders are possible. Could the ion He_2^+ exist? Its molecular orbital electron configuration is $(\sigma_{1s})^2(\sigma^*_{1s})^1$. In this ion, there are two electrons in a bonding molecular orbital, but only one in an antibonding orbital. MO theory predicts that He_2^+ should have a bond order of 0.5; that is, a weak bond should exist between helium atoms in the ion. Interestingly, this ion has been identified in the gas phase using special experimental techniques.

EXAMPLE 9.4

Molecular Orbitals and Bond Order

Problem Write the electron configuration of the H_2^- ion in molecular orbital terms. What is the bond order of the ion?

What Do You Know? Combining the 1*s* orbitals on the two hydrogen atoms will give two molecular orbitals (Figure 9.13). One is a bonding orbital (σ_{1s}) and the second is an antibonding orbital (σ^*_{1s}).

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Strategy Count the number of valence electrons in the ion, and then place those electrons in the MO diagram for the H_2 molecule. Find the bond order using Equation 9.1.

SOLUTION This ion has three electrons (one each from the H atoms plus one for the negative charge). Therefore, its electronic configuration is $(\sigma_{1s})^2(\sigma^*_{1s})^1$, identical with the configuration for He_2^+. This means H_2^- has a net bond order of 0.5.

Think about Your Answer There is a weak bond in this ion, so it is predicted to exist only under special circumstances.

Check Your Understanding

What is the electron configuration of the H_2^+ ion? Compare the bond order of this ion with He_2^+ and H_2^-. Do you expect H_2^+ to exist?

Molecular Orbitals of Li_2 and Be_2

A **fourth principle of molecular orbital theory** is that *atomic orbitals combine to form molecular orbitals most effectively when the atomic orbitals are of similar energy.* This principle becomes important when we move past He_2 to Li_2, dilithium, and heavier molecules such as O_2 and N_2.

A lithium atom has electrons in two orbitals of the *s* type (1*s* and 2*s*), so a $1s \pm 2s$ combination is theoretically possible. Because the 1*s* and 2*s* orbitals are quite different in energy, however, this interaction can be disregarded. Thus, the molecular orbitals come only from $1s \pm 1s$ and $2s \pm 2s$ combinations (Figure 9.14b). This means the molecular orbital electron configuration of dilithium, Li_2, is

Diatomic Molecules Molecules such as H_2, Li_2, and N_2, in which two identical atoms are bonded, are examples of *homonuclear* diatomic molecules.

$$Li_2 \text{ MO Configuration:} \qquad (\sigma_{1s})^2(\sigma^*_{1s})^2(\sigma_{2s})^2$$

The bonding effect of the σ_{1s} electrons is canceled by the antibonding effect of the σ^*_{1s} electrons, so these pairs make no net contribution to bonding in Li_2. Bonding in Li_2 is due to the electron pair assigned to the σ_{2s} orbital, and the bond order is 1.

The fact that the σ_{1s} and σ^*_{1s} electron pairs of Li_2 make no net contribution to bonding makes sense. In the valence bond description of bonding in this molecule, these electrons are core electrons. In MO theory, just as in valence bond theory, the bond between lithium atoms arises by overlap of valence orbitals and sharing of valence electrons; core electrons can be ignored.

EXAMPLE 9.5

Molecular Orbitals in Homonuclear Diatomic Molecules

Problem Should the Be_2 molecule or Be_2^+ ion exist? Describe their electron configurations in molecular orbital terms, and give the net bond order of each.

What Do You Know? The MO diagram in Figure 9.14b applies to this question because we are dealing only with 1*s* and 2*s* orbitals in the original atoms.

Strategy Count the number of electrons in the molecule or ion, and place them in the MO diagram in Figure 9.14b. Write the electron configuration, and calculate the bond order from Equation 9.1.

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

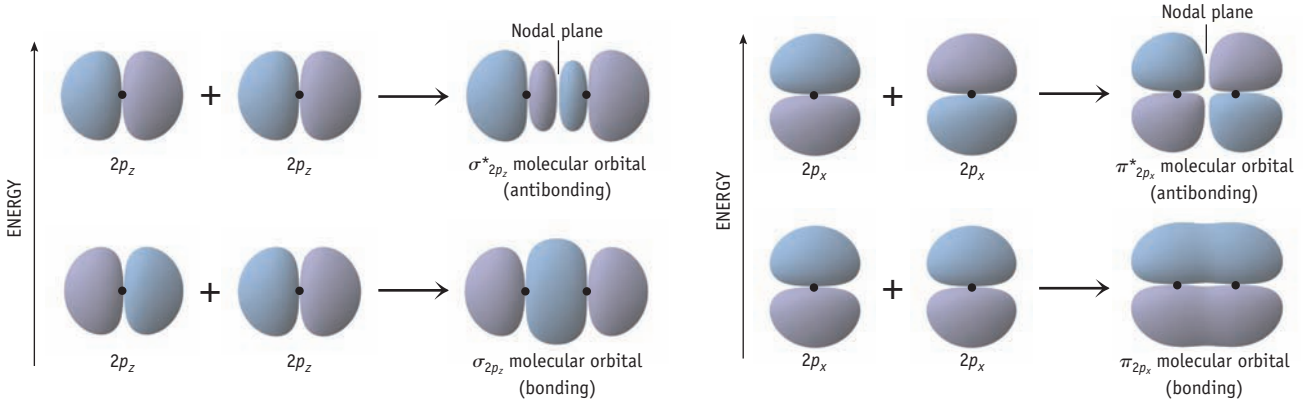
Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

SOLUTION The Be_2 molecule has eight electrons, of which four are core electrons. (The four core electrons are assigned to σ_{1s} and σ^*_{1s} molecular orbitals.) The remaining four electrons are assigned to the σ_{2s} and σ^*_{2s} molecular orbitals, so the MO electron configuration for Be_2 is [core electrons]$(\sigma_{2s})^2(\sigma^*_{2s})^2$. This leads to a net bond order of 0, so the Be_2 molecule does not exist.

The Be_2^+ ion has only seven electrons, of which four are core electrons. The remaining three electrons are assigned to the σ_{2s} and σ^*_{2s} molecular orbitals, so the MO electron configuration of Be_2^+ is [core electrons]$(\sigma_{2s})^2(\sigma^*_{2s})^1$. This means the net bond order is 0.5.

Think about Your Answer Be_2^+ is predicted to exist under special circumstances. Scientists might search for such species in gas discharge experiments (gaseous atoms subjected to a strong electrical potential) and use spectroscopy to confirm their existence.

Check Your Understanding



Could the anion Li_2^- exist? What is the ion's bond order?

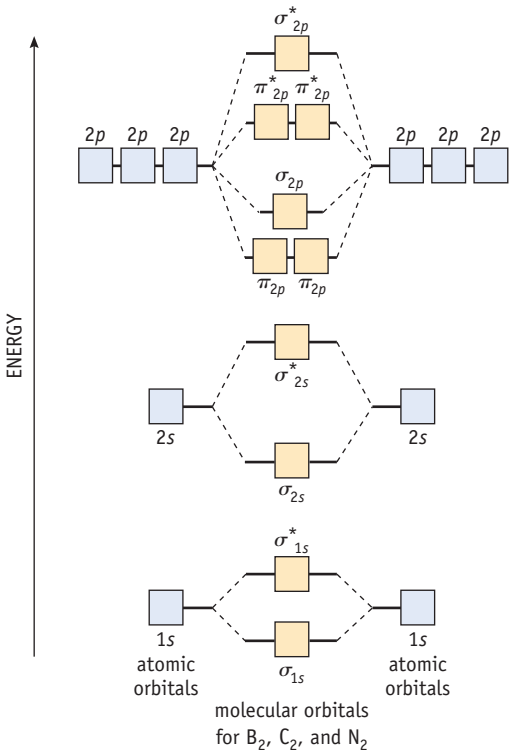
Molecular Orbitals from Atomic *p* Orbitals

With the principles of molecular orbital theory in place, we are ready to account for bonding in such important homonuclear diatomic molecules as N_2, O_2, and F_2. To describe the bonding in these molecules, we will have to use both *s* and *p* valence orbitals in forming molecular orbitals.

For *p*-block elements, sigma-bonding and antibonding molecular orbitals are formed by their *s* orbitals interacting as in Figure 9.14b. Similarly, it is possible for a *p* orbital on one atom to interact with a *p* orbital on the other atom to produce a pair of σ-bonding and σ^*-antibonding molecular orbitals (Figure 9.15a).

In addition, each *p*-block atom has *two p* orbitals in planes perpendicular to the σ bond connecting the two atoms. These *p* orbitals can interact in a side-by-side fashion to give *two* π-bonding molecular orbitals (π_{2p}) and *two* π-antibonding molecular orbitals (π^*_{2p}) (Figure 9.15b).

(a) Sigma (σ) molecular orbitals from *p* atomic orbitals. Sigma-bonding (σ_{2p}) and antibonding (σ^*_{2p}) molecular orbitals arise from overlap of 2*p* orbitals. Each molecular orbital can accommodate two electrons.



(b) Pi (π) molecular orbitals. Sideways overlap of atomic 2*p* orbitals that lie in the same direction in space gives rise to pi-bonding (π_{2p}) and pi-antibonding (π^*_{2p}) molecular orbitals.

Figure 9.15 Combinations of *p* atomic orbitals to yield σ and π molecular orbitals. The *p* orbitals in electron shells of higher *n* give σ and π molecular orbitals of the same basic shape.

Figure 9.16 Molecular orbitals for homonuclear diatomic molecules of second period elements. The diagram in (a) leads to correct conclusions regarding bond order and magnetic behavior for all second period homonuclear diatomic molecules, but the energy ordering of the MOs in this figure is correct only for B_2, C_2, and N_2. *(A Closer Look: Molecular Orbitals for Molecules Formed from p-Block Elements)*. Another feature of molecular orbitals to notice is that, *for a given set of orbitals, their energy increases as the number of nodes increases*. Thus, the σ^*_{2s} orbital (one node) is higher in energy than the σ_{2s} (no node).

(a) Energy level diagram for B_2, C_2, and N_2. For O_2 and F_2, the σ_{2p} MO is lower in energy than the π_{2p} MOs.

N_2 molecular orbitals

(b) Computer-generated molecular orbitals for N_2. Color scheme: occupied MOs are blue/green. Unoccupied MOs are red/yellow. The different colors in a given orbital reflect the different phases [positive or negative signs] of the wave functions.

Electron Configurations for Homonuclear Molecules for Boron Through Fluorine

Orbital interactions in a second-period, homonuclear, diatomic molecule lead to the energy level diagram in Figure 9.16. Electron assignments can be made using this diagram, and the results for the diatomic molecules B_2 through F_2 are summarized in Table 9.1, which has two noteworthy features.

First, notice the correlation between the electron configurations and the bond orders, bond lengths, and bond energies at the bottom of Table 9.1. As the bond order between a pair of atoms increases, the energy required to break the bond increases, and the bond length decreases. Dinitrogen, N_2, with a bond order of 3, has the largest bond energy and shortest bond length in this group of five homonuclear diatomic molecules.

Second, notice the configuration for dioxygen, O_2. Dioxygen has 12 valence electrons (six from each atom), so it has the molecular orbital configuration

$$\textit{O}_2\ \textit{MO Configuration:}\qquad [\text{core electrons}](\sigma_{2s})^2(\sigma^*_{2s})^2(\sigma_{2p})^2(\pi_{2p})^4(\pi^*_{2p})^2$$

This configuration leads to a bond order of 2 in agreement with experiment and also specifies two unpaired electrons (in π^*_{2p} molecular orbitals) (Table 9.1), thus predicting that dioxygen should be paramagnetic. This is in contrast to a Lewis dot (valence bond) model, which predicts incorrectly that dioxygen should be diamagnetic. Molecular orbital theory succeeds where valence bond theory fails. MO theory explains both the observed bond order and the paramagnetism of O_2 (page 412).

HOMO and LUMO Chemists often refer to the highest energy MO that contains electrons as the HOMO (for "highest occupied molecular orbital"). For O_2, this is the π^*_{2p} orbital. They also use the term LUMO for the "lowest unoccupied molecular orbital." For O_2, this would be σ^*_{2p}.

EXAMPLE 9.6

Electron Configuration for a Homonuclear Diatomic Ion

Problem Potassium superoxide, KO_2, one of the products from the reaction of K and O_2, contains the superoxide ion, O_2^-. Write the molecular orbital electron configuration for the ion, and predict its bond order and magnetic behavior.

What Do You Know? The 2*s* and 2*p* orbitals on the two oxygen atoms can be combined to give the series of molecular orbitals shown in Table 9.1. The O_2^- ion has 13 valence electrons.

Strategy Use the energy level diagram for O_2 in Table 9.1 to generate the electron configuration of the ion, and use Equation 9.1 to determine the bond order. The magnetism is determined by whether there are unpaired electrons.

SOLUTION The MO configuration for O_2^-, an ion with 13 valence electrons, is

$$O_2^- \text{ MO Configuration:} \quad [\text{core electrons}](\sigma_{2s})^2(\sigma^*_{2s})^2(\sigma_{2p})^2(\pi_{2p})^4(\pi^*_{2p})^3$$

The ion is predicted to be paramagnetic to the extent of one unpaired electron, a prediction confirmed by experiment. The bond order is 1.5, because there are eight bonding electrons and five antibonding electrons. The bond order for O_2^- is lower than for O_2 so we predict the O—O bond in O_2^- should be longer than the oxygen–oxygen bond in O_2. The superoxide ion in fact has an O—O bond length of 134 pm, whereas the bond length in O_2 is 121 pm.

Think about Your Answer The superoxide ion contains an odd number of electrons. This is another diatomic species (in addition to NO and O_2) for which it is not possible to write a Lewis structure that accurately represents the bonding.

Check Your Understanding

The cations O_2^+ and N_2^+ are formed when molecules of O_2 and N_2 are subjected to intense, high-energy solar radiation in Earth's upper atmosphere. Write the electron configuration for O_2^+. Predict its bond order and magnetic behavior.

A CLOSER LOOK

Molecular Orbitals for Molecules Formed from *p*-Block Elements

Several features of the molecular orbital energy level diagram in Figure 9.16 and Table 9.1 should be described in more detail.

(a) The bonding and antibonding σ orbitals from $2s$ interactions are lower in energy than the σ and π MOs from $2p$ interactions. The reason is that $2s$ orbitals have a lower energy than $2p$ orbitals in the separated atoms.

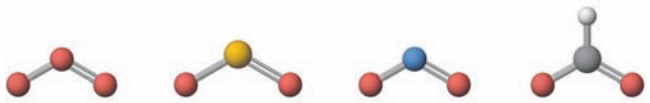
(b) The energy separation of the bonding and antibonding orbitals is greater for σ_{2p} than for π_{2p}. This happens greater for σ_{2p} than for π_{2p}. This happens because p orbitals overlap to a greater extent when they are oriented head to head (to give σ_{2p} MOs) than when they are side by side (to give π_{2p} MOs). The greater the orbital overlap, the greater the stabilization of the bonding MO and the greater the destabilization of the antibonding MO.

(c) You may have been surprised that Figure 9.16 shows the π_{2p} orbitals lower in energy than the σ_{2p} orbital. Why would the π_{2p} orbitals be lower? A more sophisticated approach to constructing MOs takes into account the "mixing" of s and p atomic orbitals, which have similar energies. This causes the σ_{2s} and σ^*_{2s} molecular orbitals to be lower in energy than otherwise expected, and the σ_{2p} and σ^*_{2p} orbitals to be higher in energy.

(d) The mixing of s and p orbitals is important for B_2, C_2, and N_2, so Figure 9.16 applies strictly only to these molecules. For O_2 and F_2 mixing is less important, so σ_{2p} is lower in energy than π_{2p} (as shown in Table 9.1).

Electron Configurations for Heteronuclear Diatomic Molecules

Molecules such as CO, NO, and ClF, which contain two different elements, are examples of *heteronuclear* diatomic molecules. Molecular orbital descriptions for heteronuclear diatomic molecules resemble those for homonuclear diatomic molecules, but there can be significant differences.

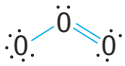


Carbon monoxide is an important molecule, so it is worth looking at its bonding. The $2s$ and $2p$ orbitals of O are at a lower relative energy than the $2s$ and $2p$ orbitals of C (page 322). These atoms and their orbitals can nonetheless be combined in the same way as in homonuclear diatomic molecules to give an ordering of molecular orbitals that is similar to N_2. The 10 valence electrons of CO are added to the available molecular orbitals from lowest to highest energy, and the molecular orbital electron configuration for CO is

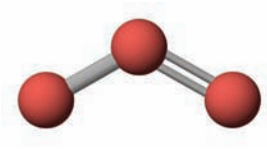
$$\textit{CO MO Configuration:} \qquad [\text{core electrons}](\sigma_{2s})^2(\sigma^*_{2s})^2(\pi_{2p})^4(\sigma_{2p})^2$$

This shows that CO has a bond order of 3 (two π bonds and one σ bond), as expected from the Lewis electron dot structure.

Resonance and MO Theory



Ozone, O_3, is a simple triatomic molecule with equal oxygen–oxygen bond lengths. Equal X—O bond lengths are also observed in other molecules and ions, such as SO_2, NO_2^-, and HCO_2^-. Valence bond theory introduced resonance to represent the equivalent bonding to the oxygen atoms in these structures, but MO theory also provides a useful view of bonding in these molecules and ions.



To understand the bonding in ozone, let's begin by looking at the valence bond picture. First, assume that all three O atoms are sp^2 hybridized. The central atom uses its sp^2 hybrid orbitals to form two σ bonds and to accommodate a lone pair. The terminal atoms use their sp^2 hybrid orbitals to form one σ bond and to accommodate two lone pairs. Thus, seven of the nine valence electron pairs in O_3 are either lone pairs or bonding pairs in the σ framework of O_3 (Figure 9.17a). The π bond in ozone arises from the two remaining pairs (Figure 9.17b). Because we have assumed

Lewis structure of O_3. All O atoms are sp^2 hybridized.

Molecular model

Representation of the σ bonding framework of O_3 using sp^2 hybrid orbitals.

(a) Ozone, O_3, has equal-length oxygen–oxygen bonds, which, in valence bond theory, would be rationalized by resonance structures. The σ bonding framework of O_3 is formed by utilizing sp^2 hybrid orbitals on each O atom. These accommodate two σ bonds and five lone pairs.

(b) The π molecular orbital diagram for ozone. Again note that the MOs increase in energy as the number of nodes increases.

Figure 9.17 A bonding model for ozone, O_3.

that each oxygen atom in O_3 is sp^2 hybridized, an unhybridized p orbital perpendicular to the O_3 plane remains on each of the three oxygen atoms. These orbitals are in the correct orientation to form a π bond.

To simplify matters, let's now apply MO theory only to these three p orbitals that can be involved in π bonding in ozone. We begin by remembering a principle of MO theory: the number of molecular orbitals must equal the number of combining atomic orbitals. Thus, the three $2p$ atomic orbitals must be combined in a way that forms three molecular orbitals.

One π_p MO for ozone is a bonding orbital because the three p orbitals are "in phase" across the molecule (Figure 9.17b). Another π_p MO is an antibonding orbital because the atomic orbital on the central atom is "out of phase" with the terminal atom p orbitals. The third π_p MO is a *nonbonding* orbital because the middle p orbital does not participate in the MO. (Electrons in this molecular orbital would reside on the two terminal atoms only; they do not overlap, and thus they neither help nor hinder the bonding in the molecule.)

One of the two pairs of π_p electrons of O_3 occupies the lowest energy or π_p-bonding MO, which is delocalized, or "spread over," the molecule (just as the resonance hybrid of valence bond theory implies). The π_p-nonbonding orbital is also occupied, but the electrons in this orbital are concentrated near the two terminal oxygens. Thus, there is a net of only one pair of π_p-bonding electrons for two O—O bonds, giving a π bond order for O_3 of 0.5 for each O—O bond. Because the σ bond order is 1.0 and the π bond order is 0.5 for each O—O linkage, each oxygen–oxygen bond order is 1.5—the same value given by valence bond theory.

The observation that the π molecular orbitals for ozone extend over three atoms illustrates an important point regarding molecular orbital theory: *Molecular orbitals can extend beyond two atoms.* In valence bond theory, in contrast, all representations for bonding are based on being able to localize pairs of electrons in bonds between two atoms. To further illustrate the MO approach, look again at benzene (Figure 9.18). On page 426, we noted that the π electrons in this molecule were spread out over all six carbon atoms. You can now see how the same case can be made with MO theory. Six p orbitals contribute to the π system. Because the number of molecular orbitals must equal the number of atomic orbitals, there must be six π molecular orbitals in benzene. An energy level diagram for benzene shows that the six π electrons reside in the three lowest-energy (bonding) molecular orbitals.

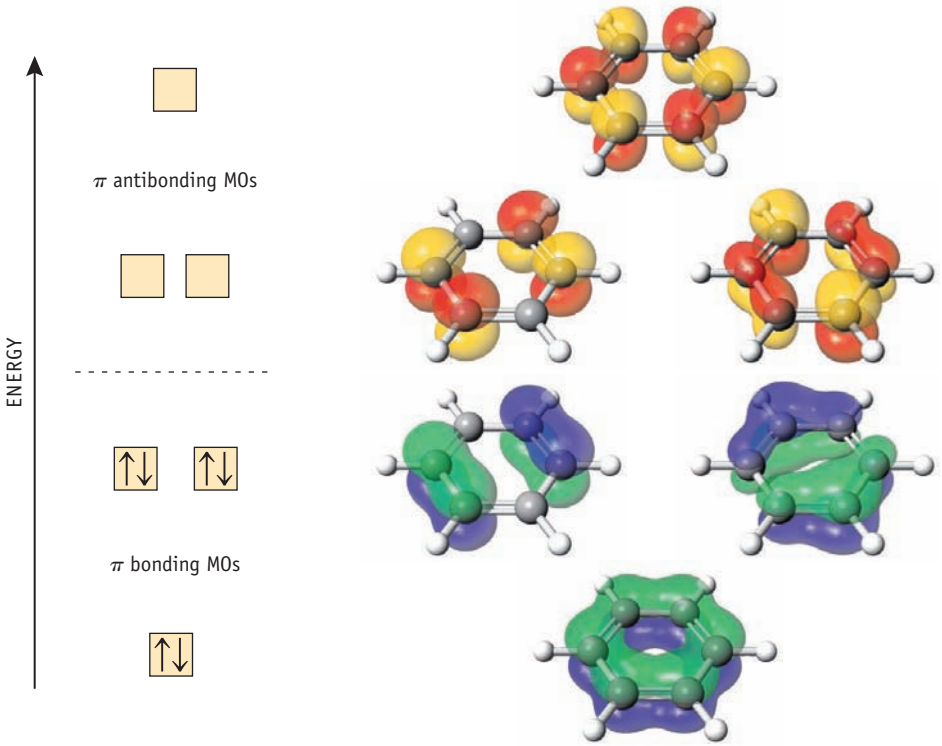

Figure 9.18 Molecular orbital energy level diagram for benzene. Because there are six unhybridized *p* orbitals (one on each C atom), six π molecular orbitals can be formed—three bonding and three antibonding. The three bonding molecular orbitals accommodate the six π electrons. Finally, note that the MOs increase in energy as the number of nodes increases.

9.3 Theories of Chemical Bonding: A Summary

Goal for Section 9.3

- Understand and use valence bond theory and molecular orbital theory, the two commonly used theories for covalent bonding, to describe bonding in small molecules and ions.

In this chapter, we have introduced two different models of chemical bonding: valence bond theory and molecular orbital theory. Both theories give good descriptions of the bonding in molecules and polyatomic ions, but they are useful in different situations. Valence bond theory is generally the method of choice to provide a qualitative, visual picture of molecular structure and bonding. This theory is particularly useful for molecules made up of many atoms, and it provides a good description of bonding for molecules in their ground or lowest energy state.

The key idea in both theories is that orbitals on two or more atoms overlap as effectively as possible so that the bonding electrons are brought under the influence of the nuclei of the bonded atoms. In valence bond theory, we picture bonds as resulting from the overlap of atomic orbitals in the valence shells of two atoms. In order to match the electron-pair geometry of the central atom, valence bond theory adds the idea that the valence orbitals of the central atom hybridize to match this geometry. Considering only *s* and *p* valence orbitals, the hybrid orbital sets encountered in compounds of main group elements are:

Hybrid Orbitals	Atomic Orbitals Used	Number of Hybrid Orbitals	Electron-Pair Geometry
sp	$s + p$	2	Linear
sp^2	$s + p + p$	3	Trigonal-planar
sp^3	$s + p + p + p$	4	Tetrahedral

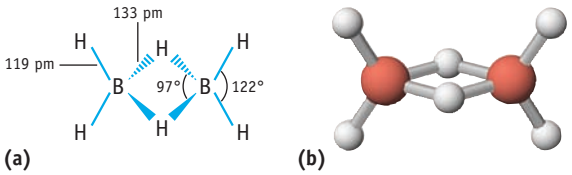
A CLOSER LOOK

Three-Center Bonds in HF_2^-, B_2H_6, and SF_6

Although a large majority of known compounds can be described by Lewis electron dot pictures, nature (and chemistry) has a surprise now and then. You have already seen several examples (most notably O_2 and NO) where it is not possible to draw simple dot structures. In these instances we turned to MO theory to understand the bonding.

Let's look at the ion HF_2^-, formed from F^- and HF. This ion has a linear structure (F—H—F) with a hydrogen atom midway between two fluorine atoms. Of the 16 valence electrons in the ion, there are 4 that can be utilized in bonding (the other 12 are lone pairs on F).

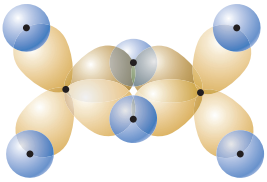
But how can we account for bonding in the ion? The best way is to use MO theory. We begin with three atomic orbitals, the $2p_z$ orbitals on each fluorine atom and the $1s$ orbital on hydrogen.



valence orbitals available in F—H—F^-

Three atomic orbitals of H and F combine to produce three molecular orbitals, one a bonding orbital occupied by a pair of electrons.

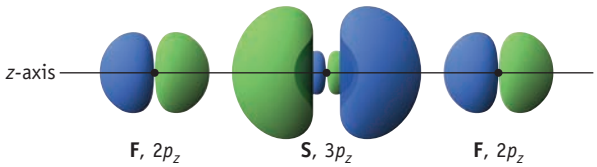
As in the model used for π bonding in ozone (Figure 9.17) three orbitals (here, the $1s$ for H and the $2p_z$ orbitals for each F) combine to form three molecular orbitals, one bonding, one nonbonding, and one antibonding. One pair of valence electrons is placed in the bonding MO and one in the nonbonding MO, to give a net of one bond. This result, which nicely accounts for the bonding, is often referred to as a *three-center/four-electron bond* model.



Diborane, B_2H_6, is another molecule for which an acceptable Lewis dot structure cannot be drawn. As the structure below shows, each boron atom has distorted tetrahedral geometry.

The structure of diborane, B_2H_6, a molecule involving three-center, two-electron B—H—B bonds

The molecule has two terminal hydrogen atoms bonded to each boron atom, and two hydrogen atoms bridge the two boron atoms. Chemists refer to diborane as "electron deficient" because two B atoms and six H atoms do not contribute enough electrons (only 6 pairs) for eight, two-electron bonds.



We can again account for the bonding in this molecule using MO theory with three-center bonds, each involving the two boron atoms and an H atom. Let's begin by assuming that each B atom is sp^3 hybridized. The four terminal H atoms bond to the B atoms with two-electron bonds using 8 of the 12 electrons and two of the sp^3 hybrid orbitals on each B atom. The 4 remaining electrons account for the two B—H—B bridges. Three molecular orbitals encompassing the B—H—B atoms in each bridge can be constructed from the remaining two sp^3 hybrid orbitals on each B atom and an H atom $1s$ orbital. Again, one MO is bonding, one is nonbonding, and one is antibonding. Two electrons are assigned to the bonding orbital, resulting in a *three-center/two-electron* bond. Not surprisingly, this kind of bond is weaker than a typical two-electron/two-center bond, and diborane dissociates to two BH_3 molecules at fairly low temperatures.

An overlap of sp^3 orbitals, one from each B atom, and an H $1s$ creates two, three-center/two-electron bonds.

And finally we return to an issue introduced earlier: *whether* d *orbitals are involved in bonding in some main group element compounds.* Theory suggests that *d* orbitals are not significantly involved in bonding in ions such as SO_4^{2-} and PO_4^{3-} (page 370). If we accept the idea that *d* orbitals are too high in energy to be used in bonding in main group element compounds, how can we use hybrid orbitals that involve *d* orbitals to describe bonding in PF_5 and SF_6, for example? Another bonding model is needed, and molecular orbital theory provides the alternative without the use of *d* orbitals.

Consider SF_6 with an octahedral electron-pair geometry. The molecule has a total of 24 valence electron pairs. Of these, 18 are involved as lone pairs on the F atoms, so 6 electron pairs remain to account for 6 S-F bonds. Let's look specifically at the bonding between sulfur and two fluorine atoms across from each other along each of the three axes.

Three atomic orbitals of S and F combine to produce three molecular orbitals, one a bonding orbital occupied by a pair of electrons.

Along the *z*-axis, for example, bonding, nonbonding, and antibonding orbitals can be constructed from combinations of the $3p_z$ orbital on sulfur and the two $2p_z$ orbitals on fluorine. Four electrons are placed in the bonding and nonbonding orbitals. This description is repeated on the *x*- and *y*-axis, which means that two electron pairs are involved in the F—S—F group along each axis. That is, each of the three F—S—F "groups" is bonded with a three-center/four-electron bond, thus accounting nicely for the bonding in SF_6 without using *d* orbitals.

Be sure to notice that the number of hybrid orbitals is equal to the number of orbitals combined. The resulting orbitals then combine with other atomic or hybrid orbitals to accommodate either bond pairs or lone pairs. If orbitals are unused in forming hybrid orbitals, they may be empty (and lead to a particularly reactive molecule) or they may be used to form π bonds.

In molecular orbital theory, we picture that the atomic orbitals on atoms combine to form new orbitals belonging to the molecule as a whole. As in forming hybrid orbitals, the number of molecular orbitals is always the same as the number of combined orbitals. Bonding molecular orbitals are lower in energy than their parent orbitals, and antibonding orbitals are higher in energy; in some cases, nonbonding molecular orbitals are also present. As you can see in many figures in Section 9.2 (see Figure 9.17 in particular), the energy of the molecular orbitals increases with the number of nodal planes.

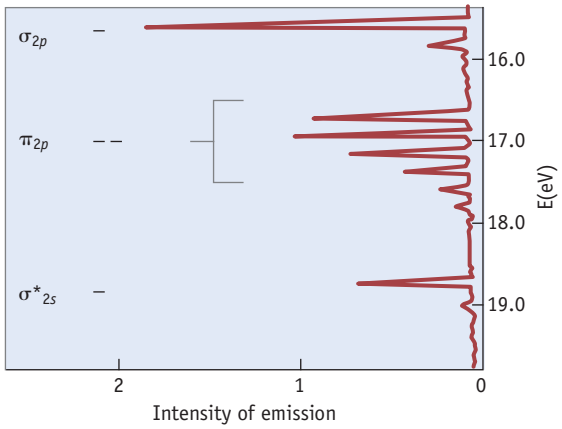
In contrast to valence bond theory, molecular orbital theory is used when a quantitative picture of bonding is needed, and it is essential if we want to describe molecules in higher-energy, excited states. Among other things, this is important in explaining the colors of compounds. Finally, for a few molecules such as NO and O_2, MO theory is the only one of the two theories that can describe their bonding accurately.

APPLYING CHEMICAL PRINCIPLES

9.1 Probing Molecules with Photoelectron Spectroscopy

Photoelectron spectroscopy is an instrumental technique that enables the measurement of orbital energies in atoms and molecules. (See page 333 for an introduction to the technique.) In this technique gas phase atoms or molecules are ionized by high-energy radiation. For a molecule (M), the process is as follows:

$$M + h\nu \rightarrow M^+ + e^-$$



A photon with sufficient energy ($h\nu$) can cause an electron to be ejected from the atom or molecule. If the photon has energy that is above the threshold required for ionization, the excess energy is imparted as kinetic energy to the ejected electron. The ionization energy, the energy of the absorbed photon, and the kinetic energy of the ejected electron are related by the equation.

$$IE = h\nu - KE(\text{electron})$$

Photoelectron spectroscopy may be used to study orbital energies of either core or valence electrons. Ionization of a core electron requires x-ray radiation, whereas ionization of valence electrons (which are responsible for bonding in molecules) requires lower energy ultraviolet (UV) radiation.

Helium gas is the most common UV radiation source used for the photoelectron spectroscopy of molecules. When electronically excited, He atoms emit nearly monochromatic (single wavelength) radiation at a wavelength of 58.4 nm. The energy of these photons is above the threshold required to eject electrons from many valence shell molecular orbitals.

The figure shows the valence shell photoelectron spectrum for N_2 molecules. The molecular orbital diagram (Figure 9.16 and Table 9.1) indicates that N_2 has four types of filled orbitals: σ_{2s}, σ^*_{2s}, π_{2p}, and σ_{2p}. The photoelectron spectrum detects three groupings of ejected electrons with average ionization energies of 15.6 eV, 16.7 eV, and 18.6 eV (where 1 electron volt = 1.60218×10^{-19} J). These electrons are ejected from the σ^*_{2s}, π_{2p}, and σ_{2p} orbitals, respectively. A fourth peak is not seen because the energy required to remove an electron from the σ_{2s} orbital is higher than that of the photons emitted by the excited helium atoms.

The photoelectron spectrum of N_2 gas. (Adapted from G. L. Miessler and D. A. Tarr, *Inorganic Chemistry,* Pearson, 3rd edition, 2004, page 131.)

The extra peaks, most obvious around 17–18 eV, are associated with ionization from the π orbital. They result from coupling of the ionization energy and the energy resulting from molecular vibrations.

Questions:

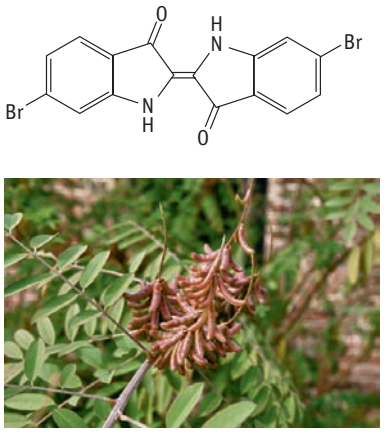
1. Photoelectron spectroscopy is similar to the photoelectric effect (Section 6.2). However, in the photoelectric effect, electrons are ejected when light strikes the surface of a(n) _____.
2. What is the energy of a photon with a wavelength of 58.4 nm in kilojoules/mole?
3. Using the accompanying figure, state which molecular orbital (σ^*_{2s}, π_{2p}, or σ_{2p}) has an ionization energy of 15.6 eV.
4. The kinetic energy of an electron ejected from the σ^*_{2s} molecular orbital of N_2 using 58.4 nm radiation is 4.23×10^{-19} J. What is the ionization energy, in both kJ/mol and eV, of an electron from this orbital?
5. The N_2^+ ions that are formed when electrons with ionization energies of 15.6 eV and 16.7 eV are ejected have longer bond lengths than the ion when an electron with an ionization energy of 18.6 eV is created. Why?

9.2 Green Chemistry, Safe Dyes, and Molecular Orbitals

Chemists are obligated not only to search for useful new materials but also to ensure they are safe to use and to produce them in the safest manner possible. This is the essence of "green chemistry," and one recent success has been in the dye industry.

Dyes and pigments have been used for centuries because humans want colorful clothing and objects. Dyes have always been extracted from plants such as onion skins, red cabbage, and fruits and berries. Some, however, also came from animals, and one, Tyrian purple, was especially prized. This dye, known to the ancient Greeks, can be extracted from a marine snail, *Murex brandaris*. The problem is that it takes over 12,000 tiny snails to produce enough dye to color a small portion of one garment. Fortunately, it was later discovered that a beautiful deep blue dye could be obtained from the indigo plant, and indigo plantations were established in parts of colonial America. (Indigo and Tyrian purple have the same molecular framework, but indigo lacks the two Br atoms.)

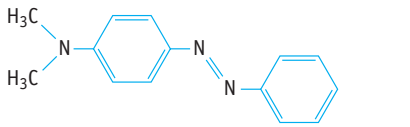
The first synthetic dye was produced by accident in 1856. William Perkin, then 18, was searching for an antimalarial drug, but the route he chose to make it led instead to the dye mauveine. Because dyes were so highly prized, his discovery led to the synthesis of many more dyes. Indeed, some say Perkin's discovery led to the modern chemical industry.



Chemists have developed large numbers of dyes, among them azo dyes, so named because they contain a N═N double bond (an azo group). One example is "butter yellow" (Figure B). It was given this name because it was originally used to give butter a more appealing yellow color. The problem is that the molecule is carcinogenic.

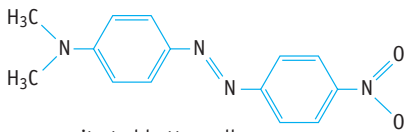
The fact that some dyes were unsafe led chemists to look for ones that would produce the desired color but were not toxic. In the case of butter yellow, the solution was to add an $—NO_2$ group to the molecule to give a new yellow dye that is easy to synthesize and safe to use.

The structure of indigo is typical of many dyes: It has alternating double bonds (C═C and C═O) extending across the molecule. Azo dyes similarly have extended frameworks of alternating double bonds. Indeed, all organic dye molecules have extended π bonding networks, and it is this that leads to their color. The extended π bonds give rise to low-energy π antibonding molecular orbitals. When visible light strikes such a molecule, an electron can be excited from a bonding or nonbonding molecular orbital to an antibonding molecular orbital, and light is absorbed (Figure C). Your eye sees the wavelengths of light not absorbed by the molecule, so it has the color of the remaining wavelengths of light. For example, on page 204 you see a case where a substance absorbs wavelengths of light in the blue region of the spectrum, so you see red light.



Questions:

1. What is the empirical formula of Tyrian purple?
2. Butter yellow absorbs light with a wavelength of 408 nm, whereas the nitrated form absorbs at 478 nm. Which absorbs the higher energy light?
3. How many alternating double bonds are there in Tyrian purple? In nitrated butter yellow?



John C. Kotz

FIGURE A Indigo. (above) Tyrian purple or 6,6′-dibromoindigo ($C_{16}H_8N_2O_2Br_2$). (below) Indigo plant. The indigo molecule has no Br atoms.

butter yellow

nitrated butter yellow

FIGURE B The structure of "butter yellow" and "nitrated butter yellow." The first is a synthetic dye originally used to color butter. It is in the class of azo dyes, all characterized by an N═N double bond. The nitrated version is safe for human consumption.

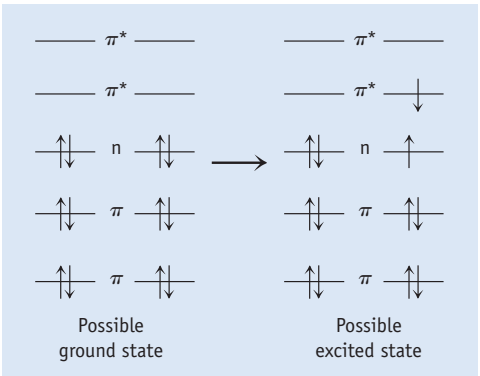


FIGURE C Light is absorbed by a dye molecule by the promotion of an electron from a nonbonding molecular orbital to an antibonding π molecular orbital. (Light absorption by all molecules occurs by promotion of an electron from a low-lying to a higher-lying molecular orbital.)

CHAPTER GOALS REVISITED

The goals for this chapter are keyed to specific Study Questions to help you organize your review.

9.1 Valence Bond Theory

- Understand how sigma (σ) and pi (π) bonds arise through orbital overlap. **1, 3, 5, 32-33, 48, 55, 56, 68.**
- Identify the hybrid orbitals used to match the electron-pair geometry of the central atom. **1-6, 15, 16, 55, 56, 58.**

9.2 Molecular Orbital Theory

- Write molecular orbital configurations for simple diatomic molecules or ions, determine the bond order of each species, and predict its magnetic behavior. **21–28, 42, 45–47.**

9.3 Theories of Chemical Bonding: A Summary

- Understand and use valence bond theory and molecular orbital theory, the two commonly used theories for covalent bonding, to describe bonding in small molecules and ions. **21, 23, 43, 64.**

KEY EQUATION

Equation 9.1 (page 429) Used to calculate the order of a bond from the molecular orbital electron configuration.

$$\text{Bond order} = 1/2\ (\text{number of electrons in bonding MOs} - \text{number of electrons in antibonding MOs})$$

STUDY QUESTIONS

▲ denotes challenging questions. **Blue-numbered questions** have answers in Appendix N and fully worked solutions in the *Student Solutions Manual*.

Practicing Skills

Valence Bond Theory

(See Examples 9.1–9.3.)

1. Draw the Lewis structure for chloroform, $CHCl_3$. What are its electron-pair and molecular geometries? What orbitals on C, H, and Cl overlap to form bonds involving these elements?
2. Draw the Lewis structure for NF_3. What are its electron-pair and molecular geometries? What is the hybridization of the nitrogen atom? What orbitals on N and F overlap to form bonds between these elements?
3. Draw the Lewis structure for hydroxylamine, H_2NOH. What is the hybridization for nitrogen and oxygen in this molecule? What orbitals overlap to form the bond between nitrogen and oxygen?
4. Draw the Lewis structure for 1,1-dimethylhydrazine [$(CH_3)_2NNH_2$, a compound used as a rocket fuel]. What is the hybridization for the two nitrogen atoms in this molecule? What orbitals overlap to form the bond between the nitrogen atoms?
5. Draw the Lewis structure for carbonyl fluoride, COF_2. What are the electron-pair geometry and molecular geometry around the central atom? What is the hybridization of the carbon atom? What orbitals overlap to form the σ and π bonds between carbon and oxygen?

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

6. Draw the Lewis structure for acetamide, CH_3CONH_2. What are the electron-pair geometry and molecular geometry around the two C atoms? What is the hybridization of each of the C atoms? What orbitals overlap to form the σ and π bonds between carbon and oxygen?

7. Specify the electron-pair and molecular geometry for each underlined atom in the following list. Describe the hybrid orbital set used by this atom in each molecule or ion.

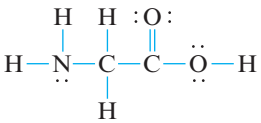
   (a) $\underline{B}Br_3$ (c) $\underline{C}H_2Cl_2$

   (b) $\underline{C}O_2$ (d) $\underline{C}O_3^{2-}$

8. Specify the electron-pair and molecular geometry for each underlined atom in the following list. Describe the hybrid orbital set used by this atom in each molecule or ion.

   (a) $\underline{C}Se_2$ (c) $\underline{C}H_2O$

   (b) $\underline{S}O_2$ (d) $\underline{N}H_4^+$



9. What hybrid orbital set is used by each of the indicated atoms in the molecules below?

   (a) the carbon atoms and the oxygen atom in dimethyl ether, CH_3OCH_3

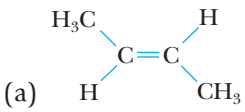
   (b) each carbon atom in propene

   (c) the two carbon atoms and the nitrogen atom in the amino acid glycine

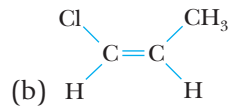
10. What is the hybrid orbital set used by each of the underlined atoms in the following molecules?

11. Draw the Lewis structures of the acid HPO_2F_2 and its anion $PO_2F_2^-$. What is the molecular geometry and hybridization for the phosphorus atom in each species? (H is bonded to an O atom in the acid.)

12. Draw the Lewis structures of the acid HSO_3F and its anion SO_3F^-. What is the molecular geometry and hybridization for the sulfur atom in each species? (H is bonded to an O atom in the acid.)

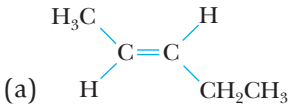


13. What is the hybridization of the carbon atom in phosgene, Cl_2CO? Give a complete description of the σ and π bonding in this molecule.

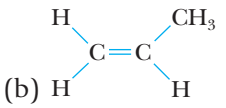


14. What is the hybridization of the carbon atoms in benzene, C_6H_6? Describe the σ and π bonding in this compound.

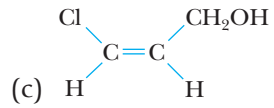
15. What is the electron-pair and molecular geometry around the central S atom in thionyl chloride, $SOCl_2$? What is the hybridization of sulfur in this compound?



16. What is the electron-pair and molecular geometry around the central S atom in sulfuryl chloride, SO_2Cl_2? What is the hybridization of sulfur in this compound?



17. The arrangement of groups attached to the C atoms involved in a C═C double bond leads to *cis* and *trans* isomers. For each compound below, draw the other isomer.



18. For each compound below, decide whether *cis* and *trans* isomers are possible. If isomerism is possible, draw the other isomer.

Molecular Orbital Theory

(See Examples 9.4–9.6.)

19. The hydrogen molecular ion, H_2^+, can be detected spectroscopically. Write the electron configuration of the ion in molecular orbital terms. What is the bond order of the ion? Is the hydrogen–hydrogen bond stronger or weaker in H_2^+ than in H_2?

20. Give the electron configurations for the ions Li_2^+ and Li_2^- in molecular orbital terms. Compare the Li—Li bond order in these ions with the bond order in Li_2.

21. Calcium carbide, CaC_2, contains the acetylide ion, C_2^{2-}. Sketch the molecular orbital energy level diagram for the ion and the electron dot strucure.

   (a) How many net σ and π bonds does the ion have?

   (b) What is the carbon–carbon bond order?

   (c) Compare the valence bond and MO pictures with regard to the number of σ and π bonds and the bond order.

   (d) How has the bond order changed on adding electrons to C_2 to obtain C_2^{2-}?

   (e) Is the C_2^{2-} ion paramagnetic?

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

22. Platinum hexafluoride is an extremely strong oxidizing agent. It can even oxidize oxygen, its reaction with O_2 giving $O_2^+PtF_6^-$. Sketch the molecular orbital energy level diagram for the O_2^+ ion. How many net σ and π bonds does the ion have? What is the oxygen–oxygen bond order? How has the bond order changed on taking away electrons from O_2 to obtain O_2^+? Is the O_2^+ ion paramagnetic?

23. When sodium and oxygen react, one of the products obtained is sodium peroxide, Na_2O_2. The anion in this compound is the peroxide ion, O_2^{2-}. Write the electron configuration for this ion in molecular orbital terms, and draw the electron dot structure.

(a) Compare the ion with the O_2 molecule with respect to the following: magnetic character, net number of σ and π bonds, bond order, and oxygen–oxygen bond length.

(b) Compare the valence bond and MO pictures with regard to the number of σ and π bonds and the bond order.

24. When potassium and oxygen react, one of the products obtained is potassium superoxide, KO_2. The anion in this compound is the superoxide ion, O_2^-. Write the electron configuration for this ion in molecular orbital terms, and then compare it with the electron configuration of the O_2 molecule with respect to the following criteria:

(a) magnetic character

(b) net number of σ and π bonds

(c) bond order

(d) oxygen–oxygen bond length

Courtesy of the Mine Safety Appliances Company

A closed-circuit breathing apparatus that generates its own oxygen. One source of oxygen is potassium superoxide (KO_2). Both carbon dioxide and moisture exhaled by the wearer into the breathing tube react with the KO_2 to generate oxygen.

25. Among the following, which has the shortest bond and which has the longest: Li_2, B_2, C_2, N_2, O_2?

26. Consider the following list of small molecules and ions: C_2, O_2^-, CN^-, O_2, CO, NO, NO^+, C_2^{2-}, OF^-. Identify

(a) all species that have a bond order of 3

(b) all species that are paramagnetic

(c) species that have a fractional bond order

27. Assume the energy level diagram shown in Figure 9.16 can be applied to the heteronuclear molecule ClO.

(a) Write the electron configuration for chlorine monoxide, ClO.

(b) What is the highest-energy, occupied molecular orbital (the HOMO)?

(c) Is the molecule diamagnetic or paramagnetic?

(d) What is the net number of σ and π bonds? What is the ClO bond order?

28. The nitrosyl ion, NO^+, has an interesting chemistry. Assume the molecular orbital diagram shown in Figure 9.16 applies to NO^+.

(a) Is NO^+ diamagnetic or paramagnetic? If paramagnetic, how many unpaired electrons does it have?

(b) What is the highest-energy molecular orbital (HOMO) occupied by electrons?

(c) What is the nitrogen–oxygen bond order?

(d) Is the N—O bond in NO^+ stronger or weaker than the bond in NO?

General Questions

These questions are not designated as to type or location in the chapter. They may combine several concepts.

29. Draw the Lewis structure for AlF_4^-. What are its electron-pair and molecular geometries? What orbitals on Al and F overlap to form bonds between these elements? What are the formal charges on the atoms? Is this a reasonable charge distribution?

30. What is the O—S—O angle and the hybrid orbital set used by sulfur in each of the following molecules or ions?

(a) SO_2 (c) SO_3^{2-}

(b) SO_3 (d) SO_4^{2-}

Do all have the same value for the O—S—O angle? Does the S atom in all these species use the same hybrid orbitals?

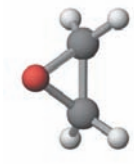
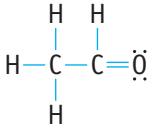
31. Sketch the resonance structures for the nitrite ion, NO_2^-. Describe the electron-pair and molecular geometries of the ion. From these geometries, decide on the O—N—O bond angle, the average NO bond order, and the N atom hybridization.

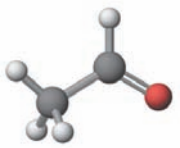


32. Sketch the resonance structures for the nitrate ion, NO_3^-. Is the hybridization of the N atom the same or different in each structure? Describe the orbitals involved in bond formation by the central N atom.

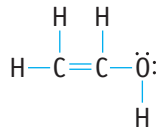
33. Sketch the resonance structures for the N_2O molecule. Is the hybridization of the N atoms the same or different in each structure? Describe the orbitals involved in bond formation by the central N atom.

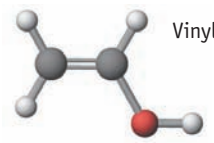


34. Compare the structure and bonding in CO_2 and CO_3^{2-} with regard to the O—C—O bond angles, the CO bond order, and the C atom hybridization.



35. Numerous molecules are detected in deep space. Three of them are illustrated here.



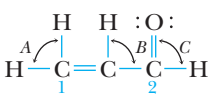


Ethylene oxide

Acetaldehyde

Vinyl alcohol

(a) Are these compounds isomers?



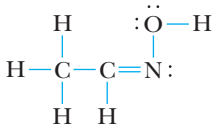
(b) Indicate the hybridization of each C atom in each molecule.

(c) What is the value of the H—C—H angle in each of the three molecules?

(d) Which of these molecules is/are polar?

(e) Which molecule should have the strongest carbon–carbon bond? The strongest carbon–oxygen bond?

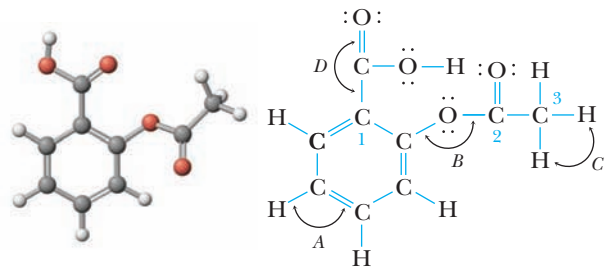
36. Acrolein, a component of photochemical smog, has a pungent odor and irritates eyes and mucous membranes.



(a) What are the hybridizations of carbon atoms 1 and 2?

(b) What are the approximate values of angles *A*, *B*, and *C*?

(c) Is *cis-trans* isomerism possible here?

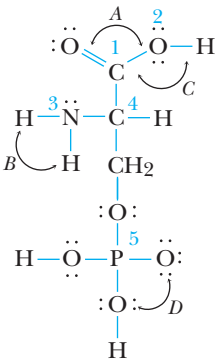


37. The organic compound below is a member of a class known as oximes.

(a) What are the hybridizations of the two C atoms and of the N atom?

(b) What is the approximate C—N—O angle?

38. The compound sketched below is acetylsalicylic acid, commonly known as aspirin.



Aspirin

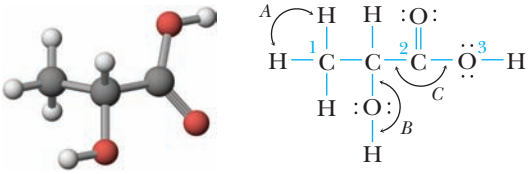
(a) What are the approximate values of the angles marked *A*, *B*, *C*, and *D*?

(b) What hybrid orbitals are used by carbon atoms 1, 2, and 3?

39. Phosphoserine is a less-common amino acid.

Phosphoserine

(a) Identify the hybridizations of atoms 1 through 5.



(b) What are the approximate values of the bond angles *A*, *B*, *C*, and *D*?

(c) What are the most polar bonds in the molecule?

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

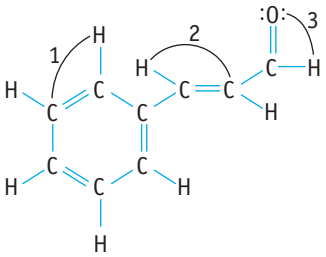
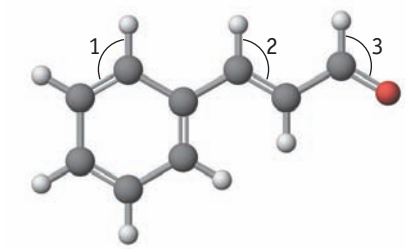
40. Lactic acid is a natural compound found in sour milk.

Lactic acid



(a) How many π bonds occur in lactic acid? How many σ bonds?

(b) What is the hybridization of atoms 1, 2, and 3?



(c) Which CO bond is the shortest in the molecule? Which CO bond is the strongest?

(d) What are the approximate values of the bond angles *A*, *B*, and *C*?

41. Cinnamaldehyde occurs naturally in cinnamon oil.

Cinnamaldehyde

(a) What is the most polar bond in the molecule?

(b) How many σ bonds and how many π bonds are there?

(c) Is *cis-trans* isomerism possible? If so, draw the isomers of the molecule.

(d) Give the hybridization of the C atoms in the molecule.

(e) What are the values of the bond angles *1*, *2*, and *3*?

42. The ion Si_2^- was reported in a laboratory experiment in 1996.

(a) Using molecular orbital theory, predict the bond order for the ion.

(b) Is the ion paramagnetic or diamagnetic?

(c) What is the highest energy molecular orbital that contains one or more electrons?

43. The simple valence bond picture of O_2 does not agree with the molecular orbital view. Compare these two theories with regard to the peroxide ion, O_2^{2-}.

(a) Draw an electron dot structure for O_2^{2-}. What is the bond order of the ion?

(b) Write the molecular orbital electron configuration for O_2^{2-}. What is the bond order based on this approach?

(c) Do the two theories of bonding lead to the same magnetic character and bond order for O_2^{2-}?

44. Nitrogen, N_2, can ionize to form N_2^+ or add an electron to give N_2^-. Using molecular orbital theory, compare these species with regard to (a) their magnetic character, (b) net number of π bonds, (c) bond order, (d) bond length, and (e) bond strength.

45. Which of the homonuclear, diatomic molecules of the second-period elements (from Li_2 to Ne_2) are paramagnetic? Which have a bond order of 1? Which have a bond order of 2? Which diatomic molecule has the highest bond order?

46. Which of the following molecules or ions are paramagnetic? What is the highest occupied molecular orbital (HOMO) in each one? Assume the molecular orbital diagram in Figure 9.16 applies to all of them.

(a) NO

(b) OF^-

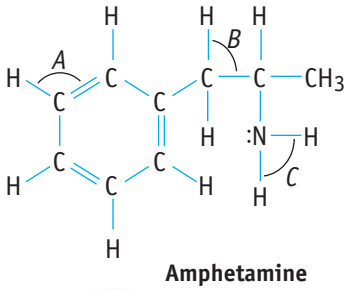
(c) O_2^{2-}

(d) Ne_2^+

47. The CN molecule has been found in interstellar space. Assuming the electronic structure of the molecule can be described using the molecular orbital energy level diagram in Figure 9.16, answer the following questions.

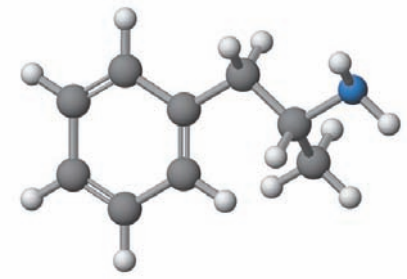
(a) What is the highest energy occupied molecular orbital (HOMO) to which an electron (or electrons) is (are) assigned?

(b) What is the bond order of the molecule?

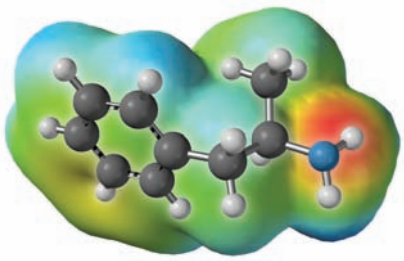


(c) How many net σ bonds are there? How many net π bonds?

(d) Is the molecule paramagnetic or diamagnetic?



Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203



Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

48. The structure of amphetamine, a stimulant, is shown below. (Replacing one H atom on the NH_2, or amino, group with CH_3 gives methamphetamine, a particularly dangerous drug commonly known as "speed.")

Amphetamine

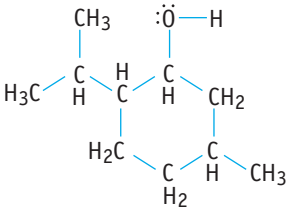
(a) What are the hybrid orbitals used by the C atoms of the C_6 ring, by the C atoms of the side chain, and by the N atom?

(b) Give approximate values for the bond angles *A*, *B*, and *C*.

(c) How many σ bonds and π bonds are in the molecule?

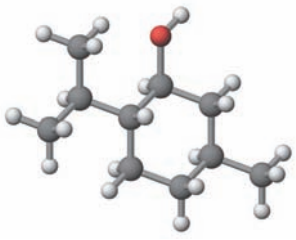
(d) Is the molecule polar or nonpolar?

(e) Amphetamine reacts readily with a proton (H^+) in aqueous solution. Where does this proton attach to the molecule? Explain how the electrostatic potential map predicts this site of protonation.



49. Menthol is used in soaps, perfumes, and foods. It is present in the common herb mint, and it can be prepared from turpentine.

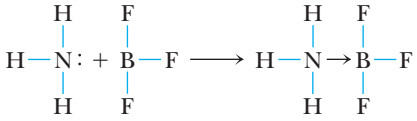
(a) What are the hybridizations used by the C atoms in the molecule?



(b) What is the approximate C—O—H bond angle?

(c) Is the molecule polar or nonpolar?

(d) Is the six-member carbon ring planar or nonplanar? Explain why or why not.



Menthol

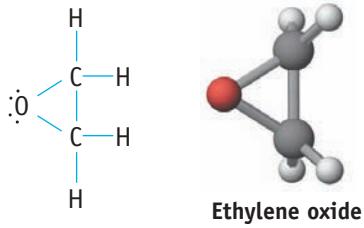
50. The elements of the second period from boron to oxygen form compounds of the type $X_nE—EX_n$, where X can be H or a halogen. Sketch possible Lewis structures for B_2F_4, C_2H_4, N_2H_4, and O_2H_2. Give the hybridizations of E in each molecule and specify approximate X—E—E bond angles.

In the Laboratory

51. Suppose you carry out the following reaction of ammonia and boron trifluoride in the laboratory.

(a) What is the geometry of the boron atom in BF_3? In $H_3N{\rightarrow}BF_3$?

(b) What is the hybridization of the boron atom in the two compounds?



(c) Considering the structures and bonding of NH_3 and BF_3, why do you expect the nitrogen on NH_3 to donate an electron pair to the B atom of BF_3?

(d) BF_3 also reacts readily with water. Based on the ammonia reaction above, speculate on how water can interact with BF_3.

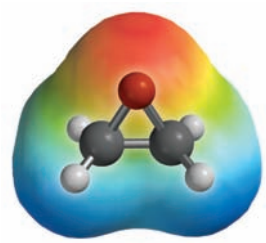
Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.



52. ▲ Ethylene oxide is an intermediate in the manufacture of ethylene glycol (antifreeze) and polyester polymers. More than 4 million tons are produced annually in the United States. The molecule has a three-member ring of two C atoms and an O atom.

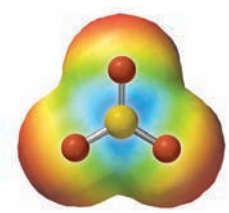
Ethylene oxide

(a) What are the bond angles in the ring? Comment on the relation between the bond angles expected based on hybridization and the bond angles expected for a three-member ring.

(b) Is the molecule polar? Based on the electrostatic potential map shown below, where do the negative and positive charges lie in the molecule?

Electrostatic potential map for ethylene oxide

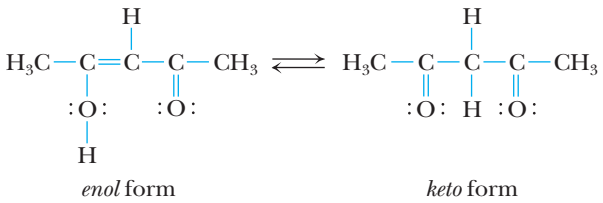
53. The sulfamate ion, $H_2NSO_3^-$, can be thought of as having been formed from the amide ion, NH_2^-, and sulfur trioxide, SO_3.



(a) What are the electron-pair and molecular geometries of the amide ion and of SO_3? What are the hybridizations of the N and S atoms, respectively?

(b) Sketch a structure for the sulfamate ion, and estimate the bond angles.

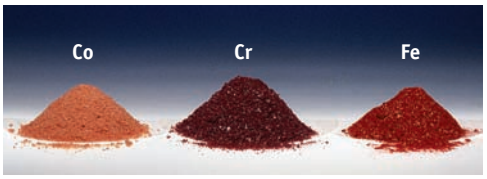
(c) What changes in hybridization do you expect for N and S in the course of the reaction



$$NH_2^- + SO_3 \rightarrow H_2N{-}SO_3^-?$$

(d) Is SO_3 the donor of an electron pair or the acceptor of an electron pair in the reaction with amide ion? Does the electrostatic potential map shown below confirm your prediction?

Electrostatic potential map for sulfur trioxide



54. ▲ The compound whose structure is shown here is acetylacetone. It exists in two forms: the *enol* form and the *keto* form.

enol form ⇌ *keto* form

Acetylacetone

The molecule reacts with OH^- to form an anion, $[CH_3COCHCOCH_3]^-$ (often abbreviated $acac^-$ for acetylacetonate ion). One of the most interesting aspects of this anion is that one or more of them can react with transition metal cations to give stable, highly colored compounds.

© Cengage Learning/ Charles D. Winters

Acetylacetonate complexes $(CH_3COCHCOCH_3)_3M$ where M = Co, Cr, and Fe

(a) Are the *keto* and *enol* forms of acetylacetone resonance forms? Explain your answer.

(b) What is the hybridization of each atom (except H) in the *enol* form? What changes in hybridization occur when it is transformed into the *keto* form?

(c) What are the electron-pair geometry and molecular geometry around each C atom in the *keto* and *enol* forms? What changes in geometry occur when the *keto* form changes to the *enol* form?

(d) Draw three possible resonance structures for the $acac^-$ ion.

(e) Is *cis-trans* isomerism possible in either the *enol* or the *keto* form of acetylacetone?

(f) Is the *enol* form of acetylacetone polar? Where do the positive and negative charges lie in the molecule?

55. Draw the two resonance structures that describe the bonding in the acetate ion. What is the hybridization of the carbon atom of the $—CO_2^-$ group? Select one of the two resonance structures and identify the orbitals that overlap to form the bonds between carbon and the three elements attached to it.

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

56. Carbon dioxide (CO_2), dinitrogen monoxide (N_2O), the azide ion (N_3^-), and the cyanate ion (OCN^-) have the same geometry and the same number of valence shell electrons. However, there are significant differences in their electronic structures.

(a) What hybridization is assigned to the central atom in each species? Which orbitals overlap to form the bonds between atoms in each structure.

(b) Evaluate the resonance structures of these four species. Which most closely describe the bonding in these species? Comment on the differences in bond lengths and bond orders that you expect to see based on the resonance structures.

57. Draw the two resonance structures that describe the bonding in SO_2. Then describe the bonding in this compound using MO theory. How does MO theory rationalize the bond order of 1.5 for the two S—O bonds in this compound?

58. Draw a Lewis structure for diimide, H—N═N—H. Then, using valence bond theory, describe the bonding in this compound. What orbitals overlap to form the bond between nitrogen atoms in this compound?

Summary and Conceptual Questions

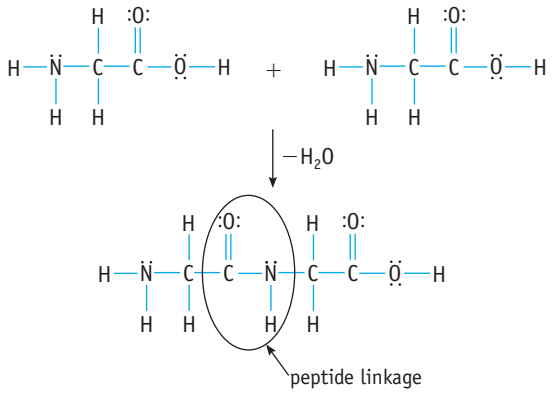
The following questions may use concepts from this and previous chapters.

59. What is the maximum number of hybrid orbitals that a carbon atom may form? What is the minimum number? Explain briefly.

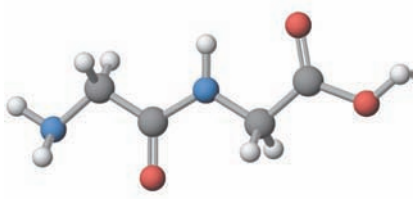
60. Consider the three fluorides BF_4^-, SiF_4, and SF_4.

(a) Identify a molecule that is isoelectronic with BF_4^-.

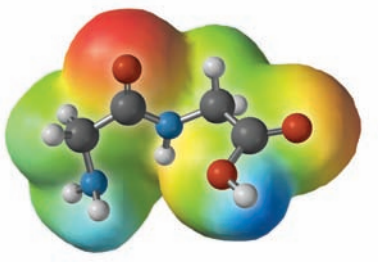
(b) Are SiF_4 and SF_4 isoelectronic?



(c) What is the hybridization of the central atom in BF_4^- and SiF_4?



61. ▲ When two amino acids react with each other, they form a linkage called an *amide group*, or a peptide link. (If more linkages are added, a protein or polypeptide is formed.)



(a) What are the hybridizations of the C and N atoms in the peptide linkage?

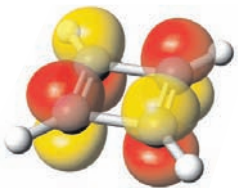
(b) Is the structure illustrated the only resonance structure possible for the peptide linkage? If another resonance structure is possible, compare it with the one shown. Decide which is the more important structure.

(c) The computer-generated structure shown here, which contains a peptide linkage, shows that this linkage is flat. This is an important feature of proteins. Speculate on reasons that the CO—NH linkage is planar. What are the sites of positive and negative charge in this dipeptide?

Electrostatic potential map for a peptide

62. What is the connection between bond order, bond length, and bond energy? Use ethane (C_2H_6), ethylene (C_2H_4), and acetylene (C_2H_2) as examples.

63. When is it desirable to use MO theory rather than valence bond theory?



64. Show how valence bond theory and molecular orbital theory rationalize the O—O bond order of 1.5 in ozone.

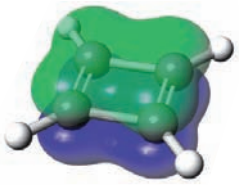
Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

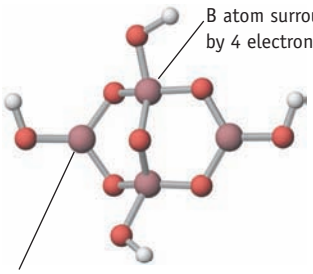
65. Three of the four π molecular orbitals for cyclobutadiene are pictured here. Place them in order of increasing energy. (See Figures 9.13, 9.15, 9.16, and 9.18 and the relation of orbital energy and nodes.)



Orbital A

Orbital B

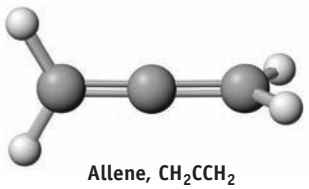
Orbital C



66. Let's look more closely at the process of hybridization.

(a) What is the relationship between the number of hybrid orbitals produced and the number of atomic orbitals used to create them?

(b) Do hybrid atomic orbitals form between different *p* orbitals without involving *s* orbitals?



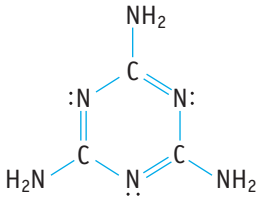
(c) What is the relationship between the energy of hybrid atomic orbitals and the atomic orbitals from which they are formed?

67. Borax has the molecular formula $Na_2B_4O_5(OH)_4$. The structure of the anion in this compound is shown below. What is the electron pair geometry and molecular geometry surrounding each of the boron atoms in this anion? What hybridization can be assigned to each of the boron atoms? What is the formal charge of each boron atom?

The structure of the borax anion

68. A model of the organic compound allene is shown below.

Allene, CH_2CCH_2



(a) Explain why the allene molecule is not flat. That is, explain why the CH_2 groups at opposite ends do not lie in the same plane.

(b) What is the hybridization of each of the carbon atoms in allene?

(c) What orbitals overlap to form the bonds between carbon atoms in allene?

69. Should the energy required to break one of the H—F bonds in HF_2^- ($HF_2^- \rightarrow HF + F^-$) be greater than, less than, or the same as the energy required to break the bond in HF ($HF \rightarrow H + F$). Explain your answer, considering the 3-center-4-electron bond model for HF_2^- described in *A Closer Look: Three-Center Bonds in HF_2^-, B_2H_6, and SF_6.*

70. Melamine is an important industrial chemical, used to make fertilizers and plastics.

Melamine

(a) The carbon-nitrogen bond lengths in the ring are all the same length (about 140 pm). Explain.

(b) Melamine is made by the decomposition of urea, $(H_2N)_2CO$.

$$6\ (H_2N)_2CO(s) \rightarrow C_3H_6N_6(s) + 6\ NH_3(g) + 3\ CO_2(g)$$

Calculate the enthalpy change for this reaction. Is it endo- or exothermic? [$\Delta_f H°$ for melamine(s) = −66.1 kJ/mol and for urea(s) = −333.1 kJ/mol]

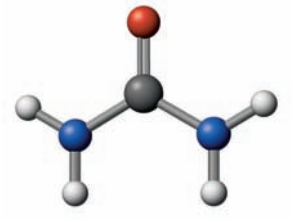
71. Bromine forms a number of oxides of varying stability.

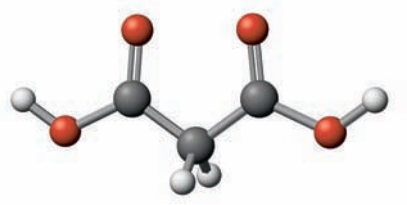
(a) One oxide has 90.90% Br and 9.10% O. Assuming its empirical and molecular formulas are the same, draw a Lewis structure of the molecule and specify the hybridization of the central atom (O).

(b) Another oxide is unstable BrO. Assuming the molecular orbital diagram in Figure 9.16 applies to BrO, write its electron configuration (where Br uses 4*s* and 4*p* orbitals). What is the highest occupied molecular orbital (HOMO) for the molecule?

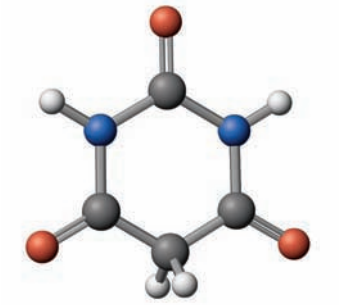


72. The following problem is taken from the Theoretical Examination of the 44th annual International Chemistry Olympiad in 2012, a competition attended by four secondary school students from each of about 70 countries. (Used with permission.)

Graphene is a sheet of carbon atoms arranged in a two-dimensional honeycomb pattern. It can be considered as an extreme case of a polyaromatic hydrocarbon with essentially infinite length in two dimensions. Graphene has remarkable strength, flexibility, and electrical properties. The Nobel Prize for Physics was awarded in 2010 to Andre Geim and Konstantin Novoselov for groundbreaking experiments on graphene. A section of the graphene sheet is shown below.



The area of one hexagonal 6-carbon unit is ~52400 pm^2. Calculate the number of π electrons in a tiny 25 nm $\times$ 25 nm sheet of graphene. For this problem you can ignore edge electrons (i.e., those outside the full hexagons in the picture).



73. Urea reacts with malonic acid to produce barbituric acid, a member of the class of compounds called phenobarbitals, which are widely prescribed as sedatives.

Urea

Malonic acid

Barbituric acid

(a) What bonds are broken and what bonds are made when malonic acid and urea combine to make barbituric acid? Is the reaction predicted to be exo- or endothermic?

(b) Write a balanced equation for the reaction.

(c) Specify the bond angles in barbituric acid.

(d) Give the hybridization of the C atoms in barbituric acid.

(e) What is(are) the most polar bond(s) in barbituric acid?

(f) Is the molecule polar?

10.1 Modeling a State of Matter: Gases and Gas Pressure

10.2 Gas Laws: The Experimental Basis

10.3 The Ideal Gas Law

10.4 Gas Laws and Chemical Reactions

10.5 Gas Mixtures and Partial Pressures

10.6 The Kinetic-Molecular Theory of Gases

10.7 Diffusion and Effusion

10.8 Nonideal Behavior of Gases

10.1 Modeling a State of Matter: Gases and Gas Pressure

Goal for Section 10.1

- Describe how pressure measurements are made and the units of pressure, especially atmospheres (atm) and millimeters of mercury (mm Hg).

Of the three states of matter, the behavior of gases is reasonably simple when viewed at the molecular level and, as a result, it is well understood. It is possible to describe the properties of gases qualitatively in terms of the behavior of the molecules that make up the gas. As you will see, a remarkably accurate description of most gases requires knowing only four quantities: the pressure (***P***), volume (***V***), temperature (***T***, kelvins), and amount (***n***) of the gas. Volume, temperature, and amount (moles) are straightforward quantities; a gas takes the volume of its container (one of the properties of a gas), temperature reflects the thermal energy of individual particles, and amount deals with the number of molecules. Pressure, on the other hand, is a topic that we want to look at in some depth and so we begin with a description of how pressure is measured.

Pressure is the force exerted on an object divided by the area over which it is exerted. Atmospheric pressure can be measured with a barometer. A barometer can be made by filling a tube with a liquid, often mercury, and inverting the tube in a dish containing the same liquid (Figure 10.1). The liquid in the tube will assume a level such that the pressure exerted by the mass of the column of liquid in the tube is balanced by the pressure of the atmosphere pressing down on the surface of the liquid in the dish

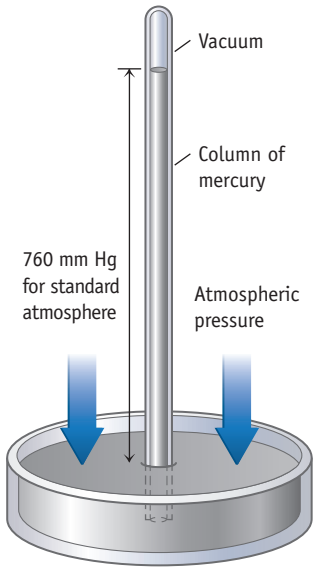

Figure 10.1 A barometer. The pressure of the atmosphere on the surface of the mercury in the dish is balanced by the downward pressure exerted by the column of mercury. The barometer was invented in 1643 by Evangelista Torricelli (1608–1647). A unit of pressure called the *torr* in his honor is equivalent to 1 mm Hg.

◀ **Hot air balloons rely on the fact that the density of gases (air) at constant volume and pressure decreases with increasing temperature.**

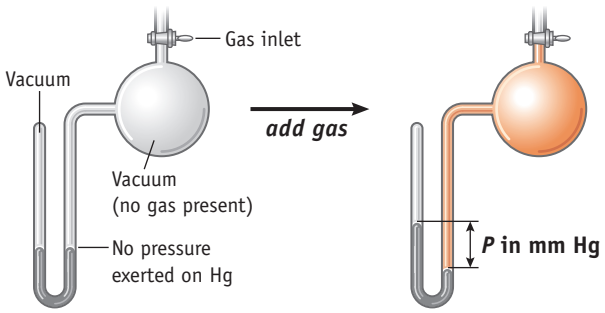
A CLOSER LOOK

Measuring Gas Pressure

Pressure is the force exerted on an object divided by the area over which the force is exerted:

Pressure = force/area



A print copy of this book, for example, weighs more than 4 lb and has an area of 96 in^2, so it exerts a pressure of about 0.04 lb/in^2 when it lies flat on a surface. (In metric units, the pressure is about 300 Pa.)

Now consider the pressure that the column of mercury exerts on the mercury in the dish in the barometer shown in Figure 10.1. This pressure exactly balances the pressure of the atmosphere. Thus, the pressure of the atmosphere (or of any other gas) is equal to the height of the column of mercury (or any other liquid) the gas can support.

Mercury is the liquid of choice for barometers because of its high density. A barometer filled with water would be over 10 m in height. [The water column is about 13.6 times as high as a column of mercury because mercury's density (13.53 g/cm^3) is 13.6 times that of water (density = 0.997 g/cm^3, at 25 °C).]

In the laboratory, we often use a U-tube manometer, which is a mercury-filled, U-shaped glass tube. The closed side of the tube has been evacuated so that no gas remains to exert pressure on the mercury on that side. The other side is open to the gas whose pressure we want to measure. When the gas presses on the mercury in the open side, the gas pressure is read directly (in mm Hg) as the difference in mercury levels on the closed and open sides.

You may have used a tire gauge to check the pressure in your car or bike tires. In the United States, such gauges usually indicate the pressure in pounds per square inch (psi) where 1 atm = 14.7 psi. Some newer gauges give the pressure in kilopascals as well. Be sure to recognize that the reading on the scale refers to the pressure *in excess of atmospheric pressure.* (A flat tire is not a vacuum; it contains air at atmospheric pressure.) For example, if the gauge reads 35 psi (2.4 atm), the pressure in the tire is actually about 50 psi or 3.4 atm.

Using a manometer to measure pressure.

Pressure is often reported in units of **millimeters of mercury (mm Hg)**, the height (in mm) of the mercury column in a mercury barometer above the surface of the mercury in the dish. At sea level, this height is about 760 mm. Pressures are also reported as **standard atmospheres (atm)**, a unit defined as follows:

1 standard atmosphere (1 atm) = 760 mm Hg (exactly)

The SI unit of pressure is the **pascal (Pa)**.

1 pascal (Pa) = 1 $newton/meter^2$

(The newton is the SI unit of force.) Because the pascal is a very small unit compared with ordinary pressures, the unit kilopascal (kPa) is more often used. Another unit used for gas pressures is the **bar**, where 1 bar = 100,000 Pa = 100 kPa.

To summarize, the units used in science for pressure are

1 atm = 760 mm Hg (exactly) = 101.325 kilopascals (kPa) = 1.01325 bar

or

1 bar = 1×10^5 Pa (exactly) = 1×10^2 kPa = 0.98692 atm

EXAMPLE 10.1

Pressure Unit Conversions

Problem Convert a pressure of 635 mm Hg into its corresponding value in units of atmospheres (atm), bars, and kilopascals (kPa).

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

What Do You Know? You will need the following conversion factors:

$$1\ \text{atm} = 760\ \text{mm Hg} = 1.013\ \text{bar} \qquad 760\ \text{mm Hg} = 101.3\ \text{kPa}$$

Strategy Use the relationships between millimeters of Hg, atmospheres, bars, and pascals described in the text. (The use of dimensional analysis, page 43, is highly recommended.)

SOLUTION

(a) Convert pressure in units of mm Hg to units of atm.

$$635\ \cancel{\text{mm Hg}} \times \frac{1\ \text{atm}}{760\ \cancel{\text{mm Hg}}} = 0.836\ \text{atm}$$

(b) Convert pressure in units of mm Hg to units of bar.

$$635\ \cancel{\text{mm Hg}} \times \frac{1.013\ \text{bar}}{760\ \text{mm Hg}} = 0.846\ \text{bar}$$

(c) Convert pressure in units of mm Hg to units of kilopascals.

$$635\ \cancel{\text{mm Hg}} \times \frac{101.3\ \text{kPa}}{760\ \cancel{\text{mm Hg}}} = 84.6\ \text{kPa}$$

Think about Your Answer The original pressure, 635 mm Hg, is less than 1 atm, so the pressure is also less than 1 bar and less than 100 kPa.

Check Your Understanding

At the summit of Mount Everest (altitude = 8848 m), atmospheric pressure is 0.29 atm (or 29% of the pressure at sea level). Convert the pressure into its corresponding value in units of mm Hg, bars, and kilopascals.

10.2 Gas Laws: The Experimental Basis

Goal for Section 10.2

- Understand the basis of the gas laws (Boyle's law, Charles's law, Avogadro's hypothesis) and know how to use those laws.

Boyle's Law: The Compressibility of Gases

The Englishman Robert Boyle (1627–1691) (page 459) first studied the compressibility of gases and observed that the volume of a fixed amount of gas at a given temperature is inversely proportional to the pressure exerted by the gas. All gases behave in this manner, and we now refer to this relationship as **Boyle's law**.

Boyle's law can be demonstrated in many ways. In Figure 10.2, a hypodermic syringe was filled with air (n moles) and sealed. When pressure was applied to the movable plunger of the syringe, the air inside was compressed. As the pressure (P) increased on the syringe, the gas volume in the syringe (V) decreased. When $1/V$ of the gas in the syringe is plotted as a function of P (as measured by mass of lead on the plunger), a straight line results. This type of plot demonstrates that the pressure and volume of the gas are inversely proportional; that is, they change in opposite directions.

Mathematically, we can write Boyle's law as:

$$P \propto \frac{1}{V} \quad \text{when } n \text{ (amount of gas) and } T \text{ (temperature) are constant}$$

where the symbol $\propto$ means "proportional to."

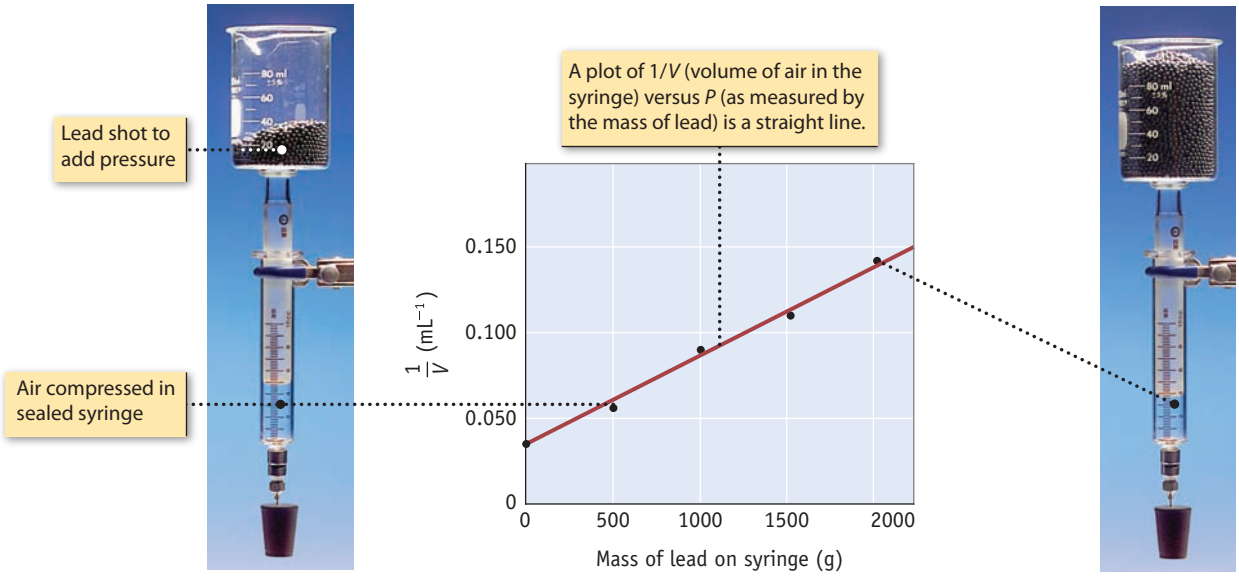

Figure 10.2 An experiment to demonstrate Boyle's law. A syringe filled with air was sealed. Pressure was applied by adding lead shot to the beaker on top of the syringe. As the mass of lead increased, the pressure on the air in the sealed syringe increased, and the gas was compressed.

When two quantities are proportional to each other, they can be equated if a *proportionality constant*, here called C_B, is introduced.

$$P = C_B \times \frac{1}{V} \quad \text{or} \quad PV = C_B \text{ at constant } n \text{ and } T$$

This form of Boyle's law expresses the fact that *the product of the pressure and volume of a gas sample is a constant*, assuming no change in the temperature and the amount of gas. If PV is known for a gas sample under one set of conditions (P_1 and V_1), then it is known for another set of conditions (P_2 and V_2).

$$P_1V_1 = P_2V_2 \text{ at constant } n \text{ and } T \qquad (10.1)$$

This form of **Boyle's law** is useful when we want to know, for example, what happens to the volume of a given amount of gas when the pressure changes at a constant temperature.

Strategy Map 10.2

PROBLEM

Calculate the **pressure** when the *volume of a gas* is **reduced.**

↓

DATA/INFORMATION

- *Initial* pressure
- *Initial* volume
- *Final* volume

Rearrange **Boyle's law** (Equation 10.1) to calculate **final pressure** (P_2).

Pressure (P_2) after reducing the volume

EXAMPLE 10.2

Boyle's Law

Problem A bicycle pump has a volume of 1400 cm^3. If a sample of air in the pump has a pressure of 730 mm Hg, what is the pressure when the volume is reduced to 460 cm^3?

What Do You Know? This is a Boyle's law problem because you are dealing with changes in pressure and/or volume of a given amount of gas at constant temperature. Here the original pressure and volume of gas (P_1 and V_1) and the new volume (V_2) are known, but the final pressure (P_2) is not known. Both volumes are in the same unit so no unit changes are necessary.

Initial Conditions	Final Conditions
$P_1 = 730$ mm Hg	$P_2 = ?$
$V_1 = 1400$ cm^3	$V_2 = 460$ cm^3

Strategy Use Boyle's law, Equation 10.1.

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

SOLUTION You can solve this problem by substituting data into a rearranged version of Boyle's law.

$$P_2 = P_1 (V_1/V_2)$$

$$P_2 = (730 \text{ mm Hg}) \times \frac{1400 \text{ cm}^3}{460 \text{ cm}^3} = 2.2 \times 10^3 \text{ mm Hg}$$

Think about Your Answer You know P and V change in opposite directions. In this case, the volume has decreased, so the new pressure (P_2) must be greater than the original pressure (P_1). The answer of about 2200 mm Hg is reasonable; because the volume decreased by a factor of about 3, the pressure is expected to increase by the same factor.

Check Your Understanding

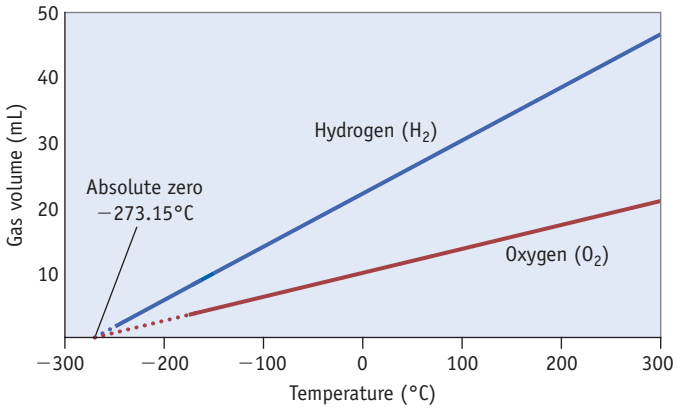
A large balloon contains 65.0 L of helium gas at 25 °C and a pressure of 745 mm Hg. The balloon ascends to 3000 m, at which the external pressure has decreased by 30.%. What would be the volume of the balloon, assuming it expands so that the internal and external pressures are equal? (Assume the temperature is still 25 °C.)

The Effect of Temperature on Gas Volume: Charles's Law

In 1787, the French scientist Jacques Charles (1746–1823) discovered that the volume of a fixed quantity of gas at constant pressure decreases with decreasing temperature. The demonstration in Figure 10.3 shows a dramatic decrease in volume with temperature, and the graph shown in Figure 10.4 illustrates more quantitatively how the volumes of two different gas samples change with temperature (at a constant pressure). When the plots of volume versus temperature are extrapolated to lower temperatures, they both reach zero volume at the same temperature, −273.15 °C. (Of course, gases will not actually reach zero volume; they liquefy or solidify above that temperature.) This extrapolated temperature is significant, however. William Thomson (1824–1907), also known as Lord Kelvin, proposed a temperature scale—now known as the Kelvin scale—for which the zero point is −273.15 °C (page 30). It is important to recognize that the Kelvin scale places an absolute limit (0 K) on the lowest attainable temperature.

(a) Air-filled balloons are placed in liquid nitrogen (77 K). The volume of the gas in the balloons is dramatically reduced at this temperature.

(b) Here all of the balloons have been placed in the flask of liquid nitrogen.



(c) When the balloons are removed they warm to room temperature and reinflate to their original volume.

T (°C)	T (K)	Vol. H_2 (mL)	Vol. O_2 (mL)
300	573	47.0	21.1
200	473	38.8	17.5
100	373	30.6	13.8
0	273	22.4	10.1
−100	173	14.2	6.39
−200	73	6.00	—

Figure 10.4 Charles's law. The solid lines represent the volumes of samples of hydrogen (0.00100 mol) and oxygen (0.000450 mol) at a pressure of 1.00 atm but at different temperatures. The volumes decrease as the temperature is lowered (at constant pressure). These lines, if extended, intersect the temperature axis at approximately −273 °C.

When Kelvin temperatures are used with volume measurements, the volume–temperature relationship is

$$V = C_c \times T \text{ at constant } n \text{ and } P$$

where C_c is a proportionality constant at constant n and P. This is **Charles's law**, which states that *if a given amount of gas is held at a constant pressure, its volume is directly proportional to the Kelvin temperature*.

If the amount of gas and its pressure are held constant and if we know the volume and temperature of a given quantity of gas (V_1 and T_1), we can find the volume, V_2, at some other temperature, T_2, using the equation

$$\frac{V_1}{T_1} = \frac{V_2}{T_2} \quad \text{at constant } n \text{ and } P \tag{10.2}$$

A calculation using Charles's law is illustrated by the following example. Be sure to notice that the temperature T *must always be expressed in kelvins.*

EXAMPLE 10.3

Charles's Law

Problem A sample of CO_2 in a gas-tight syringe (as in Figure 10.2) has a volume of 25.0 mL at room temperature (20.0 °C). What is the final volume of the gas if you hold the syringe in your hand to raise its temperature to 37 °C (and hold the pressure constant)?

What Do You Know? This is a Charles's law problem: There is a change in volume of a gas sample with temperature at constant pressure. You know the original volume and temperature, and you want to know the volume at a new temperature. Recall that, to use Charles's law, the temperature must be expressed in kelvins.

Initial Conditions	**Final Conditions**
$V_1 = 25.0$ mL	$V_2 = ?$
$T_1 = 20.0 + 273.2 = 293.2$ K	$T_2 = 37 + 273 = 310.$ K

Strategy Use Charles's Law, Equation 10.2.

SOLUTION Rearrange Equation 10.2 to solve for V_2:

$$V_2 = V_1 \times \frac{T_2}{T_1} = 25.0 \text{ mL} \times \frac{310. \text{ K}}{293.2 \text{ K}} = 26.4 \text{ mL}$$

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Think about Your Answer While the temperature increase might seem large, the change in volume is small. Mathematically, this is because the change depends on the *ratio* of Kelvin temperatures, which is only slightly greater than 1.

Check Your Understanding

A balloon is inflated with helium to a volume of 45 L at room temperature (25 °C). If the balloon is cooled to −10 °C, what is the new volume of the balloon? Assume that the pressure does not change.

Combining Boyle's and Charles's Laws: The General Gas Law

You now know that the volume of a given amount of gas is inversely proportional to its pressure at constant temperature (Boyle's law) and directly proportional to the Kelvin temperature at constant pressure (Charles's law). But what if you need to know what happens to the gas when two of the three parameters (*P*, *V*, and *T*) change? You can deal with this situation by combining the two equations that express Boyle's and Charles's laws.

$$\frac{P_1V_1}{T_1} = \frac{P_2V_2}{T_2} \quad \text{for a given amount of gas, } n \tag{10.3}$$

This equation is sometimes called the **general gas law** or **combined gas law**. It applies specifically to situations in which the *amount of gas does not change.*

Mette Fairgrieve/Shutterstock.com

A weather balloon is filled with helium. As it ascends in the troposphere, both the pressure and temperature change, so the volume changes as well.

EXAMPLE 10.4

General Gas Law

Problem Helium-filled balloons are used to carry scientific instruments high into the atmosphere. Suppose a balloon is launched when the temperature is 22.5 °C and the barometric pressure is 754 mm Hg. If the balloon's volume is 4.19×10^3 L (and no helium escapes from the balloon), what will the volume be at a height of 20 miles, where the pressure is 76.0 mm Hg and the temperature is −33.0 °C?

What Do You Know? Here you know the initial volume, temperature, and pressure of the gas. You want to know the volume of the same amount of gas at a new pressure and temperature.

Initial Conditions	Final Conditions
$V_1 = 4.19 \times 10^3$ L	$V_2 = ?$ L
$P_1 = 754$ mm Hg	$P_2 = 76.0$ mm Hg
$T_1 = 22.5$ °C (295.7 K)	$T_2 = -33.0$ °C (240.2 K)

Strategy It is most convenient to use Equation 10.3, the general gas law.

SOLUTION You can rearrange the general gas law to calculate the new volume V_2:

$$V_2 = \left(\frac{T_2}{P_2}\right) \times \left(\frac{P_1V_1}{T_1}\right) = V_1 \times \frac{P_1}{P_2} \times \frac{T_2}{T_1}$$

$$= 4.19 \times 10^3 \text{ L} \times \left(\frac{754 \text{ mm Hg}}{76.0 \text{ mm Hg}}\right) \times \left(\frac{240.2 \text{ K}}{295.7 \text{ K}}\right) = 3.38 \times 10^4 \text{ L}$$

Strategy Map 10.4

PROBLEM

Calculate the **volume** of a gas sample after it undergoes a change in ***T*** and ***P***.

↓

DATA/INFORMATION

Think about Your Answer The pressure decreased by almost a factor of 10, which should lead to about a ten-fold volume increase. This increase is partly offset by a drop in temperature that leads to a volume decrease. On balance, the volume increases because the pressure has dropped so substantially.

Check Your Understanding

You have a 22-L cylinder of helium at a pressure of 150 atm (above atmospheric pressure) and at 31 °C. How many balloons can you fill, each with a volume of 5.0 L, on a day when the atmospheric pressure is 755 mm Hg and the temperature is 22 °C?

Tire pressure versus temperature Tire manufacturers recommend checking tire pressures when the tires are cold. After driving for some distance, friction warms a tire and increases the internal pressure. Filling a warm tire to the recommended pressure may lead to an underinflated tire.

The general gas law leads to other, useful predictions of gas behavior. For example, if a given amount of gas is held in a closed container, that is, n and V are constant, the pressure of the gas will increase with increasing temperature.

$$\frac{P_1}{T_1} = \frac{P_2}{T_2} \text{ at constant } n \text{ and } V, \text{ so } P_2 = P_1 \times \frac{T_2}{T_1}$$

That is, when T_2 is greater than T_1, P_2 will be greater than P_1.

Avogadro's Hypothesis

The relationship between volume and amount of gas was first noted by Amedeo Avogadro (1776–1856). In 1811, he used work on gases by the chemist (and early experimenter with hot air balloons) Joseph Gay-Lussac (1778–1850) to propose that *equal volumes of gases under the same conditions of temperature and pressure have equal numbers of particles* (either molecules or atoms, depending on the composition of the gas). This idea is now called **Avogadro's hypothesis**. Stated another way, the volume of a gas at a given temperature and pressure is directly proportional to the amount of gas:

$$V \propto n \quad \text{at constant } T \text{ and } P$$

EXAMPLE 10.5

Avogadro's Hypothesis

Problem Dinitrogen monoxide, commonly known as laughing gas, is used in dental procedures as an anesthetic. At elevated temperatures and with the proper catalyst, dinitrogen monoxide can be produced from the reaction of ammonia and oxygen:

$$2\ NH_3(g) + 2\ O_2(g) \rightarrow N_2O(g) + 3\ H_2O(g)$$

If you begin with 15.0 L of $NH_3(g)$, what volume of $O_2(g)$ is required for complete reaction (both gases being at the same T and P)? What is the theoretical yield of N_2O, in liters, under the same conditions?

What Do You Know? From Avogadro's hypothesis, you know that gas volume is proportional to the amount of gas. You know the volume of ammonia, and, from the balanced equation, you know the stoichiometric factors that relate the known amount of NH_3 to the unknown amounts of O_2 and N_2O.

Strategy This is a stoichiometry problem where you can substitute gas volumes for moles. That is, you can calculate the volumes of O_2 required and N_2O produced (here in liters) by multiplying the volume of NH_3 available by a stoichiometric factor obtained from the balanced chemical equation.

SOLUTION

$$V\ (O_2\ \text{required}) = (15.0\ \text{L}\ NH_3\ \text{available})\left(\frac{2\ \text{L}\ O_2\ \text{required}}{2\ \text{L}\ NH_3\ \text{available}}\right) = 15.0\ \text{L}\ O_2\ \text{required}$$

$$V\ (N_2O\ \text{produced}) = (15.0\ \text{L}\ NH_3\ \text{available})\left(\frac{1\ \text{L}\ N_2O\ \text{produced}}{2\ \text{L}\ NH_3\ \text{available}}\right) = 7.50\ \text{L}\ N_2O\ \text{produced}$$

Think about Your Answer The balanced equation informs you that the amount of O_2 required is equal to the amount of NH_3 present, and the amount of N_2O produced is 1/2 of the amount of NH_3.

Check Your Understanding

Methane burns in oxygen to give CO_2 and H_2O, according to the balanced equation

$$CH_4(g) + 2\ O_2(g) \rightarrow CO_2(g) + 2\ H_2O(g)$$

If 22.4 L of gaseous CH_4 is burned, what volume of O_2 is required for complete combustion? What volumes of CO_2 and H_2O are produced? Assume all gases have the same temperature and pressure.

A CLOSER LOOK

Studies on Gases—Robert Boyle and Jacques Charles

Robert Boyle (1627–1691) was born in Ireland as the 14th and last child of the first Earl of Cork. In his book *Uncle Tungsten*, Oliver Sacks tells us that "Chemistry as a true science made its first emergence with the work of Robert Boyle in the middle of the seventeenth century. Twenty years [Isaac] Newton's senior, Boyle was born at a time when the practice of alchemy still held sway, and he maintained a variety of alchemical beliefs and practices, side by side with his scientific ones. He believed gold could be created, and that he had succeeded in creating it (Newton, also an alchemist, advised him to keep silent about this)."

Boyle examined crystals, explored color, devised an acid–base indicator from the syrup of violets, and provided the first modern definition of an element. He was also a physiologist and was the first to show that the healthy human body has a constant temperature. Today, Boyle is best known for his studies of gases, which were described in his book *The Sceptical Chymist*, published in 1680.

The French chemist and inventor Jacques Alexandre César Charles began his career as a clerk in the French finance ministry, but his real interest was science. He developed several inventions and was best known in his lifetime for inventing the hydrogen balloon. In August 1783, Charles exploited his recent studies on hydrogen gas by inflating a balloon with this gas. Because hydrogen would escape easily from a paper bag, he made a silk bag coated with rubber. Inflating the bag took several days and required nearly 225 kg of sulfuric acid and 450 kg of iron to produce the H_2 gas. The balloon stayed aloft for almost 45 minutes and traveled about 15 miles. When it landed in a village, however, the people were so terrified they tore it to shreds. Several months later, Charles and a passenger flew a new hydrogen-filled balloon some distance across the French countryside and ascended to the then-incredible altitude of 2 miles.

See K. R. Williams, "Robert Boyle: Founder of Modern Chemistry," *Journal of Chemical Education*, Vol. 86, page 148, 2009.

10.3 The Ideal Gas Law

Goals for Section 10.3

- Understand the origin of the ideal gas law and how to use the equation.
- Calculate the molar mass of a compound from the pressure of a known quantity of a gas in a given volume at a known temperature.
- Relate gas density to molar mass, pressure, and temperature.

Four interrelated quantities can be used to describe a gas: pressure, volume, temperature, and amount (moles). We know from experiments that the following gas laws can be used to describe the relationship of these properties.

Boyle's Law	Charles's Law	Avogadro's Hypothesis
$V \propto (1/P)$	$V \propto T$	$V \propto n$
(constant T, n)	(constant P, n)	(constant T, P)

If all three laws are combined, the result is

$$V \propto \frac{nT}{P}$$

This can be made into a mathematical equation by introducing a proportionality constant, now labeled ***R***. This constant, called the **gas constant**, is a *universal constant*, a number used to interrelate the properties of any gas:

Properties of an Ideal Gas For ideal gases, it is assumed that there are no forces of attraction between molecules and that the molecules themselves occupy no volume.

$$V = R\left(\frac{nT}{P}\right)$$

or

$$PV = nRT \tag{10.4}$$

The equation $PV = nRT$ is called the **ideal gas law**. It describes the behavior of a so-called ideal gas. Unfortunately, there is no such thing as an ideal gas, but real gases at pressures around one atmosphere and room temperature usually behave close enough to the ideal that $PV = nRT$ adequately describes their behavior.

To use the equation $PV = nRT$, we need a value for R. This is readily determined experimentally. By carefully measuring P, V, n, and T for a sample of gas, we can calculate the value of R from these values using the ideal gas law equation. For example, under conditions of **standard temperature and pressure (STP)** (a gas temperature of 0 °C or 273.15 K and a pressure of 1 atm), 1 mol of an ideal gas occupies 22.414 L, a quantity called the **standard molar volume**. Substituting these values into the ideal gas law gives a value for R:

STP—What Is It? STP stands for standard temperature and pressure, defined as 0 °C (or 273.15 K) and 1 atm. Under these conditions, exactly 1 mol of an ideal gas occupies 22.414 L.

$$R = \frac{PV}{nT} = \frac{(1.0000\ \text{atm})(22.414\ \text{L})}{(1.0000\ \text{mol})(273.15\ \text{K})} = 0.082057\ \frac{\text{L} \cdot \text{atm}}{\text{K} \cdot \text{mol}}$$

With a value for R, we can now use the ideal gas law in calculations.

EXAMPLE 10.6

Ideal Gas Law

Problem The nitrogen gas in an automobile air bag, with a volume of 65 L, exerts a pressure of 829 mm Hg at 25 °C. What amount of N_2 gas (in moles) is in the air bag?

What Do You Know? You are given P, V, and T for a gas sample and want to calculate the amount of gas (n). P = 829 mm Hg, V = 65 L, T = 25 °C, n = ? You also know R = 0.082057 L · atm/K · mol.

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Strategy Use the ideal gas law, Equation 10.4.

SOLUTION To use the ideal gas law with R having units of L · atm/K · mol, the pressure must be expressed in atmospheres and the temperature in kelvins. Therefore, you should first convert the pressure and temperature to values with these units.

$$P = 829 \text{ mm Hg} \left(\frac{1 \text{ atm}}{760 \text{ mm Hg}} \right) = 1.091 \text{ atm}$$

$$T = 25 + 273 = 298 \text{ K}$$

Now substitute the values of P, V, T, and R into the ideal gas law, and solve for the amount of gas, n:

$$n = \frac{PV}{RT} = \frac{(1.091 \text{ atm})(65 \text{ L})}{(0.082057 \text{ L} \cdot \text{atm/K} \cdot \text{mol})(298 \text{ K})} = 2.9 \text{ mol}$$

Notice that units of atmospheres, liters, and kelvins cancel to leave the answer in units of moles.

Think about Your Answer You know that 1 mol of an ideal gas at STP occupies 22.4 L, so it is reasonable to guess that 65 L of gas (under only slightly different conditions) would be about three times this amount, or 3 mol.

Check Your Understanding

The balloon used by Jacques Charles in his historic balloon flight in 1783 (see page 459) was filled with about 1300 mol of H_2. If the temperature of the gas was 23 °C and the gas pressure was 750 mm Hg, what was the volume of the balloon?

divided by its molar mass (M), we can substitute m/M for n in the ideal gas equation.

$$PV = \left(\frac{m}{M}\right)RT$$

Density (d) is defined as mass divided by volume (m/V). We can rearrange the form of the gas law above to give the following equation, which has the term (m/V) on the left. This is the density of the gas expressed in units of g/L.

$$d = \frac{m}{V} = \frac{PM}{RT} \qquad (10.5)$$

Gas density is directly proportional to the pressure and molar mass and inversely proportional to the temperature. Equation 10.5 is useful because gas density can be calculated from the molar mass, or the molar mass can be found from a measurement of gas density at a given pressure and temperature.

EXAMPLE 10.7

Density and Molar Mass

Problem Calculate the density of CO_2 at STP.

What Do You Know? The known quantities are molar mass of CO_2 (M = 44.0 g/mol), gas pressure *(P)* = 1.00 atm, temperature (*T*) = 273.15 K, and the gas constant *(R)*. The density of CO_2 gas *(d)* is unknown.

Strategy Use Equation 10.5.

SOLUTION The known values are substituted into Equation 10.5 for density *(d)*:

$$d = \frac{PM}{RT} = \frac{(1.00\text{ atm})(44.0\text{ g/mol})}{(0.082057\text{ L}\cdot\text{atm/K}\cdot\text{mol})(273.15\text{ K})} = 1.96\text{ g/L}$$

Think about Your Answer The density of CO_2 is considerably greater than that of dry air at STP (1.29 g/L).

Check Your Understanding

At 1.00 atm and 25 °C, the density of dry air is 1.18 g/L. If the air is heated to 55 °C at constant pressure, what is its density?

© Cengage Learning/Charles D. Winters

Figure 10.6 Gas density. Because carbon dioxide from fire extinguishers is denser than air, it settles on top of a fire and smothers it. (When CO_2 gas is released from the tank, it expands and cools significantly. The white cloud is condensed moisture from the air.)

Gas density has practical implications. From the equation $d = PM/RT$, you recognize that the density of a gas is directly proportional to its molar mass. Dry air, which has an average molar mass of about 29 g/mol, has a density of about 1.18 g/L at 1 atm and 25 °C. Gases or vapors with molar masses greater than 29 g/mol have densities larger than 1.2 g/L under these same conditions. Therefore, gases such as CO_2, SO_2, and gasoline vapor settle along the ground if released into the atmosphere (Figure 10.6). Conversely, gases such as H_2, He, CO, CH_4 (methane), and NH_3 rise if released into the atmosphere.

Calculating the Molar Mass of a Gas from *P*, *V*, and *T* Data

When a new compound is isolated in the laboratory, one of the first things we often do is determine its molar mass. If the compound is easily volatilized, a classical method of determining the molar mass is to measure the pressure and volume exerted by a given mass of the gas at a given temperature.

EXAMPLE 10.8

Calculating the Molar Mass of a Gas from *P*, *V*, and *T* Data

Problem You are trying to determine, by experiment, the formula of a gaseous compound you made to replace chlorofluorocarbons in air conditioners. You have determined the empirical formula is CHF_2, but to determine the molecular formula you need to know the molar mass. You find that a 0.100-g sample of the compound exerts a pressure of 70.5 mm Hg in a 256-mL container at 22.3 °C. What is the molar mass of the compound? What is its molecular formula?

What Do You Know? You know the mass of a gas in a given volume at a known pressure and temperature. The molar mass of the gas, *M,* is unknown.

m = mass of gas = 0.100 g P = 70.5 mm Hg, or 0.09276 atm

V = 256 mL, or 0.256 L T = 22.3 °C, or 295.5 K

Strategy Dividing the mass of the gas by its volume gives its density, which is related to the molar mass through Equation 10.5. Alternatively, the *P, V*, and *T* data can be used to calculate the amount of gas (moles). The molar mass is then the quotient of the mass of gas and its amount.

SOLUTION The density of the gas is the mass of the gas divided by the volume.

$$d = \frac{0.100\ \text{g}}{0.256\ \text{L}} = 0.3906\ \text{g/L}$$

Use this value of density along with the values of pressure and temperature in Equation 10.5 ($d = PM/RT$), and solve for the molar mass (M).

$$M = \frac{dRT}{P} = \frac{(0.3906\ \text{g/L})(0.082057\ \text{L} \cdot \text{atm/K} \cdot \text{mol})(295.5\ \text{K})}{0.09276\ \text{atm}} = 102.1\ \text{g/mol}$$

$$= 102\ \text{g/mol}$$

With this result, you can compare the experimentally determined molar mass with the mass of a mole of gas having the empirical formula CHF_2.

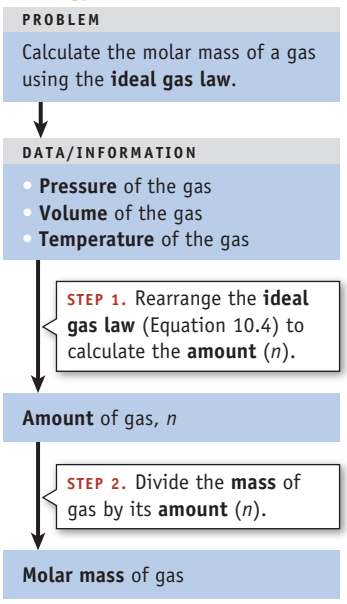
$$\frac{\text{Experimental molar mass}}{\text{Mass of 1 mol } CHF_2} = \frac{102.1\ \text{g/mol}}{51.0\ \text{g/formula unit}} = 2\ \text{formula units of } CHF_2 \text{ per mole}$$

Therefore, the formula of the compound is $C_2H_2F_4$.

In the alternative approach, you use the ideal gas law to calculate the amount of gas, *n*.

$$n = \frac{PV}{RT} = \frac{(0.09276\ \text{atm})(0.256\ \text{L})}{(0.082057\ \text{L} \cdot \text{atm/K} \cdot \text{mol})(295.5\ \text{K})} = 9.794 \times 10^{-4}\ \text{mol}$$

You now know that 0.100 g of gas is equivalent to 9.794×10^{-4} mol. Therefore,



$$\text{Molar mass} = \frac{0.100\ \text{g}}{9.794 \times 10^{-4}\ \text{mol}} = 102\ \text{g/mol}$$

Think about Your Answer If the calculated molar mass is not the same as that for the empirical formula or a simple multiple of that value, then you can assume that there is an error somewhere.

Check Your Understanding

A 0.105-g sample of a gaseous compound has a pressure of 561 mm Hg in a volume of 125 mL at 23.0 °C. What is its molar mass?

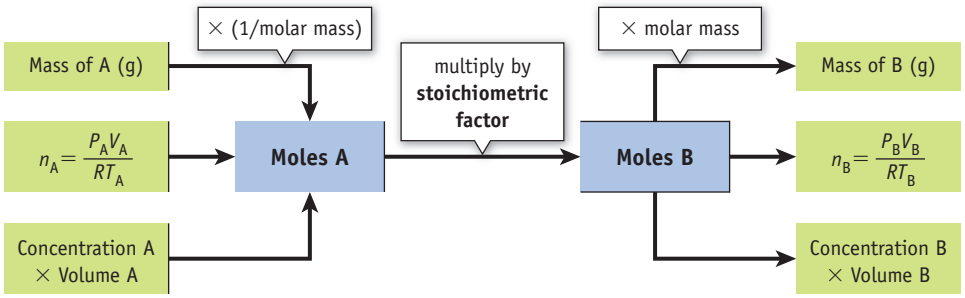

Figure 10.7 A scheme for stoichiometry calculations. Here, A and B may be either reactants or products. The amount of A (mol) can be calculated from its mass in grams and its molar mass, from the concentration and volume of a solution, or from *P*, *V*, and *T* data by using the ideal gas law. Once the amount of B is determined, this value can be converted to a mass or solution concentration or volume, or to a property of a gas.

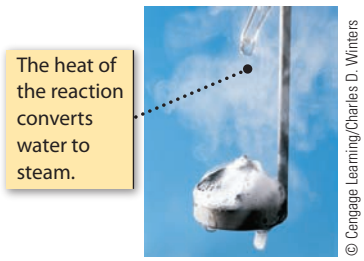
10.4 Gas Laws and Chemical Reactions

Goal for Section 10.4

- Apply the gas laws to study the stoichiometry of reactions.



Many industrially important reactions involve gases. Two examples are the combination of nitrogen and hydrogen to produce ammonia,

$$N_2(g) + 3\ H_2(g) \rightarrow 2\ NH_3(g)$$

and the electrolysis of aqueous NaCl to produce hydrogen and chlorine,

$$2\ NaCl(aq) + 2\ H_2O(\ell) \rightarrow 2\ NaOH(aq) + H_2(g) + Cl_2(g)$$

If we want to understand the quantitative aspects of such reactions, we need to carry out stoichiometry calculations. The scheme in Figure 10.7 connects these calculations for gas reactions with the stoichiometry calculations in Chapter 4.

© Cengage Learning/Charles D. Winters

Lithium and water produce H_2 gas and LiOH.

EXAMPLE 10.9

Gas Laws and Stoichiometry

Problem Hydrogen gas is produced from the reaction of lithium and water. What mass of lithium is required to produce 23.5 L of $H_2(g)$ at 17.0 °C and a pressure of 743 mm Hg? The gas-producing reaction is

$$2\ Li(s) + 2\ H_2O(aq) \rightarrow 2\ LiOH(aq) + H_2(g)$$

What Do You Know? You know the pressure, volume, and temperature of the H_2 gas to be produced, and you know the balanced equation that relates the amounts of the reactant, Li, to the product, H_2.

$$P = 743\ mm\ Hg\ (1\ atm/760\ mm\ Hg) = 0.9776\ atm$$

$$V = 23.5\ L$$

$$T = 17.0\ °C,\ or\ 290.2\ K$$

You want to know the mass of Li required to produce a given amount of H_2. This will require knowing the molar mass of Li.

Strategy The general logic to be used here follows a pathway in Figure 10.7 and in Strategy Map 10.9. First, use $PV = nRT$ with gas data to calculate the amount of H_2 produced. Then use that amount with a stoichiometric factor and the molar mass of Li to calculate the mass of Li required.

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

SOLUTION

Step 1: Find the amount (mol) of gas produced.

$$n = \text{H}_2 \text{ produced (mol)} = \frac{PV}{RT}$$

$$n = \frac{(0.9776 \text{ atm})(23.5 \text{ L})}{(0.082057 \text{ L} \cdot \text{atm/K} \cdot \text{mol})(290.2 \text{ K})} = 0.9648 \text{ mol H}_2$$

Step 2: Calculate the quantity of lithium that will produce 0.965 mol of H_2 gas.

$$\text{Mass of Li} = 0.9648 \text{ mol H}_2 \left(\frac{2 \text{ mol Li}}{1 \text{ mol H}_2}\right)\left(\frac{6.941 \text{ g}}{1 \text{ mol Li}}\right) = 13.4 \text{ g Li}$$

Think about Your Answer You know that at STP, 1 mol of an ideal gas has a volume of 22.4 L. While not at STP exactly, the conditions here are close to it, so a volume of 23.5 L should correspond to about 1 mol of H_2. Based on the stoichiometry of the reaction, you will need twice this amount of Li, or about 2 mol. Based on the molar mass of Li (6.941 g/mol) this will be about 14 g.

Check Your Understanding

10.5 Gas Mixtures and Partial Pressures

Goal for Section 10.5

- Use Dalton's law of partial pressures.

The air you breathe is a mixture of nitrogen, oxygen, argon, carbon dioxide, water vapor, and small amounts of other gases (Table 10.1). Each of these gases exerts its own pressure, and atmospheric pressure is the sum of the pressures exerted by each gas. The pressure of each gas in the mixture is called its **partial pressure**.

John Dalton (1766–1844) was the first to observe that the pressure of a mixture of ideal gases is the sum of the partial pressures of the different gases in the mixture. This observation is now known as **Dalton's law of partial pressures** (Figure 10.8). Mathematically, we can write Dalton's law of partial pressures as

$$P_{\text{total}} = P_A + P_B + P_C \ldots \qquad (10.6)$$

where P_A, P_B, and P_C are the pressures of the different gases in a mixture, and P_{total} is the total pressure. Additionally, for a mixture of three ideal gases in a given

TABLE 10.1 Major Components of Atmospheric Dry Air

Figure 10.8
Dalton's law.

In a 1.0-L flask at 25 °C, 0.010 mol of N_2 exerts a pressure of 186 mm Hg, and 0.0050 mol of O_2 in a 1.0-L flask at 25 °C exerts a pressure of 93 mm Hg.

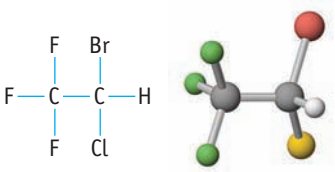
The N_2 and O_2 samples are placed in a 1.0-L flask at 25 °C. The total pressure, 279 mm Hg, is the sum of the pressures that each gas alone exerts in the flask.

volume *(V)* and at a given temperature *(T)*, we can calculate the total pressure if we know the total number of moles of gas in the system:

$$P_{total} = P_A + P_B + P_C = n_A\left(\frac{RT}{V}\right) + n_B\left(\frac{RT}{V}\right) + n_C\left(\frac{RT}{V}\right)$$

$$P_{total} = (n_A + n_B + n_C)\left(\frac{RT}{V}\right)$$

$$P_{total} = (n_{total})\left(\frac{RT}{V}\right) \qquad (10.7)$$



For mixtures of gases, it is convenient to introduce a quantity called the **mole fraction**, ***X***, which is defined as the number of moles of a particular substance in a mixture divided by the total number of moles of all substances present. Mathematically, the mole fraction of a substance A in a mixture with B and C is expressed as

$$X_A = \frac{n_A}{n_A + n_B + n_C} = \frac{n_A}{n_{total}}$$

Now we can substitute this equation (written as $n_{total} = n_A/X_A$) into Equation 10.7 and derive the equation

$$P_A = X_A P_{total} \qquad (10.8)$$

This equation tells us that *the pressure of a gas in a mixture of gases is the product of its mole fraction and the total pressure of the mixture.* In other words, the partial pressure of a gas is directly related to the fraction of particles of that gas in the mixture. For example, the mole fraction of N_2 in air is 0.78, so, at STP, its partial pressure is 0.78 atm or 590 mm Hg.

1,1,1-trifluorobromochloroethane, halothane

What Do You Know? You know the identity and mass of each gas, so you can calculate the amount of each. You also know the total pressure of the gas mixture.

Strategy Because you can calculate the amount of each gas, you can determine the total amount (moles) of gas and thus the mole fraction of each. The partial pressure of a gas is given by the total pressure of the mixture multiplied by the mole fraction of the gas (Equation 10.8).

SOLUTION

Step 1. Calculate mole fractions.

$$\text{Amount of } C_2HBrClF_3 = 15.0 \text{ g} \left(\frac{1 \text{ mol}}{197.4 \text{ g}} \right) = 0.07599 \text{ mol}$$

$$\text{Amount of } O_2 = 23.5 \text{ g} \left(\frac{1 \text{ mol}}{32.00 \text{ g}} \right) = 0.7344 \text{ mol}$$

$$\text{Total amount of gas} = 0.07599 \text{ mol } C_2HBrClF_3 + 0.7344 \text{ mol } O_2 = 0.8104 \text{ mol}$$

$$\text{Mole fraction of } C_2HBrClF_3 = \frac{0.07599 \text{ mol } C_2HBrClF_3}{0.8104 \text{ total moles}} = 0.09377$$

Because the sum of the mole fraction of halothane and of O_2 must equal 1.0000, this means that the mole fraction of oxygen is 0.9062.

$$X_{\text{halothane}} + X_{\text{oxygen}} = 1.0000$$

$$0.09377 + X_{\text{oxygen}} = 1.0000$$

$$X_{\text{oxygen}} = 0.9062$$

Step 2. Calculate partial pressures.

$$\text{Partial pressure of halothane} = P_{\text{halothane}} = X_{\text{halothane}} \times P_{\text{total}}$$

$$P_{\text{halothane}} = 0.09377 \times P_{\text{total}} = 0.09377 \text{ (855 mm Hg)}$$

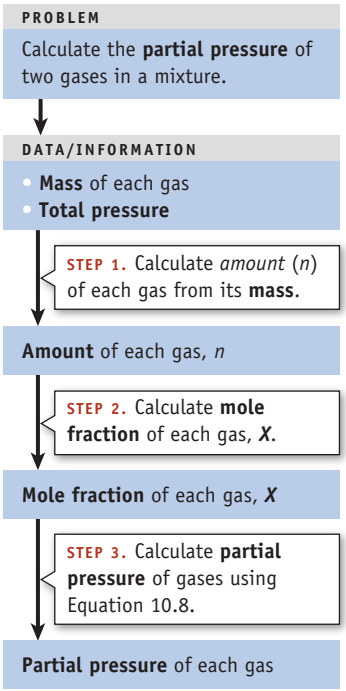
$$P_{\text{halothane}} = 80.17 \text{ mm Hg} = 80.2 \text{ mm Hg}$$

The total pressure of the mixture is the sum of the partial pressures of the gases in the mixture.

$$P_{\text{halothane}} + P_{\text{oxygen}} = 855 \text{ mm Hg}$$

and so

$$P_{\text{oxygen}} = 855 \text{ mm Hg} - P_{\text{halothane}}$$



$$P_{\text{oxygen}} = 855 \text{ mm Hg} - 80.17 \text{ mm Hg} = 775 \text{ mm Hg}$$

Think about Your Answer The amount of halothane is about 1/10th of the amount of oxygen so we would expect the ratio of partial pressures of the two gases to be in a similar ratio.

Check Your Understanding

The halothane–oxygen mixture described in this Example is placed in a 5.00-L tank at 25.0 °C. What is the total pressure (in mm Hg) of the gas mixture in the tank? What are the partial pressures (in mm Hg) of the gases?

10.6 The Kinetic-Molecular Theory of Gases

Goal for Section 10.6

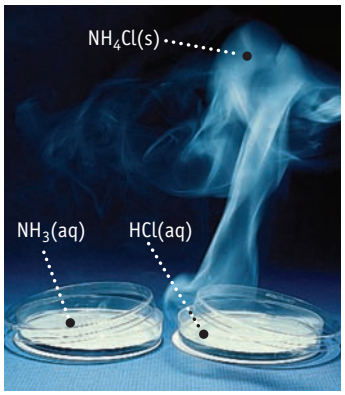
- Understand kinetic-molecular theory as it is applied to gases, especially the distribution of molecular speeds (energies).

© Cengage Learning/Charles D. Winters

Figure 10.9 A molecular view of gases and liquids. The fact that a large volume of N_2 gas can be condensed to a small volume of liquid indicates that the distance between molecules in the gas phase is very large as compared with the distances between molecules in liquids.

So far, we have discussed the macroscopic properties of gases. Now we turn to a description of the behavior of matter at the molecular or atomic level using kinetic-molecular theory (page 6). Hundreds of experimental observations have led to the following postulates regarding the behavior of gases.

- Gases consist of particles (molecules or atoms) whose separation is much greater than the size of the particles themselves (Figure 10.9).
- The particles of a gas are in continual, random, and rapid motion. As they move, they collide with one another and with the walls of the container in a way in which the total energy is unchanged.
- The average kinetic energy of gas particles is proportional to the gas temperature. *All gases, regardless of their molecular mass, have the same average kinetic energy at the same temperature.*



Let us discuss the behavior of gases from this point of view.

Molecular Speed and Kinetic Energy

Suppose your friend walks into your room carrying a large, flat box. How could you know there is a pizza in the box? You could tell by the odors coming from the box, because we know that the odor-causing molecules of food enter the gas phase and drift through space until they reach the cells of your body that react to odors. The same thing happens in the laboratory when dishes of aqueous ammonia (NH_3) and hydrochloric acid (HCl) sit side by side (Figure 10.10). Molecules of the two compounds enter the gas phase and drift along until they encounter one another, at which time they react and form a cloud of tiny particles of solid ammonium chloride (NH_4Cl).

If you lower the temperature of the environment of the containers in Figure 10.10, you would find that it took a longer time for the cloud of ammoniun chloride to form. The reason for this is that the speed at which molecules move depends on the temperature.

Let us expand on our experimental observations with pizza and ammonia. First, it is important to understand that the molecules in a gas sample do not all move at the same speed. Rather, as illustrated in Figure 10.11 for O_2 molecules, there is a distribution of speeds and the distribution depends on temperature. There are several important observations we can make.

© Cengage Learning/Charles D. Winters

Figure 10.10 The movement of gas molecules. Open dishes of aqueous ammonia and hydrochloric acid are placed side by side. When molecules of NH_3 and HCl escape from solution to the atmosphere and encounter one another, a cloud of solid ammonium chloride, NH_4Cl, is observed.

- At a given temperature some molecules in a sample have high speeds and others have low speeds.
- Most of the molecules in the sample have intermediate speeds, and their most probable speed corresponds to the maximum in the curve. For oxygen gas at 25 °C, for example, most molecules have speeds in the range from 200 m/s to 700 m/s, and their most probable speed is about 400 m/s. (These are very high speeds, indeed. A speed of 400 m/s corresponds to about 900 miles per hour!)
- When you compare the distribution curves for O_2 molecules at 25 °C and 1000 °C, you see that, as the temperature increases the most probable speed increases and the number of molecules traveling at very high speeds increases greatly.

The kinetic energy of a single molecule of mass m (in kg) in a gas sample is given by the equation

$$KE = \frac{1}{2}(mass)(speed)^2 = \frac{1}{2}\ mu^2$$

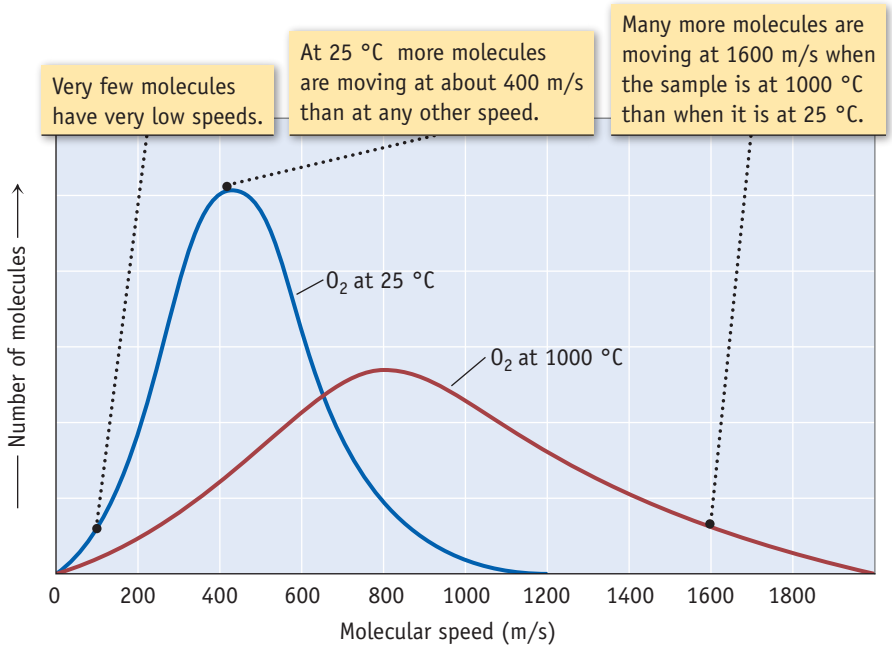

Figure 10.11 The distribution of molecular speeds. The figure depicts how the distribution of molecular speeds in a gas sample changes with temperature. The areas under the curves are the same because the number of molecules in the sample is fixed.

where u is the speed of that molecule (in m/s). We can calculate the kinetic energy of a single gas molecule from this equation but not of a collection of molecules because, as you see in Figure 10.11, not all of the molecules in a gas sample are moving at the same speed. However, we can calculate the *average* kinetic energy of a collection of molecules by relating it to other averaged quantities of the system. In particular, the average kinetic energy of a mole of molecules in a gas sample is related to the average speed:

$$\overline{KE} = \frac{1}{2} N_A m \overline{u^2}$$

where N_A is Avogadro's number. (The horizontal bar over the symbols $\overline{KE}$ and $\overline{u}$ indicates an average value.) The product of the mass per molecule and Avogadro's constant is the molar mass (in units of kg/mol), so we can write

$$\overline{KE} = \frac{1}{2} M \overline{u^2}$$

This equation states that the average kinetic energy of the molecules in a gas sample, $\overline{KE}$, is related to $\overline{u^2}$, the average of the squares of their speeds (called the "mean square speed").

Experiments also show that the average kinetic energy, $\overline{KE}$, of a mole of gas molecules is directly proportional to temperature with a proportionality constant of $^3/_2 R$,

$$\overline{KE} = \frac{3}{2} RT$$

where R is the gas constant expressed in SI units (8.3144598 J/K · mol).

The two kinetic energy equations can be combined to yield an equation that relates mass, average speed, and temperature (Equation 10.9).

$$\sqrt{\overline{u^2}} = \sqrt{\frac{3RT}{M}} \qquad (10.9)$$

Here, the square root of the mean square speed ($\sqrt{\overline{u^2}}$, called the **root-mean-square speed**, or **rms speed**), the temperature (T, in kelvins), and the molar mass (M) are related. This equation shows that the speeds of gas molecules are indeed related to

Maxwell-Boltzmann Curves
Plots such as those in Figures 10.11 and 10.12 are often referred to as Maxwell-Boltzmann curves. They are named for two scientists who studied the physical properties of gases: James Clerk Maxwell (1831–1879) and Ludwig Boltzmann (1844–1906).

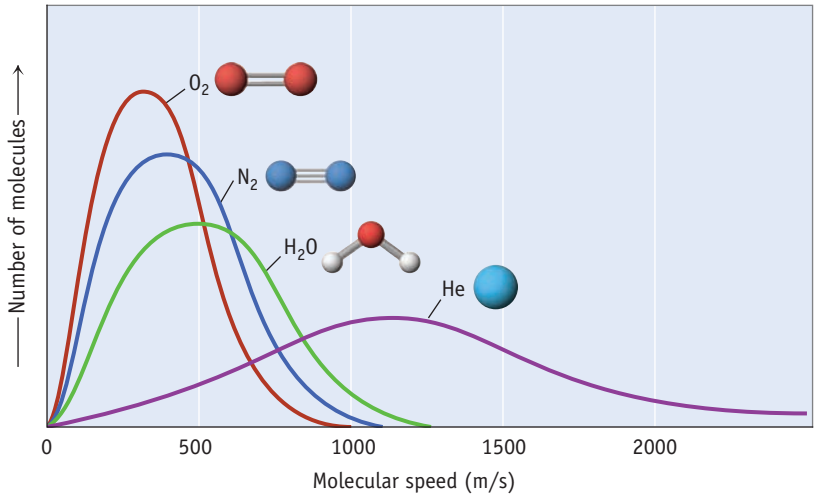

Figure 10.12 The effect of molecular mass on the distribution of speeds. At a given temperature, molecules with higher masses have lower speeds.

the temperature (Figure 10.12). The rms speed is a useful quantity because of its relationship to the average kinetic energy and because it is very close to the true average speed for a sample. (The average speed is 92% of the rms speed.)

All gases have the same average kinetic energy at the same temperature. However, if you compare a sample of one gas with another, say compare O_2 and N_2, this does not mean the molecules have the same rms speed (Figure 10.12). Instead, Equation 10.9 shows that the smaller the molar mass of the gas the greater the rms speed.

EXAMPLE 10.11

Molecular Speed

Problem Calculate the rms speed of oxygen molecules at 298 K (25 °C).

What Do You Know? You know the molar mass of O_2 and the temperature, the main determinants of speed.

Strategy Use Equation 10.9 with M in units of kg/mol. The reason for this is that R is in units of J/K · mol, and 1 J = 1 kg · m²/s².

SOLUTION The molar mass of O_2 is 32.0×10^{-3} kg/mol.

$$\sqrt{\overline{u^2}} = \sqrt{\frac{3(8.3145\ \text{J/K} \cdot \text{mol})(298\ \text{K})}{32.0 \times 10^{-3}\ \text{kg/mol}}} = \sqrt{2.323 \times 10^5\ \text{J/kg}}$$

To obtain the answer in meters per second, use the relation 1 J = 1 kg · m²/s². This means you have

$$\sqrt{\overline{u^2}} = \sqrt{2.323 \times 10^5\ \text{kg} \cdot \text{m}^2/(\text{kg} \cdot \text{s}^2)} = \sqrt{2.323 \times 10^5\ \text{m}^2/\text{s}^2} = 482\ \text{m/s}$$

Think about Your Answer The calculated rms speed is equivalent to about 1100 miles per hour! This is greater than the speed of sound in air, 343 m/s.

Check Your Understanding

Calculate the rms speeds of helium atoms and N_2 molecules at 298 K.

Kinetic-Molecular Theory and the Gas Laws

The gas laws, which come from experiment, can be explained by the kinetic-molecular theory. The starting place is to describe how pressure arises from collisions of gas molecules with the walls of the container holding the gas (Figure 10.13). Pressure is related to the force of the collisions.

$$\text{Gas pressure} = \frac{\text{force of collisions}}{\text{area}}$$

The force exerted by the collisions depends on the number of collisions and the average force per collision. When the temperature of a gas is increased, we know the average kinetic energy of the molecules increases. This causes the average force of the collisions with the walls to increase as well. Also, because the speed of gas molecules increases with temperature, more collisions occur per second. Thus, the collective force per square centimeter is greater, and the pressure increases. Mathematically, this is related to the direct proportionality between P and T when n and V are fixed, that is, $P = (nR/V)T$.

Increasing the number of molecules of a gas at a fixed temperature and volume does not change the average collision force, but it does increase the number of collisions occurring per second. Thus, the pressure increases, and we can say that P is proportional to n when V and T are constant, that is, $P = n(RT/V)$.

If the pressure is to remain constant when either the number of molecules of gas or the temperature is increased, then the volume of the container (and the area over which the collisions occur) must increase. This is expressed by stating that V is proportional to nT when P is constant [$V = nT(R/P)$], a statement that is a *combination of Avogadro's hypothesis and Charles's law*.

Finally, if the temperature is constant, the average impact force of molecules of a given mass with the container walls must be constant. If n is kept constant while the volume of the container is made smaller, the number of collisions with the container walls per second must increase. This means the pressure increases, and so P is proportional to $1/V$ when n and T are constant, as stated by *Boyle's law*, that is, $P = (1/V)(nRT)$.

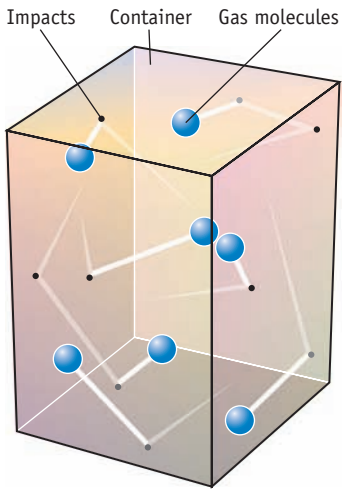

Figure 10.13 Gas pressure. According to the kinetic-molecular theory, gas pressure is caused by gas molecules bombarding the container walls.

10.7 Diffusion and Effusion

Goal for Section 10.7

- Understand the phenomena of diffusion and effusion and apply Graham's law.

When a warm pizza is brought into a room, the volatile aroma-causing molecules vaporize and mix with gases in the atmosphere. Even if there were no movement of the air in the room the odor would eventually reach everywhere in the room. This mixing of molecules of two or more gases due to their random molecular motions is the result of **diffusion**. Given time, the molecules of one component in a gas mixture will thoroughly and completely mix with all other components of the mixture (Figure 10.14).

Diffusion is also illustrated by the experiment in Figure 10.15. Here, we placed cotton moistened with hydrochloric acid at one end of a glass U-tube and cotton moistened with aqueous ammonia at the other end. Molecules of HCl and NH_3 diffused into the tube, and, when they met, they produced white, solid NH_4Cl.

$$HCl(g) + NH_3(g) \rightarrow NH_4Cl(s)$$

Note that the gases did not meet in the middle. Rather, because the heavier HCl molecules diffuse less rapidly than the lighter NH_3 molecules, the molecules met closer to the HCl end of the U-tube.

Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

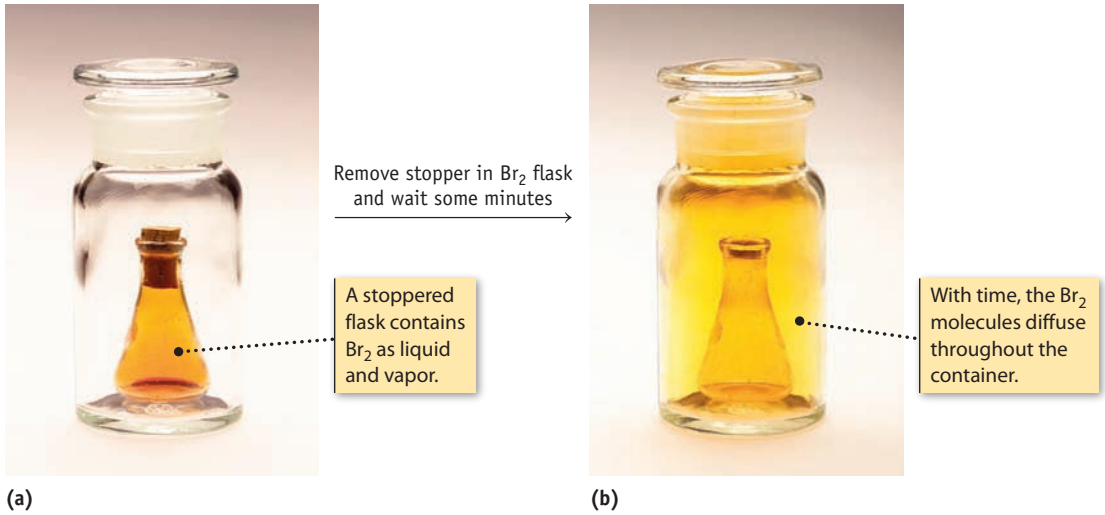

Figure 10.14 Gaseous diffusion. Here bromine diffuses out of a flask and mixes with air in the bottle over time.

Closely related to diffusion is **effusion**, which is the movement of gas through a tiny opening in a container into another container where the pressure is very low (Figure 10.16). Thomas Graham (1805–1869), a Scottish chemist, studied the effusion of gases and found that the rate of effusion of a gas—the amount of gas moving from one place to another in a given amount of time—is inversely proportional to the square root of its molar mass. Based on these experimental results, the rates of effusion of two gases can be compared:

$$\frac{\text{Rate of effusion of gas 1}}{\text{Rate of effusion of gas 2}} = \sqrt{\frac{\text{molar mass of gas 2}}{\text{molar mass of gas 1}}} \qquad (10.10)$$

The relationship in Equation 10.10—now known as **Graham's law**—is derived from Equation 10.9 by recognizing that the rate of effusion depends on the speed

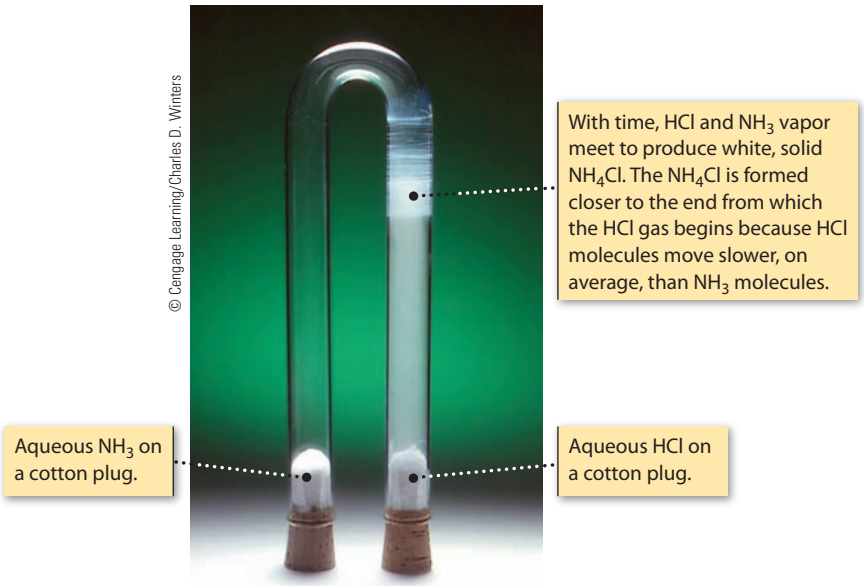

Figure 10.15 Gaseous diffusion. Here, HCl gas (from hydrochloric acid) and ammonia gas (from aqueous ammonia) diffuse from opposite ends of a glass U-tube.

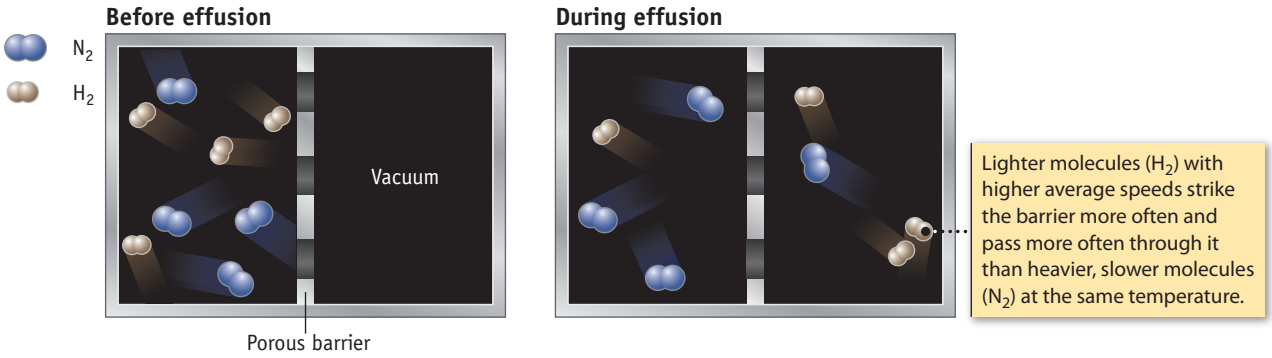

Figure 10.16 Gaseous effusion. H_2 and N_2 gas molecules effuse through the pores of a porous barrier. According to Graham's law, H_2 molecules effuse 3.72 times faster than N_2 molecules at the same temperature.

of the molecules. The ratio of the rms speeds is the same as the ratio of the effusion rates:

$$\frac{\text{Rate of effusion of gas 1}}{\text{Rate of effusion of gas 2}} = \frac{\sqrt{u^2 \text{ of gas 1}}}{\sqrt{u^2 \text{ of gas 2}}} = \frac{\sqrt{3RT/(M \text{ of gas 1})}}{\sqrt{3RT/(M \text{ of gas 2})}}$$

Canceling out like terms gives the expression in Equation 10.10.

EXAMPLE 10.12

Using Graham's Law of Effusion to Calculate a Molar Mass

Problem Tetrafluoroethylene, C_2F_4, effuses through a barrier at a rate of 4.6×10^{-6} mol/h. An unknown gas, consisting only of boron and hydrogen, effuses at the rate of 5.8×10^{-6} mol/h under the same conditions. What is the molar mass of the unknown gas?

What Do You Know? You have two gases, one with a known molar mass (C_2F_4, 100.0 g/mol) and the other unknown. The rate of effusion for both gases is known.

Strategy Substitute the experimental data into Graham's law equation (Equation 10.10).

SOLUTION

$$\frac{5.8 \times 10^{-6} \text{ mol/h}}{4.6 \times 10^{-6} \text{ mol/h}} = 1.26 = \sqrt{\frac{100.0 \text{ g/mol}}{M \text{ of unknown}}}$$

To solve for the unknown molar mass, square both sides of the equation and rearrange to find M for the unknown.

$$1.59 = \frac{100.0 \text{ g/mol}}{M \text{ of unknown}}$$

$$M = 63 \text{ g/mol}$$

Think about Your Answer From Graham's law, we know that a light molecule will effuse more rapidly than a heavier one. Because the unknown gas effuses more rapidly than C_2F_4 ($M = 100.0$ g/mol), the unknown must have a molar mass less than 100 g/mol. A boron–hydrogen compound corresponding to this molar mass is B_5H_9, called *pentaborane*.

Check Your Understanding

A sample of methane, CH_4, is found to effuse through a porous barrier in 1.50 minutes. Under the same conditions, an equal number of molecules of an unknown gas effuses through the barrier in 4.73 minutes. What is the molar mass of the unknown gas?

A CLOSER LOOK

Surface Science and the Need for Ultrahigh Vacuum Systems

Surface science is the study of processes that occur at interfaces between phases. The interface between a solid and a gas is particularly important in areas such as catalysis and microelectronics. An automobile's catalytic converter facilitates the decomposition of hazardous molecules in an automobile's exhaust. In the electronics industry, as the size of semiconductor devices is decreased, surface atoms play an increasingly important role in their behavior. Understanding and controlling the chemical and physical processes that occur at these surfaces is important.

In order to study surface phenomena, surface scientists often need to have a clean surface, but obtaining one is a challenge. When real gases collide with a clean surface they often stick to the surface, quickly forming a monolayer—approximately 10^{15} molecules/cm^2—of adsorbed molecules on the surface. To avoid this contamination, surface scientists conduct studies in vacuum chambers, where contact between gas phase molecules and surfaces may be minimized. But, how good a vacuum is needed to keep a surface clean of adsorbed molecules?

Cultura Creative (RF)/Alamy Stock Photo

A high vacuum chamber is made of polished steel or aluminum. The chamber often has multiple portals where vacuum pumps, instruments, or windows into the chamber may be attached.

The term "high vacuum" describes a system where gas pressure is less than 10^{-6} mm Hg. The ideal gas law can be used to show that at 10^{-6} mm Hg and room temperature over 3×10^{13} gas particles occupy each liter of space. Even at this pressure, over 10^{14} collisions/cm^2 per second occur between gas molecules and a surface. In only a few seconds a clean surface will be completely covered with adsorbed molecules.

To maintain a clean surface, ultrahigh vacuum (10^{-9} mm Hg or better) conditions are required. Reducing the number of gas phase molecules by a factor of one thousand also reduces the rate of gas-surface collisions by the same factor. Under ultrahigh vacuum conditions, a surface will stay clean for over an hour, which is usually enough time for an analysis of the surface.

Is it possible to remove all gas particles in a vacuum chamber? No, a variety of factors limit an achievable vacuum. These factors include the efficiency of the vacuum pumps, the ability to avoid any leaks into the system, and, perhaps most importantly, the rate of "outgassing" in the system. Outgassing is a process in which molecules desorb from the surfaces within the system. Prior to pumping out a vacuum chamber, the inner surfaces are saturated with adsorbed molecules. As these molecules desorb, they increase the pressure in the vacuum system. Under ideal conditions, pressures might be reduced below 10^{-10} mm Hg, at which point the rate at which gas is pumped out of the system equals the rate of outgassing.

10.8 Nonideal Behavior of Gases

Goal for Section 10.8

- Recognize why gases do not behave like ideal gases under some conditions. Deviations from ideal behavior are largest at high pressure and low temperature.

If you are working at approximately room temperature and a pressure of one atmosphere or less, the ideal gas law is remarkably successful in relating the amount of gas and its pressure, volume, and temperature. At higher pressures or lower temperatures, however, deviations from the ideal gas law occur. To begin thinking about this, consider the ideal gas law, $PV = nRT$. If we divide both sides of this equation by nRT, we obtain the equation $PV/nRT = 1$. For n = 1 mole of gas, this becomes $PV/RT = 1$. The ideal gas law thus predicts that the ratio PV/RT should be exactly 1 for 1 mole of an ideal gas, regardless of pressure.

Now consider Figure 10.17, which shows the actual values of PV/RT for 1 mol of various gases plotted as the y-axis of the graph versus pressure on the x-axis. For reference, the prediction of the ideal gas law is plotted as the black line on the graph at $PV/nRT = 1$. It is clear that there are deviations from what the ideal gas law predicts.

The curves traced for real gases in Figure 10.17 show there are two effects. For all but He, there is an initial decrease in the value of PV/RT. The two curves shown for CO_2 suggest that this effect is related to the temperature; the effect is larger at the lower temperature. (Helium would presumably show an initial decrease in the value of PV/RT at a low enough temperature.) The second effect is the steady increase of

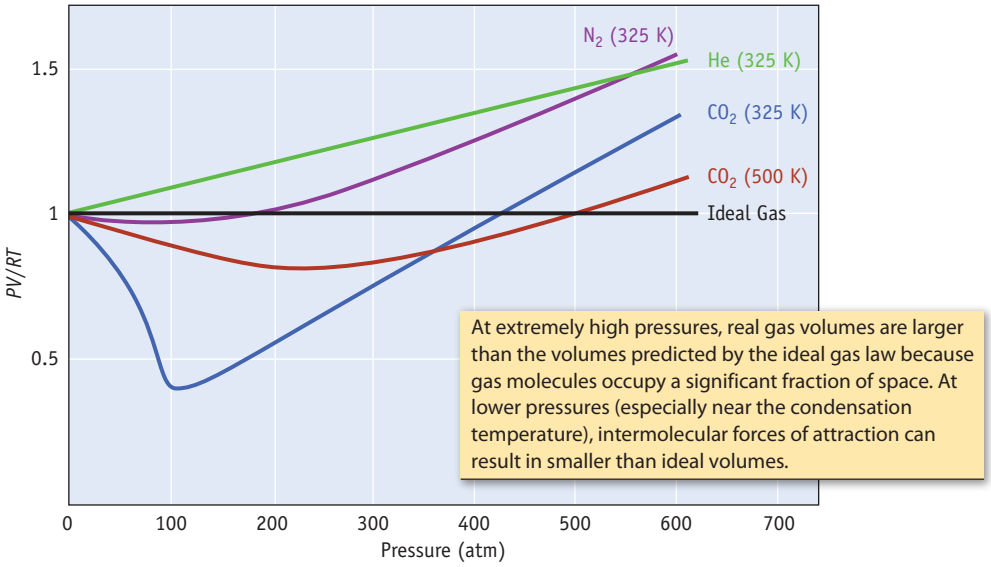

Figure 10.17 Real gas deviations from ideal behavior. Here, PV/RT for 1 mol of N_2, He, and CO_2 gases are plotted versus P. For 1 mol of an ideal gas $PV/RT = 1$ at all pressures.

the value of PV/RT at higher pressures. For all gases, the product PV/RT is eventually greater than 1.00 if the pressure is high enough.

From these observations we can conclude that the product of the measured pressure and measured volume ($P \times V$) for real gases may be either smaller than predicted (related to attractive forces between molecules) or greater than predicted (related to molecular volume). The values of pressure and temperature are the key factors influencing the deviation of this quantity from ideality.

The concept of ideality for gas behavior was based on two assumptions, that the gas molecules occupy no space and that there are no attractive forces between molecules. Clearly neither assumption is rigorously true. Molecules do have a volume. For example, a helium atom has a radius of 31 pm and a volume of 1.2×10^{-31} m^3. But the volume occupied by gas molecules is ordinarily a small part of the total volume of a gas. At 1 atm and 25 °C it would occupy about the same space to move about as a pea has inside a basketball. As a result, the error made by assuming the molecule has no volume is going to be small. Suppose, however, that the pressure is much greater, say 1000 atm. Now, the volume available to each molecule is a sphere with a radius of only about 200 pm, which means the situation is now like that of a pea inside a sphere a bit larger than a Ping-Pong ball. The volume occupied by gas molecules cannot be ignored in such cases.

The assumption that there are no attractive forces between molecules is also not accurate. We know that there are attractive forces; gases will condense to form a liquid when the attractive forces between molecules are sufficient to overcome the kinetic energy associated with molecular motion. We also know that the effect of these attractive forces is temperature dependent, the lower the temperature the greater the effect of these forces.

The Dutch physicist Johannes van der Waals (1837–1923) studied the breakdown of the ideal gas law equation and developed an equation to correct for some of the errors arising from nonideality. This equation is known as the **van der Waals equation**:

observed pressure — container V

$$\left(P + a\left[\frac{n}{V}\right]^2\right)(V - bn) = nRT$$

correction for intermolecular forces — correction for molecular volume

where a and b are experimentally determined constants (Table 10.2). Although Equation 10.11 might seem complicated at first glance, the terms in parentheses are those of the ideal gas law, each corrected for the effects discussed previously. The pressure correction term, $a(n/V)^2$, accounts for intermolecular forces. Owing to intermolecular forces, the observed gas pressure is lower than the ideal pressure ($P_{observed} < P_{ideal}$ where P_{ideal} is calculated using the equation $PV = nRT$). Therefore, the term $a(n/V)^2$ is *added* to the observed pressure. The constant a typically has values in the range 0.01 to 10 atm · L^2/mol^2. The actual volume available to the molecules is smaller than the volume of the container because the molecules themselves take up space. Therefore, an amount is *subtracted* from the container volume ($= bn$) to take this into account. Here, n is the number of moles of gas, and b is an experimental quantity that corrects for the molecular volume. Typical values of b range from 0.01 to 0.1 L/mol, roughly increasing with increasing molecular size.

As an example of the importance of these corrections, consider a sample of 4.00 mol of chlorine gas, Cl_2, in a 4.00-L tank at 100.0 °C. The ideal gas law would lead you to expect a pressure of 30.6 atm. A better estimate of the pressure, obtained from the van der Waals equation, is 26.0 atm.

APPLYING CHEMICAL PRINCIPLES

10.1 The Atmosphere and Altitude Sickness

Some of you may have dreamed of climbing to the summits of the world's tallest mountains, or you may be an avid skier and visit high-mountain ski areas. In either case, "acute mountain sickness" (AMS) is a possibility. AMS is common at higher altitudes and is characterized by a headache, nausea, insomnia, dizziness, lassitude, and fatigue. It can be prevented by a slow ascent, and its symptoms can be relieved by a mild pain reliever.

Courtesy Ciprian Popoviciu

AMS and more serious forms of high-altitude sickness are generally due to oxygen deprivation, also called hypoxia. The oxygen concentration in Earth's atmosphere is 21%. As you go higher into the atmosphere, the concentration remains 21%, but the atmospheric pressure drops. When you reach 3000 m (the altitude of some ski resorts) the barometric pressure is about 70% of that at sea level. At 5000 m, barometric pressure is only 50% of sea level, and on the summit of Mount Everest (altitude = 8848 m), it is only 29% of the sea level pressure. At sea level, where the partial pressure of oxygen is 160 mm Hg, your blood is nearly saturated with oxygen, but as the partial pressure of oxygen [$P(O_2)$] drops, the percent saturation drops as well. At $P(O_2)$ of 50 mm Hg, hemoglobin in the red blood cells is about 80% saturated. Other saturation levels (measured at a pH of 7.4) are given in the table.

$P(O_2)$ (mm Hg)	Approximate Percent Saturation
90	95%
80	92%
70	90%
60	85%
50	80%
40	72%

Questions:

1. How does atmospheric pressure vary with altitude? Using data from this discussion, prepare a graph of altitude vs. atmospheric pressure and comment on the relationship.
2. Based on the graph from question 1, predict the altitude where the partial pressure of oxygen is 90 mm Hg.

10.2 The Goodyear Blimp

Goodyear blimps are a familiar sight at sporting events. They hover at altitudes between 1000–3000 feet, providing a stable platform for television cameras. The outer surface, or envelope, of a Goodyear blimp is constructed of polyester fabric impregnated with neoprene rubber. The envelope contains the lighter-than-air gas helium. Within the fore and aft sections of the envelope are two air-filled structures called ballonets, which serve two purposes. As the blimp changes altitude, the ballonets are inflated or deflated with air to maintain a helium pressure within the envelope that is similar to the external air pressure. The ballonets also are used to keep the craft level. The pilot and passengers ride in the gondola, which is attached to the bottom of the envelope.

One of the Goodyear blimps has a gross weight of 12,840 lbs (5820 kg), and the volume of the inner envelope is 202,700 ft^3 (5740 m^3). The ballonets, when both fully inflated with air, occupy a total of 18,000 ft^3 (510 m^3) of the envelope. Helium is neither added nor removed from the envelope during operation. Loss of helium through the rubber impregnated polyester fabric is slow, at approximately 10,000 ft^3 (280 m^3) per month.

Karl R. Martin/Shutterstock.com

Goodyear blimp.

Questions:

1. At sea level, atmospheric pressure is 1.00 atm. Calculate the density (in g/L) of helium at this pressure and 25 °C.
2. Use the data provided in Table 10.1 to calculate the density of dry air at 1.00 atm and 25 °C.
3. To stay aloft, a blimp must achieve neutral buoyancy; that is, its density must equal that of the surrounding air. The density of the blimp is its total weight (blimp, helium and air, passengers, and ballast) divided by its volume. Assume that the gross weight of the blimp includes the blimp's structure and the helium, but does not include the air in the ballonets or the weights of the passengers and ballast. If the ballonets are filled with 12,000 ft^3 (340 m^3) of air at 1.00 atm and 25 °C, what additional weight (of passengers and ballast) is required for neutral buoyancy?

10.3 The Chemistry of Airbags

Front and side air bags are now mandatory in automobiles because so many drivers and passengers have been saved from serious injury or death when airbags deployed in an accident.

In the event of an accident, a nylon or polyamide bag is rapidly inflated with nitrogen gas generated by a chemical reaction. The airbag unit has a sensor that is sensitive to sudden deceleration of the vehicle and will send an electrical signal that will trigger the reaction. The process from impact to full inflation should take only about 40 milliseconds and then the airbag begins to deflate before the driver or passenger is thrown against the bag. Inflation rate is important because smashing into a fully inflated bag would be like hitting a solid wall.

When a car decelerates in a collision, an electrical contact is made in the sensor unit. The propellant (green solid) detonates, releasing nitrogen gas, and the folded nylon bag explodes out of the plastic housing.

Autoliv/ASP

Driver-side airbags inflate with 35–70 L of N_2 gas, whereas passenger air bags hold 60–160 L.

Driver-side airbags inflate to a volume of 35–70 L, and passenger airbags inflate to 60–160 L. The final volume of the bag will depend on the amount of nitrogen gas generated. In many types of airbags, the explosion of sodium azide generates nitrogen gas.

$$2\ NaN_3(s) \rightarrow 2\ Na(s) + 3\ N_2(g)$$

The sodium produced in the reaction is converted to harmless salts by adding KNO_3 and silica to the mixture.

$$10\ Na(s) + 2\ KNO_3(s) \rightarrow K_2O(s) + 5\ Na_2O(s) + N_2(g)$$

$$K_2O(s) + Na_2O(s) + SiO_2(s) \rightarrow \text{powdered sodium silicate and potassium silicate}$$

Airbags have been common in passenger cars since the late 1900s. Because a sizeable number of these are now junked cars, this has raised another problem: how to dispose of the

NaN_3 in the airbags. Junked cars are often crushed to recycle the metal parts, and the airbag unit must be removed first. If not, the NaN_3 can be exposed to the elements, and, if wet it decomposes to the toxic and explosive gas, HN_3.

$$NaN_3(s) + H_2O(\ell) \rightarrow NaOH(aq) + HN_3(g)$$

Around 2000 a leading producer of airbag units decided to use a less expensive propellent, NH_4NO_3. As illustrated on page 271 (Study Question 5.97), ammonium nitrate can decompose explosively to two gases. It is also well-known that it is unstable when damp.

$$NH_4NO_3(s) \rightarrow N_2O(g) + 2\ H_2O(g)$$

Unfortunately, within a few years people reported that airbags exploded randomly. The explosion rate was sometimes too great for the bag, and the airbags exploded. In addition, the inflator housing would sometimes burst and send metal pieces into the car. Millions of cars were eventually recalled. At the time this was written it is still not clear why this occurred, but the chemistry of ammonium nitrate is complex, and it is known that the problem existed particularly in humid climates.

A search is on for new propellants and two promising ones are tetrazole (CH_2N_4) and guanidinium nitrate ($C(NH_2)_3NO_3$).

Questions:

1. Nitrogen gas is produced not only by NaN_3 decomposition, but also in the reaction that captures the sodium by-product. You need to fill a 75 L airbag at 25 °C to a pressure of 3.0 atm.
   a. What mass of NaN_3 is required?
   b. What mass of KNO_3 needs to be in the bag to capture the sodium byproduct?
2. You wish to fill a 75 L airbag at 25 °C to 3.0 atm using ammounium nitrate.
   a. What mass of NH_4NO_3 would be required?
   b. What are the partial pressures of N_2O and H_2O in the airbag?

CHAPTER GOALS REVISITED

The goals for this chapter are keyed to specific Study Questions to help you organize your review.

10.1 Modeling a State of Matter: Gases and Gas Pressure

- Describe how pressure measurements are made and the units of pressure, especially atmospheres (atm) and millimeters of mercury (mm Hg). 1–4.

10.2 Gas Laws: The Experimental Basis

- Understand the basis of the gas laws (Boyle's law, Charles's law, Avogadro's hypothesis) and know how to use those laws. 6, 8, 12, 14–16.

10.3 The Ideal Gas Law

- Understand the origin of the ideal gas law and how to use the equation. 17–20, 63, 85.
- Calculate the molar mass of a compound from the pressure of a known quantity of a gas in a given volume at a known temperature. 26–29.
- Relate gas density to molar mass, pressure, and temperature. 23, 24.

10.4 Gas Laws and Chemical Reactions

- Apply the gas laws to study the stoichiometry of reactions. 31, 32, 65.

10.5 Gas Mixtures and Partial Pressures

- Use Dalton's law of partial pressures. 37–40, 76, 80.

10.6 The Kinetic-Molecular Theory of Gases

- Understand kinetic-molecular theory as it is applied to gases, especially the distribution of molecular speeds (energies). 41–46.

10.7 Diffusion and Effusion

- Understand the phenomena of diffusion and effusion and apply Graham's law. **47–50, 81, 83.**

10.8 Nonideal Behavior of Gases

- Recognize why gases do not behave like ideal gases under some conditions. Deviations from ideal behavior are largest at high pressure and low temperature. **51, 53, 55, 82.**

KEY EQUATIONS

Equation 10.1 (page 454) Boyle's law (where P is the pressure and V is the volume).

$$P_1V_1 = P_2V_2 \text{ at constant } n \text{ and } T$$

Equation 10.2 (page 456) Charles's law (where T is the Kelvin temperature).

$$\frac{V_1}{T_1} = \frac{V_2}{T_2} \quad \text{at constant } n \text{ and } P$$

Equation 10.3 (page 457) General gas law (combined gas law).

$$\frac{P_1V_1}{T_1} = \frac{P_2V_2}{T_2} \quad \text{for a given amount of gas, } n$$

Equation 10.4 (page 460) Ideal gas law (where n is the amount of gas in moles and R is the universal gas constant, 0.082057 L · atm/K · mol).

$$PV = nRT$$

Equation 10.5 (page 462) Density of gases (where d is the gas density in g/L and M is the molar mass of the gas).

$$d = \frac{m}{V} = \frac{PM}{RT}$$

Equation 10.6 (page 465) Dalton's law of partial pressures. The total pressure of a gas mixture is the sum of the partial pressures of the component gases (P_n).

$$P_{\text{total}} = P_A + P_B + P_C + \ldots$$

Equation 10.7 (page 466) The total pressure of a gas mixture is equal to the total number of moles of gases multiplied by (RT/V).

$$P_{\text{total}} = (n_{\text{total}})\left(\frac{RT}{V}\right)$$

Equation 10.8 (page 466) The pressure of a gas (A) in a mixture is the product of its mole fraction (X_A) and the total pressure of the mixture.

$$P_A = X_A P_{\text{total}}$$

Equation 10.9 (page 469) The rms speed ($\sqrt{\overline{u^2}}$) depends on the molar mass of a gas (M) and its temperature (T).

$$\sqrt{\overline{u^2}} = \sqrt{\frac{3RT}{M}}$$

Equation 10.10 (page 472) Graham's law. The rate of effusion of a gas is inversely proportional to the square root of its molar mass.

$$\frac{\text{Rate of effusion of gas 1}}{\text{Rate of effusion of gas 2}} = \sqrt{\frac{\text{molar mass of gas 2}}{\text{molar mass of gas 1}}}$$

Equation 10.11 (page 475) The van der Waals equation, which relates pressure, volume, temperature, and amount of gas for a nonideal gas.

STUDY QUESTIONS

▲ denotes challenging questions. **Blue-numbered questions** have answers in Appendix N and fully worked solutions in the *Student Solutions Manual*.

Practicing Skills

Pressure

(See Section 10.1 and Example 10.1.)

1. The pressure of a gas is 440 mm Hg. Express this pressure in units of (a) atmospheres, (b) bars, and (c) kilopascals.
2. The average barometric pressure at an altitude of 10 km is 210 mm Hg. Express this pressure in atmospheres, bars, and kilopascals.
3. Indicate which represents the higher pressure in each of the following pairs:
   (a) 534 mm Hg or 0.754 bar
   (b) 534 mm Hg or 650 kPa
   (c) 1.34 bar or 934 kPa
4. Put the following in order of increasing pressure: 363 mm Hg, 363 kPa, 0.256 atm, and 0.523 bar.

Boyle's Law and Charles's Law

(See Section 10.2 and Examples 10.2 and 10.3.)

5. A sample of nitrogen gas has a pressure of 67.5 mm Hg in a 500.-mL flask. What is the pressure of this gas sample when it is transferred to a 125-mL flask at the same temperature?
6. A sample of CO_2 gas has a pressure of 56.5 mm Hg in a 125-mL flask. The sample is transferred to a new flask, where it has a pressure of 62.3 mm Hg at the same temperature. What is the volume of the new flask?
7. You have 3.5 L of NO at a temperature of 22.0 °C. What volume would the NO occupy at 37 °C? (Assume the pressure is constant.)
8. A 5.0-mL sample of CO_2 gas is enclosed in a gas-tight syringe (Figure 10.2) at 22 °C. If the syringe is immersed in an ice bath (0 °C), what is the new gas volume, assuming that the pressure is held constant?

The General Gas Law

(See Section 10.2 and Example 10.4.)

9. You have 3.6 L of H_2 gas at 380 mm Hg and 25 °C. What is the pressure of this gas if it is transferred to a 5.0-L flask at 0.0 °C?
10. You have a sample of CO_2 in flask A with a volume of 25.0 mL. At 20.5 °C, the pressure of the gas is 436.5 mm Hg. To find the volume of another flask, B, you move the CO_2 to that flask and find that its pressure is now 94.3 mm Hg at 24.5 °C. What is the volume of flask B?
11. You have a sample of gas in a flask with a volume of 250 mL. At 25.5 °C, the pressure of the gas is 360 mm Hg. If you decrease the temperature to −5.0 °C, what is the gas pressure at the lower temperature?
12. A sample of gas occupies 135 mL at 22.5 °C; the pressure is 165 mm Hg. What is the pressure of the gas sample when it is placed in a 252-mL flask at a temperature of 0.0 °C?

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

13. One of the cylinders of an automobile engine has a volume of 400. cm^3. The engine takes in air at a pressure of 1.00 atm and a temperature of 15 °C and compresses the air to a volume of 50.0 cm^3 at 77 °C. What is the final pressure of the gas in the cylinder? (The ratio of before and after volumes—in this case, 400:50 or 8:1—is called the *compression ratio*.)

14. A helium-filled balloon of the type used in long-distance flying contains 420,000 ft^3 (1.2×10^7 L) of helium. Suppose you fill the balloon with helium on the ground, where the pressure is 737 mm Hg and the temperature is 16.0 °C. When the balloon ascends to a height of 2 miles, where the pressure is only 600. mm Hg and the temperature is −33 °C, what volume is occupied by the helium gas? Assume the pressure inside the balloon matches the external pressure.

Avogadro's Hypothesis

(See Section 10.2 and Example 10.5.)

15. Nitrogen monoxide reacts with oxygen to give nitrogen dioxide.

$$2\ NO(g) + O_2(g) \rightarrow 2\ NO_2(g)$$

(a) You wish to react NO and O_2 in the correct stoichiometric ratio. The sample of NO has a volume of 150 mL. What volume of O_2 is required (at the same pressure and temperature)?

(b) What volume of NO_2 (at the same pressure and temperature) is formed in this reaction?

16. Ethane burns in air to give H_2O and CO_2.

$$2\ C_2H_6(g) + 7\ O_2(g) \rightarrow 4\ CO_2(g) + 6\ H_2O(g)$$

What volume of O_2 (L) is required for complete reaction with 5.2 L of C_2H_6? What volume of H_2O vapor (L) is produced? Assume all gases are measured at the same temperature and pressure.

Ideal Gas Law

(See Section 10.3 and Example 10.6.)

17. A 1.25-g sample of CO_2 is contained in a 750.-mL flask at 22.5 °C. What is the pressure of the gas?

18. A balloon holds 30.0 kg of helium. What is the volume of the balloon if its pressure is 1.20 atm and the temperature is 22 °C?

19. A flask is first evacuated so that it contains no gas at all. Then, 2.2 g of CO_2 is introduced into the flask. On warming to 22 °C, the gas exerts a pressure of 318 mm Hg. What is the volume of the flask?

20. A steel cylinder holds 1.50 g of ethanol, C_2H_5OH. What is the pressure of the ethanol vapor if the cylinder has a volume of 251 cm^3 and the temperature is 250 °C? (Assume all of the ethanol is in the vapor phase at this temperature.)

21. A balloon for long-distance flying contains 1.2×10^7 L of helium. If the helium pressure is 737 mm Hg at 25 °C, what mass of helium (in grams) does the balloon contain?

22. What mass of helium, in grams, is required to fill a 5.0-L balloon to a pressure of 1.1 atm at 25 °C?

Gas Density and Molar Mass

(See Section 10.3 and Examples and 10.7 and 10.8.)

23. Forty miles above Earth's surface, the temperature is 250 K, and the pressure is only 0.20 mm Hg. What is the density of air (in grams per liter) at this altitude? (Assume the molar mass of air is 28.96 g/mol.)

24. Diethyl ether, $(C_2H_5)_2O$, vaporizes easily at room temperature. If the vapor exerts a pressure of 233 mm Hg in a flask at 25 °C, what is the density of the vapor?

25. A gaseous organofluorine compound has a density of 0.355 g/L at 17 °C and 189 mm Hg. What is the molar mass of the compound?

26. Chloroform is a common liquid used in the laboratory. It vaporizes readily. If the pressure of chloroform vapor in a flask is 195 mm Hg at 25.0 °C and the density of the vapor is 1.25 g/L, what is the molar mass of chloroform?

27. A 1.007-g sample of an unknown gas exerts a pressure of 715 mm Hg in a 452-mL container at 23 °C. What is the molar mass of the gas?

28. A 0.0130-g sample of a gas with an empirical formula of C_4H_5 is placed in a 165-mL flask. It has a pressure of 13.7 mm Hg at 22.5 °C. What is the molecular formula of the compound?

29. A new boron hydride, B_xH_y, has been isolated. To find its molar mass, you measure the pressure of the gas in a known volume at a known temperature. The following experimental data are collected:

Mass of gas = 12.5 mg Pressure of gas = 24.8 mm Hg

Temperature = 25 °C Volume of flask = 125 mL

Which formula corresponds to the calculated molar mass?

(a) B_2H_6
(b) B_4H_{10}
(c) B_5H_9
(d) B_6H_{10}
(e) $B_{10}H_{14}$

30. Acetaldehyde is a common liquid compound that vaporizes readily. Determine the molar mass of acetaldehyde from the following data:

Sample mass = 0.107 g Volume of gas = 125 mL

Temperature = 0.0 °C Pressure = 331 mm Hg

Gas Laws and Chemical Reactions

(See Section 10.4 and Example 10.9.)

31. Iron reacts with hydrochloric acid to produce iron(II) chloride and hydrogen gas:

$$Fe(s) + 2\ HCl(aq) \rightarrow FeCl_2(aq) + H_2(g)$$

The H_2 gas from the reaction of 2.2 g of iron with excess acid is collected in a 10.0-L flask at 25 °C. What is the pressure of the H_2 gas in this flask?

32. Silane, SiH_4, reacts with O_2 to give silicon dioxide and water:

$$SiH_4(g) + 2\ O_2(g) \rightarrow SiO_2(s) + 2\ H_2O(\ell)$$

A 5.20-L sample of SiH_4 gas at 356 mm Hg pressure and 25 °C is allowed to react with O_2 gas. What volume of O_2 gas, in liters, is required for complete reaction if the oxygen has a pressure of 425 mm Hg at 25 °C?

33. Sodium azide, the explosive compound in automobile air bags, decomposes according to the following equation:

$$2\ NaN_3(s) \rightarrow 2\ Na(s) + 3\ N_2(g)$$

What mass of sodium azide is required to provide the nitrogen needed to inflate a 75.0-L bag to a pressure of 1.3 atm at 25 °C?

34. The hydrocarbon octane (C_8H_{18}) burns to give CO_2 and water vapor:

$$2\ C_8H_{18}(g) + 25\ O_2(g) \rightarrow 16\ CO_2(g) + 18\ H_2O(g)$$

If a 0.048-g sample of octane burns completely in O_2, what will be the pressure of water vapor in a 4.75-L flask at 30.0 °C? If the O_2 gas needed for complete combustion was contained in a 4.75-L flask at 22 °C, what would its pressure be?

35. Hydrazine reacts with O_2 according to the following equation:

$$N_2H_4(g) + O_2(g) \rightarrow N_2(g) + 2\ H_2O(\ell)$$

Assume the O_2 needed for the reaction is in a 450-L tank at 23 °C. What must the oxygen pressure be in the tank to have enough oxygen to consume 1.00 kg of hydrazine completely?

36. A self-contained underwater breathing apparatus (SCUBA) uses canisters containing potassium superoxide. The superoxide consumes the CO_2 exhaled by a person and replaces it with oxygen.

$$4\ KO_2(s) + 2\ CO_2(g) \rightarrow 2\ K_2CO_3(s) + 3\ O_2(g)$$

What mass of KO_2, in grams, is required to react with 8.90 L of CO_2 at 22.0 °C and 767 mm Hg?

Gas Mixtures and Dalton's Law

(See Section 10.5 and Example 10.10.)

37. What is the total pressure in atmospheres of a gas mixture that contains 1.0 g of H_2 and 8.0 g of Ar in a 3.0-L container at 27 °C? What are the partial pressures of the two gases?

38. A cylinder of compressed gas is labeled "Composition (mole %): 4.5% H_2S, 3.0% CO_2, balance N_2." The pressure gauge attached to the cylinder reads 46 atm. Calculate the partial pressure of each gas, in atmospheres, in the cylinder.

39. A halothane–oxygen mixture ($C_2HBrClF_3 + O_2$) can be used as an anesthetic. A tank containing such a mixture has the following partial pressures: P (halothane) = 170 mm Hg and P (O_2) = 570 mm Hg.

(a) What is the ratio of the number of moles of halothane to the number of moles of O_2?

(b) If the tank contains 160 g of O_2, what mass of $C_2HBrClF_3$ is present?

40. A collapsed balloon is filled with He to a volume of 12.5 L at a pressure of 1.00 atm. Oxygen, O_2, is then added so that the final volume of the balloon is 26 L with a total pressure of 1.00 atm. The temperature, which remains constant throughout, is 21.5 °C.

(a) What mass of He does the balloon contain?

(b) What is the final partial pressure of He in the balloon?

(c) What is the partial pressure of O_2 in the balloon?

(d) What is the mole fraction of each gas?

Kinetic-Molecular Theory

(See Section 10.6 and Example 10.11.)

41. You have two flasks of equal volume. Flask A contains H_2 at 0 °C and 1 atm pressure. Flask B contains CO_2 gas at 25 °C and 2 atm pressure. Compare these two gases with respect to each of the following:

(a) average kinetic energy per molecule

(b) root mean square speed

(c) number of molecules

(d) mass of gas

42. Equal masses of gaseous N_2 and Ar are placed in separate flasks of equal volume at the same temperature. Tell whether each of the following statements is true or false. Briefly explain your answer in each case.
   (a) There are more molecules of N_2 present than atoms of Ar.
   (b) The pressure is greater in the Ar flask.
   (c) The Ar atoms have a greater rms speed than the N_2 molecules.
   (d) The N_2 molecules collide more frequently with the walls of the flask than do the Ar atoms.

43. If the rms speed of an oxygen molecule is 4.28×10^4 cm/s at a given temperature, what is the rms speed of a CO_2 molecule at the same temperature?

44. Calculate the rms speed for CO molecules at 25 °C. What is the ratio of this speed to that of Ar atoms at the same temperature?

45. Place the following gases in order of increasing rms speed at 25 °C: Ar, CH_4, N_2, CH_2F_2.

46. The reaction of SO_2 with Cl_2 gives dichlorine oxide, which is used to bleach wood pulp and to treat wastewater:

$$SO_2(g) + 2\ Cl_2(g) \rightarrow SOCl_2(g) + Cl_2O(g)$$

Assume all of the compounds involved in the reaction are gases. List them in order of increasing rms speed.

Diffusion and Effusion

(See Section 10.7 and Example 10.12.)

47. In each pair of gases below, tell which will effuse faster:
   (a) CO_2 or F_2
   (b) O_2 or N_2
   (c) C_2H_4 or C_2H_6
   (d) two chlorofluorocarbons: $CFCl_3$ or $C_2Cl_2F_4$

48. Argon gas is 10 times denser than helium gas at the same temperature and pressure. Which gas is predicted to effuse faster? How much faster?

49. A gas whose molar mass you wish to know effuses through an opening at a rate one third as fast as that of helium gas. What is the molar mass of the unknown gas?

50. ▲ A sample of uranium fluoride is found to effuse at the rate of 17.7 mg/h. Under comparable conditions, gaseous I_2 effuses at the rate of 15.0 mg/h. What is the molar mass of the uranium fluoride? (*Hint:* Rates must be converted to units of moles per time.)

Nonideal Gases

(See Section 10.8.)

51. Under which set of conditions will CO_2 deviate most from ideal gas behavior?
   (a) 1 atm, 0 °C
   (b) 0.1 atm, 100 °C
   (c) 10 atm, 0 °C
   (d) 1 atm, 100 °C

52. Under which set of conditions will Cl_2 deviate least from ideal gas behavior?
   (a) 1 atm, 0 °C
   (b) 0.1 atm, 100 °C
   (c) 10 atm, 0 °C
   (d) 1 atm, 100 °C

53. In the text, it is stated that the pressure of 4.00 mol of Cl_2 in a 4.00-L tank at 100.0 °C should be 26.0 atm if calculated using the van der Waals equation. Verify this result, and compare it with the pressure predicted by the ideal gas law.

54. You want to store 165 g of CO_2 gas in a 12.5-L tank at room temperature (25 °C). Calculate the pressure the gas would have using (a) the ideal gas law and (b) the van der Waals equation. (For CO_2, $a = 3.59$ atm · L^2/mol^2 and $b = 0.0427$ L/mol.)

55. Consider a 5.00-L tank containing 325 g of H_2O at a temperature of 275 °C.
   (a) Calculate the pressure in the tank using both the ideal gas law and the van der Waals equation.
   (b) Which correction term, $a(n/V)^2$ or bn, has the greatest influence on the pressure of this system?

56. Consider a 5.00-L tank containing 375 g of Ar at a temperature of 25 °C.
   (a) Calculate the pressure in the tank using both the ideal gas law and the van der Waals equation.
   (b) Which correction term, $a(n/V)^2$ or bn, has the greatest influence on the pressure of this system?

General Questions

These questions are not designated as to type or location in the chapter. They may combine several concepts.

57. Complete the following table:

	atm	mm Hg	kPa	bar
Standard atmosphere	____	____	____	____
Partial pressure of N_2 in the atmosphere	____	593	____	____
Tank of compressed H_2	____	____	____	133
Atmospheric pressure at the top of Mount Everest	____	____	33.7	____

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

58. On combustion, 1.0 L of a gaseous compound of hydrogen, carbon, and nitrogen gives 2.0 L of CO_2, 3.5 L of H_2O vapor, and 0.50 L of N_2 at STP. What is the empirical formula of the compound?

59. ▲ You have a sample of helium gas at −33 °C, and you want to increase the rms speed of helium atoms by 10.0%. To what temperature should the gas be heated to accomplish this?

60. If 12.0 g of O_2 is required to inflate a balloon to a certain size at 27 °C, what mass of O_2 is required to inflate it to the same size (and pressure) at 5.0 °C?

61. Butyl mercaptan, C_4H_9SH, has a very bad odor and is among the compounds added to natural gas to help detect a leak of otherwise odorless natural gas. In an experiment, you burn 95.0 mg of C_4H_9SH and collect the product gases (SO_2, CO_2, and H_2O) in a 5.25-L flask at 25 °C. What is the total gas pressure in the flask, and what is the partial pressure of each of the product gases?

62. A bicycle tire has an internal volume of 1.52 L and contains 0.406 mol of air. The tire will burst if its internal pressure reaches 7.25 atm. To what temperature, in degrees Celsius, does the air in the tire need to be heated to cause a blowout?

63. The temperature of the atmosphere on Mars can be as high as 27 °C at the equator at noon, and the atmospheric pressure is about 8 mm Hg. If a spacecraft could collect 10. m^3 of this atmosphere, compress it to a small volume, and send it back to Earth, how many moles would the sample contain?

64. If you place 2.25 g of solid silicon in a 6.56-L flask that contains CH_3Cl with a pressure of 585 mm Hg at 25 °C, what mass of dimethyldichlorosilane, $(CH_3)_2SiCl_2$, can be formed?

$$Si(s) + 2\ CH_3Cl(g) \rightarrow (CH_3)_2SiCl_2(g)$$

What pressure of $(CH_3)_2SiCl_2(g)$ would you expect in this same flask at 95 °C on completion of the reaction? (Dimethyldichlorosilane is one starting material used to make silicones, polymeric substances used as lubricants, antistick agents, and water-proofing caulk.)

65. What volume (in liters) of O_2, measured at standard temperature and pressure, is required to oxidize 0.400 mol of phosphorus (P_4)?

$$P_4(s) + 5\ O_2(g) \rightarrow P_4O_{10}(s)$$

66. Nitroglycerin decomposes into four different gases when detonated:

$$4\ C_3H_5(NO_3)_3(\ell) \rightarrow 6\ N_2(g) + O_2(g) + 12\ CO_2(g) + 10\ H_2O(g)$$

The detonation of a small quantity of nitroglycerin produces a total pressure of 4.2 atm at a temperature of 450 °C.

(a) What is the partial pressure of N_2?

(b) If the gases occupy a volume of 1.5 L, what mass of nitroglycerin was detonated?

67. $Ni(CO)_4$ can be made by reacting finely divided nickel with gaseous CO. If you have CO in a 1.50-L flask at a pressure of 418 mm Hg at 25.0 °C, along with 0.450 g of Ni powder, what is the theoretical yield of $Ni(CO)_4$?

68. Ethane burns in air to give H_2O and CO_2.

$$2\ C_2H_6(g) + 7\ O_2(g) \rightarrow 4\ CO_2(g) + 6\ H_2O(g)$$

(a) Four gases are involved in this reaction. Place them in order of increasing rms speed. (Assume all are at the same temperature.)

(b) A 3.26-L flask contains C_2H_6 at a pressure of 256 mm Hg and a temperature of 25 °C. Suppose O_2 gas is added to the flask until C_2H_6 and O_2 are in the correct stoichiometric ratio for the combustion reaction. At this point, what is the partial pressure of O_2 and what is the total pressure in the flask?

69. You have four gas samples:

1. 1.0 L of H_2 at STP
2. 1.0 L of Ar at STP
3. 1.0 L of H_2 at 27 °C and 760 mm Hg
4. 1.0 L of He at 0 °C and 900 mm Hg

(a) Which sample has the largest number of gas particles (atoms or molecules)?

(b) Which sample contains the smallest number of particles?

(c) Which sample represents the largest mass?

70. Propane reacts with oxygen to give carbon dioxide and water vapor.

$$C_3H_8(g) + 5\ O_2(g) \rightarrow 3\ CO_2(g) + 4\ H_2O(g)$$

If you mix C_3H_8 and O_2 in the correct stoichiometric ratio, and if the total pressure of the mixture is 288 mm Hg, what are the partial pressures of C_3H_8 and O_2? If the temperature and volume do not change, what is the pressure of the water vapor after reaction?

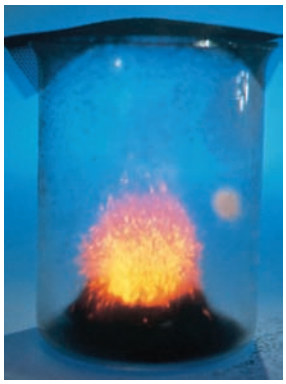
71. Iron carbonyl can be made by the direct reaction of iron metal and carbon monoxide.

$$Fe(s) + 5\ CO(g) \rightarrow Fe(CO)_5(\ell)$$

What is the theoretical yield of $Fe(CO)_5$ if 3.52 g of iron is treated with CO gas having a pressure of 732 mm Hg in a 5.50-L flask at 23 °C?



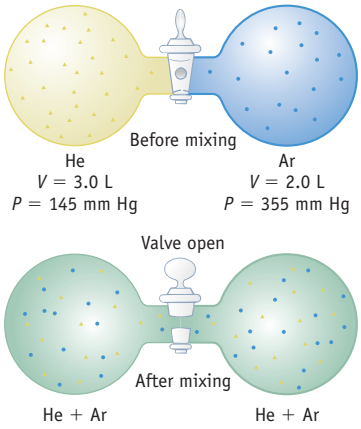
72. Analysis of a gaseous chlorofluorocarbon, CCl_xF_y, shows that it contains 11.79% C and 69.57% Cl. In another experiment, you find that 0.107 g of the compound fills a 458-mL flask at 25 °C with a pressure of 21.3 mm Hg. What is the molecular formula of the compound?

73. There are five compounds in the family of sulfur–fluorine compounds with the general formula S_xF_y. One of these compounds is 25.23% S. If you place 0.0955 g of the compound in a 89-mL flask at 45 °C, the pressure of the gas is 83.8 mm Hg. What is the molecular formula of S_xF_y?

74. A miniature volcano can be made in the laboratory with ammonium dichromate. When ignited, it decomposes in a fiery display.

$$(NH_4)_2Cr_2O_7(s) \rightarrow N_2(g) + 4\ H_2O(g) + Cr_2O_3(s)$$

If 0.95 g of ammonium dichromate is used and the gases from this reaction are trapped in a 15.0-L flask at 23 °C, what is the total pressure of the gas in the flask? What are the partial pressures of N_2 and H_2O?



© Cengage Learning/Charles D. Winters

Thermal decomposition of $(NH_4)_2Cr_2O_7$

75. The density of air 20 km above Earth's surface is 92 g/m^3. The pressure of the atmosphere is 42 mm Hg, and the temperature is −63 °C.
   (a) What is the average molar mass of the atmosphere at this altitude?
   (b) If the atmosphere at this altitude consists of only O_2 and N_2, what is the mole fraction of each gas?

76. A 3.0-L bulb containing He at 145 mm Hg is connected by a valve to a 2.0-L bulb containing Ar at 355 mm Hg (see figure). Calculate the partial pressure of each gas and the total pressure after the valve between the flasks is opened.

77. Chlorine dioxide, ClO_2, reacts with fluorine to give a new gas that contains Cl, O, and F. In an experiment, you find that 0.150 g of this new gas has a pressure of 17.2 mm Hg in a 1850-mL flask at 21 °C. What is the identity of the unknown gas?

78. A xenon fluoride can be prepared by heating a mixture of Xe and F_2 gases to a high temperature in a pressure-proof container. Assume that xenon gas was added to a 0.25-L container until its pressure reached 0.12 atm at 0.0 °C. Fluorine gas was then added until the total pressure reached 0.72 atm at 0.0 °C. After the reaction was complete, the xenon was consumed completely, and the pressure of the F_2 remaining in the container was 0.36 atm at 0.0 °C. What is the empirical formula of the xenon fluoride?

79. Several small molecules (besides water) are important in biochemical systems: O_2, CO, CO_2, and NO. You have isolated one of these and to identify it you determine its molar mass. You release 0.37 g of the gas into a flask with a volume of 732 mL at 21 °C. The gas pressure in the flask is 209 mm Hg. What is the unknown gas?

80. Consider the following gases: He, SO_2, CO_2, and Cl_2.
   (a) Which has the largest density (assuming that all gases are at the same T and P)?
   (b) Which gas will effuse fastest through a porous plate?

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

81. Which of the following is *not* correct?

(a) Diffusion of gases occurs more rapidly at higher temperatures.

(b) Effusion of H_2 is faster than effusion of He (assume similar conditions and a rate expressed in units of mol/h).

(c) Diffusion will occur faster at low pressure than at high pressure.

(d) The rate of effusion of a gas (mol/h) is directly proportional to molar mass.

82. The ideal gas law is least accurate under conditions of high pressure and low temperature. In those situations, using the van der Waals equation is advisable.

(a) Calculate the pressure exerted by 12.0 g of CO_2 in a 500-mL vessel at 298 K, using the ideal gas equation. Then, recalculate the pressure using the van der Waals equation. Assuming the pressure calculated from van der Waals equation is correct, what is the percent error in the answer when using the ideal gas equation?

(b) Next, cool this sample to −70 °C. Then perform the same calculation for the pressure exerted by CO_2 at this new temperature, using both the ideal gas law and the van der Waals equation. Again, what is the percent error when using the ideal gas equation?

83. Carbon dioxide, CO_2, was shown to effuse through a porous plate at the rate of 0.033 mol/min. The same quantity of an unknown gas, 0.033 moles, is found to effuse through the same porous barrier in 104 seconds. Calculate the molar mass of the unknown gas.

84. In an experiment, you have determined that 0.66 moles of CF_4 effuse through a porous barrier over a 4.8-minute period. How long will it take for 0.66 moles of CH_4 to effuse through the same barrier?

85. A balloon is filled with helium gas to a gauge pressure of 22 mm Hg at 25 °C. The volume of the gas is 305 mL, and the barometric pressure is 755 mm Hg. What amount of helium is in the balloon? (Remember that gauge pressure = total pressure − barometric pressure. See page 452.)

86. If you have a sample of water in a closed container, some of the water will evaporate until the pressure of the water vapor, at 25 °C, is 23.8 mm Hg. How many molecules of water per cubic centimeter exist in the vapor phase?

87. You are given 1.56 g of a mixture of $KClO_3$ and KCl. When heated, the $KClO_3$ decomposes to KCl and O_2,

$$2\ KClO_3(s) \rightarrow 2\ KCl(s) + 3\ O_2(g)$$

and 327 mL of O_2 with a pressure of 735 mm Hg is collected at 19 °C. What is the weight percentage of $KClO_3$ in the sample?

88. A study of climbers who reached the summit of Mount Everest without supplemental oxygen showed that the partial pressures of O_2 and CO_2 in their lungs were 35 mm Hg and 7.5 mm Hg, respectively. The barometric pressure at the summit was 253 mm Hg. Assume the lung gases are saturated with moisture at a body temperature of 37 °C [which means the partial pressure of water vapor in the lungs is $P(H_2O) = 47.1$ mm Hg]. If you assume the lung gases consist of only O_2, N_2, CO_2, and H_2O, what is the partial pressure of N_2?

89. Nitrogen monoxide reacts with oxygen to give nitrogen dioxide:

$$2\ NO(g) + O_2(g) \rightarrow 2\ NO_2(g)$$

(a) Place the three gases in order of increasing rms speed at 298 K.

(b) If you mix NO and O_2 in the correct stoichiometric ratio and NO has a partial pressure of 150 mm Hg, what is the partial pressure of O_2?

(c) After reaction between NO and O_2 is complete, what is the pressure of NO_2 if the NO originally had a pressure of 150 mm Hg and O_2 was added in the correct stoichiometric amount?

90. ▲ Ammonia gas is synthesized by combining hydrogen and nitrogen:

$$3\ H_2(g) + N_2(g) \rightarrow 2\ NH_3(g)$$

(a) If you want to produce 562 g of NH_3, what volume of H_2 gas, at 56 °C and 745 mm Hg, is required?

(b) Nitrogen for this reaction will be obtained from air. What volume of air, measured at 29 °C and 745 mm Hg pressure, will be required to provide the nitrogen needed to produce 562 g of NH_3? Assume the sample of air contains 78.1 mole % N_2.

91. Nitrogen trifluoride is prepared by the reaction of ammonia and fluorine.

$$4\ NH_3(g) + 3\ F_2(g) \rightarrow 3\ NH_4F(s) + NF_3(g)$$

If you mix NH_3 with F_2 in the correct stoichiometric ratio, and if the total pressure of the mixture is 120 mm Hg, what are the partial pressures of NH_3 and F_2? When the reactants have been completely consumed, what is the total pressure in the flask? (Assume T is constant.)

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

92. Chlorine trifluoride, ClF_3, is a valuable reagent because it can be used to convert metal oxides to metal fluorides:

$$6\ NiO(s) + 4\ ClF_3(g) \rightarrow 6\ NiF_2(s) + 2\ Cl_2(g) + 3\ O_2(g)$$

(a) What mass of NiO will react with ClF_3 gas if the gas has a pressure of 250 mm Hg at 20 °C in a 2.5-L flask?

(b) If the ClF_3 described in part (a) is completely consumed, what are the partial pressures of Cl_2 and of O_2 in the 2.5-L flask at 20 °C (in mm Hg)? What is the total pressure in the flask?

93. ▲ Relative humidity is the ratio of the partial pressure of water in air at a given temperature to the vapor pressure of water at that temperature. Calculate the mass of water per liter of air under the following conditions:

(a) at 20 °C and 45% relative humidity

(b) at 0 °C and 95% relative humidity

Under which circumstances is the mass of H_2O per liter greater? (See Appendix G for the vapor pressure of water.)

94. What mass of water vapor is present in a dormitory room when the relative humidity is 55% and the temperature is 23 °C? The dimensions of the room are 4.5 m^2 floor area and 3.5 m ceiling height. (See Study Question 93 for a definition of relative humidity and Appendix G for the vapor pressure of water.)

In the Laboratory

95. ▲ You have a 550.-mL tank of gas with a pressure of 1.56 atm at 24 °C. You thought the gas was pure carbon monoxide gas, CO, but you later found it was contaminated by small quantities of gaseous CO_2 and O_2. Analysis shows that the tank pressure is 1.34 atm (at 24 °C) if the CO_2 is removed. Another experiment shows that 0.0870 g of O_2 can be removed chemically. What are the masses of CO and CO_2 in the tank, and what is the partial pressure of each of the three gases at 25 °C?

96. ▲ Methane is burned in a laboratory Bunsen burner to give CO_2 and water vapor. Methane gas is supplied to the burner at the rate of 5.0 L/min (at a temperature of 28 °C and a pressure of 773 mm Hg). At what rate must oxygen be supplied to the burner (at a pressure of 742 mm Hg and a temperature of 26 °C)?

97. ▲ Iron forms a series of compounds of the type $Fe_x(CO)_y$. In air, these compounds are oxidized to Fe_2O_3 and CO_2 gas. After heating a 0.142-g sample of $Fe_x(CO)_y$ in air, you isolate the CO_2 in a 1.50-L flask at 25 °C. The pressure of the gas is 44.9 mm Hg. What is the empirical formula of $Fe_x(CO)_y$?

98. ▲ Group 2A metal carbonates are decomposed to the metal oxide and CO_2 on heating:

$$MCO_3(s) \rightarrow MO(s) + CO_2(g)$$

You heat 0.158 g of a white, solid carbonate of a Group 2A metal (M) and find that the evolved CO_2 has a pressure of 69.8 mm Hg in a 285-mL flask at 25 °C. Identify M.

99. One way to synthesize diborane, B_2H_6, is the reaction

$$2\ NaBH_4(s) + 2\ H_3PO_4(\ell) \rightarrow B_2H_6(g) + 2\ NaH_2PO_4(s) + 2\ H_2(g)$$

(a) If you have 0.136 g of $NaBH_4$ and excess H_3PO_4, and you collect the resulting B_2H_6 in a 2.75-L flask at 25 °C, what is the pressure of the B_2H_6 in the flask?

(b) A by-product of the reaction is H_2 gas. If both B_2H_6 and H_2 gas come from this reaction, what is the *total* pressure in the 2.75-L flask (after reaction of 0.136 g of $NaBH_4$ with excess H_3PO_4) at 25 °C?

100. You are given a solid mixture of $NaNO_2$ and NaCl and are asked to analyze it for the amount of $NaNO_2$ present. To do so, you allow the mixture to react with sulfamic acid, HSO_3NH_2, in water according to the equation

$$NaNO_2(aq) + HSO_3NH_2(aq) \rightarrow NaHSO_4(aq) + H_2O(\ell) + N_2(g)$$

What is the weight percentage of $NaNO_2$ in 1.232 g of the solid mixture if reaction with sulfamic acid produces 295 mL of dry N_2 gas with a pressure of 713 mm Hg at 21.0 °C?

101. ▲ You have 1.249 g of a mixture of $NaHCO_3$ and Na_2CO_3. You find that 12.0 mL of 1.50 M HCl is required to convert the sample completely to NaCl, H_2O, and CO_2.

$$NaHCO_3(aq) + HCl(aq) \rightarrow NaCl(aq) + H_2O(\ell) + CO_2(g)$$

$$Na_2CO_3(aq) + 2\ HCl(aq) \rightarrow 2\ NaCl(aq) + H_2O(\ell) + CO_2(g)$$

What volume of CO_2 is evolved at 745 mm Hg and 25 °C?

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

102. ▲ A mixture of $NaHCO_3$ and Na_2CO_3 has a mass of 2.50 g. When treated with HCl(aq), 665 mL of CO_2 gas is liberated with a pressure of 735 mm Hg at 25 °C. What is the weight percent of $NaHCO_3$ and Na_2CO_3 in the mixture? (See Study Question 101 for the reactions that occur.)

103. ▲ Many nitrate salts can be decomposed by heating. For example, blue, anhydrous copper(II) nitrate produces the gases nitrogen dioxide and oxygen when heated. In the laboratory, you find that a sample of this salt produced a 0.195-g mixture of gaseous NO_2 and O_2 with a total pressure of 725 mm Hg at 35 °C in a 125-mL flask (and black, solid CuO was left as a residue). What is the average molar mass of the gas mixture? What are the mole fractions of NO_2 and O_2 in the mixture? What amount of each gas is in the mixture? Do these amounts reflect the relative amounts of NO_2 and O_2 expected based on the balanced equation? Is it possible that the fact that some NO_2 molecules combine to give N_2O_4 plays a role?

© Cengage Learning/Charles D. Winters

Heating copper(II) nitrate produces nitrogen dioxide and oxygen gas and leaves a residue of copper(II) oxide.

104. ▲ A compound containing C, H, N, and O is burned in excess oxygen. The gases produced by burning 0.1152 g are first treated to convert the nitrogen-containing product gases into N_2, and then the resulting mixture of CO_2, H_2O, N_2, and excess O_2 is passed through a bed of $CaCl_2$ to absorb the water. The $CaCl_2$ increases in mass by 0.09912 g. The remaining gases are bubbled into water to form H_2CO_3, and this solution is titrated with 0.3283 M NaOH; 28.81 mL is required to achieve the second equivalence point. The excess O_2 gas is removed by reaction with copper metal (to give CuO). Finally, the N_2 gas is collected in a 225.0-mL flask, where it has a pressure of 65.12 mm Hg at 25 °C. In a separate experiment, the unknown compound is found to have a molar mass of 150 g/mol. What are the empirical and molecular formulas of the unknown compound?

105. You have a gas, one of the three known phosphorus–fluorine compounds (PF_3, PF_5, and P_2F_4). To find out which, you have decided to measure its molar mass.

(a) First, you determine that the density of the gas is 5.60 g/L at a pressure of 0.971 atm and a temperature of 18.2 °C. Calculate the molar mass and identify the compound.

(b) To check the results from part (a), you decide to measure the molar mass based on the relative rates of effusion of the unknown gas and CO_2. You find that CO_2 effuses at a rate of 0.050 mol/min, whereas the unknown phosphorus fluoride effuses at a rate of 0.028 mol/min. Calculate the molar mass of the unknown gas based on these results.

106. A 1.50 L constant-volume calorimeter (Figure 5.12) contains $C_3H_8(g)$ and $O_2(g)$. The partial pressure of C_3H_8 is 0.10 atm and the partial pressure of O_2 is 5.0 atm. The temperature is 20.0 °C. A reaction occurs between the two compounds, forming $CO_2(g)$ and $H_2O(\ell)$. The heat from the reaction causes the temperature to rise to 23.2 °C.

(a) Write a balanced chemical equation for the reaction.

(b) How many moles of $C_3H_8(g)$ are present in the flask initially?

(c) What is the mole fraction of $C_3H_8(g)$ in the flask before reaction?

(d) After the reaction, the flask contains excess oxygen and the products of the reaction, $CO_2(g)$ and $H_2O(\ell)$. What amount of unreacted $O_2(g)$ remains?

(e) After the reaction, what is the partial pressure exerted by the $CO_2(g)$ in this system?

(f) What is the partial pressure exerted by the excess oxygen remaining after the reaction?

Summary and Conceptual Questions

The following questions may use concepts from this and previous chapters.

107. A 1.0-L flask contains 10.0 g each of O_2 and CO_2 at 25 °C.

(a) Which gas has the greater partial pressure, O_2 or CO_2, or are they the same?

(b) Which molecules have the greater rms speed, or are they the same?

(c) Which molecules have the greater average kinetic energy, or are they the same?

108. If equal masses of O_2 and N_2 are placed in separate containers of equal volume at the same temperature, which of the following statements is true? If false, explain why it is false.

(a) The pressure in the flask containing N_2 is greater than that in the flask containing O_2.

(b) There are more molecules in the flask containing O_2 than in the flask containing N_2.

109. You have two pressure-proof steel cylinders of equal volume, one containing 1.0 kg of CO and the other containing 1.0 kg of acetylene, C_2H_2.

(a) In which cylinder is the pressure greater at 25 °C?

(b) Which cylinder contains the greater number of molecules?

110. Two flasks, each with a volume of 1.00 L, contain O_2 gas with a pressure of 380 mm Hg. Flask A is at 25 °C, and flask B is at 0 °C. Which flask contains the greater number of O_2 molecules?

111. ▲ State whether each of the following samples of matter is a gas. If there is not enough information for you to decide, write "insufficient information."

(a) A material is in a steel tank at 100 atm pressure. When the tank is opened to the atmosphere, the material suddenly expands, increasing its volume by 1%.

(b) A 1.0-mL sample of material weighs 8.2 g.

(c) The material is transparent and pale green in color.

(d) One cubic meter of material contains as many molecules as 1.0 m^3 of air at the same temperature and pressure.

112. Each of four flasks is filled with a different gas. Each flask has the same volume, and each is filled to the same pressure, 3.0 atm, at 25 °C. Flask A contains 116 g of air, flask B has 80.7 g of neon, flask C has 16.0 g of helium, and flask C has 160. g of an unknown gas.

(a) Do all four flasks contain the same number of gas molecules? If not, which one has the greatest number of molecules?

(b) How many times heavier is a molecule of the unknown gas than an atom of helium?

(c) In which flask do the molecules have the largest kinetic energy? The highest rms speed?

113. You have two gas-filled balloons, one containing He and the other containing H_2. The H_2 balloon is twice the volume of the He balloon. The pressure of gas in the H_2 balloon is 1 atm, and that in the He balloon is 2 atm. The H_2 balloon is outside in the snow (−5 °C), and the He balloon is inside a warm building (23 °C).

(a) Which balloon contains the greater number of molecules?

(b) Which balloon contains the greater mass of gas?

114. The sodium azide required for automobile air bags is made by the reaction of sodium metal with dinitrogen monoxide in liquid ammonia:

$$3\ N_2O(g) + 4\ Na(s) + NH_3(\ell) \rightarrow NaN_3(s) + 3\ NaOH(s) + 2\ N_2(g)$$

(a) You have 65.0 g of sodium, a 35.0-L flask containing N_2O gas with a pressure of 2.12 atm at 23 °C, and excess ammonia. What is the theoretical yield (in grams) of NaN_3?

(b) Draw a Lewis structure for the azide ion. Include all possible resonance structures. Which resonance structure is most likely?

(c) What is the shape of the azide ion?

115. If the absolute temperature of a gas doubles, by how much does the rms speed of the gaseous molecules increase?

116. ▲ Chlorine gas (Cl_2) is used as a disinfectant in municipal water supplies, although chlorine dioxide (ClO_2) and ozone are becoming more widely used. ClO_2 is a better choice than Cl_2 in this application because it leads to fewer chlorinated by-products, which are themselves pollutants.

(a) How many valence electrons are in ClO_2?

(b) The chlorite ion, ClO_2^-, is obtained by reducing ClO_2. Draw a possible electron dot structure for ClO_2^-. (Cl is the central atom.)

(c) What is the hybridization of the central Cl atom in ClO_2^-? What is the shape of the ion?

(d) Which species has the larger bond angle, O_3 or ClO_2^-? Explain briefly.

(e) Chlorine dioxide, ClO_2, a yellow-green gas, can be made by the reaction of chlorine with sodium chlorite:

$$2\ NaClO_2(s) + Cl_2(g) \rightarrow 2\ NaCl(s) + 2\ ClO_2(g)$$

Assume you react 15.6 g of $NaClO_2$ with chlorine gas, which has a pressure of 1050 mm Hg in a 1.45-L flask at 22 °C. What mass of ClO_2 can be produced?

CHAPTER OUTLINE

11.1 States of Matter and Intermolecular Forces

11.2 Interactions between Ions and Molecules with a Permanent Dipole

11.3 Interactions between Molecules with a Permanent Dipole

11.4 Intermolecular Forces Involving Nonpolar Molecules

11.5 A Summary of van der Waals Intermolecular Forces

11.6 Properties of Liquids

11.1 States of Matter and Intermolecular Forces

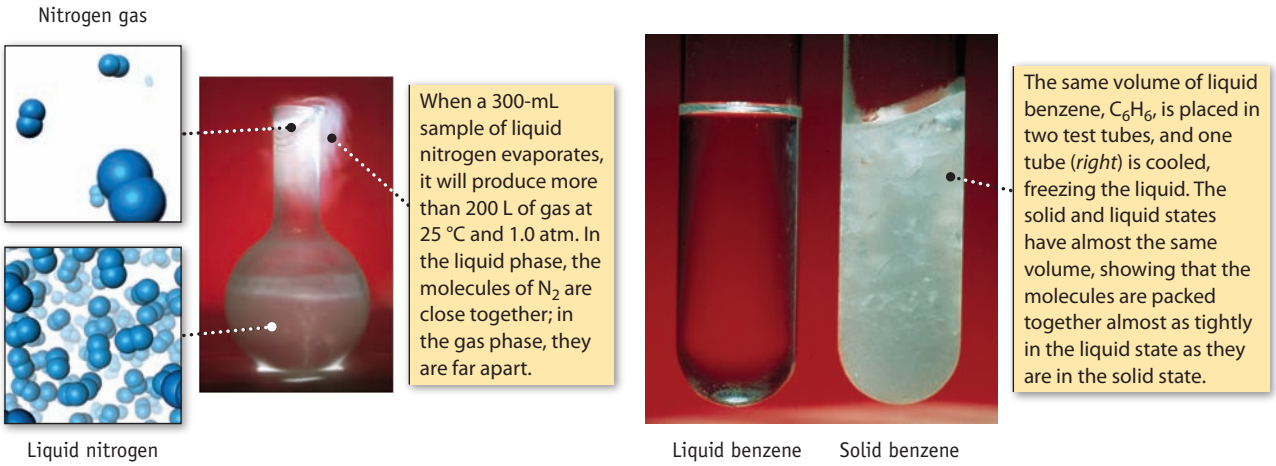
Goal for Section 11.1

- Know what types of intermolecular forces exist and what molecular properties they can influence.

Under most conditions it is possible to describe gas behavior with the ideal gas law equation, $PV = nRT$. One reason this is such a simple relationship is that ideal behavior assumed the absence of any forces of attraction between molecules. However, it is obvious that forces of attraction between gas molecules do exist; all gases condense to liquids if the temperature is low enough.

We can make no such assumption about the absence of intermolecular forces of attraction with liquids and solids, the condensed states of matter. Forces of attraction must be present to hold particles in close proximity. These forces may be small, as in the sample of nitrogen, which is not liquid until the temperature is decreased to −196 °C (Figure 11.1, *left*). Or, they may be larger, with the result that substances are liquids or solids at higher temperatures (Figure 11.1, *right*).

Forces of attractions between particles in liquid and solids are important if we want to discuss or explain their properties. So, as we move to a discussion of these states of matter, intermolecular forces of attraction must become our main focus.



Collectively, intermolecular forces are called **van der Waals forces**; they include the attractive and repulsive forces between

- molecules with permanent dipoles (*dipole–dipole forces,* Section 11.3)
- polar molecules and nonpolar ones (*dipole-induced dipole forces,* sometimes called *Debye* forces, Section 11.4)
- nonpolar molecules (*induced dipole-induced dipole forces,* also called *London dispersion forces*, Section 11.4)

◀ **Dew on a flower.** Intermolecular hydrogen bonds bind water molecules in a droplet, and the surface tension causes the drops to have the smallest surface area possible for their mass. The result is a sphere.

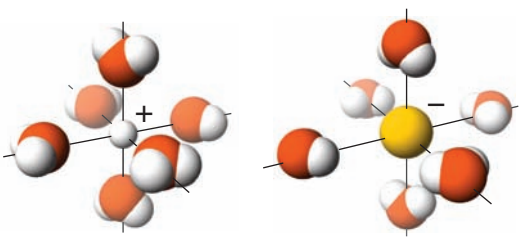
Figure 11.1 Intermolecular forces. Both N_2 and benzene (C_6H_6) are nonpolar molecules. However, at a low enough temperature the forces between molecules allow them to condense to a liquid or solid, respectively.

You will find that, even though intermolecular forces are relatively weak (generally less than about 15% of covalent bond energies), they can have a profound effect on molecular properties. Among other things, they are

- directly related to melting point, boiling point, and the energy needed to convert a solid to a liquid or a liquid to a vapor.
- important in determining the solubility of gases, liquids, and solids in various solvents.
- crucial in determining the structures of biologically important molecules such as DNA and proteins.



This leads us to some of the questions about intermolecular forces we want to explore: What is the nature of these forces and how do they arise? How and why do they differ from one type of molecule to another? What effect do they have on the properties of a compound, particularly in the liquid state?

11.2 Interactions between Ions and Molecules with a Permanent Dipole

Goal for Section 11.2

- Know what determines the strength of the interaction between ions and molecules with permanent dipoles and the effect of that interaction.

Many molecules are polar, a result of the polarity of individual bonds and their geometry (Section 8.8). Conceptually, we can view polar molecules as having positive and negative ends. When a polar molecule such as water encounters an ionic compound, the negative end of the dipole is attracted to the positive cation and the positive end of the dipole is attracted to the negative anion. Forces of attraction between a positive or negative ion and polar molecules—ion–dipole forces—are less than those for ion–ion attractions (but greater than other types of forces between molecules).

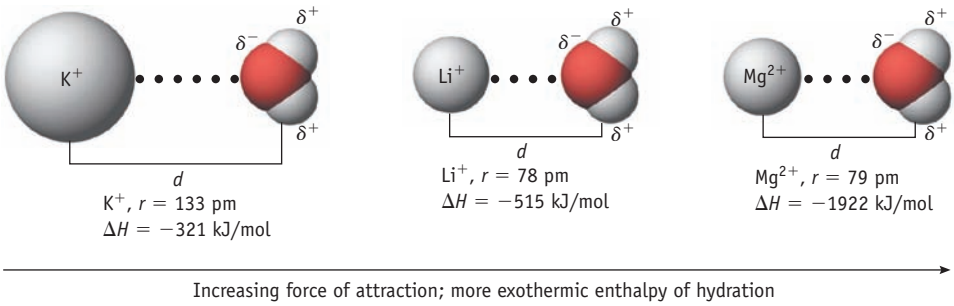
Ion–dipole attractions can be evaluated using Coulomb's law, that is, the force of attraction between two charged objects depends on the product of their charges divided by the square of the distance between them (see Section 2.5). Therefore, when a polar molecule encounters an ion, the attractive forces depend on three factors:

- The distance between the ion and the dipole. The closer they are, the stronger the attraction.
- The charge on the ion. The higher the ion charge, the stronger the attraction.
- The magnitude of the dipole. The greater the magnitude of the dipole, the stronger the attraction.

Coulomb's Law The force of attraction between oppositely charged particles depends directly on the product of their charges and inversely on the square of the distance (d) between them ($1/d^2$) (Equation 2.3, page 85). The energy of the attraction is also proportional to the product of charges, but it is inversely proportional to the distance between them ($1/d$).



The enthalpy of solvation of ions—which is generally called the *enthalpy of hydration for ions in water*—is substantial. For example, the hydration of sodium ions is described by the following reaction:

$$Na^+(g) + \text{water} \rightarrow Na^+(aq) \qquad \Delta_{\text{hydration}}H° = -405 \text{ kJ/mol}$$

Enthalpy of Solvation. We should note that the enthalpy of solvation for an individual ion such as Na^+ cannot be measured directly, but values can be estimated.

The value of the enthalpy of hydration depends on two factors: the charge of the ion and the distance (d) between the center of the ion and the oppositely charged "pole" of the water dipole.

- As ion size increases the value of d increases, and the magnitude of the enthalpy of hydration decreases, as seen for the alkali metal cations (Table 11.1).
- The magnitude of $\Delta_{\text{hydration}}H°$ increases as the ion charge increases, as you see by comparing values for Li^+ and Mg^{2+}.

It is interesting to compare these values with the enthalpy of hydration of the H^+ ion, estimated to be −1090 kJ/mol. This extraordinarily large value for a 1+ ion is due to the tiny size of the H^+ ion and the formation of a strong covalent bond between H^+ and H_2O.

TABLE 11.1 Radii and Enthalpies of Hydration of Alkali Metal Ions

Cation	Ion Radius (pm)	Enthalpy of Hydration (kJ/mol)
Li^+	78	−515
Na^+	98	−405
K^+	133	−321
Rb^+	149	−296
Cs^+	165	−263

A CLOSER LOOK

Hydrated Salts: A Result of Ion–Dipole Bonding

Hydrated salts are common. The formulas of these compounds are given by adding a specific number of water molecules to the end of the formula, as in $BaCl_2 \cdot 2\ H_2O$. Sometimes, the water molecules simply fill in empty spaces in a crystalline lattice, but often the water molecules are bound directly to the cation. For example, the compound $CrCl_3 \cdot 6\ H_2O$ is better written as $[Cr(H_2O)_4Cl_2]Cl \cdot 2\ H_2O$. Four of the six water molecules are bound to the Cr^{3+} ion by ion–dipole attractive forces; the remaining two water molecules are in the lattice. Common examples of hydrated salts are listed in the table.

Compound	Common Name	Uses
$Na_2CO_3 \cdot 10\ H_2O$	Washing soda	Water softener
$Na_2S_2O_3 \cdot 5\ H_2O$	Hypo	Photography
$MgSO_4 \cdot 7\ H_2O$	Epsom salt	Cathartic, dyeing and tanning
$CaSO_4 \cdot 2\ H_2O$	Gypsum	Wallboard
$CuSO_4 \cdot 5\ H_2O$	Blue vitriol	Biocide

© Cengage Learning/Charles D. Winters

Hydrated cobalt(II) chloride, $CoCl_2 \cdot 6\ H_2O$. The ion Co^{2+} ion is surrounded by six water molecules in water. Cobalt(II) ions and water molecules interact by ion–dipole forces. This is an example of a coordination compound, a class of compounds discussed in detail in Chapter 22.

EXAMPLE 11.1

Hydration Energy

Problem Explain why the enthalpy of hydration of Na^+ (−405 kJ/mol) is more negative than that of Cs^+ (−263 kJ/mol), whereas that of Mg^{2+} is much more negative (−1922 kJ/mol) than that of either Na^+ or Cs^+.

What Do You Know? You know the ion charges and the trend in their sizes. (From Figure 7.11 we have: $Na^+ = 98$ pm, $Cs^+ = 165$ pm, and $Mg^{2+} = 79$ pm.)

Strategy The energy associated with ion–dipole attractions depends directly on the size of the ion charge and the magnitude of the dipole, and inversely on the distance between them. Here the water dipole is a constant factor, so the answer is determined by comparing ion size and charge.

SOLUTION From the ion sizes, we can predict that the distances between the center of the positive charge of the ion and the water dipole will vary in this order: $Mg^{2+} < Na^+ < Cs^+$. The hydration energy varies in the reverse order (with the hydration energy of Mg^{2+} being the most negative value). Notice also that Mg^{2+} has a 2+ charge, whereas the other ions are 1+. The greater charge on Mg^{2+} leads to a much greater force of ion–dipole attraction than for the other two ions, which have only a 1+ charge. As a result, the hydration energy for Mg^{2+} is much more negative than for the other two ions.

Thinking about Your Answer The charge difference between Mg^{2+} and the other ions has a much greater effect than the size difference.

Check Your Understanding

Which should have the more negative hydration energy, F^- or Cl^-? Explain briefly.

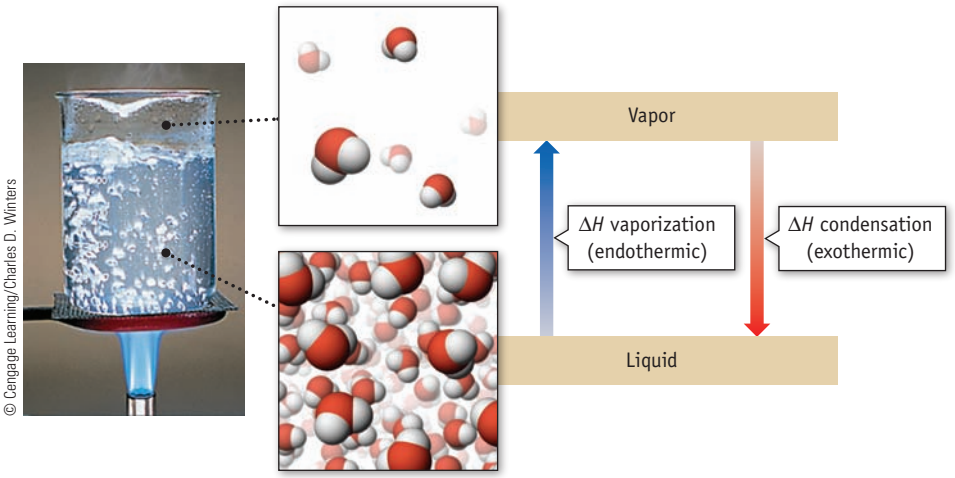
11.3 Interactions between Molecules with a Permanent Dipole

Goals for Section 11.3

- Recognize that two polar molecules can interact through dipole–dipole forces.
- Understand how hydrogen bonding can occur and can affect the properties of water.

Dipole–Dipole Forces



When a polar molecule encounters another polar molecule, of the same or a different kind, the positive end of one molecule is attracted to the negative end of the other polar molecule. This is called a **dipole–dipole interaction**.

Intermolecular forces, such as dipole–dipole attractions, influence the evaporation of a liquid and the condensation of a gas, among other things (Figure 11.2). An energy change occurs in both processes. Evaporation requires the input of energy, specifically the enthalpy of vaporization ($\Delta_{vap}H°$) (Sections 5.3 and 11.6). The value for the enthalpy of vaporization has a positive sign, indicating that evaporation is an endothermic process. The enthalpy change for the condensation process—the reverse of evaporation—has a negative value.

The greater the forces of attraction between molecules in a liquid, the greater the energy that must be supplied to separate them. Thus, we expect polar compounds to have a higher value for their enthalpy of vaporization ($\Delta_{vap}H°$) than nonpolar compounds with similar molar masses (Table 11.2).

The boiling point of a liquid depends on intermolecular forces of attraction. As the temperature of a substance is raised, its molecules gain kinetic energy. Eventually, when the boiling point is reached, the molecules have sufficient kinetic energy to escape the forces of attraction with their neighbors. For molecules of similar molar mass, the greater the polarity, the higher the temperature required for the liquid to boil. In Table 11.2, you see, for example, that the boiling point for polar ICl is greater than that for nonpolar Br_2, a molecule of almost identical mass.

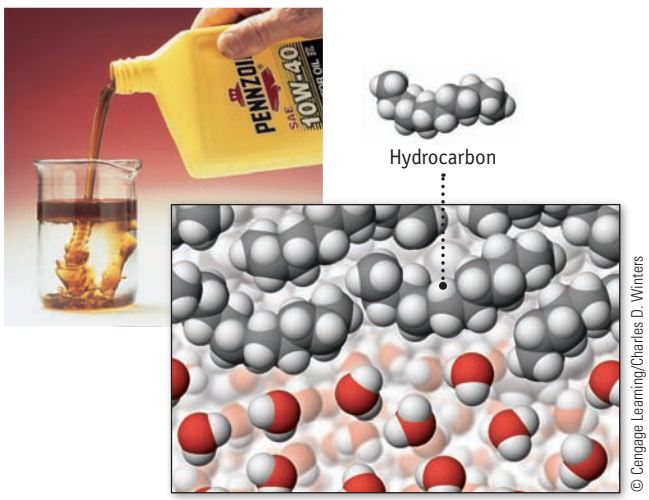
TABLE 11.2 Molar Masses, Boiling Points, and $\Delta_{vap}H°$ of Nonpolar and Polar Substances



NONPOLAR				POLAR			
	M (g/mol)	BP (°C)	$\Delta_{vap}H°$ (kJ/mol)		M (g/mol)	BP (°C)	$\Delta_{vap}H°$ (kJ/mol)
N_2	28	−196	5.57	CO	28	−192	6.04
SiH_4	32	−112	12.10	PH_3	34	−88	14.06
GeH_4	77	−90	14.06	AsH_3	78	−62	16.69
Br_2	160	59	29.96	ICl	162	97	—

Intermolecular forces also influence solubility. A qualitative observation you have perhaps made yourself is that *like dissolves like*. That is, polar molecules are likely to dissolve in a polar solvent, and nonpolar molecules are likely to dissolve in a nonpolar solvent (Figure 11.3). The converse is also true: it is unlikely that polar molecules will dissolve in nonpolar solvents or that nonpolar molecules will dissolve in polar solvents.

For example, water and polar ethanol (C_2H_5OH) can be mixed in any ratio to give a homogeneous mixture. In contrast, water does not dissolve in gasoline to an appreciable extent. The difference in these two situations is that ethanol and water are polar molecules, whereas the hydrocarbon molecules in gasoline (such as octane, C_8H_{18}) are nonpolar. The water–ethanol interactions are strong enough that the energy expended in pushing water molecules apart to make room for ethanol molecules is compensated for by the energy of attraction between the two kinds of polar molecules. In contrast, water–hydrocarbon attractions are weak. The hydrocarbon molecules cannot disrupt the stronger water–water attractions.

(a) Ethylene glycol ($HOCH_2CH_2OH$), a polar compound used as antifreeze in automobiles, dissolves in water.

(b) Nonpolar motor oil (a hydrocarbon) dissolves in nonpolar solvents such as gasoline or CCl_4. It will not dissolve in a polar solvent such as water, however. Commercial spot removers use nonpolar solvents to dissolve oil and grease from fabrics.

Figure 11.3 "Like dissolves like."

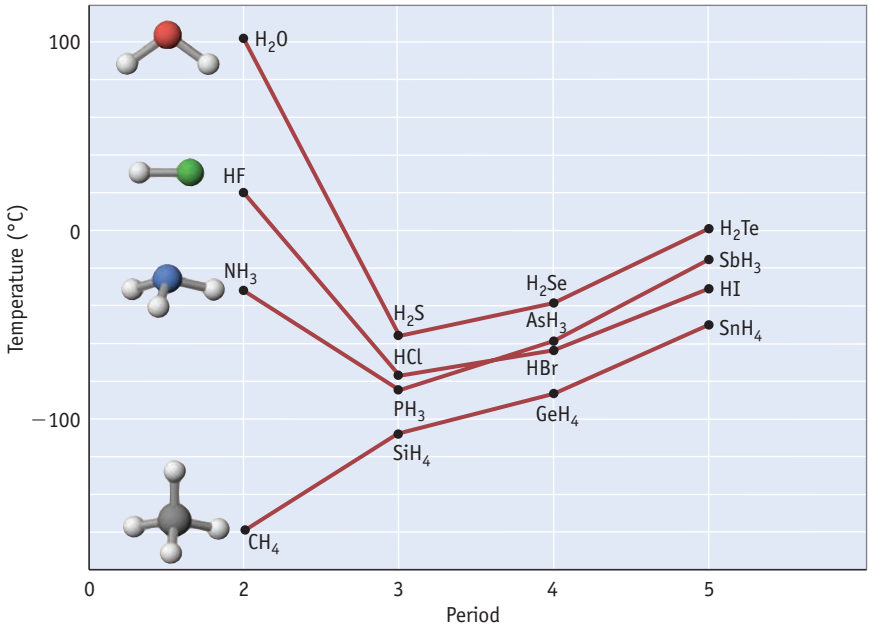

Figure 11.4 The boiling points of some simple hydrogen compounds. The effect of hydrogen bonding is apparent in the unusually high boiling points of H_2O, HF, and NH_3. (Also, notice that the boiling point of HCl is somewhat higher than expected based on the data for HBr and HI, suggesting that some degree of hydrogen bonding also occurs in liquid HCl.)

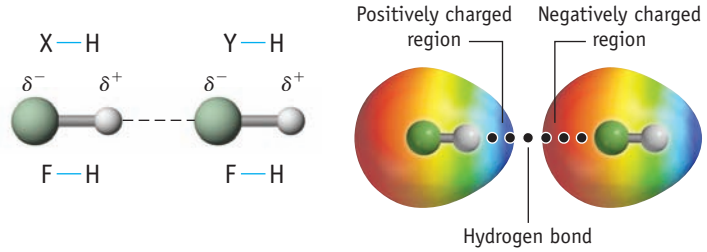
Hydrogen Bonding



Hydrogen fluoride, water, ammonia, and many other compounds with O—H and N—H bonds have exceptional properties. Notable examples are the boiling points for hydrogen compounds of elements in Groups 4A through 7A (Figure 11.4). Generally, the boiling points of related compounds increase with molar mass, and this trend is seen in the boiling points of the hydrogen compounds of Group 4A elements. The same effect is also observed for the heavier molecules of the hydrogen-containing compounds of Group 5A, 6A, and 7A elements. The boiling points of NH_3, H_2O, and HF, however, deviate significantly from what might be expected based on molar mass alone. If we extrapolate the curve for the boiling points of H_2Te, H_2Se, and H_2S, the boiling point of water is predicted to be around −90 °C. However, the boiling point of water is almost 200 °C higher than this value! Similarly, the boiling points of NH_3 and HF are much higher than would be expected based on molar mass. Because the temperature at which a substance boils depends on the attractive forces between molecules, the high boiling points of H_2O, HF, and NH_3 indicate strong intermolecular attractions.

Why should H_2O, NH_3, and HF have such strong intermolecular forces? The classical explanation is based on dipole–dipole interactions. The electronegativities of N (3.0), O (3.5), and F (4.0) are among the highest of all the elements, whereas the electronegativity of hydrogen is much lower (2.2). This large difference in electronegativity means that N—H, O—H, and F—H bonds are very polar. In bonds between H and N, O, or F, the more electronegative element takes on a significant negative charge (Figure 8.11), and the hydrogen atom acquires a significant positive charge. Because the H atom bonded to N, O, or F (designated X) can be so highly positively charged, there is an exceptionally strong electrostatic interaction with another electronegative atom (Y) in the same or different molecule to form a **hydrogen bond**, X—H - - - Y—. The hydrogen atom becomes a bridge between the two electronegative atoms X and Y, and the dashed line in the figure represents the hydrogen bond. The most pronounced effects of hydrogen bonding occur where both

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. X and Y are N, O, or F. Energies associated with most hydrogen bonds involving these elements are in the range of 5 to 30 kJ/mol.

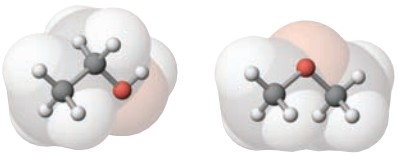
Hydrogen bonding between HF molecules. The partially negative F atom of one HF molecule interacts through hydrogen bonding with a neighboring HF molecule. (Red regions of the molecule are negatively charged, whereas blue regions are positively charged. For more on electrostatic potential surfaces, see page 387.)



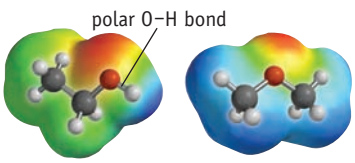
The Importance of H Atom Charge Density in Hydrogen Bonding The H atom has an extraordinarily small radius. This means that the partial charge on the H atom in a hydrogen bond is concentrated in a small volume; that is, it has a high charge density (charge density = charge/volume). The result is that it is strongly attracted to the negative charge on a neighboring molecule.

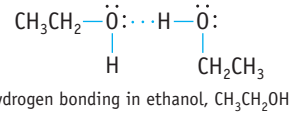
Hydrogen bonding has important implications for any property of a compound that is influenced by intermolecular forces of attraction. It is responsible for the unique properties of water (described below) and plays a central role in biochemistry (*A Closer Look: Hydrogen Bonding in Biochemistry*).

EXAMPLE 11.2

The Effect of Hydrogen Bonding

Problem Ethanol, CH_3CH_2OH, and dimethyl ether, CH_3OCH_3, have the same molecular formula but a different arrangement of atoms. Predict which of these compounds has the higher boiling point.





ethanol, CH_3CH_2OH dimethyl ether, CH_3OCH_3

What Do You Know? You know these compounds have the same molar mass and that, when comparing compounds of the same mass, the compound with the stronger intermolecular forces will have the higher boiling point.

Strategy Inspect the structure of each molecule to decide whether each is polar and, if polar, whether hydrogen bonding is possible.

SOLUTION Ethanol has a polar O—H group and so can participate in hydrogen bonding. Dimethyl ether is polar, and the O atom has a partial negative charge. However, no H atom is attached to the O atom. Thus, there is no opportunity for hydrogen bonding in dimethyl ether. We can predict, therefore, that intermolecular forces will be stronger in ethanol than in dimethyl ether and that ethanol will have the higher boiling point.

hydrogen bonding in ethanol, CH_3CH_2OH

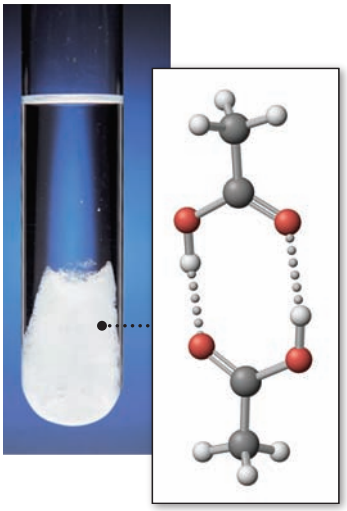
Think about Your Answer Ethanol boils at 78.3 °C, whereas dimethyl ether has a boiling point of −24.8 °C, more than 100 °C lower. At room temperature and 1 atm pressure, dimethyl ether is a gas, whereas ethanol is a liquid.

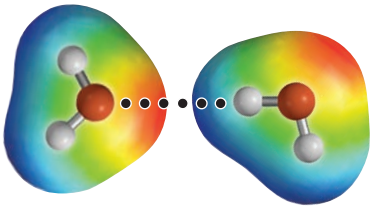
Check Your Understanding



Using structural formulas, describe the hydrogen bonding between methanol (CH_3OH) molecules. What physical properties of methanol are affected by hydrogen bonding?

Hydrogen Bonding and the Unusual Properties of Water

We might not think of the properties of water as unique, but almost no other substance behaves in a similar manner. Water's unique features are a consequence of the ability of H_2O molecules to cling tenaciously to one another by hydrogen bonding.



The strong intermolecular forces of attraction between water molecules are a result of the fact that each water molecule can participate in *four* hydrogen bonds. An individual water molecule has two polar O—H bonds and two lone pairs. Both hydrogen atoms are available to hydrogen-bond to oxygen atoms in adjacent water molecules. In addition, the oxygen lone pairs can participate in hydrogen bonding to the hydrogen atoms in two other water molecules (Figure 11.5). The result, seen particularly in ice, is a tetrahedral arrangement for the hydrogen atoms around each oxygen, involving two covalently bonded hydrogen atoms and two hydrogen-bonded hydrogen atoms.

One consequence of the fact that each water molecule can be involved in four hydrogen bonds is that ice has an open-cage structure with lots of empty space (Figure 11.5c). The result is that ice has a density about 10% less than that of liquid water, which explains why ice floats on water. (In contrast, the vast majority of other solids sink in their liquid phase.) Another feature of the ice structure is that the oxygen atoms are arranged at the corners of puckered, hexagonal rings. Snowflakes are always based on six-sided figures (page 75), a reflection of this internal molecular structure of ice.

Hydrogen Bonding in Acetic Acid, CH_3CO_2H. Two acetic acid molecules can interact through hydrogen bonds. This photo shows solid glacial acetic acid. Notice that the solid is denser than the liquid, a property shared by virtually all substances, the notable exception being water.

(a) Electrostatic potential surfaces for two water molecules.

(b) The oxygen atom of a water molecule attaches itself to two other water molecules by hydrogen bonds. Each O atom is covalently bonded to two H atoms and hydrogen bonded to H atoms from two other molecules. The hydrogen bonds are longer than the covalent bonds.

(c) In ice, the structural unit shown in part (b) is repeated in the crystalline lattice. This computer-generated structure shows a small portion of the extensive lattice. The water molecules form six-member, hexagonal rings. The vertices of each hexagon are O atoms, and each side is composed of two oxygen atoms with a hydrogen atom in between. One of the oxygen atoms is covalently bonded to the hydrogen atom, and the other is attracted to it by a hydrogen bond.

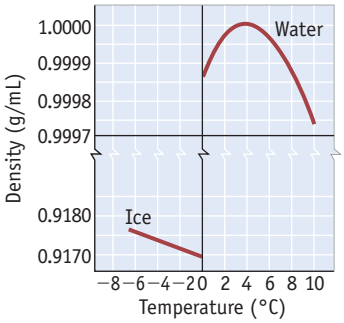

Figure 11.6 The temperature dependence of the densities of ice and water.

When ice melts at 0 °C, the regular structure imposed on the solid state by hydrogen bonding breaks down, and a relatively large increase in density occurs (Figure 11.6). Another surprising thing occurs when the temperature of liquid water is raised from 0 °C to 4 °C: The density of water increases. For almost every other substance known, density decreases as the temperature is raised. Once again, hydrogen bonding is the reason for this seemingly odd behavior. At a temperature just above the melting point, some of the water molecules continue to cluster in ice-like arrangements, which require extra space. As the temperature is raised from 0 °C to 4 °C, the final vestiges of the ice structure disappear, and the volume contracts further, giving rise to the increase in density. Water's density reaches a maximum at about 4 °C. From this point, the density declines with increasing temperature as observed for most substances.

Because of the way that water's density changes as the temperature approaches the freezing point, lakes do not freeze from the bottom up in the winter. When lake water cools with the approach of winter, its density increases, the cooler water sinks,

A CLOSER LOOK

Hydrogen Bonding in Biochemistry

Hydrogen bonding in water and in biochemical systems makes life possible on earth. Perhaps the most important occurrence is in DNA and RNA where the organic bases adenine, cytosine, guanine, and thymine (in DNA) or uracil (in RNA) are attached to sugar-phosphate chains (Figure A). The chains in DNA are joined by the pairing of bases, adenine with thymine and guanine with cytosine.

Figure B illustrates the hydrogen bonding between adenine and thymine. These models show that the molecules naturally fit together to form a six-sided ring, where two of the six sides involve hydrogen bonds. One side consists of a N · · · H—N grouping, and the other side is N—H · · · O. Here, the electrostatic potential surfaces show that the N atoms of adenine and the O atoms of thymine bear partial negative charges, and the H atoms of the N—H groups bear a positive charge. These charges and the geometry of the bases lead to these very specific interactions.

The fact that base pairing through hydrogen bonding leads to the joining of the sugar-phosphate chains of DNA, and to the double helical form of DNA, was first recognized by James Watson and Francis Crick on the basis of experimental work by Rosalind Franklin and Maurice Wilkins in the 1950s. Determination of the DNA structure was a key development in the molecular biology revolution in the last part of the 20th century. (See page 396 for more on these scientists.)

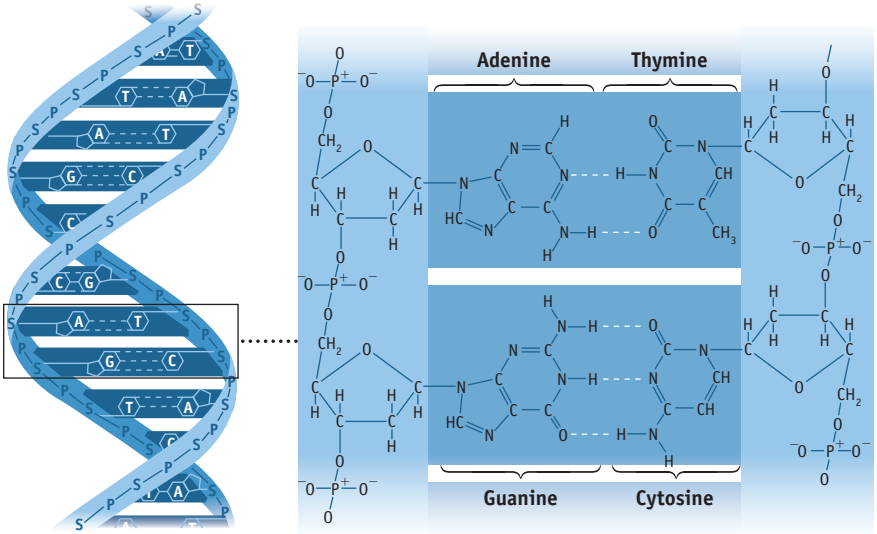

Figure A Hydrogen bonding in DNA. With the four bases in DNA, the usual pairings are adenine with thymine and guanine with cytosine. This pairing is promoted by hydrogen bonding.

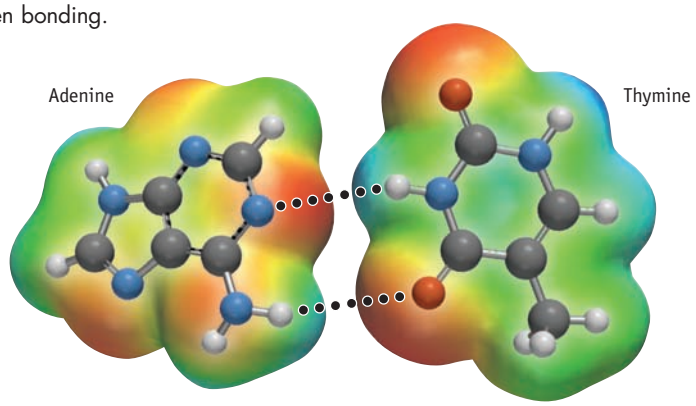

FIGURE B Hydrogen bonding between adenine and thymine. Electrostatic potential surfaces depict the hydrogen bonding interactions between adenine and thymine. The polar N—H bond on one molecule can hydrogen bond to an electronegative N or O atom in a neighboring molecule.

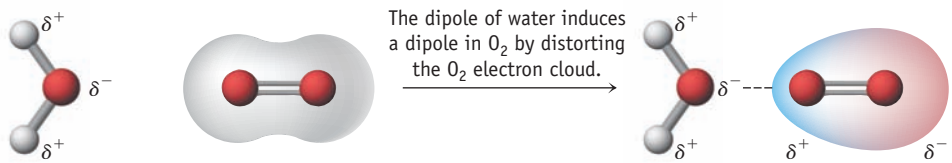
and the warmer water rises. This "turn over" process continues until all the water reaches 4 °C, the maximum density. (This is the way oxygen-rich water moves to the lake bottom to restore the oxygen used during the summer and nutrients are brought to the top layers of the lake.) As the temperature decreases further, the colder water stays on the top of the lake, because water cooler than 4 °C is less dense than water at 4 °C. With further heat loss, ice can then begin to form on the surface, floating there and protecting the underlying water and aquatic life from further heat loss.

Extensive hydrogen bonding is also the origin of the extraordinarily high specific heat capacity of water (4.184 J/g · K). Although liquid water does not have the regular structure of ice, hydrogen bonding still occurs. There must be a significant input of energy to disrupt the intermolecular forces and to raise the temperature even a small amount.

The high specific heat capacity of water is, in large part, why oceans and lakes can have a large effect on local weather. In autumn, when the temperature of the air is lower than the temperature of the ocean or lake, water transfers energy as heat to the atmosphere, moderating the drop in air temperature. Furthermore, so much energy is available to be transferred for each degree drop in temperature that the decline in water temperature is gradual. For this reason, the temperature of the ocean or of a large lake is generally higher than the average air temperature until late in the autumn.

11.4 Intermolecular Forces Involving Nonpolar Molecules



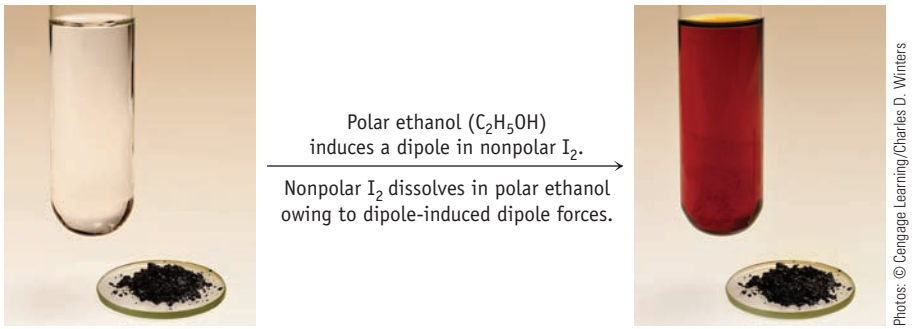
Goals for Section 11.4

- Identify instances where a dipole can be induced by interaction with a polar molecule (Debye forces).
- Identify instances where molecules interact by induced dipole–induced dipole forces (London dispersion forces).

Many important molecules such as O_2, N_2, and the halogens are not polar. Why, then, does O_2 dissolve in polar water? Why can the N_2 of the atmosphere be liquefied? Some intermolecular forces must be acting between O_2 and water and between N_2 molecules, but what is their nature?

Dipole-Induced Dipole Forces: Debye Forces

Polar molecules such as water can induce, or create, a dipole in molecules that do not have a permanent dipole. To see how this can happen, picture a polar water molecule approaching a nonpolar molecule such as O_2.



The electron cloud of an isolated (gaseous) O_2 molecule is symmetrically distributed between the two oxygen atoms. As the negative end of the polar H_2O molecule approaches, however, the O_2 electron cloud becomes distorted. In this process, the O_2 molecule itself becomes polar; that is, a dipole is *induced* in the otherwise nonpolar O_2 molecule. The result is that H_2O and O_2 molecules are now weakly attracted to one another. Oxygen can dissolve in water because a force of attraction exists between water's permanent dipole and the induced dipole in O_2. Chemists refer to these as **dipole-induced dipole interactions** or as **Debye forces.**

The process of inducing a dipole is called **polarization**, and the degree to which the electron cloud of an atom or a molecule can be distorted depends on the **polarizability** of that atom or molecule. The electron cloud of an atom or molecule with a large, extended electron cloud such as I_2 can be polarized more readily than the electron cloud in a much smaller atom or molecule, such as He or H_2, in which the valence electrons are close to the nucleus and more tightly held. Here you see that polar ethanol (C_2H_5OH) can interact with nonpolar I_2, and iodine dissolves readily in ethanol.

Photos: © Cengage Learning/Charles D. Winters

In general, for an analogous series of substances, say the halogens or alkanes (such as CH_4, C_2H_6, C_3H_8, and so on), the higher the molar mass, the greater the polarizability of the molecule. Indeed, the solubilities of common gases in water illustrate the effect of interactions between a dipole and an induced dipole. As the molar mass of the gas increases, polarizability of the electron cloud increases, the strength of the dipole-induced dipole interaction increases, and solubility in a polar solvent increases (Table 11.3).

Induced Dipole-Induced Dipole Forces: London Dispersion Forces

Nonpolar compounds can be liquids or solids if the intermolecular forces are sufficient to bind the molecules together. Nonpolar iodine, I_2, is a solid and not a gas around room temperature and pressure for this reason.

The enthalpy of vaporization of a substance at its boiling point is a good indicator of the magnitude of intermolecular forces. The data in Table 11.4 suggest that forces between nonpolar molecules can range from very weak (N_2, O_2, and CH_4 with low enthalpies of vaporization and very low boiling points) to more substantial (I_2 and benzene).

Two nonpolar atoms or molecules (depicted as having an electron cloud that has a time-averaged spherical shape).

Momentary attractions and repulsions between nuclei and electrons in neighboring molecules lead to induced dipoles.

Correlation of the electron motions between the two atoms or molecules (which are now polar) leads to a lower energy and stabilizes the system.

Figure 11.7 Induced dipole-induced dipole interactions or London dispersion forces. Momentary attractions and repulsions between nuclei and electrons create induced dipoles and lead to a net stabilization due to attractive forces. Nonpolar Br_2 and I_2 are a liquid and a solid, respectively, indicating that such forces are sufficient to cause them to be in a condensed phase.

Br_2 I_2

© Cengage Learning/Charles D. Winters

To understand how two nonpolar molecules can attract each other, recall that the electron cloud surrounding atoms or molecules can be distorted. Thus, when two atoms or nonpolar molecules approach each other, attractions or repulsions between their electrons and nuclei can lead to distortions in their electron clouds (Figure 11.7). That is, dipoles can be induced momentarily in neighboring atoms or molecules, and these *induced* dipoles lead to intermolecular attractions. The intermolecular force of attraction in gases, liquids, and solids composed of nonpolar molecules is an **induced dipole-induced dipole force**. Chemists often call them **London dispersion forces**, and we should make three important points regarding these forces.

- London dispersion forces occur between all molecules, both nonpolar and polar, but London dispersion forces are the only intermolecular forces between nonpolar molecules (Figure 11.8).
- London dispersion forces can account for a major part of the net intermolecular force, even for polar molecules (Figure 11.8).
- London dispersion forces increase with molar mass in a related series of compounds (such as the series CH_4 … SnH_4 in Figure 11.4).

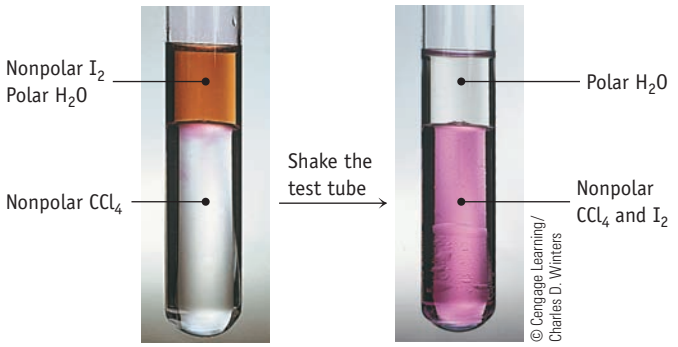
EXAMPLE 11.3

Intermolecular Forces



Problem Suppose you have a mixture of solid iodine, I_2, and the liquids water and carbon tetrachloride (CCl_4). What intermolecular forces exist between each possible pair of molecules?

What Do You Know? Iodine, I_2, is a nonpolar molecule composed of large iodine atoms. It has an extensive electron cloud and is polarizable. CCl_4 is a symmetrical tetrahedral molecule and is not polar (see Figure 8.13). Polar H_2O could be involved in hydrogen bonding with other water molecules or with other molecules with highly polar groups.

Strategy You know whether each substance is polar or nonpolar so you need only to determine the types of intermolecular forces that can exist between the different pairs.

SOLUTION Nonpolar iodine, I_2, is easily polarized, and iodine can interact with polar water molecules by dipole-induced dipole and London dispersion forces. Nonpolar carbon tetrachloride can interact with nonpolar iodine only by London dispersion forces. Water and CCl_4 could interact by dipole-induced dipole and London dispersion forces.

Think about Your Answer The photos here show the result of mixing these three compounds. Iodine does dissolve to a small extent in water to give a brown solution. When this brown solution is added to a test tube containing CCl_4, the liquid layers do not mix. (Polar water does not dissolve in nonpolar CCl_4.) (Notice the more dense CCl_4 layer [$d = 1.58$ g/mL] is underneath the less dense water layer.) When the test tube is shaken, nonpolar I_2 is extracted into nonpolar CCl_4, as evidenced by the disappearance of the color of I_2 in the water layer (top) and the appearance of the purple I_2 color in the CCl_4 layer (bottom).

Check Your Understanding

You mix water, CCl_4, and hexane ($CH_3CH_2CH_2CH_2CH_2CH_3$). What type of intermolecular forces can exist between each pair of these compounds?

11.5 A Summary of van der Waals Intermolecular Forces

Goal for Section 11.5

- Describe the various kinds of intermolecular forces in liquids and solids.

Van der Waals intermolecular forces involve molecules that are polar or those in which polarity can be induced (Table 11.5). It is important to recognize that

- several types of intermolecular forces may contribute to the overall ability of a molecule to interact with another of the same or different kind (Figure 11.8).

Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

TABLE 11.5 Summary of Intermolecular Forces

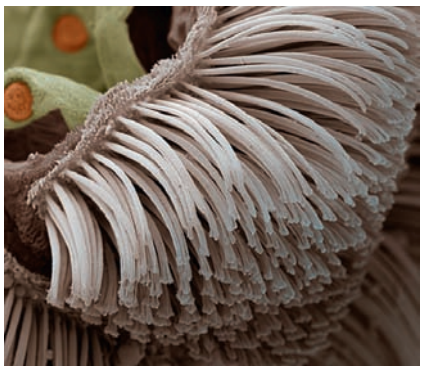
Type of Interaction	Factors Responsible for Interaction	Example
Hydrogen bonding, X—H · · · :Y	Very polar X—H bond and atom Y with lone pair of electrons (where X and Y are often F, N, O).	$H_2O \cdots H_2O$
Dipole–dipole	Dipole moment (depends on electronegativities and molecular structure).	$(CH_3)_2O \cdots (CH_3)_2O$
Dipole-induced dipole (Debye forces)	Dipole moment of polar molecule and polarizability of nonpolar molecule.	$H_2O \cdots I_2$
Induced dipole-induced dipole (London dispersion forces)	Polarizability (depends on molar mass)	$I_2 \cdots I_2$

The Balance of Intermolecular Forces For water, for example, it is estimated that the net intermolecular force consists of 85% dipole–dipole (including H-bonding), 5% dipole-induced dipole, and 10% dispersion force. See Figure 11.8.

- induced dipole-induced dipole (London dispersion) forces can be quite substantial, even in a polar molecule like HCl (Figure 11.8).
- among the various types of van der Waals forces, hydrogen bonding can be a particularly important factor that influences molecular properties.

A CLOSER LOOK

Geckos Can Climb Up der Waals



Thanakorn Hongphan/Shutterstock.com

Just like the comic-book hero Spider-Man, a little lizard, the gecko, can climb walls and hang from the ceiling.

This fact intrigued Kellar Autumn, a professor of biology at Lewis and Clark College in Portland, Oregon. An interdisciplinary team of Autumn and his students, along with scientists and engineers from Stanford University and the Universities of California at Berkeley and Santa Barbara, realized that gecko toes are covered with an array of stiff hair-like *setae*. Each of these is about as long as the thickness of a human hair or about 0.1 mm long. But each seta is further divided into about 1000 even tinier pads called *spatulae*. And these are only about 200 nm wide, a distance smaller than the wavelength of visible light!

The design of gecko feet is the secret to their wall-crawling abilities. Autumn said, "We discovered that the seta is 10 times more adhesive than predicted from prior measurements on whole animals. In fact, the adhesive is so strong that a single seta can lift the weight of an ant. A million setae, which could easily fit onto the area of a dime, could lift a 45-pound child. Our discovery explains why the gecko can support its entire body weight with only a single finger."

"When the gecko attaches itself to a surface, it uncurls its toes like a party favor that uncurls when you blow into it," Autumn says. "But," he adds, "getting yourself to stick isn't really that difficult. It's getting off the surface that is the major problem. When a gecko runs, it has to attach and detach its feet 15 times a second."

Eye of Science/Science Source

Gecko setae. The tiny setae on gecko toes. The length and width of this view is 60 μm.

But what is the "adhesive effect" that allows a gecko to climb a wall? It is *van der Waals force*. This ordinarily weak force operates only over a very short distance. However, each *spatula* of the millions in each toe experiences an attractive van der Waals force with the surface.

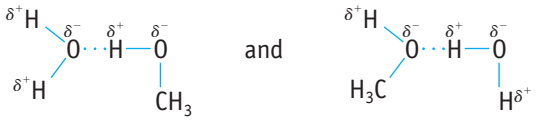
EXAMPLE 11.4

Intermolecular Forces

Problem Identify the types of intermolecular forces that exist between each of the following: (a) between molecules in liquid methane, CH_4; (b) between molecules of water and methanol (CH_3OH); and (c) between molecules of bromine and water.



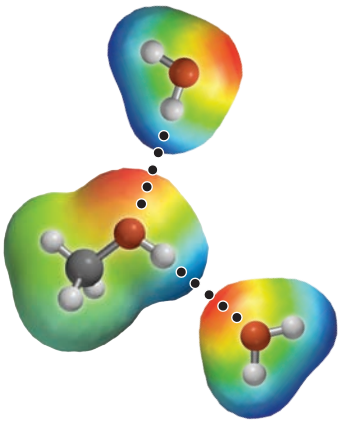
What Do You Know? Methane, CH_4, is a symmetrical, tetrahedral molecule and so is not polar. Both water and methanol are polar, and both have —OH groups that can be involved in hydrogen bonding. Bromine, Br_2, is nonpolar, but it is a large molecule and has an extensive, polarizable electron cloud.

Strategy Determine the type of interaction possible between pairs of molecules based on the structure and characteristics of each species.

SOLUTION

(a) Methane is not polar. Therefore, the only way methane molecules can interact with one another is through induced dipole-induced dipole forces (London dispersion forces).

(b) Both water and methanol are polar, and both have an O—H bond. They therefore interact through the special dipole–dipole force called hydrogen bonding as well as London dispersion forces.



(c) Nonpolar molecules of bromine, Br_2, and polar water molecules interact through dipole-induced dipole forces (and London dispersion forces). (This is similar to the I_2–ethanol interaction on page 502.)

Think about Your Answer The fact that CH_4 is a liquid only at very low temperatures suggests it has weak attractive forces. We would expect significant forces of attraction to be those involving hydrogen bonding, and we observe that water is readily soluble in methanol.

Check Your Understanding

Decide which type of intermolecular force is involved in (a) liquid O_2; (b) liquid CH_3OH; and (c) N_2 dissolved in H_2O.

Hydrogen bonding involving methanol (CH_3OH) and water.

11.6 Properties of Liquids

Goals for Section 11.6

- Define the equilibrium vapor pressure of a liquid, and explain the relationship between the vapor pressure and boiling point of a liquid.
- Describe how intermolecular interactions affect the energy necessary to break through the surface of a liquid (surface tension), capillary action, and the resistance to flow, or viscosity, of liquids.
- Describe the phenomena of the critical temperature, T_c, and critical pressure, P_c, of a substance.
- Calculate enthalpy changes for changes of state.
- Represent the connection between vapor pressure and temperature graphically.

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

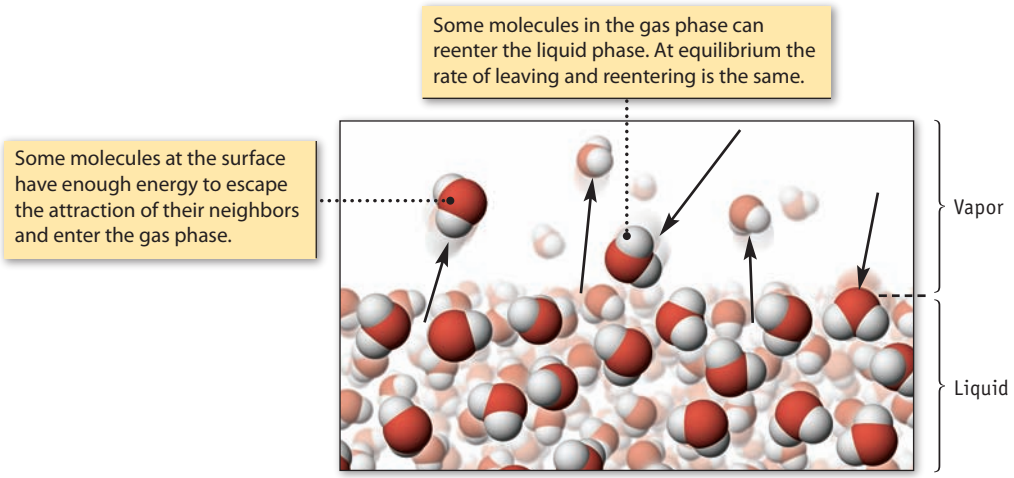
- Use the Clausius–Clapeyron equation to relate vapor pressure and enthalpy of vaporization.



Of the three states of matter, liquids are the most difficult to describe precisely. The molecules in a gas under normal conditions are far apart and may be considered more or less independent of one another. The structures of solids can be described because the particles that make up solids are usually in an orderly arrangement. The particles of a liquid interact with their neighbors, like the particles in a solid, but, unlike solids, there is little long-range order.

In spite of the fact that liquids do not have a simple or regular structure, we can still explain qualitatively many properties of liquids by viewing them at the particulate level. Here we want to look further at the process of vaporization, at the vapor pressure of liquids, at their boiling points and critical properties, and at surface tension, capillary action, and viscosity.

Vaporization and Condensation

Vaporization or evaporation is the process in which a substance in the liquid state becomes a gas, and to better understand it we have to look at molecular energies.

Molecules in a liquid have a range of energies (Figure 11.9) that resembles the distribution of speeds for molecules of a gas (Figure 10.11). As with gases, the average energy for molecules in a liquid depends only on temperature: The higher the temperature, the higher the average energy and the greater the number of molecules with high kinetic energy. In a sample of a liquid, at least a few molecules have more kinetic energy than the potential energy arising from the intermolecular attractive forces holding the liquid molecules to one another. If these high-energy molecules are at the surface of the liquid and if they are moving in the right direction, they can break free of their neighbors and enter the gas phase.

Vaporization is an endothermic process because energy is required to overcome the intermolecular forces of attraction holding the molecules together. The energy required to vaporize a sample is the standard **molar enthalpy of vaporization,** $\Delta_{vap}H°$ (at 1 bar; units of kilojoules per mole; see Tables 11.4 and 11.6).

$$\text{liquid} \xrightarrow[\text{energy absorbed by liquid}]{\text{vaporization}} \text{vapor} \qquad \Delta_{vap}H^\circ = \text{molar enthalpy of vaporization}$$

A molecule in the gas phase can transfer some of its kinetic energy by colliding with slower gaseous molecules and solid objects. If this molecule loses sufficient energy and comes in contact with the surface of the liquid, it can reenter the liquid phase and **condensation** occurs.

$$\text{vapor} \xrightarrow[\text{energy released by vapor}]{\text{condensation}} \text{liquid} \qquad -\Delta_{vap}H^\circ = \text{molar enthalpy of condensation}$$

Condensation is the reverse of vaporization and so is an exothermic process. Energy is transferred to the surroundings. *The enthalpy change for condensation is equal but opposite in sign to the enthalpy of vaporization.*

As illustrated by the data in Table 11.6, there is a relationship between the $\Delta_{vap}H°$ values for various substances and the temperatures at which they boil. Both properties reflect the attractive forces between particles in the liquid. The boiling points of nonpolar liquids (such as the hydrocarbons, atmospheric gases, and the halogens) increase with increasing atomic or molecular mass, a reflection of increased intermolecular dispersion forces. The hydrocarbons listed in Table 11.6 (methane, ethane, propane, and butane) show this trend clearly. Similarly, the boiling points and enthalpies of vaporization of the heavier hydrogen halides (HCl, HBr, HI) increase with increasing molecular mass. For these molecules, London dispersion forces and ordinary dipole–dipole forces account for their intermolecular attractions (Figure 11.8). Because dispersion forces become increasingly important with increasing mass, the enthalpies of vaporization and the boiling points are in the order HCl < HBr < HI. Among the hydrogen halides HF is the exception; the high enthalpy of vaporization and boiling point are a direct result of extensive hydrogen bonding.

EXAMPLE 11.5

Enthalpy of Vaporization

Problem You put 925 mL of water (about 4 cupfuls) in a pan at 100 °C, and the water slowly evaporates. How much energy is transferred as heat to vaporize all the water? (Density of water at 100 °C = 0.958 g/cm^3.)

What Do You Know? You know the volume of water and wish to know the energy required for evaporation. Two additional pieces of information are needed to solve this problem:

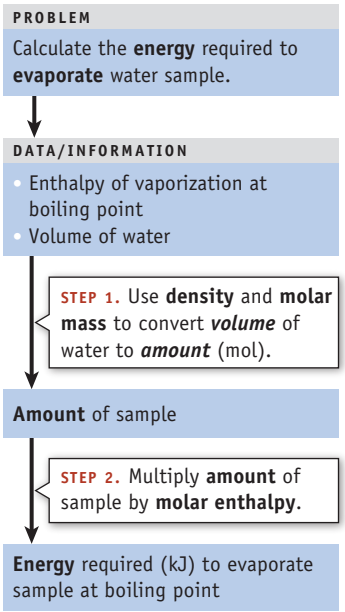
1. $\Delta_{vap}H°$ for water = +40.7 kJ/mol at 100 °C (from Table 11.6).
2. Molar mass of water = 18.02 g/mol.

Strategy $\Delta_{vap}H°$ has units of kilojoules per mole, so you first must find the mass of water and then the amount. Finally, use the enthalpy of vaporization (in kJ/mol) to calculate the energy required as heat.

SOLUTION Using the density of water at this temperature, we find that 925 mL of water is equivalent to 886 g, and this mass is in turn equivalent to 49.2 mol of water.

$$925\ \text{mL}\left(\frac{0.958\ \text{g}}{1\ \text{mL}}\right)\left(\frac{1\ \text{mol}}{18.02\ \text{g}}\right) = 49.18\ \text{mol}\ H_2O$$

Therefore, the amount of energy required is



$$49.18\ \text{mol}\ H_2O\left(\frac{40.7\ \text{kJ}}{\text{mol}}\right) = 2.00 \times 10^3\ \text{kJ}$$

Think about Your Answer 2000 kJ is equivalent to the energy obtained by burning about 60 g of carbon.

Check Your Understanding

The molar enthalpy of vaporization of methanol, CH_3OH, is 35.2 kJ/mol at 64.6 °C. How much energy is required to evaporate 1.00 kg of methanol at 64.6 °C?

Liquid water is an exceptional substance. Among its unique properties, an enormous amount of energy is required to convert liquid water to water vapor, and this fact is important to your own physical well-being. When you exercise vigorously, your body responds by sweating. Energy from your body is transferred to sweat in the process of evaporation, and your body is cooled.

Enthalpies of vaporization and condensation of water also play a role in weather (Figure 11.10). For example, if enough water condenses from the air to fall as an inch of rain on an acre of ground, the energy released exceeds 2.0×10^8 kJ! This is equivalent to the energy released by a small bomb.

John Kotz

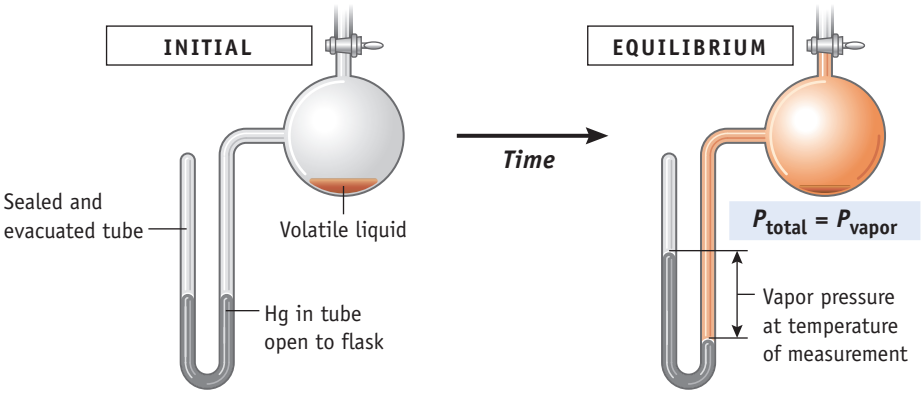
Figure 11.10 Rainstorms release an enormous quantity of energy. When water vapor condenses, energy is transferred to the surroundings. The enthalpy of condensation of water is large, so a large quantity of energy is released in a rainstorm.

Vapor Pressure

If you put some water in an open beaker, it will eventually evaporate completely. Air movement and gas diffusion remove the water vapor from the vicinity of the liquid surface, so many water molecules are not able to return to the liquid.

If you put water in a sealed flask (Figure 11.11), however, the water vapor cannot escape, and some will recondense to form liquid water. Eventually, the masses of liquid and vapor in the flask will remain constant, another example of a **dynamic equilibrium** (page 130).

$$\text{liquid} + \text{energy} \rightleftharpoons \text{vapor}$$



At equilibrium, molecules still move continuously between the liquid phase and the vapor phase (page 507). Importantly, the rate at which molecules move from liquid to vapor is the same as the rate at which they move from vapor to liquid; thus, there is no net change in the masses of the two phases.

When a liquid–vapor equilibrium has been established, the equilibrium vapor pressure (often just called the vapor pressure) can be measured. The **equilibrium vapor pressure** of a substance is the pressure exerted by the vapor in equilibrium with the liquid phase. Conceptually, the vapor pressure of a liquid is a measure of the tendency of its molecules to escape from the liquid phase and enter the vapor phase at a given temperature. This tendency is referred to qualitatively as the **volatility** of the compound. The higher the equilibrium vapor pressure at a given temperature, the more volatile the substance.

As described previously (Figure 11.9), the distribution of molecular energies in the liquid phase is a function of temperature. At a higher temperature, more molecules have sufficient energy to escape the surface of the liquid. The equilibrium vapor pressure must, therefore, increase with temperature.

Plots of vapor pressure as a function of temperature can give us a great deal of information (Figure 11.12). *All points along the vapor pressure versus temperature curves*

Figure 11.11 Vapor pressure.

A volatile liquid is placed in an evacuated flask. At the beginning, no molecules of the liquid are in the vapor phase.

After a short time some liquid evaporates, and the molecules now in the vapor phase exert a pressure. The pressure of the vapor measured when the liquid and the vapor are in equilibrium is called the *equilibrium vapor pressure.*

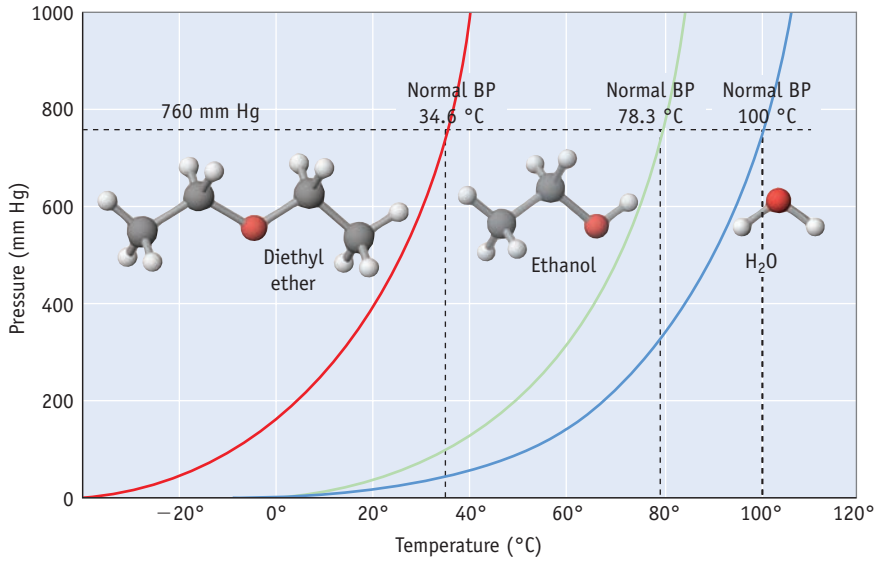

Figure 11.12 Vapor pressure curves for diethyl ether [$(C_2H_5)_2O$], ethanol (C_2H_5OH), and water. Each curve represents conditions of *T* and *P* at which the two phases, liquid and vapor, are in equilibrium. These compounds exist as liquids for temperatures and pressures to the left of the curve and as gases under conditions to the right of the curve. (See Appendix G for vapor pressures for water at various temperatures.)

represent conditions of pressure and temperature at which liquid and vapor are in equilibrium. For example, at 60 °C the vapor pressure of water is 149 mm Hg. If water is placed in an evacuated flask that is maintained at 60 °C, liquid water will evaporate until the pressure exerted by the water vapor is 149 mm Hg (assuming enough water is in the flask so that some liquid remains when equilibrium is reached).

EXAMPLE 11.6

Using Vapor Pressure

Problem You place 2.00 L of water in an open container in your dormitory room; the room has a volume of 4.25×10^4 L. You seal the room and wait for the water to evaporate. Will all of the water evaporate at 25 °C? Although it is not realistic, assume for simplicity there is zero humidity to start. (At 25 °C the density of water is 0.997 g/mL, and its vapor pressure is 23.8 mm Hg.)

What Do You Know? You know the volume of water, the density of the water, the volume of the room, and the vapor pressure of the water at 25 °C.

Strategy One approach to solving this problem is to use the ideal gas law to calculate the amount of liquid water that must evaporate for the vapor produced to exert a pressure of 23.8 mm Hg in a volume of 4.25×10^4 L at 25 °C. Next, determine the volume of liquid water from the amount and compare the answer to the 2.00 L of water available.

SOLUTION

$$P = 23.8 \text{ mm Hg}\left(\frac{1 \text{ atm}}{760 \text{ mm Hg}}\right) = 0.03132 \text{ atm}$$

$$n = \frac{PV}{RT} = \frac{(0.03132 \text{ atm})(4.25 \times 10^4 \text{ L})}{\left(0.082057 \dfrac{\text{L} \cdot \text{atm}}{\text{K} \cdot \text{mol}}\right)(298 \text{ K})} = 54.43 \text{ mol}$$

$$54.43 \text{ mol } H_2O\left(\frac{18.02 \text{ g}}{1 \text{ mol } H_2O}\right) = 980.8 \text{ g } H_2O$$

$$980.8 \text{ g } H_2O\left(\frac{1 \text{ mL}}{0.997 \text{ g } H_2O}\right) = 984 \text{ mL}$$

Only about half of the available water needs to evaporate to achieve the equilibrium water vapor pressure of 23.8 mm Hg at 25 °C. That is, not all of the water needs to evaporate.

Strategy Map 11.6

PROBLEM

Will a sample of water **evaporate completely** in a given volume at known ***T***?

↓

DATA/INFORMATION

- Volume of water
- Density of water
- Vapor pressure at *T*

STEP 1. Use **ideal gas law** to calculate *amount of water vapor* needed to have a ***P*** equal to vapor pressure in *given volume*.

Amount of water (mol) in the vapor phase to achieve ***P*** equal to the vapor pressure at given ***T***.

STEP 2. Convert **amount of water** to a **volume of liquid water** using ***molar mass*** and ***density***.

Volume of water that evaporated to achieve the ***vapor pressure*** at given ***T***.

STEP 3. **Compare** *volume of water evaporated* to *volume available before evaporation*.

Volume of water that evaporated is ***less*** than that available. **Some liquid water remains.**

Think about Your Answer Another approach to the problem is to calculate the pressure exerted if all of the water had evaporated. The answer would be 48.4 mm Hg. This is about twice the equilibrium vapor pressure at 25 °C, so only about half of the water needs to evaporate, as you found in the other approach.

Check Your Understanding

Examine the vapor pressure curve for ethanol in Figure 11.12.

(a) What is the approximate vapor pressure of ethanol at 40 °C?

(b) Are liquid and vapor in equilibrium when the temperature is 60 °C and the pressure is 600 mm Hg? If not, does the liquid evaporate to form more vapor, or does vapor condense to form more liquid?

When the natural logarithm of the vapor pressure (ln *P*) of water at various temperatures (*T*) is plotted against 1/*T*, the slope of the straight line is $-\Delta_{vap}H°/R$.

Figure 11.13 Clausius–Clapeyron equation. This equation is named after the German physicist R. Clausius (1822–1888) and the Frenchman B. P. E. Clapeyron (1799–1864). Values of *T* and *P* for water for this plot are from Appendix G.

Vapor Pressure, Enthalpy of Vaporization, and the Clausius–Clapeyron Equation

As Figure 11.12 illustrates, plotting the vapor pressure for a liquid as a function of temperature results in a curved line. However, we see a linear relationship if the reciprocal of the Kelvin temperature ($1/T$) is plotted as a function of the logarithm of the vapor pressure ($\ln P$) (Figure 11.13), and the equation for the line is

$$\ln P = -(\Delta_{vap}H°/RT) + C \qquad (11.1)$$

(In this equation R is the ideal gas constant (0.008314462 kJ/K · mol), and C is a constant characteristic of the liquid in question.)

The value of this relationship—called the **Clausius–Clapeyron equation**—is that you can calculate the enthalpy of vaporization of a liquid, $\Delta_{vap}H°$, from experimental measurements of vapor pressure and temperature. The equilibrium vapor pressure of a liquid can be measured at several different temperatures, and, if the logarithm of these pressures is plotted versus $1/T$, the result is a straight line with a slope of $-\Delta_{vap}H°/R$. For example, plotting data for water (Figure 11.13), we find the slope of the line is -4.90×10^3 K, which gives $\Delta_{vap}H° = 40.7$ kJ/mol.

As an alternative to plotting $\ln P$ versus $1/T$, we can use the following equation (derived from Equation 11.1) that allows us to estimate $\Delta_{vap}H°$ if we know the vapor pressure of a liquid at just two different temperatures.

$$\ln\frac{P_2}{P_1} = -\frac{\Delta_{vap}H°}{R}\left[\frac{1}{T_2} - \frac{1}{T_1}\right] \qquad (11.2)$$

Let us use Equation 11.2 to calculate the enthalpy of vaporization of ethylene glycol, a common ingredient in antifreeze. Suppose we do experiments where we find the liquid has a vapor pressure of 14.9 mm Hg (P_1) at 373 K (T_1), and a vapor pressure of 49.1 mm Hg (P_2) at 398 K (T_2). This gives $\Delta_{vap}H°$ of 59 kJ/mol.

$$\ln\left(\frac{49.1\text{ mm Hg}}{14.9\text{ mm Hg}}\right) = -\frac{\Delta_{vap}H°}{0.0083145\text{ kJ/K} \cdot \text{mol}}\left[\frac{1}{398\text{ K}} - \frac{1}{373\text{ K}}\right]$$

$$1.1925 = -\frac{\Delta_{vap}H°}{0.0083145\text{ kJ/K} \cdot \text{mol}}\left(-\frac{0.000168}{K}\right)$$

$$\Delta_{vap}H° = 59\text{ kJ/mol}$$

Boiling Point

If you have a beaker of water open to the atmosphere, the atmosphere presses down on the surface. If enough energy is added, a temperature is eventually reached when the vapor pressure of the liquid equals the atmospheric pressure. At this temperature, bubbles of the liquid's vapor will not be crushed by the atmospheric pressure. Instead, bubbles can rise to the surface, and the liquid boils (Figure 11.14).

The boiling point of a liquid is the temperature at which its vapor pressure is equal to the external pressure. If the external pressure is 760 mm Hg, this temperature is called the **normal boiling point**. This point is highlighted on the vapor pressure curves for the substances in Figure 11.12.

The normal boiling point of water is 100 °C, and in a great many places in the United States, water boils at or near this temperature. If you live at higher altitudes, however, such as in Salt Lake City, Utah, where the barometric pressure is about 650 mm Hg, water will boil at a noticeably lower temperature. The curve in Figure 11.12 shows that a pressure of 650 mm Hg corresponds to a boiling temperature of about 95 °C. Food, therefore, has to be cooked a little longer in Salt Lake City to achieve the same result as in New York City at sea level.

Figure 11.14 Vapor pressure and boiling. When the vapor pressure of the liquid equals the atmospheric pressure, bubbles of vapor begin to form within the body of liquid, and the liquid boils.

Critical Temperature and Pressure

On first thought, it might seem that vapor pressure–temperature curves (such as shown in Figure 11.12) should continue upward without limit, but this is not so. Instead, when a high enough temperature and pressure are reached, the interface between the liquid and the vapor disappears at the **critical point**. The temperature at which this occurs is the **critical temperature, T_c**, and the corresponding pressure is the **critical pressure, P_c** (Figure 11.15). The substance that exists under these

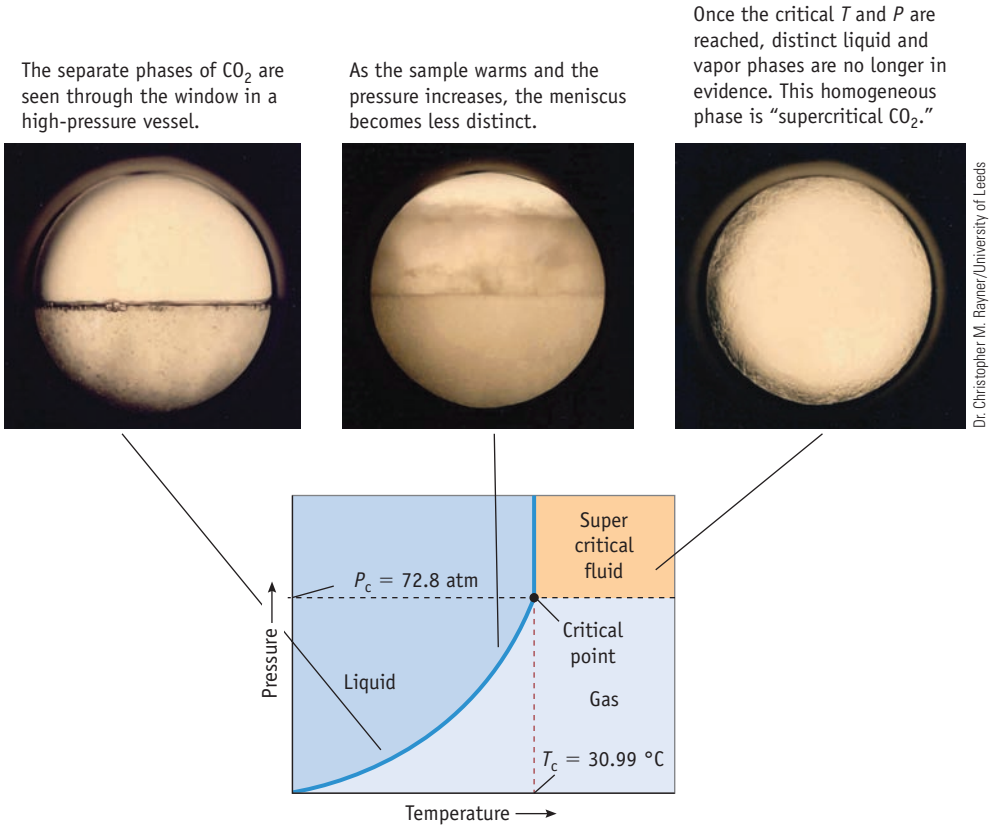

Figure 11.15 Critical temperature and pressure for CO_2. The pressure versus temperature curve representing equilibrium conditions for liquid and gaseous carbon dioxide ends at the critical point; above that temperature and pressure, CO_2 becomes a supercritical fluid.

TABLE 11.7

Critical Temperatures and Pressures for Common Compounds*

Compound	T_c (°C)	P_c (atm)
CH_4 (methane)	−82.6	45.4
C_2H_6 (ethane)	32.3	49.1
C_3H_8 (propane)	96.7	41.9
C_4H_{10} (butane)	152.0	37.3
CCl_2F_2 (CFC-12)	111.8	40.9
NH_3	132.4	112.0
H_2O	374.0	217.7
CO_2	30.99	72.8
SO_2	157.7	77.8

*Data taken from D. R. Lide: *Basic Laboratory and Industrial Chemicals*, Boca Raton, FL, CRC Press, 1993.

conditions is called a **supercritical fluid**. It is like a gas under such a high pressure that its density resembles that of a liquid, while its viscosity (resistance to flow) remains close to that of a gas.

Consider what the substance looks like at the molecular level under these conditions. The molecules have been forced almost as close together as they are in the liquid state, but, unlike the situation in liquids, molecules in the supercritical fluid have enough kinetic energy to exceed the forces holding the molecules together.
