- The *d*-orbital splitting (the energy difference between the metal *d*-orbital energies) often corresponds to the energy associated with visible light. As a consequence, many metal complexes absorb visible light and thus are colored.

22.7 Colors of Coordination Compounds

Goal for Section 22.7

- Know how color and magnetism are related to the electronic structure of a complex.

The range of colors observed for compounds of the transition elements is one of their most interesting features (Figures 22.2 and 22.25), and the underlying reason for this is *d*-orbital splitting due to the ligands surrounding the metal atom or ion. Before discussing how *d*-orbital splitting is involved, however, let us look more closely at what we mean by color.

© Cengage Learning/Charles D. Winters

Figure 22.25 Aqueous solutions of some transition metal ions. Compounds of transition metal elements are often colored, whereas those of main group metals are usually colorless. Pictured here, from *left* to *right,* are solutions of the nitrate salts of Fe^{3+}, Co^{2+}, Ni^{2+}, Cu^{2+}, and Zn^{2+}.

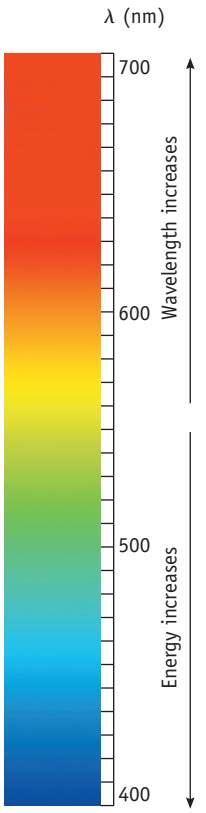
Color

Visible light consists of radiation with wavelengths from 400 to 700 nm (Section 6.1). Within this region are all the colors you see when white light passes through a prism: red, orange, yellow, green, blue, indigo, and violet (ROY G BIV). Each color is identified with a portion of the wavelength range.

Isaac Newton did experiments with light and established that the mind's perception of color requires only three colors! When we see white light, we are seeing a mixture of all of the colors—in other words, the superposition of red, green, and blue. If one or more of these colors is absent, the light of the other colors that reaches your eyes is interpreted by your mind as a color.

Figure 22.26 will help you in analyzing perceived colors. The three primary colors—red, green, and blue—are shown as overlapping disks arranged in a triangle. The secondary colors—cyan, magenta, and yellow—appear where two disks overlap. The overlap of all three disks in the center produces white light.

The colors we perceive are determined as follows:



- Light of a single primary color is perceived as that color: Red light is perceived as red, green light as green, blue light as blue.
- Light made up of two primary colors is perceived as the color shown where the disks in Figure 22.26 overlap: Red and green light together appear yellow, green and blue light together are perceived as cyan; and red and blue light are perceived as magenta.
- Light made up of the three primary colors is white (colorless).

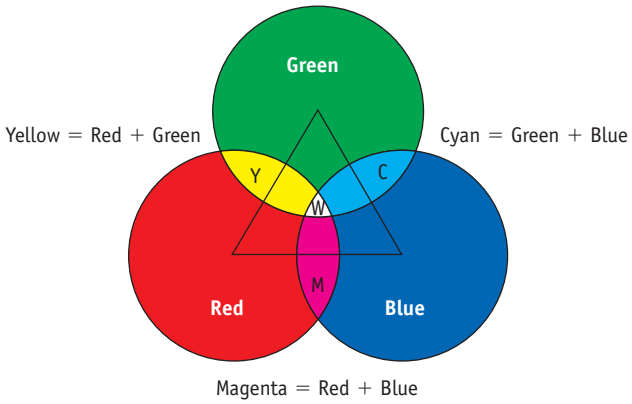
In discussing the color of a substance such as a coordination complex *in solution*, we are interested in *the light that is absorbed*.

- Red color is the result of the absorption of green and blue light by the solution.
- Green color results if red and blue light are absorbed.
- Blue color results if red and green light are absorbed.

The secondary colors are rationalized similarly. Absorption of blue light gives yellow (the color across from it in Figure 22.26); absorption of red light results in cyan; and absorption of green light results in magenta.

Now we can apply these ideas to explain colors in transition metal complexes. Focus on what kind of light is *absorbed*. A solution of $[Ni(H_2O)_6]^{2+}$ is green. Green light is the result of removing red and blue light from white light. As white light passes through an aqueous solution of Ni^{2+}, red and blue light are absorbed, and

The ROY G BIV spectrum of colors of visible light. The colors used in printing this book are cyan, magenta, yellow, and black. The blue in ROY G BIV is actually cyan, according to color industry standards. Magenta doesn't have its own wavelength region. Rather, it is a mixture of blue and red.



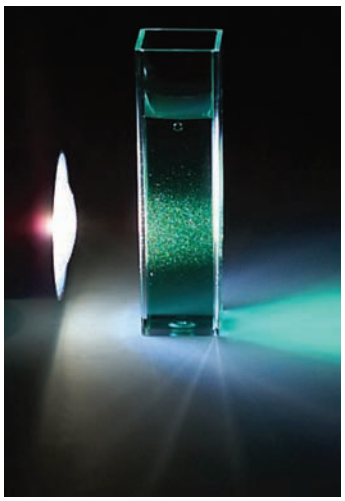


Figure 22.26 Using color disks to analyze colors. The three primary colors are red, green, and blue. Adding light of two primary colors gives the secondary colors yellow (= red + green), cyan (= green + blue), and magenta (= red + blue). Adding all three primary colors results in white light.

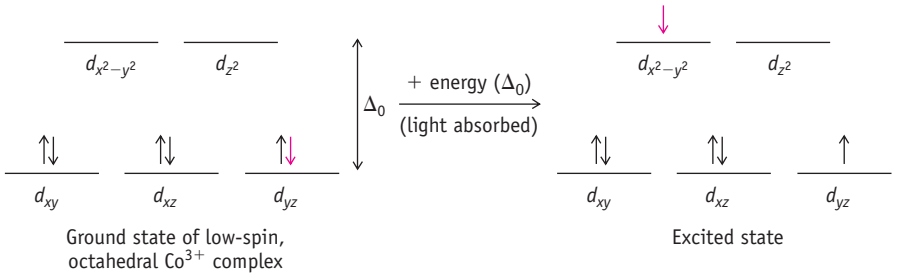

Figure 22.27 Light absorption and color. The color of a solution is due to the color of the light *not* absorbed by the solution. Here, a solution of Ni^{2+} ion in water absorbs red and blue light and so appears green (Figures 4.13–4.15).

green light is allowed to pass (Figure 22.27). Similarly, the $[Co(NH_3)_6]^{3+}$ ion is yellow because blue light has been absorbed and red and green light pass through.

The Spectrochemical Series

Recall that atomic spectra are obtained when electrons are excited from one energy level to another (Section 6.3). The energy of the light absorbed or emitted is related to the energy levels of the atom or ion. The concept that light is absorbed when electrons are excited from lower to higher energy levels applies not just to atoms but also to ions and molecules of all types, including transition metal complexes.

In coordination complexes, the energy gap in the split *d* orbitals often corresponds to the energy of visible light, so light in the visible region of the spectrum is absorbed when electrons move from a lower-energy *d* orbital to a higher-energy *d* orbital. This change, as an electron moves between two orbitals having different energies in a complex, is called a ***d*-to-*d* transition**. Qualitatively, such a transition for $[Co(NH_3)_6]^{3+}$ might be represented using an energy-level diagram such as that shown here.

Experiments with coordination complexes reveal that, for a given metal ion, some ligands cause a small energy separation of the *d* orbitals, whereas others cause a large separation. In other words, some ligands create a small ligand field, and others create a large one. An example is seen in the spectroscopic data for several cobalt(III) complexes presented in Table 22.3.

- Both $[Co(NH_3)_6]^{3+}$ and $[Co(en)_3]^{3+}$ are yellow-orange, because they absorb light in the blue portion of the visible spectrum. These compounds have very similar spectra, to be expected because in both the metal is coordinated to six N donor atoms.

Steven Hyatt

Green jade. The rich green color of this New Zealand jade comes from iron(II) and iron(III) ions in the mineral. The iron ions within the mineral are surrounded by oxide ions at the corners of an octahedron.

TABLE 22.3 The Colors of Some Co^{3+} Complexes*

Complex Ion	Wavelength of Light Absorbed (nm)	Color of Light Absorbed	Color of Complex
$[CoF_6]^{3-}$	700	Red	Blue-green
$[Co(C_2O_4)_3]^{3-}$	600, 420	Yellow, violet	Dark green
$[Co(H_2O)_6]^{3+}$	600, 400	Yellow, violet	Blue-green
$[Co(NH_3)_6]^{3+}$	475, 340	Blue, ultraviolet	Yellow-orange
$[Co(en)_3]^{3+}$	470, 340	Blue, ultraviolet	Yellow-orange
$[Co(CN)_6]^{3-}$	310	Ultraviolet	Very pale yellow, almost colorless

*The complex with fluoride ion, $[CoF_6]^{3-}$, is high spin and has one absorption band. The other complexes are low spin and have two absorption bands. Although the top of the absorption band for $[Co(CN)_6]^{3-}$ is in the UV region, the band is broad and trails into the visible region. The very pale yellow color is the result of the small absorption of blue light.

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

- Although $[Co(CN)_6]^{3-}$ does not have an absorption band whose maximum falls in the visible region, it is very pale (almost colorless) yellow. The peak of the absorption band occurs in the ultraviolet region, but the absorption band is broad and extends minimally into the visible (blue) region.
- $[Co(C_2O_4)_3]^{3-}$ and $[Co(H_2O)_6]^{3+}$ have similar absorptions, in the yellow and violet regions. Their colors are shades of green with a small difference due to the relative amount of light of each color being absorbed.
- Of the complex ions in Table 22.3, $[CoF_6]^{3-}$ absorbs the lowest energy light (red) and so transmits the highest energy light. (The complex is blue-green.)

Colors of Coordination Complexes Owing to the fact that complexes often have more than one absorption band, and that the bands are broad, it can be difficult to predict their color.

The wavelength of maximum absorption among the listed complexes ranges from 700 nm for $[CoF_6]^{3-}$ to 310 nm for $[Co(CN)_6]^{3-}$. The ligands change from member to member of this series, and we can conclude that the energy of the light absorbed by the complex is related to the different ligand field splittings, Δ_0, caused by the different ligands. Fluoride ion causes the smallest splitting of the *d* orbitals among the complexes listed in Table 22.3, whereas cyanide causes the largest splitting.

Spectra of complexes of other metals provide similar results. Based on this information, ligands can be listed in order of their ability to split the *d* orbitals in a broad range of complexes. This list is called the **spectrochemical series** because it was determined by spectroscopy. A short list, with some of the more common ligands, follows:

$$\underset{\substack{\text{small } d \text{ orbital splitting}\\ \text{small } \Delta_0}}{F^-,\ Cl^-,\ Br^-,\ I^-} < C_2O_4^{2-} < H_2O < NH_3 = en < phen < \underset{\substack{\text{large } d \text{ orbital splitting}\\ \text{large } \Delta_0}}{CN^-}$$

The spectrochemical series is applicable to a wide range of metal complexes. Indeed, the ability of ligand field theory to explain the differences in the colors of the transition metal complexes is one of the strengths of this theory.

Based on the relative position of a ligand in the series, predictions can be made about a compound's magnetic behavior. Recall that d^4, d^5, d^6, and d^7 octahedral complexes can be high or low spin, depending on the ligand field splitting, Δ_0. Complexes formed with ligands near the left end of the spectrochemical series are expected to have small Δ_0 values and, therefore, are likely to be high spin. In contrast, complexes with ligands near the right end are expected to have large Δ_0 values and low-spin configurations. The complex $[CoF_6]^{3-}$ is high spin, whereas $[Co(NH_3)_6]^{3+}$ and the other complexes in Table 22.3 are low spin.

EXAMPLE 22.6

Spectrochemical Series

Problem An aqueous solution of $[Fe(H_2O)_6]^{2+}$ is light blue-green. Do you expect the d^6 Fe^{2+} ion in this complex to have a high- or low-spin configuration? How could you test your prediction experimentally?

What Do You Know? This is an octahedral complex of Fe^{2+}, an ion with a d^6 configuration. The blue-green color is the result of the absorption of visible light due to a *d*-to-*d* transition. The complex could be either low spin (no unpaired electrons) or high spin (four unpaired electrons).

Strategy Use the color wheel in Figure 22.26 to determine what color light is transmitted and therefore what color of light has been absorbed. Based on the energy of the light absorbed, determine if Δ_0 is high or low. If it is low, then the complex is high spin. If it is high, then the complex is low spin.

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

SOLUTION In this case, the blue-green color of the solution indicates that blue and green light are transmitted. This implies that red light was absorbed. The low energy of the light absorbed suggests that Δ_0 is small and so $[Fe(H_2O)_6]^{2+}$ is likely to be a high-spin complex. If the complex is high spin, it will have four unpaired electrons and be paramagnetic; if, contrary to our prediction, it is low spin, it will have no unpaired electrons and be diamagnetic. Thus, identifying the presence of four unpaired electrons by measuring the compound's magnetism can be used to verify the high-spin configuration experimentally.

Think about Your Answer The spectrochemical series was generated by measuring the absorptions for a series of complexes of a given metal but with different ligands. As in the example here, the spectrochemical series is useful because it allows you to predict whether a complex is likely to be high or low spin. The more definitive evidence for high or low spin comes from information on the magnetism of the complex.

Check Your Understanding

1. The complex $[Co(NH_3)_5OH]^{2+}$ has an absorption maximum at 500 nm. What color of light is absorbed and what color is the complex?
2. Figure 22.15 shows a sample of yellow $[Co(NH_3)_5NO_2]^{2+}$. What color of light is absorbed by this complex? Predict whether this is a high-spin or low-spin complex.

APPLYING CHEMICAL PRINCIPLES

22.1 Life-Saving Copper

If you are admitted to a hospital in the United States, there is a 1 in 20 chance you will develop an infection. And if you do become infected, there is a 1 in 20 chance you will die from that infection. The U.S. Centers for Disease Control and Prevention (CDC) estimates that hospital-acquired infections kill about 100,000 people in the United States and cost almost $50 billion annually. Clearly it is in our interest to prevent these infections, and recent clinical trials point the way to simple and low-cost ways to do so.

Dr. Michael Schmidt of the Medical University of South Carolina said that "Bacteria present on ICU room surfaces are probably responsible for 35–80 percent of patient infections...." The hospital carried out a study in which they covered bed rails, tray tables, chair arms, call buttons, and IV poles with various copper alloys. (The alloys varied from 75% to 99% copper.) In all, they covered 282 objects in 32 rooms and compared the results with 288 non-covered items in 27 other rooms. Similar trials were done in two other large hospitals. Copper coatings reduced the "microbial burden" of pathogens by 99% on bed rails and call buttons and by 38% on chair arms. Copper was found to be effective against *Staphylococcus aureus,* a bacterium commonly found in hospitals, methicillin-resistant *Staphylococcus aureus* (MRSA), a virulent strain of antibiotic-resistant bacteria and a common cause of hospital infections and vancomycin-resistant Enterococcus (VRE), the second leading cause of hospital-acquired infections. The research team noted that "although MRSA and VRE were frequently isolated from non-copper objects, they were never isolated from copper objects over the study period."

Steven Hyatt

Copper-fitting in the Ronald McDonald House, a home for seriously ill children and their families in Charleston, SC.

But why did we not recognize this before? Hippocrates (460–370 BC), the father of medicine, recommended the use of copper to treat leg ulcers related to varicose veins. In Roman times, Pliny used copper oxide and honey to treat intestinal worms. More recently scientists from Britain and India investigated a long-held belief among people in India that illness can be warded off by storing water in pitchers made of brass (an alloy of copper and zinc). They filled brass pitchers with previously sterile water to which they had added *E. coli*, a bacterium that lives in the lower intestine of many warm-blooded animals and found in their feces. Other brass pitchers were filled with contaminated river water from India. In both cases,

fecal bacteria counts dropped from as high as 1,000,000 bacteria per milliliter to zero in 2 days. In contrast, bacteria levels stayed high in plastic or earthenware pots.

The underlying mechanism by which bacteria are destroyed by copper ions is not yet well understood, but there is research activity on this question in academic laboratories around the world.

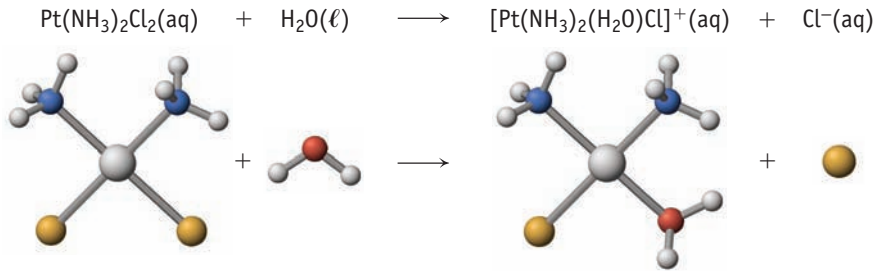
Questions:

1. What are the electron configurations of Cu(g), Cu^+(g), and Cu^{2+}(g)? Determine the number of unpaired electrons in each species.
2. Copper has a face-centered cubic unit cell. If copper has a density of 8.960 g/cm^3, what is the radius of a copper atom?
3. Assuming that Cu^{2+} ions in solution are the active agents for killing bacteria, they must be present in very low concentration. Calculate the amount of copper present in 1.0 L of a 5.0×10^{-15} M Cu^{2+} solution.

22.2 *Cisplatin:* Accidental Discovery of a Chemotherapy Agent

Chemists have synthesized various metal-based compounds for medical purposes. One of these, *cisplatin* [$PtCl_2(NH_3)_2$], was known for many years, but it was discovered serendipitously to be effective in treatment of certain kinds of cancers.

In 1965, Barnett Rosenberg, a biophysicist at Michigan State University, set out to study the effect of electric fields on living cells, but the results of his experiments were very different from his expectations. He and his students had placed an aqueous suspension of live *Escherichia coli* bacteria in an electric field between supposedly inert platinum electrodes. Much to their surprise, they found that cell growth was significantly affected. After careful experimentation, the effect on cell division was found to be due to a trace of a complex of platinum, ammonia, and chloride ion formed by an electrolytic process involving the platinum electrode in the presence of ammonia in the growth medium.



To follow up on this interesting discovery, Rosenberg and his students tested the effect of *cis*- and *trans*-$PtCl_2(NH_3)_2$ on cell growth and found that only the *cis* isomer was effective. This led Rosenberg and others to study the effect of so-called *cisplatin* on cancer cell growth, and the result is that *cisplatin* and similar compounds are now used to treat genitourinary tumors. In fact, testicular cancer is now considered largely curable because of cisplatin chemotherapy.

The chemistry of *cisplatin* has now been thoroughly studied. It has been found that *cisplatin* has a half-life of 2.5 hours for the replacement of a Cl^- ligand by water at 310 K (in a first-order reaction) and that the replacement of a second Cl^- ligand by water is slightly faster.

The aqua species are acidic and damaging to the kidneys, so *cisplatin* is generally used in a saline solution to prevent the hydrolysis reactions. It has been found that, in blood plasma at pH 7.4 and with a Cl^- ion concentration of about 1.04×10^{-5} M, $PtCl_2(NH_3)_2$ and $PtCl(OH)(NH_3)_2$ are the dominant species. In the cell nucleus, however, the Cl^- ion concentration is lower, and the aqua species are present in higher concentration.

Questions:

1. If a patient is given 10.0 mg of cisplatin, what quantity remains as cisplatin at 24 hours?
2. What is the systematic name for *cisplatin*?
3. How are the *d* electrons of Pt distributed in a *d*-orbital splitting diagram?

22.3 The Rare Earths

The lanthanide elements are often referred to as "rare earth elements." Why are they called "rare"? And what are they used for?

In this book we include the 14 elements from Ce (cerium) through Lu (lutetium) in the list of rare earths, but it is common to also include La, lanthanum. In addition, if you read about rare earth chemistry, the Group 3B elements Sc (scandium) and Y (yttrium) are often added to the list.

Why are they called "rare earth elements" and are they in fact "rare"? In 1803, German and Swedish chemists isolated a new oxide (an "earth") from a mineral found in Sweden. At first this was thought to be an oxide of a new element, cerium, but several decades later it was discovered that the "earth" was a mixture of cerium oxide and oxides of other lanthanides. The term "rare" has been attached to the elements because it is difficult to find them in concentrations great enough for

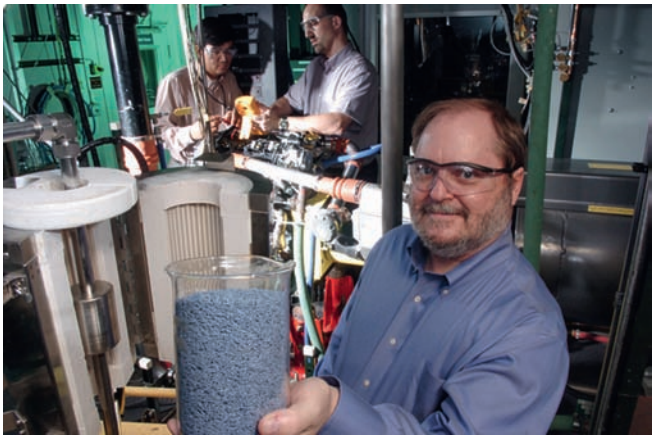
Compact fluorescent bulbs. They have an inside coating of a phosphorescent europium compound.



© Cengage Learning/Charles D. Winters

commercial purposes and because they are difficult to separate one from another. But they are in fact rather abundant. Cerium, for example, is 26th most abundant in Earth's crust, about half as abundant as chlorine and 5 times as abundant as lead.

The elements were slow to find commercial uses, but some are now crucially important in our modern economy. Cerium(IV) oxide is used in catalysts and in the coatings of self-cleaning ovens. Neodymium (Nd) and samarium (Sm) are both used to make powerful magnets. Europium (Eu) is used in the phosphors inside compact fluorescent lightbulbs. (This coating is what allows the bulb to emit a very bright light.) Other uses are in batteries and wind turbines.

One consequence of the growing importance of the rare earths is that they are becoming scarce. China presently produces about 97% of the metals and oxides, and companies in the United States and elsewhere are opening old mines or seeking new sources.

Argonne National Laboratory

Cerium-based catalyst. A chemist at Argonne National Laboratory holds a beaker of Cu-ZSM-5 catalyst used to remove harmful nitrogen oxides from diesel exhaust. The catalyst is a zeolite that contains copper ions in the lattice and is coated with cerium(IV) oxide.

Questions:

1. What are the electron configurations for Nd and Eu?
2. The lanthanide elements form ionic compounds, with the +3 oxidation state dominating. What are the electron configurations for Ce^{3+} and Nd^{3+}?
3. The compound $(NH_4)_2Ce(NO_3)_6$ is a widely used oxidizing agent in redox titrations. A 0.181 g sample of pure iron is dissolved in acid, reduced to Fe^{2+}, and then titrated with 31.33 mL of $(NH_4)_2Ce(NO_3)_6$ (to give Ce^{3+} and Fe^{3+}). Calculate the concentration of the cerium salt.
4. Cerium(IV) oxide is used in catalytic converters for the oxidation of CO (to give cerium(III) oxide and CO_2). The cerium(III) oxide is converted back to cerium(IV) oxide by atmospheric oxygen. Balance equations for these reactions.

CHAPTER GOALS REVISITED

The goals for this chapter are keyed to specific Study Questions to help you organize your review.

22.1 Overview of the Transition Elements

- Identify the general classes of transition metals based on their location in the periodic table. 1–4.
- Recognize general features of transition metals and their compounds. 5–8.

22.2 Periodic Properties of the Transition Elements

- Assess periodic trends of the transition metals based on electronic structure. 9–14.

22.3 Metallurgy

- Describe the metallurgy of iron and copper. 15–18.

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

22.4 Coordination Compounds

- Know the names and formulas of common monodentate and bidentate ligands. **19–22.**
- Given the formula for a coordination complex, identify the metal and its oxidation state, the ligands, the coordination number and coordination geometry, and the overall charge on the complex. **23–26.**
- Given a formula, name a complex; given a name of a complex, write its formula. **27–32.**

22.5 Structures of Coordination Compounds

- Identify the different types of isomers that are encountered with coordination compounds. **33, 34.**
- Given the molecular formula of a complex, determine whether isomers are possible, and draw their structures. **35–38.**

22.6 Bonding in Coordination Compounds

- Use ligand field theory to describe metal-ligand bonding in coordination compounds. **39–42.**
- Draw an energy level diagram representing splitting of the metal *d* orbitals by the ligand field. **43–48.**
- Predict and rationalize magnetism in coordination complexes. **43–48.**

22.7 Colors of Coordination Compounds

- Know how color and magnetism are related to the electronic structure of a complex. **49–52.**

STUDY QUESTIONS

▲ denotes challenging questions. **Blue-numbered questions** have answers in Appendix N and fully worked solutions in the *Student Solutions Manual.*

Practicing Skills

Properties of Transition Elements

(See Section 22.1.)

1. Identify, based on the position in the periodic table, the actinide elements among those in the following list: Co, Cm, Cd, Ce, Cf.
2. Identify, based on the position in the periodic table, the actinide elements among those in the following list: Ta, Tc, Ti, Th, Tm.
3. Use the periodic table to identify the elements in the following list with unfilled 4*d* orbitals: rhodium, rhenium, ruthenium, rutherfordium, radium.
4. Use the periodic table to identify the elements in the following list with unfilled 3*d* orbitals: cadmium, cerium, cobalt, chromium, copper.
5. Identify the following as either chemical or physical properties of most transition metals:
   (a) can be oxidized.
   (b) have unpaired electrons (paramagnetism).
   (c) solids at 25 °C.
   (d) metallic luster.
   (e) Compounds of the elements are often colored.
6. Iron is the most abundant transition element in nature. Identify common chemical and physical properties of this element.
7. Identity among the transition metals:
   (a) the most dense element.
   (b) the metal with the lowest melting point.
   (c) a radioactive *d*-block element.
   (d) an essential element in the human body.

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

8. Identify among the transition metals:
   (a) the metal with the highest melting point.
   (b) a commonly used metal in construction.
   (c) a radioactive *f*-block element.
   (d) one of the metals in nitrogenase, a nitrogen fixing catalyst.

9. Give the electron configuration for each of the following ions, and tell whether each is paramagnetic or diamagnetic.
   (a) Cr^{3+} (c) Ni^{2+}
   (b) V^{2+} (d) Cu^{+}

10. Identify two transition metal cations with each of the following electron configurations.
   (a) [Ar]$3d^6$ (c) [Ar]$3d^5$
   (b) [Ar]$3d^{10}$ (d) [Ar]$3d^8$

11. Identify a cation of a first series transition metal that is isoelectronic with each of the following.
   (a) Fe^{3+} (c) Fe^{2+}
   (b) Zn^{2+} (d) Cr^{3+}

12. Match up the isoelectronic ions on the following list.

$$Cu^{+}\ Mn^{2+}\ Fe^{2+}\ Co^{3+}\ Fe^{3+}\ Zn^{2+}\ Ti^{2+}\ V^{3+}$$

Formulas of Coordination Compounds

(See Examples 22.1 and 22.2.)

13. The lanthanide contraction is given as an explanation for the fact that the 6th period transition metals have
   (a) lower densities than the 5th period transition elements.
   (b) atomic radii similar to the 5th period transition elements.
   (c) lower melting points than the 5th period transition elements.

14. Describe how the atomic radii of the transition metals change across a period and rationalize this change based on electronic structure.

15. What is the most common form that iron is found in the Earth's crust?
   (a) free metal
   (b) iron oxide
   (c) iron sulfide
   (d) iron silicate

16. In the reaction

$$CuFeS_2(s) + 3\ CuCl_2(aq) \longrightarrow 4\ CuCl(s) + FeCl_2(aq) + 2\ S(s)$$

what element is oxidized and what element is reduced?
   (a) Sulfur is reduced, iron is oxidized.
   (b) Copper is reduced, sulfur is oxidized.
   (c) Sulfur is reduced, copper is oxidized.
   (d) This is not a redox reaction.

17. In the pyrometallurgy of iron, what two species serve as reducing agents?

18. Lime (CaO) is usually added to the blast furnace in the metallurgy of iron where it reacts with impurities present in iron ore. What of the following best describes its function?
   (a) CaO acts as an oxidizing agent.
   (b) CaO acts as a reducing agent.
   (c) CaO acts as an acid.
   (d) CaO acts as a base.

19. Which of the following ligands is expected to be monodentate, and which might be polydentate?
   (a) CH_3NH_2 (d) en
   (b) CH_3CN (e) Br^-
   (c) N_3^- (f) phen

20. One of the following nitrogen compounds or ions is not capable of serving as a ligand: NH_4^+, NH_3, NH_2^-. Identify this species, and explain your answer.

21. Give the name or structural formula for each of the following ligands.

	Name	Formula
(a)	ethylenediamine	_____
(b)	oxalate ion	_____
(c)	_____	NH_3
(d)	_____	SCN^-

22. Give the name or structural formula for each of the following ligands.

	Name	Formula
(a)	acetylacetonate	_____
(b)	nitrite ion	_____
(c)	_____	H_2O
(d)	_____	NO_2^-

23. Give the oxidation number of the metal ion in each of the following compounds.
(a) $[Mn(NH_3)_6]SO_4$ (c) $[Co(NH_3)_4Cl_2]Cl$
(b) $K_3[Co(CN)_6]$ (d) $Cr(en)_2Cl_2$

24. Give the oxidation number of the metal ion in each of the following complexes.
(a) $[Fe(NH_3)_6]^{2+}$ (c) $[Co(NH_3)_5(NO_2)]^{+}$
(b) $[Zn(CN)_4]^{2-}$ (d) $[Cu(en)_2]^{2+}$

25. Give the formula of a complex constructed from one Ni^{2+} ion, one ethylenediamine ligand, three ammonia molecules, and one water molecule. Is the complex neutral or is it charged? If charged, give the charge.

26. Give the formula of a complex constructed from one Cr^{3+} ion, two ethylenediamine ligands, and two ammonia molecules. Is the complex neutral or is it charged? If charged, give the charge.

Naming Coordination Compounds

(See Example 22.3.)

27. Write formulas for the following ions or compounds.
(a) dichlorobis(ethylenediamine)nickel(II)
(b) potassium tetrachloroplatinate(II)
(c) potassium dicyanocuprate(I)
(d) tetraamminediaquairon(II)

28. Write formulas for the following ions or compounds.
(a) diamminetriaquahydroxochromium(II) nitrate
(b) hexaammineiron(III) nitrate
(c) pentacarbonyliron(0) (where the ligand is CO)
(d) ammonium tetrachlorocuprate(II)

29. Name the following ions or compounds.
(a) $[Ni(C_2O_4)_2(H_2O)_2]^{2-}$
(b) $[Co(en)_2Br_2]^{+}$
(c) $[Co(en)_2(NH_3)Cl]^{2+}$
(d) $Pt(NH_3)_2(C_2O_4)$

30. Name the following ions or compounds.
(a) $[Co(H_2O)_4Cl_2]^{+}$ (c) $[Pt(NH_3)Br_3]^{-}$
(b) $Co(H_2O)_3F_3$ (d) $[Co(en)(NH_3)_3Cl]^{2+}$

31. Give the name or formula for each ion or compound, as appropriate.
(a) pentaaquahydroxoiron(III) ion
(b) $K_2[Ni(CN)_4]$
(c) $K[Cr(C_2O_4)_2(H_2O)_2]$
(d) ammonium tetrachloroplatinate(II)

32. Give the name or formula for each ion or compound, as appropriate.
(a) tetraaquadichlorochromium(III) chloride
(b) $[Cr(NH_3)_5SO_4]Cl$
(c) sodium tetrachlorocobaltate(II)
(d) $[Fe(C_2O_4)_3]^{3-}$

Isomerism

(See Example 22.4.)

33. A coordination compound has the formula $[Co(en)_2Cl_2]Cl$ (en = ethylenediamine, $H_2NCH_2CH_2NH_2$). What types of isomerism (geometric isomerism, optical isomerism, structural isomerism) are possible with this formula? Identify all possible answers.

34. What types of isomerism (geometric isomerism, optical isomerism, structural isomerism) are possible in the compound diamminechlorothiocyanatoplatinum(II)? Identify all possible answers.

35. Draw all possible geometric isomers for each of the following ions or molecules.
(a) $Fe(NH_3)_4Cl_2$
(b) $Pt(NH_3)_2(SCN)(Br)$ (SCN^- is bonded to Pt^{2+} through S)
(c) $Co(NH_3)_3(NO_2)_3$ (NO_2^- is bonded to Co^{3+} through N)
(d) $[Co(en)Cl_4]^{-}$

36. In which of the following complexes are geometric isomers possible? If isomers are possible, draw their structures and label them as *cis* or *trans,* or as *fac* or *mer.*
(a) $[Co(H_2O)_4Cl_2]^{+}$ (c) $[Pt(NH_3)Br_3]^{-}$
(b) $Co(NH_3)_3F_3$ (d) $[Co(en)_2(NH_3)Cl]^{2+}$

37. Determine whether the following complexes have a chiral metal center.
(a) $[Fe(en)_3]^{2+}$
(b) *trans*-$[Co(en)_2Br_2]^{+}$
(c) *fac*-$[Co(en)(H_2O)Cl_3]$
(d) square-planar $Pt(NH_3)(H_2O)(Cl)(NO_2)$

Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

38. Four geometric isomers are possible for $[Co(en)(NH_3)_2(H_2O)Cl]^+$. Draw the structures of all four. (Two of the isomers are chiral, meaning that each has a non-superimposable mirror image.)

Magnetic Properties of Complexes

(See Example 22.5.)

39. According to ligand field theory, what is the force of attraction between a metal and a ligand in a coordination complex?

40. Which of the following statements about ligand field theory are correct?
    (a) Ligands donate an electron pair to a metal ion.
    (b) Each ligand donates an electron pair to the metal.
    (c) Coordination of the ligands to a metal causes splitting of the *d* electron energy levels.
    (d) Bonding of ligands to a metal results in paramagnetism.

41. In an octahedral complex, the *d* orbitals split into two groups. Which *d* orbitals are in the lower energy group? (Assume the ligands lie along the x, y, and z axes.)

42. In a square planar complex which *d* orbital is at lowest energy? Which *d* orbital is at highest energy? (Assume the ligands lie along the x and y axes.)

43. The following are low-spin complexes. Use the ligand field model to find the electron configuration of the central metal ion in each ion. Determine which are diamagnetic. Give the number of unpaired electrons for the paramagnetic complexes.
    (a) $[Mn(CN)_6]^{4-}$ (c) $[Fe(H_2O)_6]^{3+}$
    (b) $[Co(NH_3)_6]Cl_3$ (d) $[Cr(en)_3]SO_4$

44. The following are high-spin complexes. Use the ligand field model to find the electron configuration of the central metal ion in each ion. Determine the number of unpaired electrons, if any, in each.
    (a) $K_4[FeF_6]$ (c) $[Cr(H_2O)_6]^{2+}$
    (b) $[MnF_6]^{4-}$ (d) $(NH_4)_3[FeF_6]$

45. Determine the number of unpaired electrons in the following tetrahedral complexes. All tetrahedral complexes are high spin.
    (a) $[FeCl_4]^{2-}$ (c) $[MnCl_4]^{2-}$
    (b) $Na_2[CoCl_4]$ (d) $(NH_4)_2[ZnCl_4]$

46. Determine the number of unpaired electrons in the following tetrahedral complexes. All tetrahedral complexes are high spin.
    (a) $[Zn(H_2O)_4]^{2+}$ (c) $Mn(NH_3)_2Cl_2$
    (b) $VOCl_3$ (d) $[Cu(en)_2]^{2+}$

47. For the high-spin complex $[Fe(H_2O)_6]SO_4$, identify the following:
    (a) the coordination number of iron
    (b) the coordination geometry for iron
    (c) the oxidation number of iron
    (d) the number of unpaired electrons
    (e) whether the complex is diamagnetic or paramagnetic

48. For the low-spin complex $[Co(en)(NH_3)_2Cl_2]ClO_4$, identify the following:
    (a) the coordination number of cobalt
    (b) the coordination geometry for cobalt
    (c) the oxidation number of cobalt
    (d) the number of unpaired electrons
    (e) whether the complex is diamagnetic or paramagnetic

49. The anion $[NiCl_4]^{2-}$ is paramagnetic, but when CN^- ions are added, the product, $[Ni(CN)_4]^{2-}$, is diamagnetic. Explain this observation.

$$\underset{\text{paramagnetic}}{[NiCl_4]^{2-}(aq)} + 4\ CN^-(aq) \longrightarrow \underset{\text{diamagnetic}}{[Ni(CN)_4]^{2-}(aq)} + 4\ Cl^-(aq)$$

50. An aqueous solution of iron(II) sulfate is paramagnetic. If NH_3 is added, the solution becomes diamagnetic. Why does the magnetism change?

Spectroscopy of Complexes

(See Example 22.6.)

51. In water, the titanium(III) ion, $[Ti(H_2O)_6]^{3+}$, has a broad absorption band centered at about 500 nm. What color light is absorbed by the ion?

52. In water, the chromium(II) ion, $[Cr(H_2O)_6]^{2+}$, absorbs light with a wavelength of about 700 nm. What color is the solution?

General Questions

These questions are not designated as to type or location in the chapter. They may contain several concepts.

53. Describe an experiment that would determine whether nickel in $K_2[NiCl_4]$ is square-planar or tetrahedral.

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

54. Which of the following high-spin complexes has the greatest number of unpaired electrons?

(a) $[Cr(H_2O)_6]^{3+}$ (c) $[Fe(H_2O)_6]^{2+}$

(b) $[Mn(H_2O)_6]^{2+}$ (d) $[Ni(H_2O)_6]^{2+}$

55. How many unpaired electrons are expected for high-spin and low-spin complexes of Fe^{2+}?

56. Excess silver nitrate is added to a solution containing 1.0 mol of $[Co(NH_3)_4Cl_2]Cl$. What amount of AgCl (in moles) will precipitate?

57. Which of the following complex ions is (are) square-planar?

(a) $[Ti(CN)_4]^{2-}$ (c) $[Zn(CN)_4]^{2-}$

(b) $[Ni(CN)_4]^{2-}$ (d) $[Pt(CN)_4]^{2-}$

58. Which of the following complex ions containing the oxalate ion is (are) chiral?

(a) $[Fe(C_2O_4)Cl_4]^{2-}$

(b) *cis*-$[Fe(C_2O_4)_2Cl_2]^{2-}$

(c) *trans*-$[Fe(C_2O_4)_2Cl_2]^{2-}$

59. How many geometric isomers are possible for the square-planar complex ion $[Pt(NH_3)(CN)Cl_2]^-$?

60. For a tetrahedral complex of a metal in the first transition series, which of the following statements concerning energies of the 3*d* orbitals is correct?

(a) The five *d* orbitals have the same energy.

(b) The $d_{x^2-y^2}$ and d_{z^2} orbitals are higher in energy than the d_{xz}, d_{yz}, and d_{xy} orbitals.

(c) The d_{xz}, d_{yz}, and d_{xy} orbitals are higher in energy than the $d_{x^2-y^2}$ and d_{z^2} orbitals.

61. A transition metal coordination compound absorbs 425-nm light. What is its color?

(a) red (c) yellow

(b) green (d) blue

62. For the low-spin coordination compound $[Fe(en)_2Cl_2]Cl$, identify the following.

(a) the oxidation number of iron

(b) the coordination number for iron

(c) the coordination geometry for iron

(d) the number of unpaired electrons per metal atom

(e) whether the complex is diamagnetic or paramagnetic

(f) the number of geometric isomers

63. For the high-spin coordination compound $Mn(NH_3)_4Cl_2$, identify the following.

(a) the oxidation number of manganese

(b) the coordination number for manganese

(c) the coordination geometry for manganese

(d) the number of unpaired electrons per metal atom

(e) whether the complex is diamagnetic or paramagnetic

(f) the number of geometric isomers

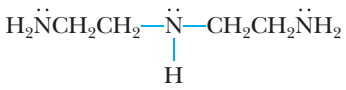
64. A platinum-containing compound, known as Magnus's green salt, has the formula $[Pt(NH_3)_4][PtCl_4]$ (in which both platinum ions are Pt^{2+}). Name the cation and the anion.

65. Early in the 20th century, coordination compounds sometimes were given names based on their colors. Two compounds with the formula $CoCl_3 \cdot 4\ NH_3$ were named praseo-cobalt chloride (*praseo* = green) and violio-cobalt chloride (violet color). We now know that these compounds are octahedral cobalt complexes and that they are *cis* and *trans* isomers. Draw the structures of these two compounds, and name them using systematic nomenclature.

66. Give the formula and name of a square-planar complex of Pt^{2+} with one nitrite ion (NO_2^-, which binds to Pt^{2+} through N), one chloride ion, and two ammonia molecules as ligands. Are isomers possible? If so, draw the structure of each isomer, and tell what type of isomerism is observed.

67. Give the formula of the coordination complex formed from one Co^{3+} ion, two ethylenediamine molecules, one water molecule, and one chloride ion. Is the complex neutral or charged? If charged, give the net charge on the ion.

68. ▲ How many geometric isomers of the complex ion $[Cr(dmen)_3]^{3+}$ can exist? (dmen is the bidentate ligand 1,1-dimethylethylenediamine.)



1,1-Dimethylethylenediamine, dmen

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

69. ▲ Diethylenetriamine (dien) is capable of serving as a tridentate ligand.

Diethylenetriamine, dien

(a) Draw the structures of *fac*-Cr(dien)Cl_3 and *mer*-Cr(dien)Cl_3.

(b) Two different geometric isomers of *mer*-Cr(dien)Cl_2Br are possible. Draw the structure for each.

(c) Three different geometric isomers are possible for $[Cr(dien)_2]^{3+}$. Two have the dien ligand in a *fac* configuration, and one has the ligand in a *mer* orientation. Draw the structure of each isomer.

70. From experiment, we know that $[CoF_6]^{3-}$ is paramagnetic and $[Co(NH_3)_6]^{3+}$ is diamagnetic. Using the ligand field model, depict the electron configuration for each ion, and use this model to explain the magnetic property. What can you conclude about the effect of these ligands on the magnitude of Δ_0?

71. Three geometric isomers are possible for $[Co(en)(NH_3)_2(H_2O)_2]^{3+}$. One of the three is chiral; that is, it has a nonsuperimposable mirror image. Draw the structures of the three isomers. Which one is chiral?

72. The square-planar complex Pt(en)Cl_2 has chloride ligands in a *cis* configuration. No *trans* isomer is known. Based on the bond lengths and bond angles of carbon and nitrogen in the ethylenediamine ligand, explain why the *trans* compound is not possible.

73. The complex $[Mn(H_2O)_6]^{2+}$ has five unpaired electrons, whereas $[Mn(CN)_6]^{4-}$ has only one. Using the ligand field model, depict the electron configuration for each ion. What can you conclude about the effects of the different ligands on the magnitude of Δ_0?

74. Experiments show that $K_4[Cr(CN)_6]$ is paramagnetic and has two unpaired electrons. The related complex $K_4[Cr(SCN)_6]$ is paramagnetic and has four unpaired electrons. Account for the magnetism of each compound using the ligand field model. Predict where the SCN^- ion occurs in the spectrochemical series relative to CN^-.

75. Give a systematic name or the formula for the following:

(a) $(NH_4)_2[CuCl_4]$

(b) tetraaquadichlorochromium(III) chloride

(c) aquabis(ethylenediamine) thiocyanatocobalt(III) nitrate

76. When $CrCl_3$ dissolves in water, three different species can be obtained.

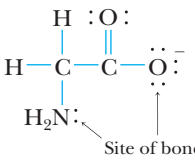
(a) $[Cr(H_2O)_6]Cl_3$, violet

(b) $[Cr(H_2O)_5Cl]Cl_2$, pale green

(c) $[Cr(H_2O)_4Cl_2]Cl$, dark green

If diethyl ether is added, a fourth complex can be obtained: $Cr(H_2O)_3Cl_3$ (brown). Describe an experiment that will allow you to differentiate these complexes.

77. ▲ The complex ion $[Co(CO_3)_3]^{3-}$, an octahedral complex with bidentate carbonate ions as ligands, has one absorption in the visible region of the spectrum at 640 nm. From this information,



(a) Predict the color of this complex and explain your reasoning.

(b) Is the carbonate ion a weak- or strong-field ligand?

(c) Predict whether $[Co(CO_3)_3]^{3-}$ will be paramagnetic or diamagnetic.

78. The glycinate ion, $H_2NCH_2CO_2^-$, formed by deprotonation of the amino acid glycine, can function as a bidentate ligand, coordinating to a metal through the nitrogen of the amino group and one of the oxygen atoms.

Glycinate ion, a bidentate ligand

A copper complex of this ligand has the formula $Cu(H_2NCH_2CO_2)_2(H_2O)_2$. For this complex, determine the following:

(a) the oxidation state of copper

(b) the coordination number of copper

(c) the number of unpaired electrons

(d) whether the complex is diamagnetic or paramagnetic

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

79. ▲ Draw structures for the five possible geometric isomers of $Cu(H_2NCH_2CO_2)_2(H_2O)_2$. Are any of these species chiral? (See the structure of the ligand in Study Question 78.)

80. A manganese compound has the formula $Mn(CO)_x(CH_3)_y$. To find the empirical formula of the compound, you burn 0.225 g of the solid in oxygen and isolate 0.283 g of CO_2 and 0.0290 g of H_2O. What is the empirical formula for the compound? That is, what are the values of x and y?

81. Nickel and palladium both form complexes of the general formula $M(PR_3)_2Cl_2$. (The ligand PR_3 is a phosphine such as $P(C_6H_5)_3$, triphenylphosphine. It is a Lewis base.) The nickel(II) compound is paramagnetic whereas the palladium(II) compound is diamagnetic.

(a) Explain the magnetic properties of these compounds.

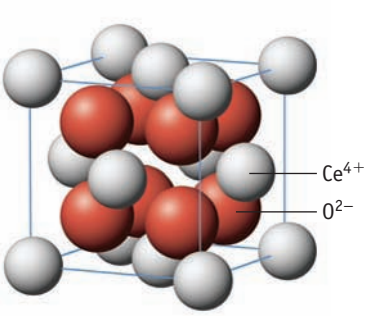
(b) How many isomers of each compound are expected?

82. ▲ The transition metals form a class of compounds called metal carbonyls, an example of which is the tetrahedral complex $Ni(CO)_4$. Given the following thermodynamic data (at 298 K):

	$\Delta_f H°$ (kJ/mol)	$S°$ (J/K · mol)
Ni(s)	0	29.87
CO(g)	−110.525	+197.674
$Ni(CO)_4$(g)	−602.9	+410.6

(a) Calculate the equilibrium constant for the formation of $Ni(CO)_4$(g) from nickel metal and CO gas.

(b) Is the reaction of Ni(s) and CO(g) product- or reactant-favored at equilibrium?



(c) Is the reaction more or less product-favored at higher temperatures? How could this reaction be used in the purification of nickel metal?

83. Cerium, as noted in *Applying Chemical Principles: 22.3 The Rare Earths*, is a relatively abundant lanthanide element that has some important uses. Cerium(IV) oxide, CeO_2, is widely used as a polishing agent for glass. Cerium(III) sulfide, Ce_2S_3, is becoming more widely used as a red pigment to replace cadmium pigments, which are environmentally less desirable.

(a) Give the electron configurations (using the noble gas notation) for Ce, Ce^{3+}, and Ce^{4+}.

(b) Is either Ce^{3+} or Ce^{4+} paramagnetic? If so, how many unpaired electrons does each have?

(c) The solid state structure for CeO_2 is shown below. Describe the unit cell of the compound. How is this structure related to the formula?

CeO_2

84. Neodymium is a component of powerful magnets.

(a) Neodymium has three common oxidation states: +2, +3, and +4. Give the electron configurations for Nd and its three positive oxidation states.

(b) Are any of the common Nd ions paramagnetic?

(c) Neodymium magnets, which are composed of Nd, Fe, and B, were developed because samarium-based magnets (SmCo) were very costly. What is the empirical formula for the neodymium-based magnet material if it is 26.68% Nd, 72.32% Fe, and the remainder B?

© Cengage Learning/Charles D. Winters

Neodymium magnets

In the Laboratory

85. Two different coordination compounds containing one cobalt(III) ion, five ammonia molecules, one bromide ion, and one sulfate ion exist. The dark violet form (A) gives a precipitate upon addition of aqueous $BaCl_2$. No reaction is seen upon addition of aqueous $BaCl_2$ to the violet-red form (B). Suggest structures for these two compounds, and write a chemical equation for the reaction of (A) with aqueous $BaCl_2$.

86. Three different compounds of chromium(III) with water and chloride ion have the same composition: 19.51% Cr, 39.92% Cl, and 40.57% H_2O. One of the compounds is violet and dissolves in water to give a complex ion with a 3+ charge and three chloride ions. All three chloride ions precipitate immediately as AgCl on adding $AgNO_3$. Draw the structure of the complex ion, and name the compound. Write a net ionic equation for the reaction of this compound with silver nitrate.

87. ▲ A 0.213-g sample of uranyl(VI) nitrate, $UO_2(NO_3)_2$, is dissolved in 20.0 mL of 1.0 M H_2SO_4 and shaken with Zn. The zinc reduces the uranyl ion, UO_2^{2+}, to a uranium ion, U^{n+}. To determine the value of n, this solution is titrated with $KMnO_4$. Permanganate is reduced to Mn^{2+} and U^{n+} is oxidized back to UO_2^{2+}.

(a) In the titration, 12.47 mL of 0.0173 M $KMnO_4$ was required to reach the equivalence point. Use this information to determine the charge on the ion U^{n+}.

(b) With the identity of U^{n+} now established, write a balanced net ionic equation for the reduction of UO_2^{2+} by zinc (assume acidic conditions).

(c) Write a balanced net ionic equation for the oxidation of U^{n+} to UO_2^{2+} by MnO_4^- in acid.

88. Fireworks contain $KClO_3$. To analyze a sample for the amount of $KClO_3$ a chemist first reacts the sample with excess iron(II),

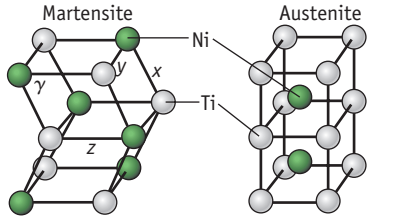
$$ClO_3^-(aq) + 6\ Fe^{2+}(aq) + 6\ H_3O^+(aq) \longrightarrow Cl^-(aq) + 9\ H_2O(\ell) + 6\ Fe^{3+}(aq)$$

and then titrates the resulting solution with Ce^{4+} [in the form of $(NH_4)_2Ce(NO_3)_6$]

$$Fe^{2+}(aq) + Ce^{4+}(aq) \longrightarrow Fe^{3+}(aq) + Ce^{3+}(aq)$$

to determine the quantity of iron(II) that did not react with ClO_3^-. (This is referred to as a "back titration.") Suppose a 0.1342-g sample of a firework was treated with 50.00 mL of 0.0960 M Fe^{2+}. The unreacted Fe^{2+} ions then required 12.99 mL of 0.08362 M Ce^{4+}. What is the weight percent of $KClO_3$ in the original sample?

Summary and Conceptual Questions



The following questions may use concepts from this and previous chapters.

89. Nitinol, a nickel-titanium alloy, is used in eyeglass frames or orthodontics. If you bend a pair of eyeglass frames out of shape, they snap back to the proper fit. That is the reason nitinol is often called "memory metal."

NASA/Science Source

Memory metal is an alloy with roughly the same number of Ni and Ti atoms. When the atoms are arranged in the highly symmetrical austenite phase, the alloy is relatively rigid. In this phase a specific shape is established that will be "remembered." If the alloy is cooled below its "phase transition temperature," it enters a less symmetrical but flexible phase (martensite). Below this transition temperature, the metal is fairly soft and may be bent and twisted out of shape. When warmed above the phase transition temperature, nitinol returns to its original shape. The temperature at which the change in shape occurs varies with small differences in the nickel-to-titanium ratio.

Two phases of nitinol. The austenite form has a structure like CsCl.

(a) What are the dimensions of the austenite unit cell? Assume the Ti and Ni atoms are just touching along the unit cell diagonal. (Atom radii: Ti = 145 pm; Ni = 125 pm.)

(b) Calculate the density of nitinol based on the austenite unit cell parameters. Does the calculated density of the austenite unit cell agree with the reported density of 6.5 g/cm^3?

(c) Are Ti and Ni atoms paramagnetic or diamagnetic?

90. ▲ In this question, we explore the differences between metal coordination by monodentate and bidentate ligands. Formation constants, K_f, for $[Ni(NH_3)_6]^{2+}(aq)$ and $[Ni(en)_3]^{2+}(aq)$ are as follows:

$$Ni^{2+}(aq) + 6\ NH_3(aq) \longrightarrow [Ni(NH_3)_6]^{2+}(aq) \qquad K_f = 10^8$$

$$Ni^{2+}(aq) + 3\ en(aq) \longrightarrow [Ni(en)_3]^{2+}(aq) \qquad K_f = 10^{18}$$

The difference in K_f between these complexes indicates a higher thermodynamic stability for the chelated complex, caused by the *chelate effect*. Recall that K is related to the standard free energy of the reaction by $\Delta_r G° = -RT \ln K$ and $\Delta_r G° = \Delta_r H° - T\Delta_r S°$. We know from experiment that $\Delta_r H°$ for the NH_3 reaction is -109 kJ/mol-rxn, and $\Delta_r H°$ for the ethylenediamine reaction is -117 kJ/mol-rxn. Is the difference in $\Delta_r H°$ sufficient to account for the 10^{10} difference in K_f? Comment on the role of entropy in the second reaction.

CHAPTER OUTLINE

23.1 Why Carbon?

23.2 Hydrocarbons

23.3 Alcohols, Ethers, and Amines

23.4 Compounds with a Carbonyl Group

23.5 Polymers

23.1 Why Carbon?

Goals for Section 23.1

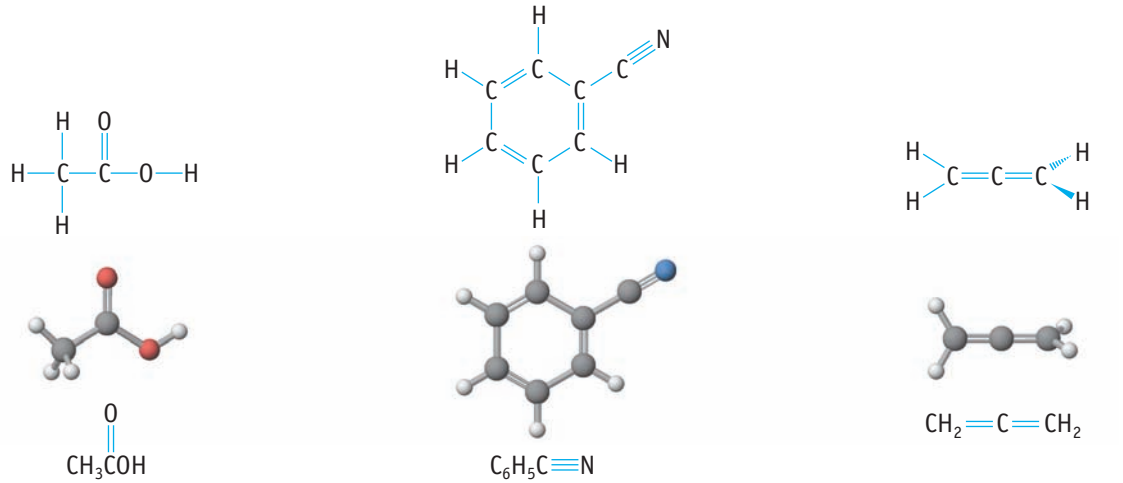
- Understand the factors that contribute to the large numbers of organic compounds and the wide array of structures.
- Recognize the types of isomerism that are seen in organic chemistry.

The vast majority of the millions of chemical compounds currently known are organic; that is, they are compounds built on a carbon framework. Organic compounds vary greatly in size and complexity, from the simplest hydrocarbon, methane (CH_4), to molecules made up of many thousands of atoms. We begin this discussion of organic chemistry with a question: What features of carbon lead to both the abundance and the complexity of organic compounds? The answer revolves around two main characteristics: structural diversity and stability.

Common and Systematic Names In organic chemistry many compounds have common names that came about when the field was developing. However, chemists have tried to standardize names, so systematic names are also used. For example, C_2H_4 is commonly called ethylene, but its systematic name is ethene.

Structural Diversity

With four electrons in its outer shell, carbon will form four bonds to reach an octet of electrons. In contrast, the elements boron and nitrogen generally form three bonds in molecular compounds; oxygen forms two bonds; and hydrogen and the halogens form one bond. With a larger number of bonds comes the opportunity to create more complex structures.



A carbon atom can reach an octet of electrons in various ways (Figure 23.1):

- *By forming four single bonds.* A carbon atom can bond to four other atoms, which can be either atoms of other elements (often H, N, or O) or other carbon atoms.
- *By forming a double bond and two single bonds.* The carbon atoms in ethene (ethylene), $H_2C{=}CH_2$, are linked in this way.
- *By forming two double bonds,* as in carbon dioxide (O=C=O).
- *By forming a triple bond and a single bond,* an arrangement seen in ethyne (acetylene), HC≡CH.

◀ **Cacao pods on a tree in an island in the Caribbean and the ultimate product.** The model is of theobromine, $C_7H_8N_4O_2$, one of many molecules in chocolate and a smooth muscle stimulator.

(a) Acetic acid. One carbon atom in this compound is attached to four other atoms by single bonds and has tetrahedral geometry. The second carbon atom, connected by a double bond to one oxygen and by single bonds to the other oxygen and to the first carbon, has trigonal-planar geometry.

(b) Benzonitrile. Six trigonal-planar carbon atoms make up the benzene ring. The seventh C atom, bonded by a single bond to carbon and a triple bond to nitrogen, has a linear geometry.

(c) Carbon is linked by double bonds to two other carbon atoms in C_3H_4, a linear molecule commonly called allene.

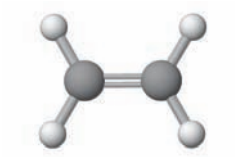

Figure 23.1 Ways that carbon atoms bond.

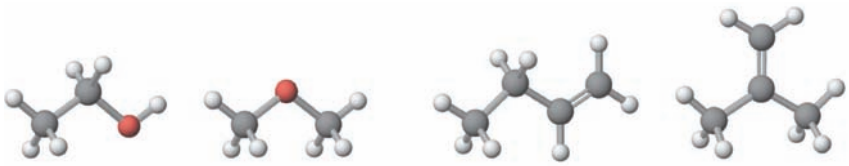
Recognize, with each of these arrangements, the various possible geometries around carbon: tetrahedral, trigonal-planar, and linear. Carbon's tetrahedral geometry is of special significance because it leads to three-dimensional chains and rings of carbon atoms, as in propane and cyclopentane.

propane, C_3H_8 cyclopentane, C_5H_{10}

Similarly, molecules with chain and ring structures are known in which there are double and triple bonds between carbon atoms.

ethene (ethylene), $H_2C{=}CH_2$

ethyne (acetylene), $HC{\equiv}CH$



Ethene and ethyne. These two-carbon hydrocarbons can be the building blocks of more complex molecules.

Isomers

Isomers are molecules that have the same molecular formula but different atom-to-atom connections or fill space in different ways. A hallmark of carbon chemistry is a remarkable array of isomers, two major groups being structural isomers and stereoisomers.

Isomers Isomers were discussed in the context of transition metal chemistry coordination compounds (page 1037).

Structural isomers are species with the same elemental composition but the atoms are linked together in different ways. For example, ethanol and dimethyl ether are structural isomers, as are 1-butene and 2-methylpropene.

ethanol — C_2H_6O — CH_3CH_2OH

dimethyl ether — C_2H_6O — CH_3OCH_3

1-butene — C_4H_8 — $CH_3CH_2CH{=}CH_2$

2-methylpropene — C_4H_8 — $CH_2{=}C(CH_3)CH_3$

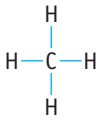
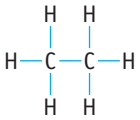
A CLOSER LOOK



Writing Formulas and Drawing Structures

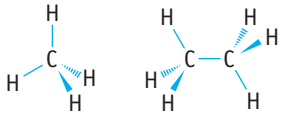
In Chapter 2, you learned that there are various ways of presenting structures (page 75). It is appropriate to return to this topic as we look at organic compounds. Consider methane and ethane, for example. We can represent these molecules in several ways:



(1) *Molecular formula:* CH_4 or C_2H_6. This type of formula gives information on composition only.

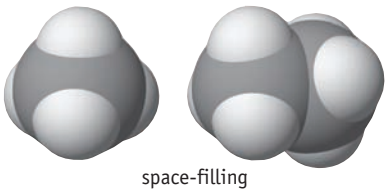
(2) *Condensed formula:* The formula for ethane is often written as CH_3CH_3. This method of writing the formula gives some information on the way atoms are connected.

(3) *Structural formula:* You will recognize this formula as the Lewis structure. An elaboration on the condensed formula in (2), this representation defines more clearly how the atoms are connected, but it fails to describe the shapes of molecules.



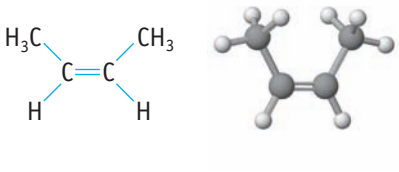
methane, CH_4

ethane, C_2H_6

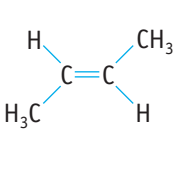


(4) *Perspective drawings:* These drawings are used to convey the three-dimensional nature of molecules. Bonds extending out of the plane of the paper are drawn with wedges, and bonds behind the plane of the paper are represented as dashed wedges. Using these guidelines, the structures of methane and ethane could be drawn as follows:

(5) *Computer-drawn ball-and-stick and space-filling models.*



ball-and-stick



space-filling

Stereoisomers are compounds with the same attachment of atoms but different orientation in space. There are two types of stereoisomers: geometric isomers and optical isomers.

Cis- and *trans*-2-butene are **geometric isomers**. Geometric isomerism in these compounds occurs as a result of the C═C double bond. *Recall that the carbon atom and the attached groups cannot rotate around a double bond* (page 424). The geometry around the C═C double bond is fixed in space. *Cis–trans* isomerism occurs if each carbon atom involved in the double bond has two different groups attached. If, on the adjacent carbons, it turns out that identical groups are on the same side of the double bond, then it is a *cis* isomer. If those groups appear on opposite sides, a *trans* isomer is produced.

cis-2-butene, C_4H_8

trans-2-butene, C_4H_8

Optical isomers are molecules that have nonsuperimposable mirror images (Figure 23.2). Molecules (and other objects) that have nonsuperimposable mirror images are termed **chiral**. Pairs of nonsuperimposable, mirror-image molecules are called **enantiomers**.

Pure samples of enantiomers have the same physical properties, such as melting point, boiling point, density, and solubility in common solvents. However, they differ in one significant way: When a beam of plane-polarized light passes through a solution of a pure enantiomer, the plane of polarization rotates. The two enantiomers rotate polarized light to an equal extent, but in opposite directions (Figure 22.18).

The most common examples of chiral organic compounds are those in which four different atoms (or groups of atoms) are attached to a tetrahedral carbon atom.

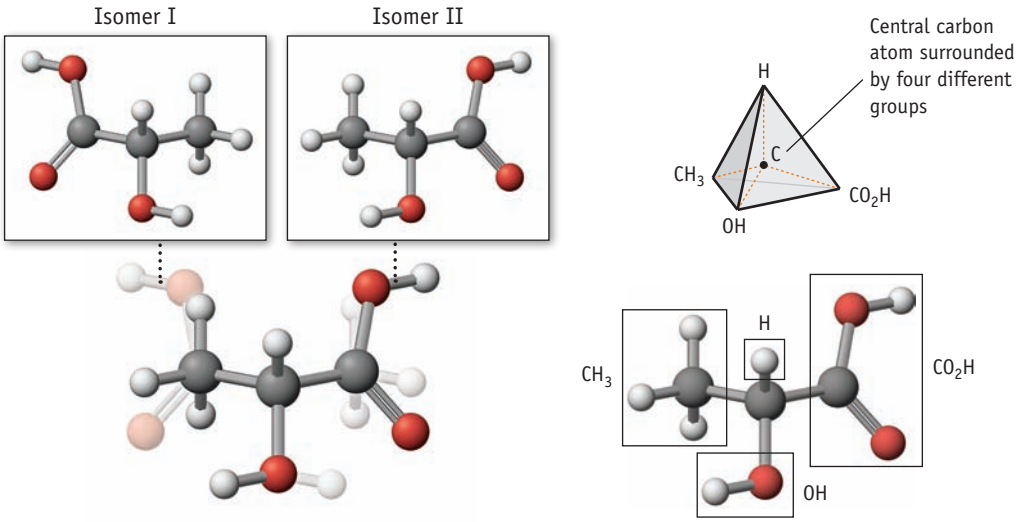

Figure 23.2 Optical isomers. Lactic acid, $CH_3CH(OH)CO_2H$, is produced when milk is fermented to make cheese. It is also found in other sour foods such as sauerkraut and is a preservative in pickled foods such as onions and olives. In our bodies, it is produced by muscle activity and normal metabolism.

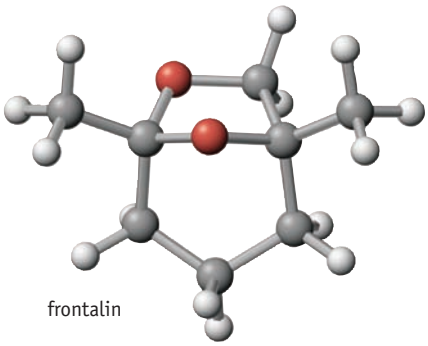
(a) Lactic acid enantiomers are nonsuperimposable, just as your right hand is not superimposable on your left hand.

(b) lactic acid, $CH_3CH(OH)CO_2H$



Chirality and Death Virtually all naturally occurring amino acids, the basis of proteins, are left-handed (Chapter 24), but right-handed amino acids exist. One such right-handed amino acid has been found to be the toxin in a strain of mushrooms in southern China, and the venom from a bite by a duck-billed platypus is based on a right-handed amino acid. See S. Everts, *Scientific American,* May 2013, pages 78–81.

Lactic acid, found in milk and a product of normal human metabolism, is an example of a chiral compound (Figure 23.2). Optical isomerism is particularly important in amino acids and other biologically important molecules. Among the many interesting examples of optically active compounds is frontalin, produced naturally by male elephants (Figure 23.3).

Stability of Carbon Compounds

Carbon compounds are notable for their resistance to chemical change. This resistance is a result of two things: strong bonds and slow reactions.

Strong bonds are needed for molecules to survive in their environment. Energetic collisions between molecules in gases, liquids, and solutions can provide enough energy to break some bonds, and bonds can be broken if the energy associated with photons of visible and ultraviolet light exceeds the bond energy. Carbon–carbon bonds are relatively strong, however, as are the bonds between carbon and most other atoms. The average C—C bond energy is 346 kJ/mol; the C—H bond energy is 413 kJ/mol; and carbon–carbon double and triple bond energies are even higher (Section 8.9). Contrast these values with bond energies for the Si—Si bond (222 kJ/mol) and the Si—H bond (328 kJ/mol). The consequence of high bond energies for bonds to carbon is that, for the most part, organic compounds do not decompose thermally under normal conditions.

One enantiomer of frontalin.

John C. Kotz

An African elephant. Fluid containing the enantiomers of frontalin flows from a gland between the elephant's eye and ear.

Figure 23.3 Chirality and elephants. During musth, a time of heightened sexual activity, male elephants produce a secretion containing the enantiomers of frontalin, $C_8H_{14}O_2$. Young males produce more of one enantiomer than the other, whereas older elephants produce a more balanced and more concentrated mixture. The secretion from older elephants repels other males while attracting ovulating female elephants.

Oxidation of most organic compounds is strongly product-favored, but most organic compounds survive continual and prolonged contact with O_2. The reason is that reactions of most organic compounds with oxygen are very slow. Typically, organic compounds burn only if their combustion is initiated by heat or by a spark. As a consequence, oxidative degradation is not a barrier to the existence of organic compounds.

23.2 Hydrocarbons

Goals for Section 23.2

- Draw structural formulas and name hydrocarbons.
- Recognize and draw structures of geometric isomers and optical isomers.
- Describe chemical and physical properties of hydrocarbons.

Hydrocarbons, compounds made only of carbon and hydrogen, are divided into several subgroups: alkanes, cycloalkanes, alkenes, alkynes, and aromatic compounds (Table 23.1).

Alkanes

Alkanes have the general formula C_nH_{2n+2}, with n having integer values (Table 23.2). Formulas of specific compounds can be generated from this formula, the first four of which are CH_4 (methane), C_2H_6 (ethane), C_3H_8 (propane), and C_4H_{10} (butane) (Figure 23.4). Methane has four hydrogen atoms arranged tetrahedrally around a single carbon atom. Replacing a hydrogen atom in methane by a —CH_3 group gives ethane. If an H atom of ethane is replaced by yet another —CH_3 group, propane results. Butane is derived from propane by replacing an H atom of one of the chain-ending carbon atoms with a —CH_3 group. In all of these compounds, each C atom is attached to four other atoms, either C or H, so alkanes are often called **saturated compounds**.

Petroleum Petroleum is a mixture of alkanes and other hydrocarbons. The petroleum industry is described briefly in Section 20.4.

TABLE 23.1 Some Types of Hydrocarbons

Type of Hydrocarbon	Characteristic Features	General Formula	Example
Alkanes	C—C single bonds and all C atoms have four single bonds	C_nH_{2n+2}	CH_4, methane C_2H_6, ethane
Cycloalkanes	C—C single bonds, C atoms arranged in a ring	C_nH_{2n}	C_6H_{12}, cyclohexane
Alkenes	C=C double bond	C_nH_{2n}	$H_2C{=}CH_2$, ethene
Alkynes	C≡C triple bond	C_nH_{2n-2}	HC≡CH, ethyne
Aromatics	Rings with π bonding extending over several C atoms	—	Benzene, C_6H_6

TABLE 23.2 Selected Hydrocarbons of the Alkane Family, C_nH_{2n+2}*

Name	Molecular Formula	State at Room Temperature
Methane	CH_4	Gas
Ethane	C_2H_6	
Propane	C_3H_8	
Butane	C_4H_{10}	
Pentane	C_5H_{12} (pent- = 5)	Liquid
Hexane	C_6H_{14} (hex- = 6)	
Heptane	C_7H_{16} (hept- = 7)	
Octane	C_8H_{18} (oct- = 8)	
Nonane	C_9H_{20} (non- = 9)	
Decane	$C_{10}H_{22}$ (dec- = 10)	
Octadecane	$C_{18}H_{38}$ (octadec- = 18)	Solid
Eicosane	$C_{20}H_{42}$ (eicos- = 20)	

*This table lists only selected straight-chain alkanes. At 25 °C straight-chain alkanes with 11–17 C atoms are liquid. Those with more than 17 C atoms are solid.

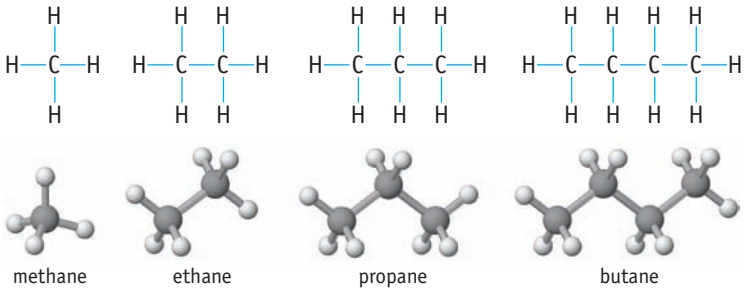

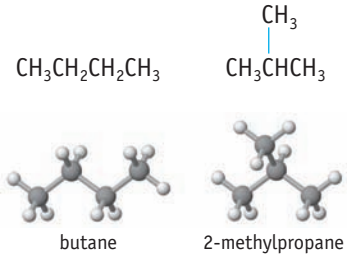

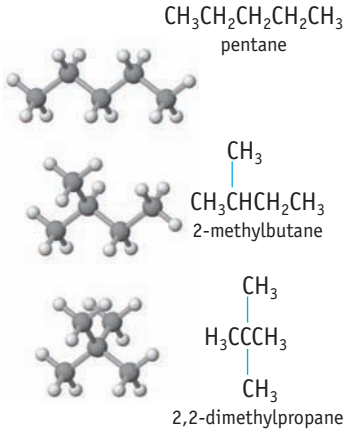

Figure 23.4 Alkanes. The lowest–molar-mass alkanes, all gases under normal conditions, are methane, ethane, propane, and butane.

Structural isomers of butane, C_4H_{10}

Structural isomers of pentane, C_5H_{12}

Structural Isomers

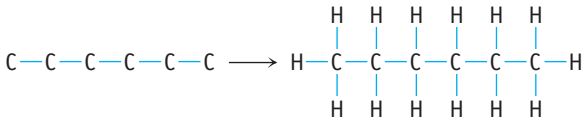
Structural isomers are possible for all alkanes larger than propane. For example, there are two structural isomers for C_4H_{10} and three for C_5H_{12}. As the number of carbon atoms in an alkane increases, the number of possible structural isomers greatly increases; there are five isomers possible for C_6H_{14} (Example 23.1), nine isomers for C_7H_{16}, 18 for C_8H_{18}, 75 for $C_{10}H_{22}$, and 1858 for $C_{14}H_{30}$.

To recognize the isomers corresponding to a given formula, keep in mind the following points:

- Each alkane has a framework of tetrahedral carbon atoms, and each carbon has four single bonds.
- An effective approach to deriving isomer structures is to create a framework of carbon atoms and then fill the remaining positions around carbon with H atoms so that each C atom has four bonds.
- Nearly free rotation occurs around carbon–carbon single bonds. Therefore, when atoms are assembled to form the skeleton of an alkane, the emphasis is on how carbon atoms are attached to one another and not on how they might lie relative to one another in the plane of the paper.

EXAMPLE 23.1

Drawing Structural Isomers of Alkanes

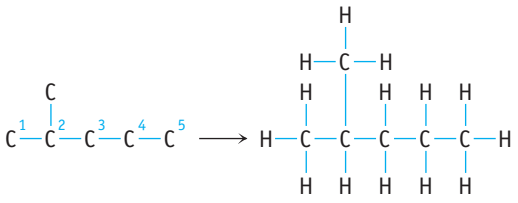


Problem Draw structures of the five isomers of C_6H_{14}. Are any of these isomers chiral?

What Do You Know? Each structure must have six carbon and 14 hydrogen atoms. There must be four single bonds to each carbon atom, and each hydrogen will form one bond.

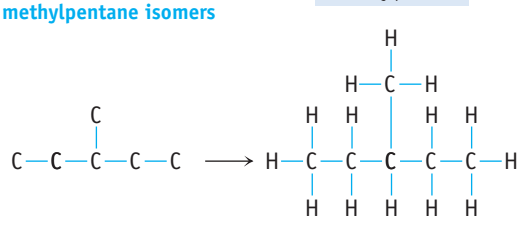
Strategy Focus first on the different frameworks that can be built from six carbon atoms. Having created a carbon framework, fill hydrogen atoms into the structure so that each carbon has four bonds.

SOLUTION



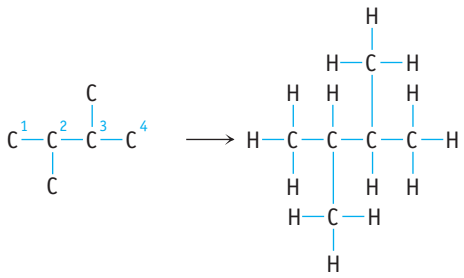
Step 1. *Placing six carbon atoms in a chain gives the framework for the first isomer. Now fill in hydrogen atoms: three on the carbons on the ends of the chain and two on each of the carbons in the middle. You have created the first isomer, hexane.*

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203



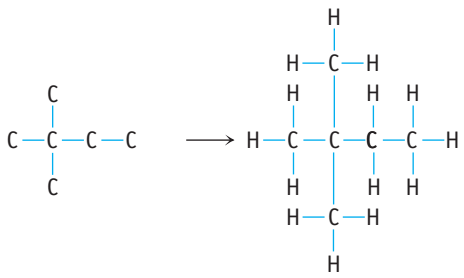
Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Step 2. *Draw a chain of five carbon atoms, then add the sixth carbon atom to one of the carbon atoms in the middle of this chain. (Adding it to a carbon at the end of the chain gives a six-carbon chain, the same framework drawn in Step 1.) Two different carbon frameworks can be built from the five-carbon chain, depending on whether the sixth carbon is linked to the 2 or 3 position. For each of these frameworks, fill in the hydrogens.*



carbon framework of methylpentane isomers

2-methylpentane



3-methylpentane

Step 3. *Draw a chain of four carbon atoms. Add in the two remaining carbons, again being careful not to extend the chain length. Two different structures are possible: one with the remaining carbon atoms in the 2 and 3 positions, and another with both extra carbon atoms attached at the 2 position. Fill in the 14 hydrogens. You have now drawn the fourth and fifth isomers.*

carbon atom frameworks for dimethylbutane isomers

2,3-dimethylbutane

2,2-dimethylbutane

None of the isomers of C_6H_{14} is chiral. *To be chiral, a compound must have at least one C atom with four different groups attached.* This condition is not met in any of these isomers.

Think about Your Answer Should you look for structures in which the longest chain is three carbon atoms? Try it, but you will see that it is not possible to add the three remaining carbons to a three-carbon chain without creating one of the carbon chains already drawn in a previous step. Thus, only five isomers of this compound are possible.

Names have been given to each of these compounds. See the text that follows this Example, and see Appendix E for guidelines on nomenclature.

Check Your Understanding

(a) Draw the nine isomers having the formula C_7H_{16}. (*Hint:* There is one structure with a seven-carbon chain, two structures with six-carbon chains [one is illustrated in the margin above], five structures with a five-carbon chain, and one structure with a four-carbon chain.)

(b) Identify the isomers of C_7H_{16} that are chiral.

Strategy Map 23.1

PROBLEM

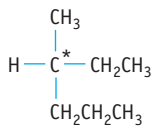
Draw ***structural isomers*** of an **alkane.**

DATA/INFORMATION

- The **formula** is known, so the *longest possible* **C atom chain** is known.

STEP 1. Draw the ***longest* C atom chain** possible.

Simplest **straight-chain alkane**



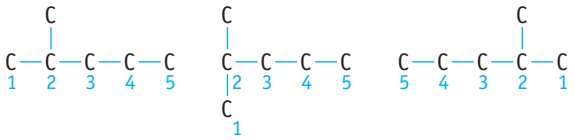
STEP 2. Draw C atom chain ***one atom shorter*** and place a C atom at other places on the chain. Fill in **H** atoms.

Alkane with **one less C atom** but with ***substituent group*** with **one C atom**

STEP 3. Draw ***shorter chains*** and place remaining C atoms at various positions on the chain.

Remaining isomers

Chirality in Alkanes To be chiral, *a compound must have at least one C atom attached to four* ***different*** *groups.* Thus, the C_7H_{16} isomer (3-methylhexane) is chiral.



The center of chirality is often indicated with an asterisk.

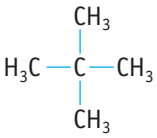
Problem Solving Tip 23.1 Drawing Structural Formulas



An error students sometimes make is to suggest that the three carbon skeletons drawn here are different. They are, in fact, the same. All are five-carbon chains with another C atom in the 2 position.

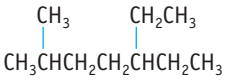
Remember that Lewis structures do not indicate the geometry of molecules.

Naming Alkanes

Systematic and Common Names The IUPAC (International Union of Pure and Applied Chemistry) has formulated rules for systematic names, which are generally used in this book (Appendix E). However, many organic compounds are known by common names. For example, 2,2-dimethylpropane is also called neopentane.

2,2-dimethylpropane

This isomer of C_5H_{12} has a three-carbon chain with two $—CH_3$ groups on the second C atom of the chain. Thus, its name is based on propane, and both $—CH_3$ groups are located at the 2 position.



With so many possible isomers for a given alkane, chemists need a systematic way of naming them. The guidelines for naming alkanes and their derivatives are:

- The names of alkanes end in "-ane."
- When naming a specific alkane, the root of the name corresponds to the longest carbon chain in the compound. (The names of alkanes with chains of 1 to 10 carbon atoms are given in Table 23.2. After the first four compounds, the names are derived from Greek and Latin numbers—pentane, hexane, heptane, octane, nonane, decane—and this regular naming continues for higher alkanes.)
- Substituent groups on a hydrocarbon chain are identified by a name and the position of substitution in the carbon chain; this information precedes the root of the name. The position is indicated by a number that refers to the carbon atom to which the substituent is attached. Numbering of the carbon atoms in a chain should begin at the end of the carbon chain that allows the first substituent encountered to have the lowest possible number. (If there is no distinction at this point, then number the carbon atoms so that the second substituent group has the lowest number.)
- Names of hydrocarbon substituents, called **alkyl groups**, are derived from the name of the hydrocarbon. The group $—CH_3$, derived by taking a hydrogen from methane, is called the *methyl* group; the $—C_2H_5$ group is the *ethyl* group.
- If two or more of the same substituent groups are present in the molecule, the prefixes di-, tri-, and tetra- are added. When different substituent groups are present, they are generally listed in alphabetical order.

EXAMPLE 23.2

Naming Alkanes

Problem Give the systematic name for

What Do You Know? You know the condensed formula and can recognize that the compound is an alkane. You also know the rules for naming alkanes.

Strategy (a) Identify the longest carbon chain and base the name of the compound on that alkane. (b) Identify the substituent groups on the chain and their locations. (c) When there are two or more substituents (the groups attached to the chain), number the parent chain from the end that gives the lower number to the substituent encountered first. (d) If the substituents are different, list them in alphabetical order.

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

SOLUTION Here, the longest chain has seven C atoms, so the root of the name is *heptane*. There is a methyl group (—CH_3) on C-2 and an ethyl group (—C_2H_5) on C-5. Giving the substituents in alphabetical order and numbering the chain from the end having the methyl group, the systematic name is 5-ethyl-2-methylheptane.

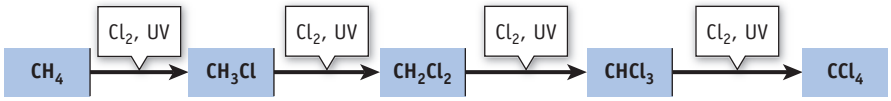
Think about Your Answer Notice that the carbon atoms in the longest chain are numbered so that the lower number is given to the substituent encountered first.

Check Your Understanding

Name the nine isomers of C_7H_{16} in "Check Your Understanding" in Example 23.1.

Properties of Alkanes

Methane, ethane, propane, and butane are gases at room temperature and pressure, whereas the higher-molar-mass compounds are liquids or solids (Table 23.2). There is also generally an increase in melting point and boiling point with molar mass in a series of similar compounds (Sections 11.4 and 11.6).



You already know about alkanes in a nonscientific context because several are common fuels. Natural gas, gasoline, kerosene, fuel oils, and lubricating oils are all mixtures of various alkanes. White mineral oil is also a mixture of alkanes, as is paraffin wax (Figure 23.5).

Pure alkanes are colorless and odorless. All are insoluble in water, a property typical of nonpolar compounds. Low polarity is expected for alkanes because the electronegativities of carbon ($\chi = 2.5$) and hydrogen ($\chi = 2.2$) are not greatly different (Section 8.8).

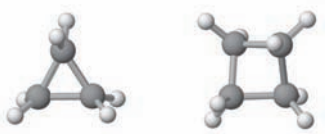
All alkanes burn readily in air to give CO_2 and H_2O in very exothermic reactions. This is, of course, the reason they are widely used as fuels.

$$CH_4(g) + 2\ O_2(g) \rightarrow CO_2(g) + 2\ H_2O(\ell) \qquad \Delta_r H° = -890.3\ \text{kJ/mol-rxn}$$

Other than in combustion reactions, alkanes exhibit relatively low chemical reactivity. One reaction that does occur, however, is the replacement of the hydrogen atoms of an alkane by chlorine atoms on reaction with Cl_2. It is formally an oxidation because Cl_2, like O_2, is a strong oxidizing agent. These reactions, which can be initiated by ultraviolet radiation, are free radical reactions (Section 14.7). Highly reactive Cl atoms are formed from Cl_2 under ultraviolet (UV) radiation. Reaction of methane with Cl_2 under these conditions proceeds in a series of steps, eventually yielding CCl_4, commonly known as carbon tetrachloride. (HCl is the other product of these reactions.)

Systematic name:	chloromethane	dichloromethane	trichloromethane	tetrachloromethane
Common name:	methyl chloride	methylene chloride	chloroform	carbon tetrachloride

The last three compounds are used as solvents, albeit infrequently anymore because of their toxicity.



Cycloalkanes, C_nH_{2n}

Cycloalkanes are constructed with tetrahedral carbon atoms joined together to form a ring. Cyclopropane and cyclobutane are the simplest cycloalkanes, although the bond angles in these species are much less than 109.5°. Chemists refer to these compounds as *strained hydrocarbons* because an unfavorable geometry is imposed around carbon. One of the features of strained hydrocarbons is that the C—C bonds are weaker and the molecules readily undergo ring-opening reactions that relieve the bond angle strain.

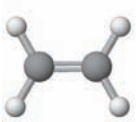
A CLOSER LOOK

Flexible Molecules

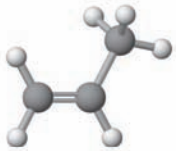
Most organic molecules are flexible; that is, they can twist and bend in various ways. Few molecules better illustrate this behavior than cyclohexane. Two structures are possible: "chair" and "boat" forms, which can interconvert by partial rotation of several bonds.

The more stable structure is the chair form, which allows the hydrogen atoms to remain as far apart as possible. A side view of this form of cyclohexane reveals two sets of hydrogen atoms in this molecule. Six hydrogen atoms, called the *equatorial hydrogens*, lie in a plane around the carbon ring. The other six hydrogens are positioned above and below the plane and are called *axial hydrogens.* Flexing the ring (a rotation around the C—C single bonds) moves the hydrogen atoms between axial and equatorial environments.

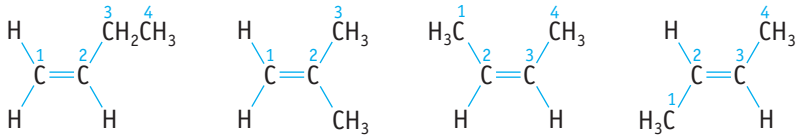


The most common cycloalkane is cyclohexane, C_6H_{12}, which has a nonplanar ring with six $—CH_2$ groups. If the carbon atoms in this compound were in the form of a regular hexagon with all carbon atoms in one plane, the C—C—C bond angles would be 120°. To have tetrahedral bond angles of 109.5° around each C atom, the ring has to pucker. The C_6 ring is flexible and exists in two interconverting forms (*A Closer Look: Flexible Molecules*).

Alkenes and Alkynes



The diversity seen for alkanes is repeated with **alkenes**, hydrocarbons with one or more C═C double bonds. The presence of a double bond adds two features missing in alkanes: the possibility of geometric isomerism and a higher degree of reactivity.



The general formula for alkenes with one double bond is C_nH_{2n}. The first two members of the series are ethene, C_2H_4 (common name, ethylene), and propene, C_3H_6 (common name, propylene). Only a single structure can be drawn for these compounds. As with alkanes, the occurrence of isomers begins with species containing four carbon atoms. Four alkene isomers have the formula C_4H_8, and each has distinct chemical and physical properties (Table 23.3). There are three structural isomers, one of which (2-butene, $CH_3CH═CHCH_3$) exists as stereoisomers.

C_2H_4
Systematic name: ethene
Common name: ethylene

C_3H_6
Systematic name: propene
Common name: propylene

Alkene names end in "-ene." As with alkanes, the root for the name of an alkene is determined by the longest carbon chain that contains the double bond. The position of the double bond is indicated with a number, and, when appropriate, the prefix *cis* or *trans* is added.

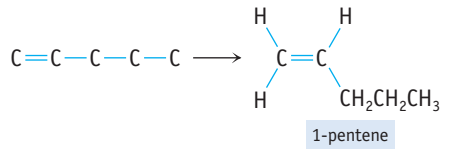
TABLE 23.3 Properties of Butene Isomers

Name	Boiling Point	Melting Point	Dipole Moment (D)	$\Delta_f H°$ (gas) (kJ/mol)
1-Butene	−6.26 °C	−185.4 °C	—	−0.63
2-Methylpropene	−6.95 °C	−140.4 °C	0.503	−17.9
Cis-2-butene	3.71 °C	−138.9 °C	0.253	−7.7
Trans-2-butene	0.88 °C	−105.5 °C	0	−10.8

Three of the C_4H_8 isomers have four-carbon chains and so are butenes. One has a three-carbon chain so the root of the name is propene. Notice that the carbon chain is numbered from the end that gives the double bond the lowest number. In the first isomer at the left, the double bond is between C atoms 1 and 2, so the name is 1-butene and not 3-butene.

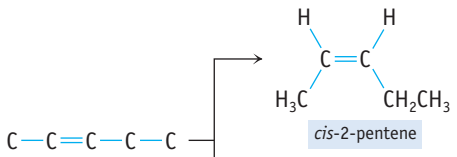
EXAMPLE 23.3

Determining Isomers of Alkenes from a Formula



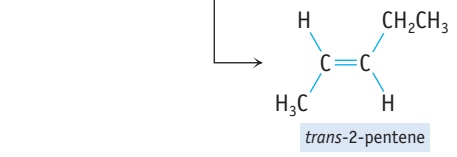
Problem Draw structures for the six possible alkene isomers with the formula C_5H_{10}. Give the systematic name of each.

What Do You Know? When linking the five carbon atoms, two will be joined with a double bond. Each carbon must have four bonds, and hydrogen atoms will fill the remaining positions.



Strategy A procedure that involved drawing the carbon skeleton and then adding hydrogen atoms worked well when drawing structures of alkanes (Example 23.1), and a similar approach can be used here. It will be necessary to put one double bond into the framework and to be alert for *cis-trans* isomerism.

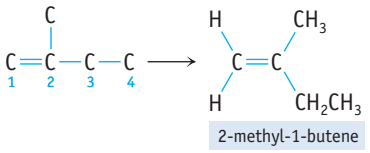
SOLUTION



Step 1. *A five-carbon chain with one double bond can be constructed in two ways. Cis–trans isomers are possible for 2-pentene.*

1-pentene

cis-2-pentene



trans-2-pentene

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

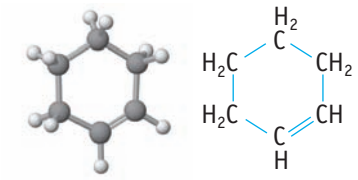
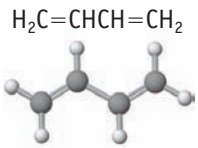
Step 2. *Draw the possible four-carbon chains containing a double bond. Add the fifth carbon atom to either the 2 or 3 position. When all the possible combinations are found, fill in the hydrogen atoms. This results in three more structures:*

2-methyl-1-butene

3-methyl-1-butene



2-methyl-2-butene



Think about Your Answer It is important to be very organized in your approach when drawing isomers. You should look carefully to see that each structure is unique, that is, that no two are the same.

Check Your Understanding

There are 17 possible alkene isomers with the formula C_6H_{12}. Draw structures of the five isomers in which the longest chain has six carbon atoms, and give the name of each. Are any of these isomers chiral? (There are also eight isomers in which the longest chain has five carbon atoms, and four isomers in which the longest chain has four carbon atoms. How many can you find?)

cyclohexene, C_6H_{10}

1,3-butadiene, C_4H_6

Cycloalkenes and dienes. Cyclohexene, C_6H_{10} (*top*) and 1,3-butadiene (C_4H_6) (*bottom*).

Hydrocarbons exist that have two or more double bonds. Butadiene, for example, has two double bonds and is known as a *diene*. Many natural products have numerous double bonds (Figure 23.6 and theobromine, page 1064). There are also cyclic hydrocarbons (cyclo alkenes), such as cyclohexene, with double bonds.

Alkynes, compounds with a carbon–carbon triple bond, have the general formula (C_nH_{2n-2}). Table 23.4 lists alkynes that have four or fewer carbon atoms. The

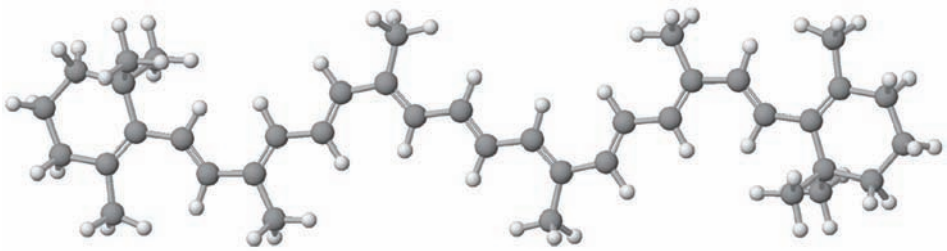

Figure 23.6 Carotene, a naturally occurring compound with 11 C=C bonds. The π electrons can be excited by visible light in the blue-violet region of the spectrum. As a result, carotene appears orange-yellow to the observer. Carotene or carotene-like molecules are partnered with chlorophyll in nature in the role of assisting in harvesting sunlight. Green leaves have a high concentration of carotene. In autumn, green chlorophyll molecules are destroyed, and the yellows and reds of carotene and related molecules are seen. The red color of tomatoes, for example, comes from a molecule very closely related to carotene. As a tomato ripens, its chlorophyll disintegrates, and the green color is replaced by the red of the carotene-like molecule.

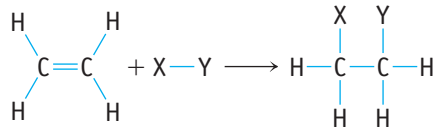
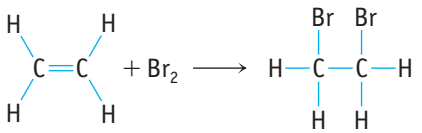
TABLE 23.4 Some Simple Alkynes C_nH_{2n-2}



Structure	Systematic Name	Common Name	BP (°C)
$HC{\equiv}CH$	ethyne	acetylene	−85
$CH_3C{\equiv}CH$	propyne	methylacetylene	−23
$CH_3CH_2C{\equiv}CH$	1-butyne	ethylacetylene	9
$CH_3C{\equiv}CCH_3$	2-butyne	dimethylacetylene	27

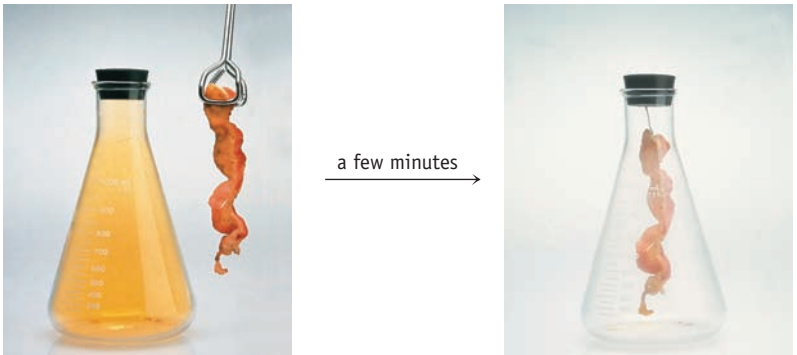
first member of this family is ethyne (common name, acetylene), a gas used as a fuel in metal cutting torches.

Properties of Alkenes and Alkynes



Like alkanes, alkenes and alkynes are colorless. Low–molar-mass compounds are gases, whereas compounds with higher molar masses are liquids or solids. Alkenes and alkynes are also oxidized by O_2 to give CO_2 and H_2O.

Alkenes and alkynes have an elaborate chemistry. We get some insight into their chemical behavior by knowing they are called **unsaturated compounds**. Carbon atoms are capable of bonding to a maximum of four other atoms, and they do so in alkanes and cycloalkanes. In alkenes, however, each carbon atom linked by a double bond is bonded to only three atoms. In alkynes, each carbon atom linked by a triple bond is bonded to only two atoms. It is possible to increase the number of groups attached to a carbon atom in an alkene or alkyne by **addition reactions**, in which molecules with the general formula X—Y (such as hydrogen, halogens, hydrogen halides, and water) add across the carbon–carbon double or triple bond (Figure 23.7). For an alkene the result is a compound with four groups bonded to each carbon.



X—Y = H_2, Cl_2, Br_2; H—Cl, H—Br, H—OH, HO—Cl

The products of some addition reactions are substituted alkanes. For example, the addition of bromine to ethene (ethylene) forms 1,2-dibromoethane.

1,2-dibromoethane

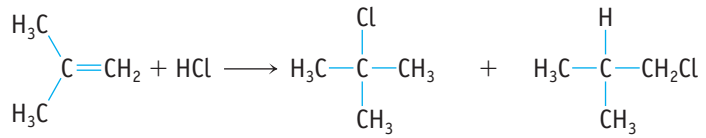
Nomenclature of Substituted Alkanes The substituent groups in substituted alkanes are identified by the name and position of the substituent on the alkane chain.



The addition of 2 mol of chlorine to ethyne (acetylene) gives 1,1,2,2-tetrachloroethane.

1,1,2,2-tetrachloroethane

Remembering Markovnikov's Rule One of the authors of this book was taught the sentence "Hydrogen goes where hydrogen is." For example, in the reaction of 2-methylpropene, H attaches to the carbon of the $=CH_2$ group.

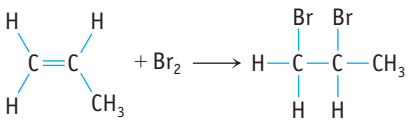
During the 1860s, the Russian chemist Vladimir Markovnikov examined a large number of alkene addition reactions. In cases in which two isomeric products were possible, he found that one was more likely to predominate. Based on these results, Markovnikov formulated *Markovnikov's rule*, which states that, when a reagent HX adds to an unsymmetrical alkene, the hydrogen atom in the reagent becomes attached to the carbon that already has the larger number of hydrogens. An example of Markovnikov's rule is the reaction of 2-methylpropene with HCl that results in formation of 2-chloro-2-methylpropane rather than 1-chloro-2-methylpropane.

2-methylpropene — 2-chloro-2-methylpropane (major product) — 1-chloro-2-methylpropane (minor product)

Catalysts A catalyst is a substance that causes a reaction to occur at a faster rate without itself being permanently changed in the reaction (Section 14.6).

If the reagent added to a double bond is hydrogen (X—Y = H_2), the reaction is called **hydrogenation**. Hydrogenation is usually a very slow reaction, but it can be speeded up by adding a catalyst, often a specially prepared form of a metal, such as platinum, palladium, or rhodium. You may have heard the term *hydrogenation* because certain foods contain "hydrogenated" or "partially hydrogenated" ingredients. One brand of crackers has a label that says, "Made with 100% pure vegetable shortening . . . (partially hydrogenated soybean oil with hydrogenated cottonseed oil)." One reason for hydrogenating an oil is to make it less susceptible to spoilage; another is to convert it from a liquid to a solid.

EXAMPLE 23.4



Reaction of an Alkene

Problem Draw the structure of the compound obtained from the reaction of Br_2 with propene, and name the compound.

What Do You Know? Propene is the three-carbon alkene. Addition reactions are among the most common reactions of alkenes, and bromine is one of several common reagents that adds to double bonds.

Strategy Bromine adds across the C=C double bond (Figure 23.7). The name of the product is based on the name of the carbon chain and indicates the positions of the Br atoms.

SOLUTION

propene — 1,2-dibromopropane

Think about Your Answer This reaction converts an unsaturated hydrocarbon to a substituted alkane. The reaction product is named as an alkane (propane) with substituents (Br atoms) identified by name and position on the three-carbon chain.

Check Your Understanding

(a) Draw the structure of the compound obtained from the reaction of HBr with ethylene, and name the compound.

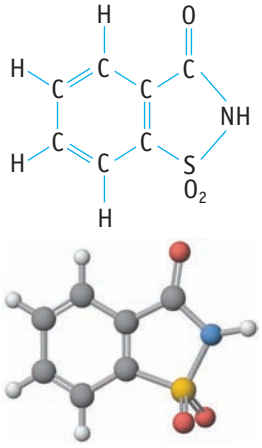
(b) Draw the structure of the product of the reaction of Br_2 with *cis*-2-butene, and name this compound.

Aromatic Compounds

Benzene, C_6H_6, is a key molecule in chemistry. It is the simplest **aromatic compound**, a class of compounds so named because they have significant, and usually not unpleasant, odors. Other members of this class, which are all based on benzene, include toluene and naphthalene. Coal is a source of many aromatic compounds. These compounds, along with other volatile substances, are released when coal is heated to a high temperature in the absence of air (Table 23.5).

benzene toluene naphthalene

Benzene occupies a pivotal place in the history and practice of chemistry. Michael Faraday discovered this compound in 1825 as a by-product in the formation of illuminating gas, a fuel produced by heating coal. Today, benzene is an important industrial chemical, usually ranking among the top 25 chemicals in production annually in the United States. It is used as a solvent and is also the starting point for making thousands of different compounds by replacing the H atoms of the ring.

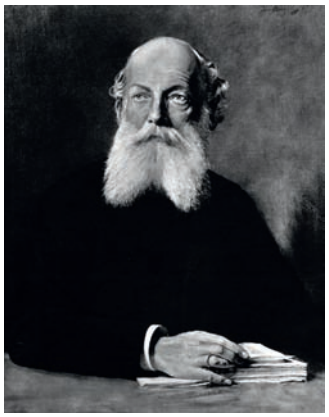


Toluene was originally obtained from tolu balsam, the pleasant-smelling gum of a South American tree, *Toluifera balsamum*. This balsam has been used in cough syrups and perfumes. Naphthalene is an ingredient in "moth balls," although 1,4-dichlorobenzene is now more commonly used. Aspartame and another artificial sweetener, saccharin, are also benzene derivatives.

The Structure of Benzene

The formula of benzene suggested to 19th-century chemists that this compound should be unsaturated, but, if viewed this way, its chemistry was perplexing. Whereas alkenes readily undergo addition reactions, benzene does not do so under

TABLE 23.5 Some Aromatic Compounds from Coal Tar



Common Name	Formula	Boiling Point (°C)	Melting Point (°C)
Benzene	C_6H_6	80	+6
Toluene	$C_6H_5CH_3$	111	−95
o-Xylene	$1,2\text{-}C_6H_4(CH_3)_2$	144	−25
m-Xylene	$1,3\text{-}C_6H_4(CH_3)_2$	139	−48
p-Xylene	$1,4\text{-}C_6H_4(CH_3)_2$	138	+13
Naphthalene	$C_{10}H_8$	218	+80

Saccharin ($C_7H_5NO_3S$). This compound, an artificial sweetener, contains an aromatic ring.

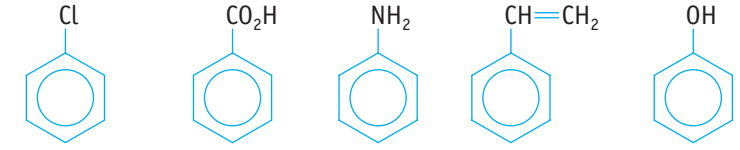
INTERFOTO/Alamy Stock Photo

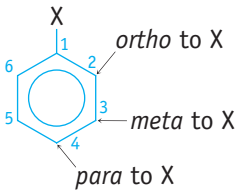
August Kekulé and the Structure of Benzene The structural question was solved by August Kekulé (1829–1896). Kekulé, one of the most prominent organic chemists in Europe in the late 19th century, argued for the ring structure with alternating double bonds based on the number of isomers possible for the structure. The legend in chemistry is that Kekulé proposed the ring structure after dreaming of a snake biting its tail.

Drawing Aromatic Rings When drawing benzene rings chemists often allow the vertices of the hexagon to represent the carbon atoms and do not show the H atoms attached to those carbon atoms. The circle inside the ring indicates the two resonance structures.

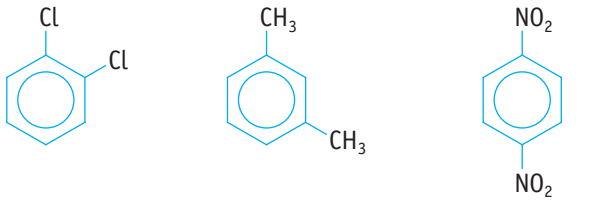


similar conditions. We now recognize that benzene's different reactivity relates to its structure and bonding, both of which are quite different from the structure and bonding in alkenes. Benzene has six equivalent carbon–carbon bonds, 139 pm in length, intermediate between a C—C single bond (154 pm) and a C═C double bond (134 pm). The π bonds are formed by the continuous overlap of the p orbitals on the six carbon atoms (Section 9.2). Using valence bond terminology, the structure is represented by two resonance structures.

representations of benzene, C_6H_6



Benzene Derivatives



Toluene, chlorobenzene, benzoic acid, aniline, styrene, and phenol are common benzene derivatives.

chlorobenzene benzoic acid aniline styrene phenol

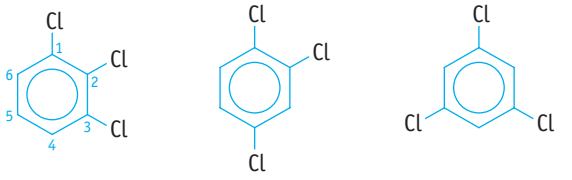
The systematic nomenclature for benzene derivatives with two or more substituent groups involves naming these groups and identifying their positions on the ring by numbering the six carbon atoms (Appendix E). Some common names, which are based on an older naming scheme, are also used. This scheme identified isomers of disubstituted benzenes with the prefixes *ortho* (*o*-, substituent groups on adjacent carbons in the benzene ring), *meta* (*m*-, substituents separated by one carbon atom), and *para* (*p*-, substituent groups on carbons on opposite sides of the ring).

Systematic name:	1,2-dichlorobenzene	1,3-dimethylbenzene	1,4-dinitrobenzene
Common name:	*o*-dichlorobenzene	*m*-xylene	*p*-dinitrobenzene

EXAMPLE 23.5

Isomers of Substituted Benzenes

Problem Draw and name the isomers of $C_6H_3Cl_3$.



What Do You Know? From the formula you can infer that $C_6H_3Cl_3$ is a substituted benzene with three hydrogen atoms replaced by chlorine atoms.

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Strategy Begin by drawing the carbon framework of benzene, and attach a chlorine atom to one of the carbon atoms. Place a second Cl atom on the ring in the *ortho, meta,* and *para* positions. Add the third Cl in one of the remaining positions, being careful not to repeat a structure already drawn.

SOLUTION The three isomers of $C_6H_3Cl_3$ are shown here. They are named as derivatives of benzene by specifying the number of substituent groups with the prefix "tri-," the name of the substituent, and the positions of the three groups around the six-member ring.

1,2,3-trichlorobenzene 1,2,4-trichlorobenzene 1,3,5-trichlorobenzene

Think about Your Answer Are there other possibilities? Try moving the chlorine atoms around in each isomer. In every case, you will find that moving one Cl atom to a different position generates one of these three isomers. For example, in the first structure, moving the Cl atom at position 1 to either position 5 or 6 leads to the second structure.

Check Your Understanding

Aniline, $C_6H_5NH_2$, is the common name for aminobenzene. Draw a structure for *p*-diaminobenzene, a compound used in dye manufacture. What is the systematic name for *p*-diaminobenzene?

Properties of Aromatic Compounds

Benzene is a colorless liquid, and simple substituted benzenes are liquids or solids under normal conditions. The properties of aromatic hydrocarbons are typical of hydrocarbons in general: They are insoluble in water, soluble in nonpolar solvents, and are oxidized by O_2 to form CO_2 and H_2O.

One of the most important properties of benzene and other aromatic compounds is an unusual stability that is associated with the unique π bonding in this molecule (Section 9.2 and Figure 9.11). Because the π bonding in benzene is typically described using resonance structures, the extra stability is termed **resonance stabilization**. The extent of resonance stabilization in benzene is evaluated by comparing the energy evolved in the hydrogenation of benzene to form cyclohexane

$$C_6H_6(\ell) + 3\ H_2(g) \xrightarrow{\text{catalyst}} C_6H_{12}(\ell) \qquad \Delta_r H° = -206.7\ \text{kJ/mol-rxn}$$

with the energy evolved in hydrogenation of three isolated double bonds.

$$3\ H_2C{=}CH_2(g) + 3\ H_2(g) \rightarrow 3\ C_2H_6(g) \qquad \Delta_r H° = -410.8\ \text{kJ/mol-rxn}$$

The hydrogenation of benzene is about 200 kJ/mol less exothermic than the hydrogenation of three moles of ethene, a difference attributable to the added stability associated with π bonding in benzene.

Although aromatic compounds are unsaturated hydrocarbons, they do not undergo the addition reactions typical of alkenes and alkynes. Instead, *substitution reactions* occur, in which one or more hydrogen atoms are replaced by other groups.

Such reactions require higher temperatures and a strong Brønsted acid such as H_2SO_4 or a Lewis acid such as $AlCl_3$ or $FeBr_3$.

Lewis Acids G. N. Lewis (page 353) defined an acid as an electron-pair acceptor (such as $AlCl_3$ and BF_3) (see Section 16.10).

$$\textit{Nitration:}\quad C_6H_6(\ell) + HNO_3(\ell) \xrightarrow{H_2SO_4} C_6H_5NO_2(\ell) + H_2O(\ell)$$

$$\textit{Alkylation:}\quad C_6H_6(\ell) + CH_3Cl(\ell) \xrightarrow{AlCl_3} C_6H_5CH_3(\ell) + HCl(g)$$

$$\textit{Halogenation:}\quad C_6H_6(\ell) + Br_2(\ell) \xrightarrow{FeBr_3} C_6H_5Br(\ell) + HBr(g)$$

23.3 Alcohols, Ethers, and Amines

Goals for Section 23.3

- Identify functional groups from organic formulas.
- Name and draw structures of alcohols and amines.
- Describe chemical properties of alcohols.

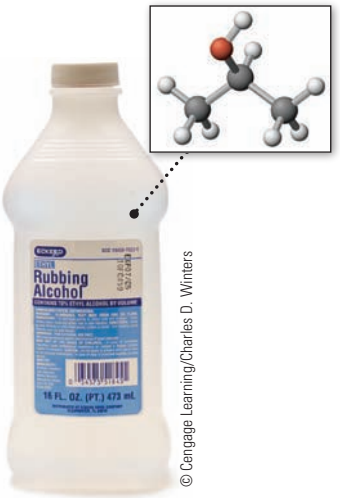
Organic compounds often contain other elements in addition to carbon and hydrogen. Two elements in particular, oxygen and nitrogen, add a rich dimension to carbon chemistry.

Organic chemistry organizes compounds containing elements other than carbon and hydrogen as derivatives of hydrocarbons. Formulas (and structures) are represented by substituting one or more hydrogens in a hydrocarbon molecule by a **functional group**. A functional group is an atom or group of atoms attached to a carbon atom in the hydrocarbon. Formulas of hydrocarbon derivatives are then written as R—X, in which R is a hydrocarbon lacking a hydrogen atom, and X is the functional group (such as —OH, $—NH_2$, a halogen atom, or $—CO_2H$) that has replaced the hydrogen. The chemical and physical properties of the hydrocarbon derivatives are a blend of the properties associated with hydrocarbons and the group that has been substituted for hydrogen.

Table 23.6 identifies some common functional groups and the families of organic compounds resulting from their attachment to a hydrocarbon.

TABLE 23.6 Common Functional Groups and Derivatives of Alkanes

Functional Group*	General Formula*	Class of Compound	Examples
F, Cl, Br, I	RF, RCl, RBr, RI	Haloalkane	CH_3CH_2Cl, chloroethane
OH	ROH	Alcohol	CH_3CH_2OH, ethanol
OR′	ROR′	Ether	$(CH_3CH_2)_2O$, diethyl ether
NH_2†	RNH_2	(Primary) Amine	$CH_3CH_2NH_2$, ethylamine
—CH (O)	RCHO	Aldehyde	CH_3CHO, ethanal (acetaldehyde)
—C(O)—R′	RCOR′	Ketone	CH_3COCH_3, propanone (acetone)
—C(O)—OH	RCO_2H	Carboxylic acid	CH_3CO_2H, ethanoic acid (acetic acid)
—C(O)—OR′	RCO_2R'	Ester	$CH_3CO_2CH_3$, methyl acetate
—C(O)—NH_2	$RCONH_2$	Amide	CH_3CONH_2, acetamide



*R and R′ can be the same or different hydrocarbon groups.
†Secondary amines (R_2NH) and tertiary amines (R_3N) are also possible; see discussion in the text.

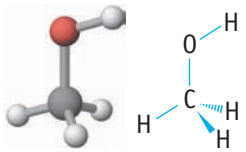
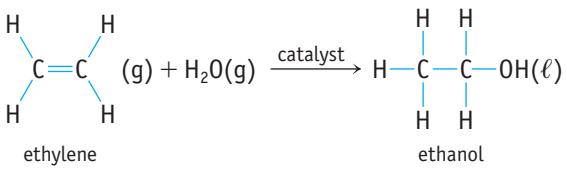
TABLE 23.7 Some Important Alcohols

Condensed Formula	BP (°C)	Systematic Name	Common Name	Use
CH_3OH	65.0	Methanol	Methyl alcohol	Fuel, gasoline additive, making formaldehyde
CH_3CH_2OH	78.5	Ethanol	Ethyl alcohol	Beverages, gasoline additive, solvent
$CH_3CH_2CH_2OH$	97.4	1-Propanol	Propyl alcohol	Industrial solvent
$CH_3CH(OH)CH_3$	82.4	2-Propanol	Isopropyl alcohol	Rubbing alcohol
$HOCH_2CH_2OH$	198	1,2-Ethanediol	Ethylene glycol	Antifreeze
$HOCH_2CH(OH)CH_2OH$	290	1,2,3-Propanetriol	Glycerol (glycerin)	Moisturizer in consumer products



Rubbing alcohol. Common rubbing alcohol is 2-propanol, also called *isopropyl alcohol.*

Alcohols and Ethers



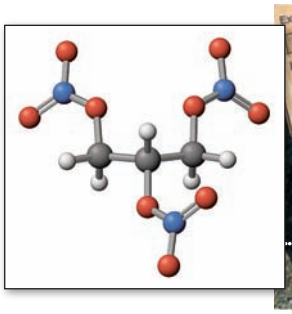
If one of the hydrogen atoms of an alkane is replaced by a hydroxyl group (—OH), the result is an **alcohol**, ROH. Methanol, CH_3OH, and ethanol, CH_3CH_2OH, are the most important alcohols, but others are also commercially important (Table 23.7). Notice that several have more than one OH functional group.

More than 5×10^8 kg of methanol is produced in the United States annually. Most of this is used to make formaldehyde (CH_2O) and acetic acid (CH_3CO_2H), both important industrial chemicals. Methanol is also used as a solvent, as a de-icer in gasoline, and as a fuel in high-powered racing cars. It is found in low concentration in new wine, where it contributes to the odor, or "bouquet." Like ethanol, methanol causes intoxication, but methanol differs in being more poisonous, largely because the human body converts it to formic acid (HCO_2H) and formaldehyde (CH_2O). These compounds attack the cells of the retina in the eye, leading to permanent blindness.

Methanol, CH_3OH, the simplest alcohol. Methanol is often called *wood alcohol* because it was originally produced by heating wood in the absence of air.

Ethanol is the "alcohol" of alcoholic beverages, in which it is formed by the anaerobic (without air) fermentation of sugar. On a much larger scale, ethanol for use as a fuel is made by fermentation of corn and other plant materials. Some ethanol (about 5%) is made from petroleum, by the reaction of ethylene and water.

Beginning with three-carbon alcohols, structural isomers are possible. For example, 1-propanol and 2-propanol (common names, propyl alcohol and isopropyl alcohol) are different compounds (Table 23.7).



Ethylene glycol and glycerol are common alcohols having two and three —OH groups, respectively. Ethylene glycol is used as antifreeze in automobiles. Glycerol's

Naming Alcohols Substitute "-ol" for the final "-e" in the name of the hydrocarbon, and designate the position of the —OH group by the number of the carbon atom. For example, $CH_3CH_2CHOHCH_3$ is named as a derivative of butane. The —OH group is attached to the second carbon, so the name is 2-butanol.

(a) **(b)** **(c)**

Concentrated nitric acid and glycerin react to form an oily, highly unstable compound called *nitroglycerin*, $C_3H_5(ONO_2)_3$. It is more stable if absorbed onto an inert solid, a combination called *dynamite*.

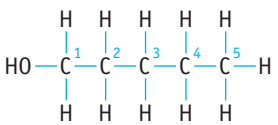
The fortune of Alfred Nobel (1833–1896), built on the manufacture of dynamite, now funds the Nobel Prizes.

most common use is as a softener in soaps and lotions. It is also a raw material for the preparation of nitroglycerin (Figure 23.8).

Systematic name:	1,2-ethanediol	1,2,3-propanetriol
Common name:	ethylene glycol	glycerol or glycerin

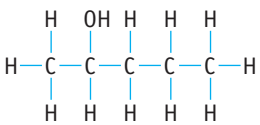
Ethers have the general formula ROR′. The best-known ether is diethyl ether, $CH_3CH_2OCH_2CH_3$. Lacking an —OH group, the properties of ethers are in sharp contrast to those of alcohols. Diethyl ether, for example, has a lower boiling point (34.5 °C) than ethanol, CH_3CH_2OH (78.3 °C), and is only slightly soluble in water.

EXAMPLE 23.6



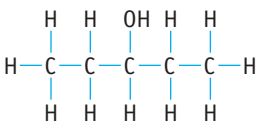
Structural Isomers of Alcohols

Problem How many different alcohols with one —OH group are derivatives of pentane? Draw their structures, and name each alcohol.



What Do You Know? The formula for pentane is C_5H_{12}. In an alcohol an —OH group will replace one H atom.

Strategy Pentane, C_5H_{12}, has a five-carbon chain. An —OH group can replace a hydrogen atom on one of the carbon atoms. Alcohols are named as derivatives of the alkane (pentane) by replacing the "-e" at the end with "-ol" and indicating the position of the —OH group by a numerical prefix (Appendix E).



SOLUTION Three different alcohols are possible, depending on whether the —OH group is placed on the first, second, or third carbon atom in the chain. (The fourth and fifth positions are identical to the second and first positions in the chain, respectively.)

1-pentanol

2-pentanol

3-pentanol

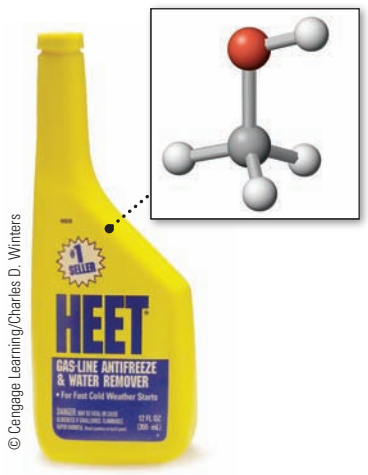
Think about Your Answer Additional structural isomers with the formula $C_5H_{11}OH$ are possible in which the longest carbon chain has three C atoms (one isomer) or four C atoms (four isomers).

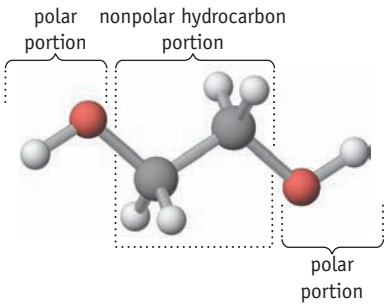
Check Your Understanding

Draw the structure of 1-butanol and alcohols that are structural isomers of the compound.



Properties of Alcohols

Methane, CH_4, is a gas (boiling point, −161 °C) with low solubility in water. Methanol, CH_3OH, by contrast, is a liquid that is *miscible* with water in all proportions. The boiling point of methanol, 65 °C, is 226 °C higher than the boiling point of methane. What a difference the addition of a single atom into the structure can make in the properties of simple molecules!



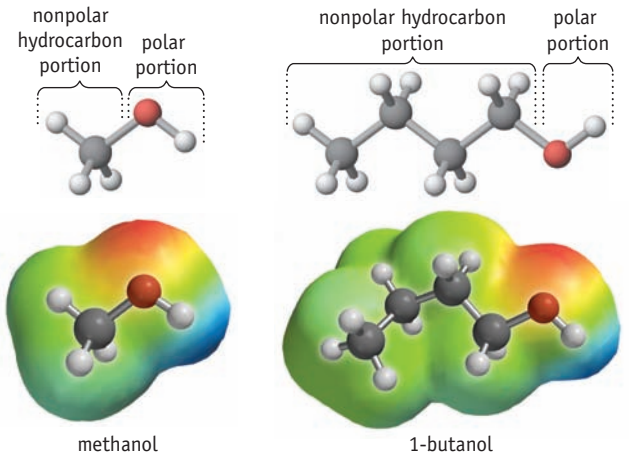
Alcohols are related to water, with one of the H atoms of H_2O being replaced by an organic group. If a methyl group is substituted for one of the hydrogens of water, methanol results. Ethanol has a $—C_2H_5$ (ethyl) group, and propanol has a $—C_3H_7$ (propyl) group in place of one of the hydrogens of water. Viewing alcohols as related to water helps in understanding their properties.

The two parts of methanol, the $—CH_3$ group and the —OH group, contribute to its properties. For example, methanol will burn, a property associated with hydrocarbons. On the other hand, its boiling point is more like that of water. The temperature at which a substance boils is related to intermolecular forces, the forces of attraction between molecules. The stronger the attractive, intermolecular forces in a sample, the higher the boiling point (Section 11.3). These forces are particularly strong in water, a result of the polarity of the —OH group in this molecule (Section 8.8). Methanol is also a polar molecule, and it is the polar —OH group that leads to a high boiling point. In contrast, methane is nonpolar and its low boiling point is the result of weak intermolecular forces.

It is also possible to explain the differences in the solubility of methane, methanol, and other alcohols in water (Figure 23.9). The solubility of methanol and ethylene glycol is conferred by the polar —OH portion of the molecule. Methane, which is nonpolar, has low water solubility.

Methanol is often added to automobile gasoline tanks in the winter to prevent water in the fuel lines from freezing. It is soluble in water and lowers the water's freezing point.

Ethylene glycol is used in automobile radiators. It is soluble in water, and lowers the freezing point and raises the boiling point of the water in the cooling system. (Section 13.4.)



Ethylene glycol, a major component of automobile antifreeze, is completely miscible with water.

Figure 23.9 Properties and uses of two alcohols, methanol and ethylene glycol.

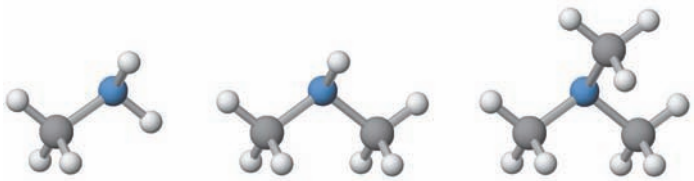
As the size of the alkyl group in an alcohol increases, the alcohol boiling point rises, a general trend seen in families of similar compounds and related to molar mass (Table 23.7). The solubility in water in this series decreases. Methanol and ethanol are completely miscible in water, whereas 1-propanol is moderately water soluble; 1-butanol is less soluble than 1-propanol. With an increase in the size of the hydrocarbon group, the organic group (the nonpolar part of the molecule) has become a larger fraction of the molecule, and properties associated with nonpolarity begin to dominate. Space-filling models show that in methanol, the polar and nonpolar parts of the molecule are approximately similar in size, but in 1-butanol the —OH group is less than 20% of the molecule. The molecule is less like water and more "organic." Electrostatic potential surfaces amplify this point.

Amines



Electrostatic potential surface for methylamine. The surface for methylamine shows that this water-soluble amine is polar with the partial negative charge on the N atom.

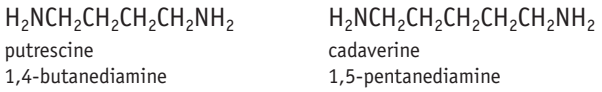
It is often convenient to think about water and ammonia as being similar molecules: They are the simplest hydrogen compounds of adjacent second-period elements. Both are polar and exhibit some similar chemistry, such as protonation (to give H_3O^+ and NH_4^+) and deprotonation (to give OH^- and NH_2^-).

This comparison of water and ammonia can be extended to alcohols and amines. Alcohols have formulas related to water in which one hydrogen in H_2O is replaced with an organic group (R—OH). In organic **amines**, one or more hydrogen atoms of NH_3 are replaced with an organic group. Amine structures are similar to ammonia's structure; that is, the geometry about the N atom is trigonal pyramidal.

Amines are categorized based on the number of organic substituents as *primary* (one organic group), *secondary* (two organic groups), or *tertiary* (three organic groups). As examples, consider the three amines with methyl groups: CH_3NH_2, $(CH_3)_2NH$, and $(CH_3)_3N$.

CH_3NH_2
primary amine
methylamine

$(CH_3)_2NH$
secondary amine
dimethylamine



$(CH_3)_3N$
tertiary amine
trimethylamine

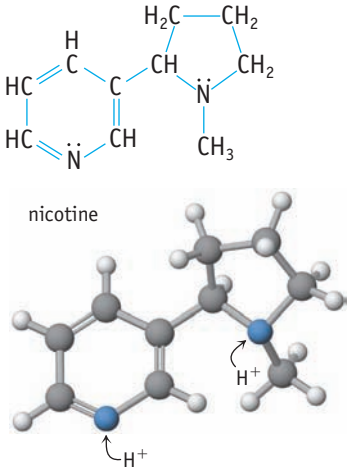
Properties of Amines

Amines usually have offensive odors. You know what the odor is if you have ever smelled decaying fish. Two appropriately named amines, putrescine and cadaverine, add to the odor of urine, rotten meat, and bad breath.

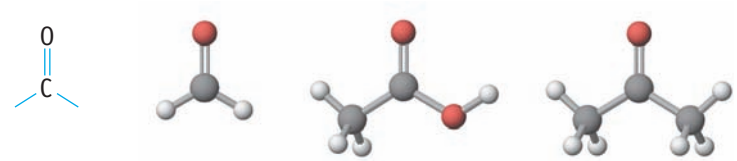


The smallest amines are water soluble, but most amines are not. All amines are bases, however, and they react with acids to give salts, many of which are water soluble. As with ammonia, the reactions involve adding H^+ to the lone pair of electrons on the N atom. This is illustrated by the reaction of aniline (aminobenzene) with H_2SO_4 to give the anilinium cation.

The facts that an amine can be protonated and that the proton can be removed again by treating the compound with a base have practical and physiological importance. Nicotine in cigarettes is normally found in the protonated form. (This water-soluble form is also used often in insecticides.) Adding a base such as ammonia removes the H^+ ion to leave nicotine in its "free-base" form.

$$NicH_2^{2+}(aq) + 2\ NH_3(aq) \rightarrow Nic(aq) + 2\ NH_4^+(aq)$$

In this form, nicotine is much more readily absorbed by the skin and mucous membranes, so the compound is a much more potent poison.

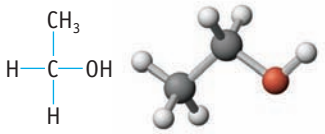


Nicotine, an amine. Two nitrogen atoms in the nicotine molecule can be protonated, which is the form in which nicotine is normally found. The protons can be removed, by treating it with a base. This "free-base" form is much more poisonous and addictive.

23.4 Compounds with a Carbonyl Group

Goals for Section 23.4

- Name and draw structures of carbonyl compounds—aldehydes, ketones, acids, esters, and amides.
- Describe reactions of carbonyl compounds.



Formaldehyde, acetic acid, and acetone are important organic compounds, and they share a common structural feature: Each contains a trigonal-planar carbon atom doubly bonded to an oxygen. The C═O group is called the **carbonyl group**, and these compounds are members of a large class of compounds called **carbonyl compounds**.

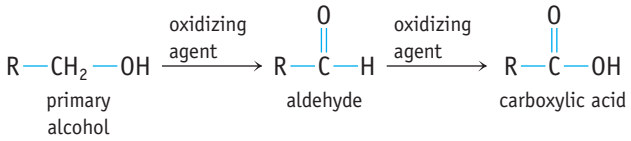
Primary alcohol: ethanol

Secondary alcohol: 2-propanol

Tertiary alcohol: 2-methyl-2-propanol

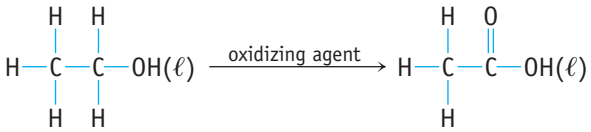


In this section, we will examine five groups of carbonyl compounds (Table 23.6):

- *Aldehydes* (RCHO) have an organic group (—R) and an H atom attached to a carbonyl group.
- *Ketones* (RCOR′) have two —R groups attached to the carbonyl carbon; they may be the same organic groups, as in acetone, or different groups.
- *Carboxylic acids* (RCO_2H) have an —R group and an —OH group attached to the carbonyl carbon.
- *Esters* (RCO_2R') have —R and —OR′ groups attached to the carbonyl carbon.
- *Amides* ($RCONR_2'$, RCONHR′, and $RCONH_2$) have an —R group and an amino group ($—NH_2$, —NHR, $—NR_2$) bonded to the carbonyl carbon.

Aldehydes, ketones, and carboxylic acids are oxidation products of alcohols and are commonly made by this route. The product obtained through oxidation of an alcohol depends on the alcohol's structure, which is classified according to the number of carbon atoms bonded to the C atom bearing the —OH group. *Primary alcohols* have one carbon and two hydrogen atoms attached, whereas *secondary alcohols* have two carbon atoms and one hydrogen atom attached. *Tertiary alcohols* have three carbon atoms attached to the C atom bearing the —OH group.

A *primary alcohol* is oxidized in two steps, first to an aldehyde and then to a carboxylic acid:



© Cengage Learning/Charles D. Winters

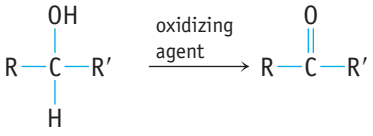


Figure 23.10 Alcohol tester. This device for testing a person's breath for the presence of ethanol relies on the oxidation of the alcohol. If present, ethanol is oxidized by potassium dichromate, $K_2Cr_2O_7$, to acetaldehyde and then to acetic acid. The yellow-orange dichromate ion is reduced to green $Cr^{3+}(aq)$, with the color change indicating that ethanol was present.

For example, the air oxidation of ethanol in wine ultimately produces wine vinegar, the most important ingredient of which is acetic acid.

Acids have a sour taste. The word "vinegar" (from the French *vin aigre*) means sour wine. A device to test a person's breath for alcohol relies on the oxidation of ethanol (Figure 23.10).

Oxidation of a *secondary alcohol* produces a ketone:

(—R and —R′ are organic groups. They may be the same or different.)

Common oxidizing agents used for these reactions are reagents such as $KMnO_4$ and $K_2Cr_2O_7$ (Table 3.3).

Finally, tertiary alcohols do *not* react with the usual oxidizing agents.

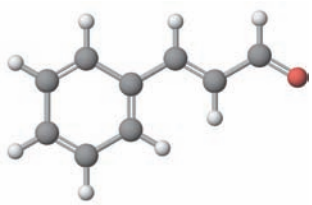
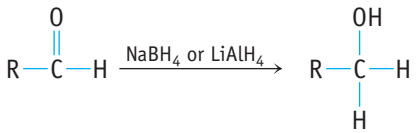
TABLE 23.8 Simple Aldehydes and Ketones



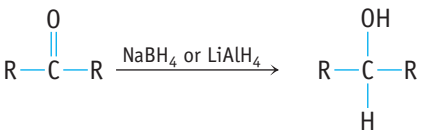
Structure	Common Name	Systematic Name	BP (°C)
$HCH(=O)$	Formaldehyde	Methanal	−19
$CH_3CH(=O)$	Acetaldehyde	Ethanal	20
$CH_3CCH_3(=O)$	Acetone	Propanone	56
$CH_3CCH_2CH_3(=O)$	Methyl ethyl ketone	Butanone	80
$CH_3CH_2CCH_2CH_3(=O)$	Diethyl ketone	3-Pentanone	102

Aldehydes and Ketones

Aldehydes and **ketones** can have pleasant odors and are often used in fragrances. Benzaldehyde is responsible for the odor of almonds and cherries; cinnamaldehyde is found in the bark of the cinnamon tree; and the ketone 4-(*p*-hydroxyphenyl)-2-butanone is responsible for the odor of ripe raspberries (a favorite of the authors of this book). Table 23.8 lists several simple aldehydes and ketones.



benzaldehyde, C_6H_5CHO



trans-cinnamaldehyde, $C_6H_5CH{=}CHCHO$

Aldehydes and ketones are the oxidation products of primary and secondary alcohols, respectively. The reverse reactions—reduction of aldehydes to primary alcohols and reduction of ketones to secondary alcohols—are also known. Commonly used reagents for such reductions are $NaBH_4$ and $LiAlH_4$, although H_2 is used on an industrial scale.

aldehyde — primary alcohol

ketone — secondary alcohol

Problem Solving Tip 23.2 Naming Aldehydes, Ketones, and Carboxylic Acids

Aldehydes: Substitute "-al" for the final "-e" in the name of the hydrocarbon. The carbon atom of an aldehyde is, by definition, carbon-1 in the hydrocarbon chain. For example, $CH_3CH(CH_3)CH_2CH_2CHO$ contains a 5-carbon chain with the aldehyde functional group being carbon-1 and the $—CH_3$ group at position 4; thus, the name is *4-methylpentanal*.

Ketones: Substitute "-one" for the final "-e" in the name of the hydrocarbon. The position of the ketone functional group (the carbonyl group) is indicated by the number of the carbon atom. For example, the compound $CH_3COCH_2CH(C_2H_5)CH_2CH_3$ has the carbonyl group at the 2 position and an ethyl group at the 4 position of a 6-carbon chain; its name is *4-ethyl-2-hexanone*.

Carboxylic acids (organic acids): Substitute "-oic" for the final "-e" in the name of the hydrocarbon. The carbon atoms in the longest chain are counted beginning with the carboxylic carbon atom. For example, *trans*-$CH_3CH{=}CHCH_2CO_2H$ is named as a derivative of *trans*-3-pentene, that is, *trans-3-pentenoic acid*.

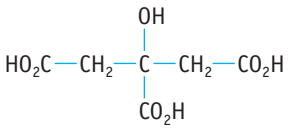
Carboxylic Acids

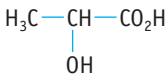
Acetic acid is the most common and most important **carboxylic acid**. For many years, acetic acid was made by oxidizing ethanol produced by fermentation. Now, however, most of the acetic acid for industrial use is made by combining carbon monoxide and methanol in the presence of a catalyst:

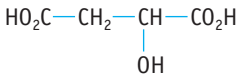
$$\underset{\text{methanol}}{CH_3OH(\ell)} + CO(g) \xrightarrow{\text{catalyst}} \underset{\text{acetic acid}}{CH_3CO_2H(\ell)}$$

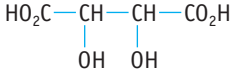
About 1 billion kilograms of acetic acid are produced annually in the United States for use in plastics, synthetic fibers, and fungicides.

Acids are recognizable by their sour taste (Figure 23.11) and occur naturally in common foods: Citric acid in fruits, acetic acid in vinegar, and tartaric acid in grapes are just three examples (Table 23.9).







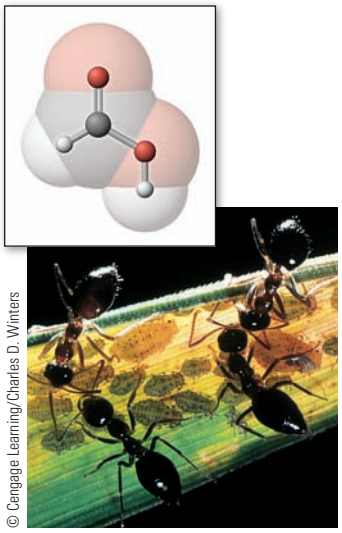


Some carboxylic acids have common names derived from the source of the acid (Tables 23.9 and 23.10). Because formic acid is found in ants, its name comes from

© Cengage Learning/Charles D. Winters

Figure 23.11 Acetic acid in bread. Acetic acid is produced in bread leavened with the yeast *Saccharomyces exiguus*. Another group of bacteria, *Lactobacillus sanfrancisco*, contributes to the flavor of sourdough bread. These bacteria metabolize the sugar maltose, excreting acetic acid and lactic acid, $CH_3CH(OH)CO_2H$, thereby giving the bread its unique sour taste.

TABLE 23.9 Some Naturally Occurring Carboxylic Acids



Name	Structure	Natural Source
Benzoic acid		Berries
Citric acid		Citrus fruits
Lactic acid		Sour milk
Malic acid		Apples
Oleic acid		Vegetable oils
Oxalic acid		Rhubarb, spinach, cabbage, tomatoes
Stearic acid		Animal fats
Tartaric acid		Grape juice, wine

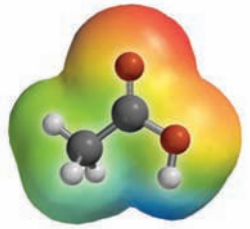
Formic acid, HCO_2H. This acid puts the sting in ant bites.



the Latin word for ant *(formica)*. Butanoic acid (commonly called butyric acid) gives rancid butter its unpleasant odor, and the name is related to the Latin word for butter (*butyrum*).

Because of the substantial electronegativity of oxygen, the two O atoms of the carboxylic acid group are slightly negatively charged, and the H atom of the —OH group is partially positively charged. This charge distribution has several important implications:

- The polar acetic acid molecule dissolves readily in water, which you already know because vinegar is an aqueous solution of acetic acid. (Acids with larger organic groups are less soluble, however.)
- The hydrogen of the —OH group is the acidic hydrogen. Recall that acetic acid is a weak acid in water, as are most other organic acids.

Carboxylic acids undergo a number of reactions. Among these is the reduction of the acid (with reagents such as $LiAlH_4$ or $NaBH_4$) first to an aldehyde and then to an alcohol. For example, acetic acid is reduced first to acetaldehyde and then to ethanol.

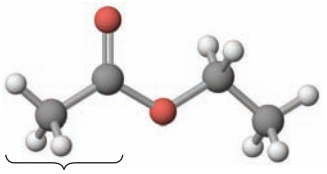
Acetic acid. The H atom of the carboxylic acid group (—CO_2H) is the acidic proton of this and other carboxylic acids.

$$CH_3CO_2H \xrightarrow{LiAlH_4} CH_3CHO \xrightarrow{LiAlH_4} CH_3CH_2OH$$

acetic acid — acetaldehyde — ethanol

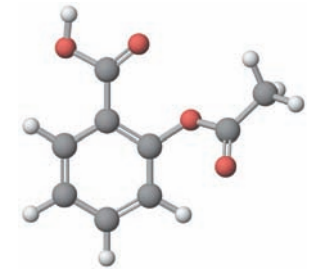
Yet another important aspect of carboxylic acid chemistry is the reaction with bases to give carboxylate anions. For example, acetic acid reacts with hydroxide ions to give acetate ions and water.

$$CH_3CO_2H(aq) + OH^-(aq) \rightarrow CH_3CO_2^-(aq) + H_2O(\ell)$$



Esters

Esters are the product of the reaction of an acid with an alcohol. Such reactions, called **esterification** reactions, are usually carried out with an acid catalyst (such as HCl). These reactions do not go to completion, but instead produce an equilibrium mixture of the reactants and products. To obtain the ester in good yield, the reaction



Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

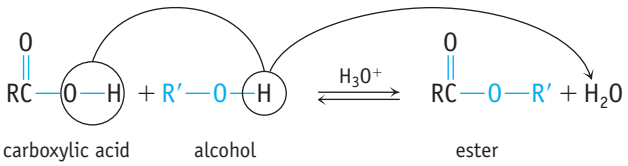
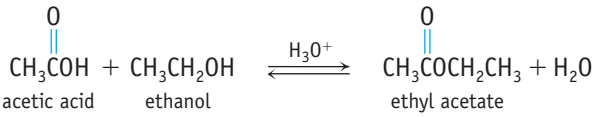
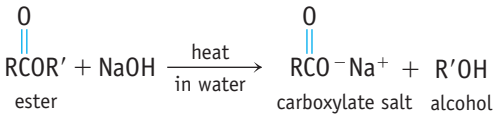
can be forced to completion. One way to do this is to remove water from the system (for example, by distilling it from the reaction mixture); this causes the equilibrium to shift to the right, thus forming more of the ester.

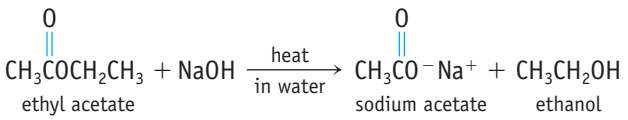




ethyl acetate, an ester
$CH_3CO_2CH_2CH_3$

Aspirin, a commonly used analgesic. It is based on benzoic acid with an acetate group, $—O_2CCH_3$, in the *ortho* position. Aspirin has both carboxylic acid and ester functional groups.





In these reactions the O atom of the alcohol ends up as part of the ester. This is known from isotope labeling experiments. If the reaction is run using an alcohol in which the alcohol oxygen is ^{18}O, all of the ^{18}O ends up in the ester molecule.

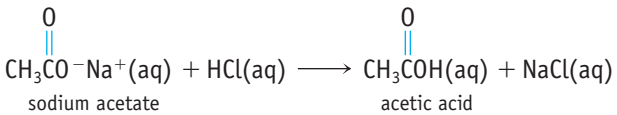


Table 23.11 lists a few common esters and the acid and alcohol from which they are formed. The two-part name of an ester is given by (1) the name of the hydrocarbon group from the alcohol and (2) the name of the carboxylate group derived from the acid name by replacing "-ic" with "-ate." For example, ethanol (commonly called ethyl alcohol) and acetic acid combine to give the ester ethyl acetate.

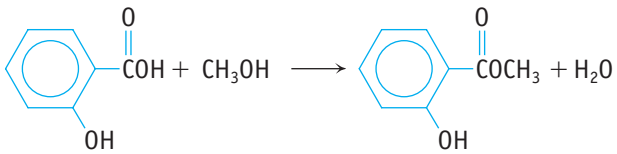
An important reaction of esters is *hydrolysis* (literally, reaction with water), a reaction that is the reverse of the reaction forming the ester. In a neutral solution, this reaction also gives an equilibrium mixture of acid and ester. In order for this reaction to reach completion, it is carried out in a basic solution. The base, NaOH for example, reacts with the acid, thus shifting the equilibrium toward the product.



The carboxylic acid can be recovered if the sodium salt is treated with a strong acid such as HCl:

Unlike the acids from which they are derived, esters often have pleasant odors (Table 23.11). Typical examples are methyl salicylate, or "oil of wintergreen," and benzyl acetate. Methyl salicylate is derived from salicylic acid, the parent compound of aspirin.

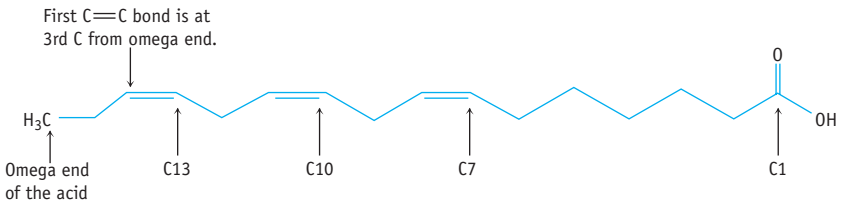
Esters. Many fruits such as bananas and strawberries as well as consumer products (here, perfume and oil of wintergreen) contain esters.

A CLOSER LOOK



Omega-3 Fatty Acids

There is considerable interest today in incorporating omega-3 fatty acids in the diet. Although potential health benefits are not fully defined, proponents say there is some evidence that they lower blood pressure and reduce the chances of heart attacks and strokes. Sources of omega-3 fatty acids include fish and plant oils.

These compounds are polyunsaturated, long-chain carboxylic acids, and there are a number of different, naturally occurring compounds in this class.

The word "omega" in the name refers to the last carbon atom in the carbon chain of the acid, and the number 3 indicates that there is a double bond between carbon atoms 3 and 4 when counted from that end of the molecule.

An example of an omega-3 fatty acid is all-*cis*-7, 10, 13-hexadecatrienoic acid,

whose structure is shown here. Naming large complicated molecules is challenging, but it is possible to decipher the structure from the name. *Hexadeca* identifies this as a 16-carbon atom compound, *triene* tells us there are 3 double bonds (all with *cis* geometry), and the *oic* ending defines it as a carboxylic acid. The numbers 7, 10, and 13 indicate the positions of the double bonds relative to the carboxylic carbon atom.

Steven Hyatt

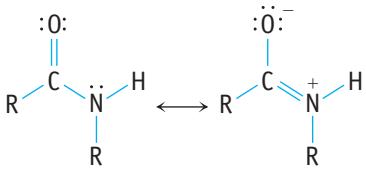
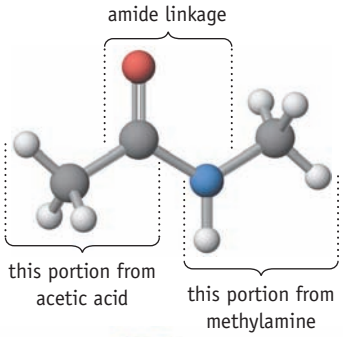
Amides



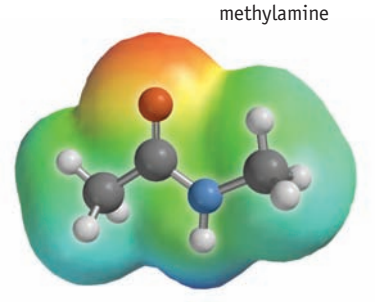
A carboxylic acid and an alcohol react by loss of water to form an ester. In a similar manner, another class of organic compounds—amides—form when a carboxylic acid reacts with an amine, again with loss of water.

Amides have an organic group and an amino group (—NH_2, —NHR′, or —NR′R) attached to the carbonyl group.

The C atom involved in the amide bond has three bonded groups and no lone pairs around it. We would predict it should be sp^2 hybridized with trigonal-planar geometry and bond angles of approximately 120°—and this is what is found. However, the structure of the amide group offers a surprise. The N atom is also observed to have trigonal-planar geometry with bonds to three attached atoms at 120°. Because the amide nitrogen is surrounded by four pairs of electrons, we would have predicted the N atom would have sp^3 hybridization and bond angles of about 109°.



Based on the observed geometry of the amide N atom, the atom is assigned sp^2 hybridization. To rationalize the observed angle and sp^2 hybridization, we can introduce a second resonance form of the amide.



Form B contains a C═N double bond, and the O and N atoms have negative and positive charges, respectively. The N atom can be assigned sp^2 hybridization, and the π bond in B arises from overlap of p orbitals on C and N.

The second resonance structure for an amide link also explains why the carbon–nitrogen bond is relatively short, about 132 pm, a value between that of a C—N single bond (149 pm) and a C═N double bond (127 pm). In addition, restricted rotation occurs around the C═N bond, making it possible for isomeric species to exist if the two groups bonded to N are different.

The amide grouping is particularly important in some synthetic polymers (Section 23.5) and in proteins, where it is referred to as a *peptide* link. The compound *N*-acetyl-*p*-aminophenol, an analgesic known by the generic name acetaminophen, is another amide. Use of this compound as an analgesic was apparently discovered by accident when a common organic compound called acetanilide (like acetaminophen but without the —OH group) was mistakenly put into a prescription for a patient. Acetanilide acts as an analgesic, but it can be toxic. An —OH group *para* to the amide group makes the compound nontoxic, an interesting example of how a seemingly small structural difference affects chemical function.

An amide, *N*-methylacetamide. The *N*-methyl portion of the name derives from the amine portion of the molecule, where the *N* indicates that the methyl group is attached to the nitrogen atom. The "-acet" portion of the name indicates the acid on which the amide is based. The electrostatic potential surface and model show the polarity and planarity of the amide linkage.

EXAMPLE 23.7

Functional Group Chemistry

Problem

(a) Draw the structure of the product of the reaction between propanoic acid and 1-propanol. What is the systematic name of the reaction product, and what functional group does it contain?

(b) What is the result of reacting 2-butanol with an oxidizing agent? Give the name, and draw the structure of the reaction product.

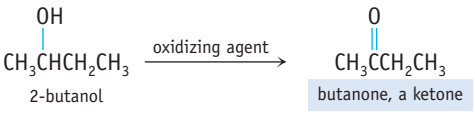
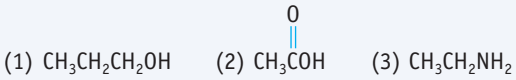
What Do You Know? From the material covered in this chapter, you know the names, structures, and common chemical reactions of organic compounds mentioned in this question.



Strategy Determine the products of these reactions, based on the discussion in the text. Propanoic acid is a carboxylic acid, and 1-propanol and 2-butanol are both alcohols.

SOLUTION

(a) Carboxylic acids such as propanoic acid react with alcohols to give esters.

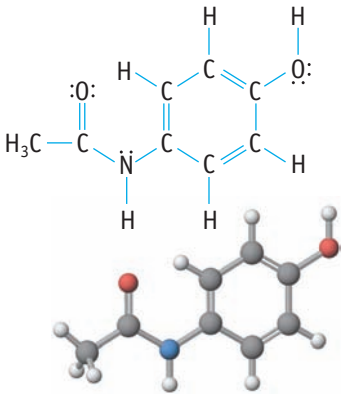


(b) 2-Butanol is a secondary alcohol. Such alcohols are oxidized to ketones.

Think about Your Answer Students sometimes find themselves overwhelmed by the large amount of information presented in organic chemistry. Your study of this material will be more successful if you carefully organize information based on the type of compound.

Check Your Understanding

(a) Name each of the following compounds and its functional group.



(b) Name the product from the reaction of compounds 1 and 2 above.

(c) What is the name and structure of the product from the oxidation of 1 with an excess of oxidizing agent?

(d) Give the name and structure of the compound that results from combining 2 and 3.

(e) What is the result of adding an acid (say HCl) to compound 3?

Acetaminophen, *N*-acetyl-*p*-aminophenol. This analgesic is an amide. It is used in over-the-counter painkillers such as Tylenol.

23.5 Polymers

Goals for Section 23.5

- Write equations for the formation of addition polymers and condensation polymers and describe their structures.
- Relate properties of polymers to their structure.

The very large molecules known as *polymers* can be either synthetic materials or naturally occurring substances such as proteins or nucleic acids. Although many different types of polymers are known with widely different compositions and structures, their properties are understandable, based on the principles developed for small molecules.

Classifying Polymers

The word *polymer* means "many parts" (from the Greek, *poly* and *meros*). Thus, **polymers** are giant molecules made by chemically joining many small molecules called **monomers**. Polymer molar masses can range from thousands to millions.

Extensive use of synthetic polymers is a fairly recent development. A few synthetic polymers (Bakelite, rayon, and celluloid) were made early in the 20th century, but most of the products with which you are likely to be familiar originated in the last 75 years. By 1976, synthetic polymers outstripped steel as the most widely used materials in the United States. The production of synthetic polymers in the United States is now about 150 kg or more per person annually.

The polymer industry classifies polymers in several different ways. One is their response to heating. **Thermoplastics** (such as polyethylene) soften and flow when they are heated and harden when they are cooled. **Thermosetting plastics** (such as Formica) are initially soft but set to a solid when heated and cannot be resoftened. Another classification scheme depends on the end use of the polymer—for example, plastics, fibers, elastomers, coatings, and adhesives.

A more chemically-oriented approach to polymer classification is based on the method of synthesis. **Addition polymers** are made by directly adding monomer units together. **Condensation polymers** are made by combining monomer units and splitting out a small molecule, often water.

Addition Polymers

Polyethylene, polystyrene, and polyvinyl chloride (PVC) are common addition polymers (Figure 23.12). They are built by "adding together" simple alkenes such as ethylene ($CH_2{=}CH_2$), styrene ($C_6H_5CH{=}CH_2$), and vinyl chloride ($CH_2{=}CHCl$). These and other addition polymers (Table 23.12), all derived from alkenes, have widely varying properties and uses.

Polyethylene and Other Polyolefins

Polyethylene is by far the leader in amount of polymer produced. Ethylene (C_2H_4), the monomer from which polyethylene is made, is a product of petroleum refining and one of the top five chemicals produced in the United States. When ethylene is heated to between 100 and 250 °C at a pressure of 1000 to 3000 atm in the presence of a catalyst, polymers with molar masses up to several million are formed. The reaction can be expressed as the chemical equation:

$$n\ H_2C{=}CH_2 \longrightarrow \left(\begin{array}{cc} H & H \\ | & | \\ C & C \\ | & | \\ H & H \end{array}\right)_n$$

ethylene — polyethylene

Figure 23.12 Common polymer-based consumer products. Recycling information is provided on most plastics (often molded into the bottom of bottles). High-density polyethylene is designated with a "2" inside a triangular symbol and the letters "HDPE." Polystyrene is designated by "6" with the symbol PS, and polyvinyl chloride, PVC, is designated with a "3" inside a triangular symbol with the symbol "V" or "PVC" below.

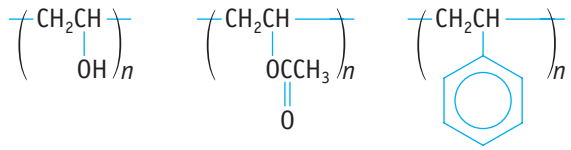
Figure 23.13 Polyethylene.

(a) The linear form, high-density polyethylene (HDPE).

(b) Branched chains occur in low-density polyethylene (LDPE).

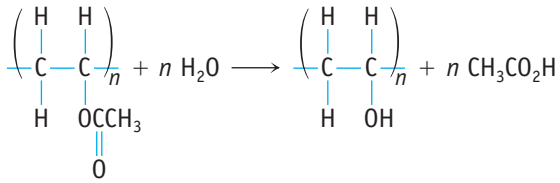
(c) Cross-linked polyethylene (CLPE).



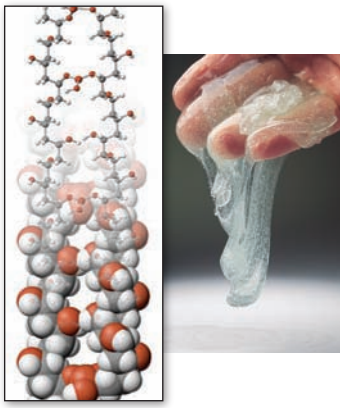
The abbreviated formula of the reaction product, $(—CH_2CH_2—)_n$, shows that polyethylene is a chain of carbon atoms, each bearing two hydrogens. The chain length for polyethylene can be very long. A polymer with a molar mass of 1 million would contain almost 36,000 linked ethylene molecules.

Samples of polyethylene formed under various pressures and catalytic conditions have different properties, as a result of different molecular structures. For example, when chromium(III) oxide is used as a catalyst, the product is almost exclusively a linear chain (Figure 23.13a). If ethylene is heated to 230 °C at high pressure, however, irregular branching occurs (Figure 23.13b). Still other conditions lead to cross-linked polyethylene, in which different chains are linked together (Figure 23.13c).

The high molar mass chains of linear polyethylene pack closely together and result in a material with a density of 0.97 g/cm^3. This material, referred to as high-density polyethylene (HDPE), is hard and tough, which makes it suitable for items such as milk bottles. If the polyethylene chain contains branches, however, the chains cannot pack as closely, and a lower-density material (0.92 g/cm^3) known as low-density polyethylene (LDPE) results. This material is softer and more flexible than HDPE. It is used in plastic wrap and sandwich bags, among other things. Linking up the polymer chains in cross-linked polyethylene (CLPE) causes the material to be more rigid and inflexible. Plastic bottle caps are often made of CLPE.



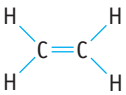
Polymers formed from substituted ethylenes (CH_2=CHX) have a range of properties and uses (Table 23.12). Sometimes, the properties are predictable based on the molecule's structure. Polymers without polar substituent groups, such as polystyrene, often dissolve in organic solvents, a property useful for some types of fabrication.

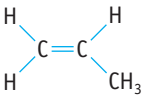


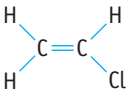
polymers based on substituted ethylenes, H_2C=CHX

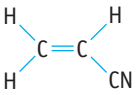
polyvinyl alcohol | polyvinyl acetate | polystyrene

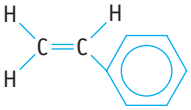
Polyvinyl alcohol is a polymer with little affinity for nonpolar solvents but an affinity for water, which is not surprising, based on the large number of polar OH groups (Figure 23.14). Vinyl alcohol (CH_2=CHOH) is not a stable compound (it isomerizes to acetaldehyde CH_3CHO), so polyvinyl alcohol cannot be made from this compound. Instead, it is made by hydrolyzing the ester groups in polyvinyl acetate.

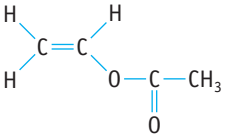


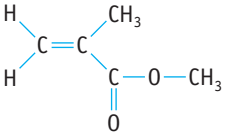












© Cengage Learning/Charles D. Winters

Figure 23.14 Slime from polyvinyl alcohol. When boric acid, $B(OH)_3$, is added to an aqueous suspension of polyvinyl alcohol, $(CH_2CHOH)_n$, the mixture becomes very viscous because boric acid reacts with the —OH groups on the polymer chain, causing cross-linking to occur. (The model shows an idealized structure of a portion of the polymer.)

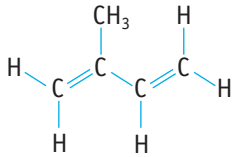
TABLE 23.12 Ethylene Derivatives That Undergo Addition

Formula	Monomer Common Name	Polymer Name (Trade Names)	Uses
	Ethylene	Polyethylene (polythene)	Squeeze bottles, bags, films, toys and molded objects, electric insulation
	Propylene	Polypropylene (Vectra, Herculon)	Bottles, films, indoor-outdoor carpets
	Vinyl chloride	Polyvinyl chloride (PVC)	Floor tile, raincoats, pipe
	Acrylonitrile	Polyacrylonitrile (Orlon, Acrilan)	Rugs, fabrics
	Styrene	Polystyrene (Styrofoam, Styron)	Food and drink coolers, building material, insulation
	Vinyl acetate	Polyvinyl acetate (PVA)	Latex paint, adhesives, textile coatings
	Methyl methacrylate	Polymethyl methacrylate (Plexiglas, Lucite)	High-quality transparent objects, latex paints, contact lenses
	Tetrafluoroethylene	Polytetrafluoroethylene (Teflon)	Gaskets, insulation, bearings, pan coatings

Solubility in water or organic solvents can be a liability for polymers. The many uses of polytetrafluoroethylene [Teflon, $(—CF_2CF_2—)_n$] stem from the fact that it does not interact with water or organic solvents.

Polystyrene, with $n = 5700$, is a clear, hard, colorless solid that can be molded easily at 250 °C. However, you are probably more familiar with the very light, foam-like material known as Styrofoam that is used widely for food and beverage containers and for home insulation (Figure 23.12). Styrofoam is produced by a process called "expansion molding." Polystyrene beads containing 4% to 7% of a low-boiling liquid like pentane are placed in a mold and heated with steam or hot air. Heat causes the solvent to vaporize, creating a foam in the molten polymer that expands to fill the shape of the mold.

Natural and Synthetic Rubber



Natural rubber was first introduced in Europe in 1740, but it remained a curiosity until 1823, when Charles Macintosh invented a way of using it to waterproof cotton cloth. The macintosh, as rain coats are still sometimes called, became popular despite major problems: Natural rubber is notably weak and is soft and tacky when warm, and is brittle at low temperatures. In 1839, after 5 years of research on natural rubber, the American inventor Charles Goodyear (1800–1860) discovered that heat-

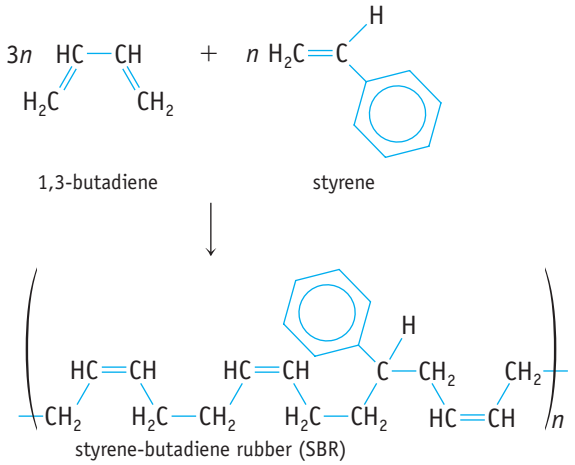
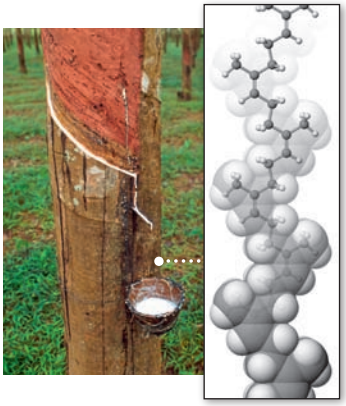
ing gum rubber with sulfur produces a material that is elastic, water-repellent, resilient, and no longer sticky.

Rubber is a naturally occurring polymer, the monomers of which are molecules of 2-methyl-1,3-butadiene, commonly called *isoprene*. In natural rubber, isoprene monomers are linked together through carbon atoms 1 and 4—that is, through the end carbon atoms of the C_4 chain (Figure 23.15). This leaves a double bond between carbon atoms 2 and 3. In natural rubber, these double bonds have a *cis* configuration.



isoprene, 2-methyl-1,3-butadiene

In vulcanized rubber, the material that Goodyear discovered, the polymer chains of natural rubber are cross-linked by short chains of sulfur atoms. Cross-linking helps to align the polymer chains, so the material does not undergo a permanent change when stretched and it springs back when the stress is removed. Substances that behave this way are called **elastomers**.



With a knowledge of the composition and structure of natural rubber, chemists began searching for ways to make synthetic rubber. When they first tried to make the polymer by linking isoprene monomers together, however, what they made was sticky and useless. The problem was that synthesis procedures gave a mixture of *cis*- and *trans*-polyisoprene. In 1955, however, chemists at the Goodyear and Firestone companies discovered special catalysts to prepare the all-*cis* polymer. This synthetic material, which was structurally identical to natural rubber, is now manufactured cheaply. In fact, more than 8.0×10^8 kg of synthetic polyisoprene is produced annually in the United States. Other kinds of polymers have further expanded the repertoire of elastomeric materials now available. Polybutadiene, for example, is currently used in the production of tires, hoses, and belts.

Some elastomers, called **copolymers**, are formed by polymerization of two (or more) different monomers. A copolymer of butadiene and styrene, made with a 3 : 1 ratio of these raw materials, is the most important synthetic rubber now made; more than 1 billion kilograms of styrene-butadiene rubber (SBR) is produced each year in the United States for making tires. And a little is left over each year to make bubble gum. The stretchiness of bubble gum once came from natural rubber, but SBR is now used to help you blow bubbles.

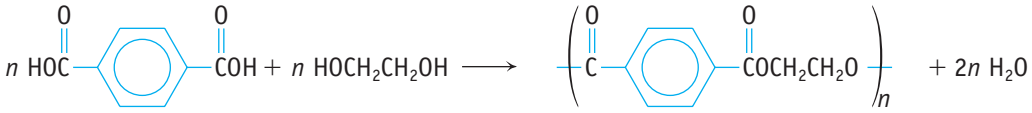
1,3-butadiene styrene

styrene-butadiene rubber (SBR)

Gavin Hellier/Alamy Stock Photo

Figure 23.15 Natural rubber. The sap that comes from the rubber tree is a natural polymer of isoprene. All the linkages in the carbon chain are *cis*. When natural rubber is heated strongly in the absence of air, it smells of isoprene. This observation provided a clue that rubber is composed of this building block.

Condensation Polymers



A chemical reaction in which two molecules react by splitting out, or eliminating, a small molecule is called a **condensation reaction**. The reaction of an alcohol with a carboxylic acid to give an ester is an example of a condensation reaction. One way to form a condensation polymer uses *two* different reactant molecules, each containing *two* functional groups. Another route uses a single molecule with two different functional groups. Commercial polyesters are made using both types of reactions.

Polyesters

Terephthalic acid contains two carboxylic acid groups, and ethylene glycol contains two alcohol groups. When mixed, the acid and alcohol functional groups at both ends of these molecules can react to form ester linkages, splitting out water. The result is a condensation polymer called polyethylene terephthalate (PET). The multiple ester linkages make this substance a **polyester** (Figure 23.16).

© Cengage Learning/Charles D. Winters

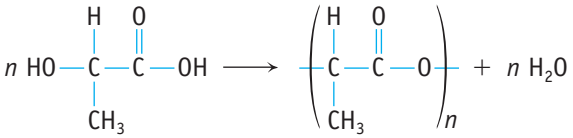

Figure 23.16 Polyesters. Polyethylene terephthalate is used to make clothing, soda bottles, car parts, and many other consumer products.

PET is also made by a reaction between methyl terephthalate and ethylene glycol, a reaction called **transesterification**. In this reaction one ester is converted to another, and removal of methanol by distillation allows the reaction to reach completion.

$$n\ CH_3O_2CC_6H_4CO_2CH_3 + n\ HOCH_2CH_2OH \rightleftharpoons -(O_2CC_6H_4CO_2CH_2CH_2)_n- + 2n\ CH_3OH$$

Polyester textile fibers made from PET are marketed as Dacron and Terylene. The inert, nontoxic, nonflammable, and non-blood-clotting properties of Dacron polymers make Dacron tubing an excellent substitute for human blood vessels in heart bypass operations, and Dacron sheets are sometimes used as temporary skin for burn victims. A polyester film, Mylar, has unusual strength and can be rolled into sheets one-thirtieth the thickness of a human hair.

There is considerable interest in another polyester, polylactic acid (PLA). Lactic acid contains both carboxylic acid and alcohol functional groups, so condensation between molecules of this monomer gives a polymer.

A CLOSER LOOK

Microplastics and Microfibers

Plastic products are increasingly recycled, but a great deal end up in the environment, and the latest environmental problem is microplastics. Until recently tiny plastic microbeads, often made of polyethylene and no longer than 5 mm, were added to body washes and facial scrubs to scour off skin. The problem is that these beads make it through wastewater treatment and end up in rivers, lakes, and oceans. It was estimated that more than 8 trillion beads were entering the aquatic environment every day. There they are taken up by marine organisms, and eventualy could make their way back to human diet. Because of the apparent environmental consquences, they were banned in late 2015.

Banning microbeads, however, does not mean the problem is solved. Plastic bottles and bags have entered the environment for years. They do degrade over time, and tiny pieces are still found in the world's oceans.

And now there is a new concern: microfibers, tiny fibers only a few microns wide and a millimeter or so long. The warm fleece jackets many of us wear are made from polyester fibers. In 2016 a research team laundered new and worn jackets and found that each released up to 2 g of microfibers in each washing. Much of this can be trapped in wastewater treatment, but some surely enters the environment where again it can be a hazard to aquatic life. Since the manufacture and sales of polyester clothing is so wide spread, manufacturers are trying to find new production methods and working to solve the problem of trapping the fibers in washing machines and wastewater plants.

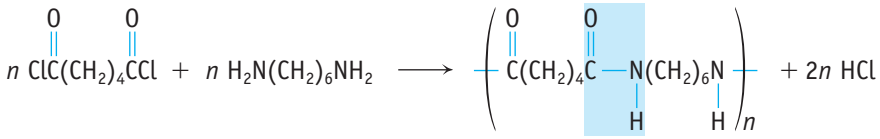
A CLOSER LOOK

Green Chemistry: Recycling PET

In 2009, the world production of polyethylene terephthalate amounted to 49.2 billion kg. Most of this was used to produce fibers and packaging materials; the remainder was used for automobile parts, luggage, filters, and much more. Currently, much of the PET used to make beverage containers is recycled.

The recycling process uses some familiar chemistry. Scrap PET is dissolved at over 220 °C in dimethyl phthalate (DMT) and then treated with methanol at 260–300 °C and 340–650 kPa. In this process, the methanol reacts with the polymer to break down the chains forming more DMT and ethylene glycol. DMT and ethylene glycol are separated, purified, and used to make more PET.



Steven Hyatt

Clothing made of recycled polyester.

The interest in polylactic acid arises because it is "green" for several reasons. First, the monomer used to make this polymer is obtained by biological fermentation of plant materials. As a result, formation of this polymer is carbon-neutral. All of the carbon in this polymer came from CO_2 in the atmosphere, and degradation at some future time will return the same quantity of CO_2 to the environment. In addition, this polymer, which is currently being used in packaging material, is biodegradable, which has the potential to alleviate landfill disposal problems.

Polyamides

In 1928, the DuPont Company embarked on a basic research program in polymer chemistry headed by Wallace Carothers (1896–1937). Carothers was interested in high molar mass compounds, such as rubbers, proteins, and resins. In 1935, his research yielded nylon-6,6 (Figure 23.17), a **polyamide** prepared from adipoyl chloride, a derivative of adipic acid (a diacid) and hexamethylenediamine (a diamine):

Nylon can be extruded easily into fibers that are stronger than natural fibers and chemically more inert, and this fact jolted the American textile industry at a critical time. Natural fibers were not meeting 20th-century needs. Silk was expensive and not durable, wool was scratchy, linen crushed easily, and cotton did not have a high-fashion image. Perhaps the most identifiable use for the new fiber was in nylon stockings. The first public sale of nylon hosiery took place on October 24, 1939, in Wilmington, Delaware (the site of DuPont's main office). This use of nylon in commercial products ended shortly thereafter, however, with the start of World War II. All nylon was diverted to making parachutes and other military gear. It was not until about 1952 that nylon reappeared in the consumer marketplace.

Figure 23.18 illustrates why nylon makes such a good fiber. To have good tensile strength (the ability to resist tearing), the polymer chains should be able to attract one another, albeit not so strongly that the plastic cannot be drawn into fibers. Ordinary covalent bonds between the chains (cross-linking) would be too strong.

© Cengage Learning/Charles D. Winters

Figure 23.17 Nylon-6,6. Hexamethylenediamine is dissolved in water *(bottom layer)*, and adipoyl chloride (a derivative of adipic acid) is dissolved in hexane *(top layer)*. The two compounds react at the interface between the layers to form nylon-6,6, which is being wound onto a stirring rod.

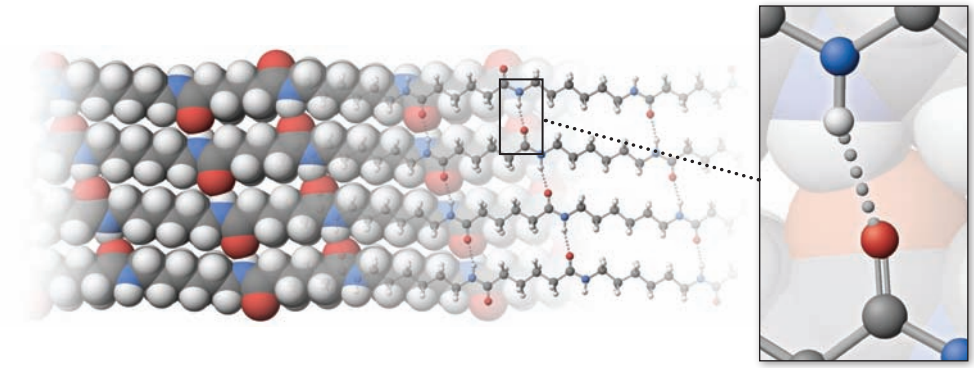

Figure 23.18 Hydrogen bonding between polyamide chains. Carbonyl oxygen atoms with a partial negative charge on one chain interact with an amine hydrogen with a partial positive charge on a neighboring chain. (Hydrogen bonding is described in more detail in Section 11.3.)

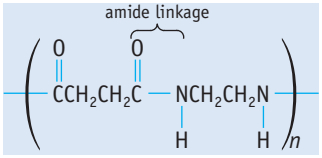
Instead, cross-linking occurs by the somewhat weaker intermolecular force called *hydrogen bonding* (Section 11.3) between the hydrogens of N—H groups on one chain and the carbonyl oxygens on another chain. The polarities of the $N^{\delta-}$—$H^{\delta+}$ group and the $C^{\delta+}{=}O^{\delta-}$ group lead to attractive forces between the polymer chains of the desired magnitude.

EXAMPLE 23.8

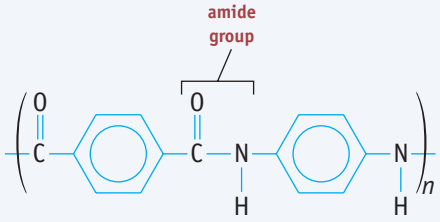


Condensation Polymers

Problem What is the repeating unit of the condensation polymer obtained by combining $HO_2CCH_2CH_2CO_2H$ (succinic acid) and $H_2NCH_2CH_2NH_2$ (1,2-ethylenediamine)?

What Do You Know? Carboxylic acids and amines react to form amides, splitting out water. Here we have a diacid and diamine that will react. The repeating unit will be the shortest sequence that when repeated gives a long polymer chain.

Strategy Recognize that the polymer will link the two monomer units through the amide linkage. The smallest repeating unit of the chain will contain two parts, one from the diacid and the other from the diamine.



SOLUTION The repeating unit of this polyamide is

Think about Your Answer Alternating fragments of the diacid and diamine appear in the polymer chain. The fragments are linked by amide bonds, making this a polyamide.

Check Your Understanding

Kevlar is a well-known polymer that is now used to make sports equipment and bullet-proof vests. The basic structure of the polymer is shown below. Is this a condensation polymer or an addition polymer? What chemicals could be used to make this polymer? Write a balanced equation for the formation of Kevlar.

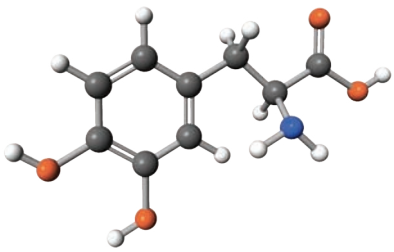
23.1 An Awakening with L-DOPA

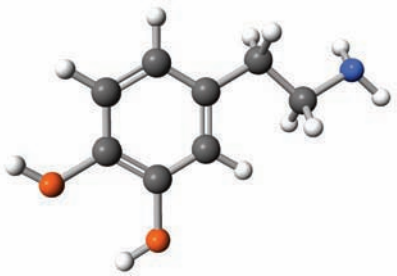
From about 1917 to 1928, millions of people worldwide were affected by a condition known as *encephalitis lethargica*, a form of sleeping sickness. Those who suffered from the condition were in a state of semi-consciousness that lasted for decades. In his book *Awakenings*, Oliver Sacks wrote about treating a patient with the compound L-DOPA, which "was started in early March 1969 and raised by degrees to 5.0 g a day. Little effect was seen for two weeks, and then a sudden 'conversion' took place. . . . Mr. L enjoyed a mobility, a health, and a happiness which he had not known in thirty years. Everything about him filled with delight: he was like a man who had awoken from a nightmare or a serious illness. . . ."



AF archive/Alamy Stock Photo

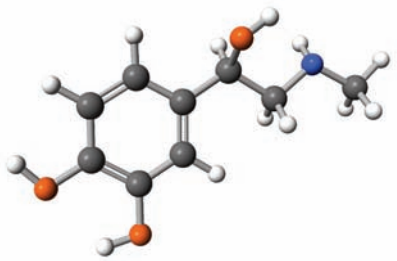
Robert DeNiro as Leonard Lowe and Robin Williams as Malcolm Sayer, a fictionalized portrayal of Oliver Sacks, in the movie version of *Awakenings*.

If you have read the book or have seen the movie of the same name, you know that Mr. L eventually could not tolerate the treatment, but that Sacks treated many others who benefitted from it. L-DOPA is now widely used in the treatment of another condition, Parkinson's disease, a degenerative disorder of the central nervous system.



L-DOPA or L-dopamine (L-3,4-dihydroxy–phenylalanine) is chiral. The symbol L stands for "levo," which means a solution of the compound rotates polarized light to the left. The compound is also a derivative of phenylalanine, one of many naturally occurring alpha-amino acids that play such an important role in protein formation and other natural processes.

L-DOPA also illustrates why chiral molecules are so interesting to chemists: Only the "levo" enantiomer is physiologically active. The enantiomer that rotates polarized light in the opposite direction has no biological function.



L-DOPA, $C_9H_{11}NO_4$,
a treatment for Parkinson's disease

When L-DOPA is ingested, it is metabolized to dopamine in a process that removes the carboxylic acid group, $—CO_2H$, and it is dopamine that is physiologically active. Dopamine is a neurotransmitter that occurs in a wide variety of animals.

dopamine, $C_8H_{11}NO_2$, a neurotransmitter

Interestingly, both L-DOPA and dopamine are closely related to another amine, epinephrine. This is sometimes referred to as adrenaline, the hormone that is released from the adrenal glands when there is an emergency or danger threatens.

epinephrine or adrenaline, $C_9H_{13}NO_3$

Questions:

1. L-DOPA is chiral. What is the center of chirality in the molecule?
2. Is either dopamine or epinephrine chiral? If so, what is the center of chirality?
3. If you are treated with 5.0 g of L-DOPA, what amount (in moles) is this?

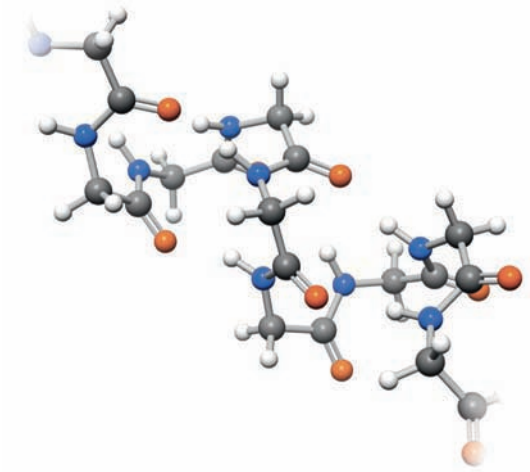
23.2 Green Adhesives

Chemist Kaichang Li does research in wood chemistry at Oregon State University. Oregon has a beautiful and rugged coast, and Li went there in search of mussels to make a special dish. As the waves pounded onshore, he was struck by the fact that the mussels could cling stubbornly to the rocks in spite of the force of the waves and tides. What "glue" enabled them to do this?

Back in his lab Li found that the strands of glue were largely protein-based. Proteins are simply polymers of amino acids with an amide link between units (Chapter 24). Li realized that such polymers could have enormous application in the wood industry.

Adhesives, or glues in common terminology, have been known and used for thousands of years. Early glues were based on animal or plant products. Now, however, adhesives are largely synthetic, among them are condensation polymers based on the combination of phenol or urea with formaldehyde. These have been used for well over a half-century in the manufacture of plywood and particle board, and your home or dormitory likely contains a significant amount of these building materials. Unfortunately, they have a disadvantage. In their manufacture and use, formaldehyde, a suspected carcinogen, can be released into the air.



Courtesy of Oregon State University

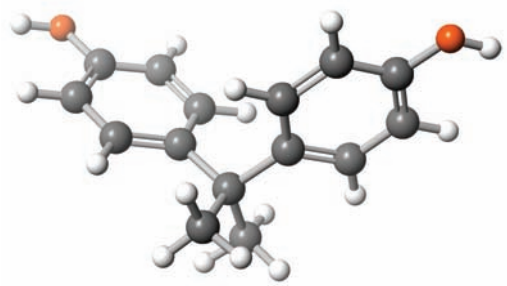
Professor K. Li, a discoverer of "green" adhesives.

Li's work with mussels eventually led to a new, safer adhesive that could be used in these same wood products. His first problem was how to make a protein-based adhesive in the laboratory. The idea came to him one day at lunch when he was eating tofu, a soy-based food very high in protein. Why not modify soy protein to make a new adhesive? Using mussels as his model, Li did exactly that, and, as he said, "We turned soy proteins into mussel adhesive proteins."

Scientists at Hercules Chemical Company provided expertise to cure (or harden) the new "green" adhesive, and the Columbia Forest Products Company adopted the environmentally friendly adhesive for use in plywood and particle board.

In 2007 Li and his coworkers, as well as Columbia Forest Products and Hercules, shared a Presidential Green Chemistry Challenge Award.

A portion of a protein chain made of repeating glycine molecules ($H_2NCH_2CO_2H$).



Questions:

1. Draw structures of phenol, urea, and formaldehyde.
2. Describe the bonding in formaldehyde.
3. It has been said that nylon is similar to a protein. Compare and contrast the structures of nylon-6,6 and a protein. (For more information on the structure of proteins, see Chapter 24.)

23.3 Bisphenol A (BPA)

Bisphenol A (BPA) is an organic compound consisting of two phenol groups linked through a carbon atom. It was first synthesized around 1900 but only recently has it become commercially important. And even more recently it has been very much in the news because of its much-debated possible toxicity.

Bisphenol A is a white solid, slightly water soluble (300 mg/L), and a weak acid (pK_a of 9.9). In 2011 the total world demand for BPA was about 5.4×10^9 kg.

bisphenol-A

Steven Hyatt

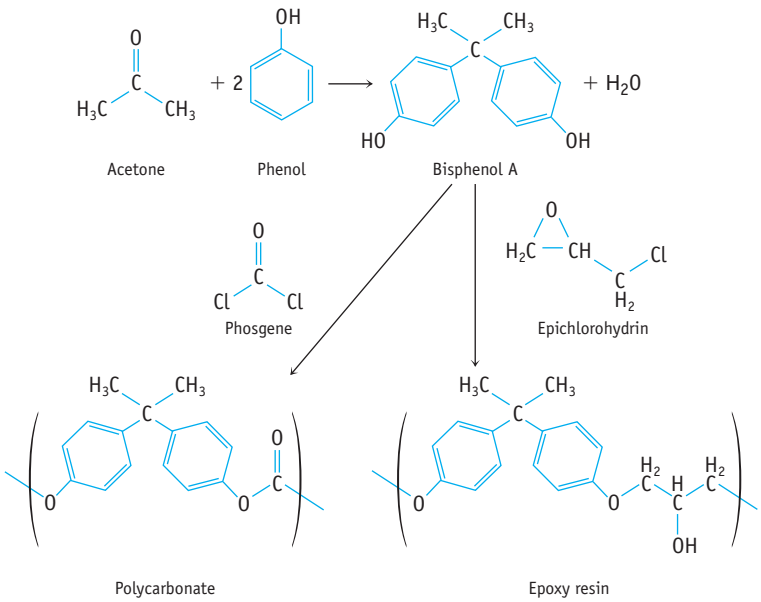
Most drinking bottles are no longer made of BPA-based polymers.

If BPA is treated with phosgene (Cl_2CO), the product is the polymer polycarbonate, and approximately 74% of the BPA is used to make this polymer. Because polycarbonate is lightweight, durable, clear, and nearly shatterproof, it is used to make, among other things, bottles, eyeglass lenses, football helmets, and CDs and DVDs.

Another 20% of BPA is converted into epoxy resins by reacting BPA with epichlorohydrin. Until recently epoxy resins were used to coat the inside of some food cans, but they still find use in paints and coatings, adhesives, and composite materials.

Some of the remaining 6% of BPA is used in thermal paper. When you get a cash register receipt in a restaurant or store, the coating on the paper may contain BPA.

BPA is such a useful material. What could go wrong? The problem is that BPA has estrogenic activity, the ability to simulate the activity of primary female sex hormones. But this is also true for some compounds found naturally in beans, olive oil, and some fruits and vegetables. Nonetheless, there has been a vigorous debate on the biological effects of BPA and its polymers.



Because of this debate the use of BPA polymers has been virtually eliminated in making bottles (especially baby bottles) and for coating food cans. Substitutes are also being found for BPA in cash register receipts.

The Environmental Protection Agency (EPA) currently states that it is safe to ingest up to 50 μg per kilogram of body weight per day. However, many scientists believe the safe limit should be much lower, or that BPA should be eliminated entirely. To put this in context, some studies have indicated that infants fed from polycarbonate bottles may ingest up to 13 μg/kg/day. A normal adult may take in about 1.5 μg/kg/day.

In a series of articles on BPA and its effects in *Chemical & Engineering News*, the authors wrote, "Given mounting knowledge of BPA's estrogen-mimicking properties and possible toxic effects, decisions have to be made on whether it should continue to be freely used, restricted for some uses, or banned completely. There are no simple answers."

QUESTIONS:

1. What is the atom economy for the reaction of acetone with phenol to make BPA? (*Applying Chemical Principles, 4.1: Green Chemistry and Atom Economy*, page 207.)
2. Are polycarbonate and epoxy resins addition polymers or condensation polymers?
3. If drinking from a polycarbonate bottle, does a 15 lb infant ingest over 50 μg of BPA per day? (1.00 lb = 454 g)
4. Assume you weigh 156 lb. How much BPA do you ingest per day?
5. What quantity of 0.050 M NaOH would be required to react with 300 mg of BPA in 1.00 L of water? (Assume both —OH groups react with NaOH.)

Synthesis of BPA and of polycarbonate and epoxy resin from BPA

CHAPTER GOALS REVISITED

The goals for this chapter are keyed to specific Study Questions to help you organize your review.

23.1 Why Carbon?

- Understand the factors that contribute to the large numbers of organic compounds and the wide array of structures. **1–4.**
- Recognize the types of isomerism that are seen in organic chemistry. **5–8.**

23.2 Hydrocarbons

- Draw structural formulas and name hydrocarbons. **11, 13, 15, 17, 29, 30, 35, 36, 39, 40.**
- Recognize and draw structures of geometric isomers and optical isomers. **19, 20, 23, 27.**
- Describe chemical and physical properties of hydrocarbons. **25, 26, 31–34, 41–44.**

23.3 Alcohols, Ethers, and Amines

- Identify functional groups from organic formulas. **69, 94.**
- Name and draw structures of alcohols and amines. **45–50.**
- Describe chemical properties of alcohols. **51–54.**

23.4 Compounds with a Carbonyl Group

- Name and draw structures of carbonyl compounds—aldehydes, ketones, acids, esters, and amides. **55–58.**
- Describe reactions of carbonyl compounds. **59–64.**

23.5 Polymers

- Write equations for the formation of addition polymers and condensation polymers and describe their structures. **71–74.**
- Relate properties of polymers to their structure. **113.**

STUDY QUESTIONS

▲ denotes challenging questions. **Blue-numbered questions** have answers in Appendix N and fully worked solutions in the *Student Solutions Manual.*

Practicing Skills

Why Carbon?

(See Section 23.1)

1. In carbon compounds, the carbon atom can achieve an octet configuration in several ways. Draw the Lewis structure of a hydrocarbon compound in which: (a) Carbon is bonded via four single bonds to adjacent atoms. (b) Carbon is bonded via two single bonds and one pi bond; (c) Carbon is bonded via one single bond and one triple bond; (d) Carbon is bonded via two double bonds.

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

2. Identify the hybridization and the bond angles for the following: (a) Carbon bonded via four single bonds to adjacent atoms. (b) Carbon bonded to adjacent atoms via two single bonds and one pi bond; (c) Carbon bonded to adjacent atoms via one single bond and one triple bond; (d) Carbon bonded to adjacent atoms via two double bonds.

3. Is violet light (with a wavelength of 400 nm) sufficiently energetic to break a carbon-carbon single bond (the average C-C bond energy is 346 kJ/mol)?

4. Ethene, C_2H_4, is unstable with respect to decomposition to the elements ($\Delta_f H° = 52.47$ kJ/mol). It is also unstable with respect to polymerization to polyethylene. Nevertheless, samples of ethane can be stored without decomposition essentially forever. Why is this so?

5. Compounds with the same elemental composition but a different arrangement of atoms are called: (a) stereoisomers, (b) structural isomers, (c) geometric isomers, (d) optical isomers.

6. Compounds with the same attachment of atoms but different orientation in space are called: (a) stereoisomers, (b) structural isomers, (c) *cis-trans* isomers, (d) optical isomers.

7. Determine how many structural isomers and geometric isomers are possible for compounds having the formula C_4H_{10}. Are any of the possible isomers chiral?

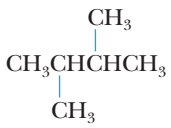
8. Determine how many non-cyclic structural isomers and geometric isomers are possible for compounds having the formula C_4H_8. Are any of the possible isomers chiral?

Alkanes and Cycloalkanes

(See Section 23.2 and Examples 23.1 and 23.2.)

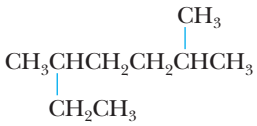
9. What is the name of the straight (unbranched) chain alkane with the formula C_7H_{16}?

10. What is the molecular formula for an alkane with 12 carbon atoms?



11. Which of the following compounds can be an alkane?
    (a) C_2H_4
    (b) C_5H_{12}
    (c) $C_{14}H_{30}$
    (d) C_7H_8

12. Which of the following compounds can be a cyclo alkane?
    (a) C_3H_5
    (b) C_5H_{10}
    (c) $C_{14}H_{30}$
    (d) C_8H_8



13. One of the structural isomers with the formula C_9H_{20} has the name 3-ethyl-2-methylhexane. Draw its structure. Draw and name another structural isomer of C_9H_{20} in which there is a five-carbon chain.

14. Isooctane, 2,2,4-trimethylpentane, is one of the possible structural isomers with the formula C_8H_{18}. Draw the structure of this isomer, and draw and name structures of two other isomers of C_8H_{18} in which the longest carbon chain is five atoms.

15. Give the systematic name for the following alkane:

16. Give the systematic name for the following alkane. Draw a structural isomer of the compound, and give its name.

17. Draw the structure of each of the following compounds:
    (a) 2,3-dimethylhexane
    (b) 2,3-dimethyloctane
    (c) 3-ethylheptane
    (d) 3-ethyl-2-methylhexane

18. Draw structures for the following compounds.
    (a) 3-ethylpentane
    (b) 2,3-dimethylpentane
    (c) 2,4-dimethylpentane
    (d) 2,2-dimethylpentane

19. Draw Lewis structures and name all possible alkanes that have a seven-carbon chain with one methyl substituent group. Which of these isomers has a chiral carbon center?

20. Four (of six possible) dimethylhexanes are named below. Draw the structures of each, and determine which of these isomers has a chiral carbon center.
    (a) 2,2-dimethylhexane
    (b) 2,3-dimethylhexane
    (c) 2,4-dimethylhexane
    (d) 2,5-dimethylhexane

21. Draw the structure of the chair form of cyclohexane. Identify the axial and equatorial hydrogen atoms in this drawing.

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

22. Draw a structure for cycloheptane. Is the seven-member ring planar? Explain your answer.

23. There are two ethylheptanes (compounds with a seven-carbon chain and one ethyl substituent). Draw the structures, and name these compounds. Is either isomer chiral?

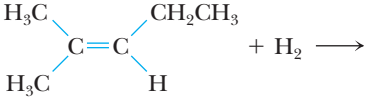
24. Among the 18 structural isomers with the formula C_8H_{18} are two with a five-carbon chain having one ethyl and one methyl substituent group. Draw their structures, and name these two isomers.

25. List several typical physical properties of C_4H_{10}. Predict the following physical properties of dodecane, $C_{12}H_{26}$: color, state (s, ℓ, g), solubility in water, solubility in a nonpolar solvent.

26. Write balanced equations for the following reactions of alkanes.
    (a) The reaction of methane with excess chlorine.
    (b) Complete combustion of cyclohexane, C_6H_{12}, with excess oxygen.

Alkenes and Alkynes

(See Section 23.2 and Examples 23.3 and 23.4.)



27. Draw structures for the *cis* and *trans* isomers of 4-methyl-2-hexene.

28. What structural requirement is necessary for an alkene to have *cis* and *trans* isomers? Can *cis* and *trans* isomers exist for an alkane? For an alkyne?

29. A hydrocarbon with the formula C_5H_{10} can be either an alkene or a cycloalkane.
    (a) Draw a structure for each of the six isomers possible for C_5H_{10}, assuming it is an alkene. Give the systematic name of each isomer.
    (b) Draw a structure for a cycloalkane having the formula C_5H_{10}.

30. Five alkenes have the formula C_7H_{14} and a seven-carbon chain. Draw their structures and name them.

31. Draw the structure and give the systematic name for the products of the following reactions:
    (a) $CH_3CH{=}CH_2 + Br_2 \rightarrow$
    (b) $CH_3CH_2CH{=}CHCH_3 + H_2 \rightarrow$

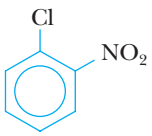
32. Draw the structure and give the systematic name for the products of the following reactions:
    (a) 
    (b) $CH_3C{\equiv}CCH_2CH_3 + 2\,Br_2 \longrightarrow$

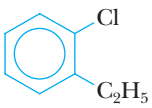
33. The compound 2-bromobutane is a product of addition of HBr to three different alkenes. Identify the alkenes and write an equation for the reaction of HBr with one of the alkenes.

34. The compound 2,3-dibromo-2-methylhexane is formed by addition of Br_2 to an alkene. Identify the alkene, and write an equation for this reaction.

35. Draw structures for the four alkenes that have the formula C_3H_5Cl, and name each compound. (These are derivatives of propene in which a chlorine atom replaces one hydrogen atom.)

36. There are seven possible dichloropropene isomers (molecular formula $C_3H_4Cl_2$). Draw their structures and name each isomer. (Hint: Don't overlook *cis-trans* isomers.)





37. Hydrogenation is an important chemical reaction of compounds that contain double bonds. Write a chemical equation for the hydrogenation of 1-hexene. Hydrogenation reactions are used extensively in the food industry. Describe this reaction and explain its use and importance.

38. Elemental analysis of a colorless liquid has given its formula as C_5H_{10}. You recognize that this could be either a cycloalkane or an alkene. A chemical test to determine the class to which this compound belongs involves adding bromine. Explain how this would allow you to distinguish between the two classes.

Aromatic Compounds

(See Section 23.2 and Example 23.5.)

39. Draw structural formulas for the following compounds:
    (a) 1,3-dichlorobenzene (alternatively called *m*-dichlorobenzene)
    (b) 1-bromo-4-methylbenzene (alternatively called *p*-bromotoluene)

40. Give the systematic name for each of the following compounds:
    (a) 
    (b) 
    (c) 

41. Write the equation for the reaction of 1,4-dimethylbenzene with CH_3Cl and $AlCl_3$. What is the structure and name of the single organic compound produced?

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

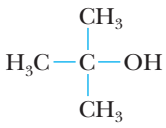
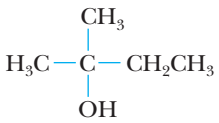
42. Write an equation for the preparation of hexylbenzene from benzene and other appropriate reagents.

43. Aromatic compounds react with a mixture of nitric and sulfuric acid to form aromatic compounds containing a nitro ($-NO_2$) group. Two isomeric compounds are formed by nitration of 1,2-dimethylbenzene. Draw the structures and name these compounds.

44. Nitration of toluene gives a mixture of two products, one with the nitro group ($-NO_2$) in the *ortho* position and one with the nitro group in the *para* position. Draw structures of the two products.



Alcohols, Ethers, and Amines



(See Section 23.3 and Example 23.6.)

45. Give the systematic name for each of the following alcohols, and tell if each is a primary, secondary, or tertiary alcohol:

(a) $CH_3CH_2CH_2OH$

(b) $CH_3CH_2CH_2CH_2OH$

(c)

(d)

46. Draw structural formulas for the following alcohols, and tell if each is primary, secondary, or tertiary:

(a) 1-butanol

(b) 2-butanol

(c) 3,3-dimethyl-2-butanol

(d) 3,3-dimethyl-1-butanol

47. Write the formula, and draw the structure, for each of the following amines:

(a) ethylamine

(b) dipropylamine

(c) butyldimethylamine

(d) triethylamine

48. Name the following amines:

(a) $CH_3CH_2CH_2NH_2$

(b) $(CH_3)_3N$

(c) $(CH_3)(C_2H_5)NH$

(d) $C_6H_{13}NH_2$

49. Draw structural formulas for the four possible alcohols with the formula $C_4H_{10}O$. Give the systematic name of each.

50. Draw structural formulas for all primary amines with the formula $C_4H_9NH_2$.

51. Complete and balance the following equations:

(a) $C_6H_5NH_2(\ell) + HCl(aq) \rightarrow$

(b) $(CH_3)_3N(aq) + H_2SO_4(aq) \rightarrow$

52. The structure of dopamine, a neurotransmitter, is given on page 1103. Predict its reaction with aqueous hydrochloric acid.

53. Draw structures of the product formed by oxidation of the following alcohols. Assume an excess of oxidizing agent is used in each case.

(a) 2-methyl-1-pentanol

(b) 3-methyl-2-pentanol

(c) $HOCH_2CH_2CH_2CH_2OH$

(d) $H_2NCH_2CH_2CH_2OH$

54. Aldehydes and carboxylic acids are formed by oxidation of primary alcohols, and ketones are formed when secondary alcohols are oxidized. Give the name and formula for the alcohol that, when oxidized, gives the following products:

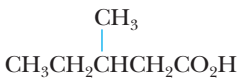
(a) $CH_3CH_2CH_2CHO$

(b) 2-hexanone

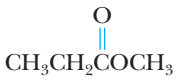
Compounds with a Carbonyl Group

(See Section 23.4 and Example 23.7.)

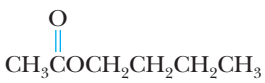
55. Draw structural formulas for (a) 2-pentanone, (b) hexanal, and (c) pentanoic acid.



56. Draw structural formulas for the following acids and esters:



(a) 2-methylhexanoic acid



(b) pentyl butanoate (which has the odor of apricots)

(c) octyl acetate (which has the odor of oranges)

57. Identify the class of each of the following compounds, and give the systematic name for each:

(a)

(b)

(c)

(d)

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

58. Identify the class of each of the following compounds, and give the systematic name for each:

(a) CH_3CCH_3 (O)

(c) $CH_3CCH_2CH_2CH_3$ (O)

(b) $CH_3CH_2CH_2CH$ (O)

59. Give the structural formula and systematic name for the organic product, if any, from each of the following reactions:

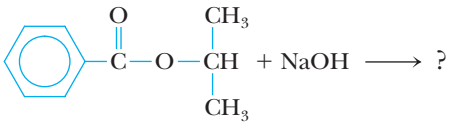
(a) pentanal and $KMnO_4$

(b) 2-octanone and $LiAlH_4$

60. Give the structural formula and name for the organic product from the following reactions.

(a) $CH_3CH_2CH_2CH_2CHO + LiAlH_4$

(b) $CH_3CH_2CH_2CH_2OH + KMnO_4$



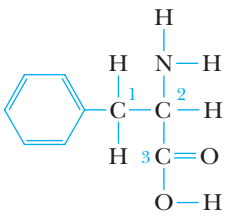
61. Describe how to prepare propyl propanoate beginning with 1-propanol as the only carbon-containing reagent.

62. Give the name and structure of the product of the reaction of benzoic acid and 2-propanol.

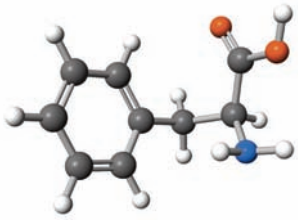
63. Draw structural formulas and give the names for the products of the following reaction:

$$CH_3COCH_2CH_2CH_2CH_3 + NaOH$$

64. Draw structural formulas, and give the names for the products of the following reaction:

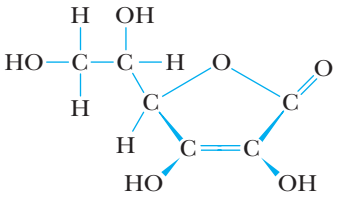


65. The structure of phenylalanine, one of the 20 amino acids that make up proteins, is drawn below (without lone pairs of electrons). The carbon atoms are numbered for the purpose of this question.

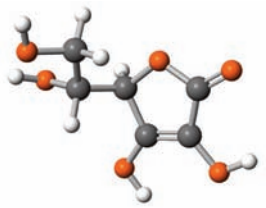


(a) What is the geometry of C_3?

(b) What is the O—C—O bond angle?



(c) Is this molecule chiral? If so, which carbon atom is chiral?



(d) Which hydrogen atom in this compound is acidic?

66. The structure of vitamin C, whose chemical name is ascorbic acid, is drawn below (without lone pairs of electrons).

(a) What is the approximate value for the O—C—O bond angle?

(b) There are four OH groups in this structure. Estimate the C—O—H bond angles for these groups. Will they be the same value (more or less), or should there be significant differences in these bond angles?

(c) Is the molecule chiral? How many chiral carbon atoms can be identified in this structure?

(d) Identify the shortest bond in this molecule.

(e) What are the functional groups of the molecule?

67. What is the structure of the product from the reaction of butanoic acid and methylamine? To what class of compounds does this belong? Write a balanced chemical equation for the reaction.

68. The structure of acetaminophen is shown on page 1095. Using structural formulas, write an equation for the reaction of an acid and an amine to form this compound.

Functional Groups

(See Section 23.4 and Example 23.7.)

69. Identify the functional groups in the following molecules.

(a) $CH_3CH_2CH_2OH$

(b) $H_3CCNHCH_3$ (O)

(c) CH_3CH_2COH (O)

(d) $CH_3CH_2COCH_3$ (O)

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

70. Consider the following molecules:

(1) $CH_3CH_2\overset{\overset{O}{\|}}{C}CH_3$

(2) $CH_3CH_2\overset{\overset{O}{\|}}{C}OH$

(3) $H_2C{=}CHCH_2OH$

(4) $CH_3CH_2\overset{\overset{OH}{|}}{C}HCH_3$

(a) What is the result of treating compound 1 with $NaBH_4$? What is the functional group in the product? Name the product.

(b) Draw the structure of the reaction product from compounds 2 and 4. What is the functional group in the product?

(c) What compound results from adding H_2 to compound 3? Name the reaction product.

(d) What compound results from adding NaOH to compound 2?

Polymers

(See Section 23.5 and Example 23.8.)

71. Polyvinyl acetate is the binder in water-based paints.

(a) Write an equation for its formation from vinyl acetate.

(b) Show a portion of this polymer with three monomer units.

(c) Describe how to make polyvinyl alcohol from polyvinyl acetate.

72. Neoprene (polychloroprene, a kind of rubber) is a polymer formed from the chlorinated butadiene $H_2C{=}CHCCl{=}CH_2$.

(a) Write an equation showing the formation of polychloroprene from the monomer.

(b) Show a portion of this polymer with three monomer units.

73. Polyacrylonitrile is a polymer of acrylonitrile, $CH_2{=}CHCN$. Write an equation for the synthesis of this polymer.

74. The structure of methyl methacrylate is given in Table 23.12. Draw the structure of a polymethyl methacrylate (PMMA) polymer that has four monomer units. (PMMA has excellent optical properties and is used to make hard contact lenses.)

General Questions

These questions are not designated as to type or location in the chapter. They may combine several concepts.

75. Three different compounds with the formula $C_2H_2Cl_2$ are known.

(a) Two of these compounds are geometric isomers. Draw their structures.

(b) The third compound is a structural isomer of the other two. Draw its structure.

76. Draw the structure of 2-butanol. Identify the chiral carbon atom in this compound. Draw the mirror image of the structure you first drew. Are the two molecules superimposable?

77. An alkene having the formula C_6H_{12} is known to have a six-carbon chain. How many isomeric species can be drawn based on this description? List the names of these species.

78. Draw structures and name the four alkenes that have the formula C_4H_8.

79. Write equations for the reactions of *cis*-2-butene with the following reagents, representing the reactants and products using structural formulas.

(a) H_2O (b) HBr (c) Cl_2

80. Draw the structure and name the product formed if the following alcohols are oxidized. Assume an excess of the oxidizing agent is used. If the alcohol is not expected to react with a chemical oxidizing agent, write NR (no reaction).

(a) $CH_3CH_2CH_2CH_2OH$

(b) 2-butanol

(c) 2-methyl-2-propanol

(d) 2-methyl-1-propanol

81. Write equations for the following reactions, representing the reactants and products using structural formulas.

(a) The reaction of acetic acid and sodium hydroxide

(b) The reaction of methylamine with HCl

82. Write equations for the following reactions, representing the reactants and products using structural formulas.

(a) The formation of ethyl acetate from acetic acid and ethanol

(b) The hydrolysis of glyceryl tristearate (the triester of glycerol with stearic acid, a fatty acid; Table 23.9)

83. Write an equation for the formation of the following polymers.

(a) Polystyrene, from styrene ($C_6H_5CH{=}CH_2$)

(b) PET (polyethylene terephthalate), from ethylene glycol and terephthalic acid

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

84. Write equations for the following reactions, representing the reactants and products using structural formulas.

(a) The hydrolysis of the amide $C_6H_5CONHCH_3$ to form benzoic acid and methylamine

(b) The hydrolysis of $(—CO(CH_2)_4CONH(CH_2)_6NH—)_n$, (nylon-6,6, a polyamide) to give a carboxylic acid and an amine

85. Draw the structure of each of the following compounds:

(a) 2,2-dimethylpentane

(b) 3,3-diethylpentane

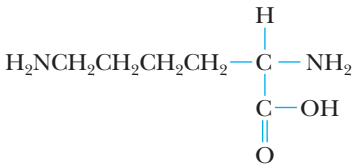
(c) 3-ethyl-2-methylpentane

(d) 3-ethylhexane

86. ▲ Structural isomers.

(a) Draw all of the isomers possible for C_3H_8O. Give the systematic name of each, and tell into which class of compound it fits.

(b) Draw the structural formulas for an aldehyde and a ketone with the molecular formula C_4H_8O. Give the systematic name of each.



87. ▲ Draw structural formulas for possible isomers of the dichlorinated propane, $C_3H_6Cl_2$. Name each compound.

88. Draw structural formulas for possible isomers with the formula C_3H_6ClBr, and name each isomer.

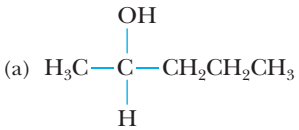
89. Give structural formulas and systematic names for the three structural isomers of trimethylbenzene, $C_6H_3(CH_3)_3$.

90. Give structural formulas and systematic names for possible isomers of dichlorobenzene, $C_6H_4Cl_2$.

91. Voodoo lilies depend on carrion beetles for pollination. Carrion beetles are attracted to dead animals, and because dead and putrefying animals give off the horrible-smelling amine cadaverine, the lily likewise releases cadaverine (and the closely related compound putrescine, page 1087). A biological catalyst, an enzyme, converts the naturally occurring amino acid lysine to cadaverine.

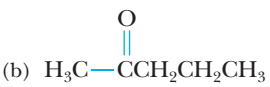
Lysine

What group of atoms must be replaced in lysine to make cadaverine? (Lysine is essential to human nutrition but is not synthesized in the human body.)



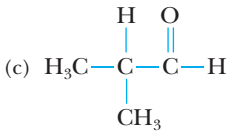
92. Benzoic acid occurs in many berries. When humans eat berries, benzoic acid is converted to hippuric acid in the body by reaction with the amino acid glycine $H_2NCH_2CO_2H$. Draw the structure of hippuric acid, knowing it is an amide formed by reaction of the carboxylic acid group of benzoic acid and the amino group of glycine. Why is hippuric acid referred to as an acid?

93. Consider the reaction of *cis*-2-butene with H_2 (in the presence of a catalyst).

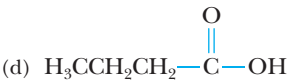


(a) Draw the structure, and give the name of the reaction product. Is this reaction product chiral?

(b) Draw an isomer of the reaction product.



94. Give the name of each compound below, and name the functional group involved.



(a)

(b)

(c)

(d)

95. Draw the structure of glyceryl trilaurate, a fat. Lauric acid (page 941) has the formula $C_{11}H_{23}CO_2H$.

(a) Write an equation for the base hydrolysis of glyceryl trilaurate.

(b) Write an equation for the reaction that could be used to prepare biodiesel fuel from this fat.

96. A well-known company sells outdoor clothing made of recycled polyethylene terephthalate (PET), the principal material in many soft drink bottles. Another company makes PET fibers by treating recycled bottles with methanol to give the diester dimethyl terephthalate and ethylene glycol and then repolymerizes these compounds to give new PET. Write a chemical equation to show how the reaction of PET with methanol can give dimethyl terephthalate and ethylene glycol.

97. Identify the reaction products, and write an equation for the following reactions of $CH_2{=}CHCH_2OH$.

(a) H_2 (hydrogenation, in the presence of a catalyst)

(b) Oxidation (excess oxidizing agent)

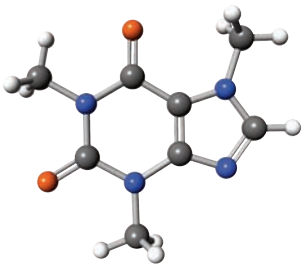
(c) Addition polymerization

(d) Ester formation, using acetic acid

98. Write a chemical equation describing the reaction between glycerol and stearic acid (Table 23.9) to give glyceryl tristearate.

99. The product of an addition reaction of an alkene is often predicted by Markovnikov's rule.

(a) Draw the structure of the product of adding HBr to propene, and give the name of the product.



(b) Draw the structure and give the name of the compound that results from adding H_2O to 2-methyl-1-butene.

(c) If you add H_2O to 2-methyl-2-butene, is the product the same or different than the product from the reaction in part (b)?

100. There are three ethers with the formula $C_4H_{10}O$. Draw their structures.

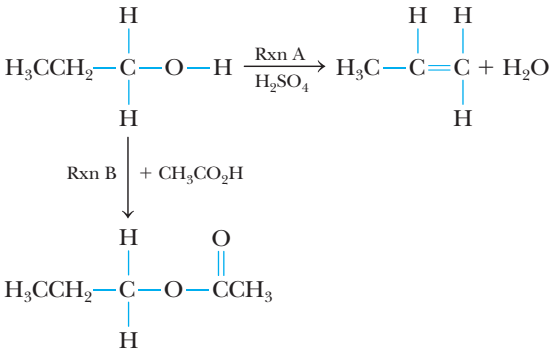
101. Review the opening photograph about chocolate (which shows the structure of an active ingredient, theobromine) and then answer the following questions.

(a) How do theobromine and caffeine differ structurally?

Caffeine, $C_8H_{10}N_4O_2$

(b) A 5.00-g sample of Hershey's cocoa contains 2.16% theobromine. What is the mass of the compound in the sample?

102. Nylon-6 is a polyamide formed by polymerizing $H_2NCH_2CH_2CH_2CH_2CH_2CO_2H$. Write an equation for this reaction.



In the Laboratory

103. Which of the following compounds produces acetic acid when treated with an oxidizing agent such as $KMnO_4$?

(a) $H_3C{-}CH_3$ (c) $H_3C{-}\underset{\displaystyle H}{\overset{\displaystyle OH}{\overset{|}{\underset{|}{C}}}}{-}H$

(b) $H_3C{-}\overset{\displaystyle O}{\overset{\|}{C}}{-}H$ (d) $H_3C{-}\overset{\displaystyle O}{\overset{\|}{C}}{-}CH_3$

104. Consider the reactions of C_3H_7OH.

(a) Name the reactant C_3H_7OH.

(b) Draw a structural isomer of the reactant, and give its name.

(c) Name the product of reaction A.

(d) Name the product of reaction B.

105. You have a liquid that is either cyclohexene or benzene. When the liquid is exposed to dark-red bromine vapor, the vapor is immediately decolorized. What is the identity of the liquid? Write an equation for the chemical reaction that has occurred.

106. ▲ Hydrolysis of an unknown ester of butanoic acid, $CH_3CH_2CH_2CO_2R$, produces an alcohol A and butanoic acid. Oxidation of alcohol A forms an acid B that is a structural isomer of butanoic acid. Give the names and structures for alcohol A and acid B.

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

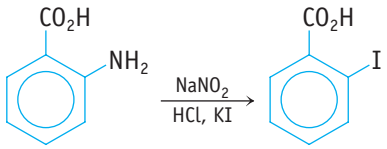
107. ▲ You are asked to identify an unknown colorless, liquid carbonyl compound. Analysis has determined that the formula for this unknown is C_3H_6O. Only two compounds match this formula.

(a) Draw structures for the two possible compounds.

(b) To decide which of the two structures is correct, you react the compound with an oxidizing agent and isolate from that reaction a compound that is found to give an acidic solution in water. Use this result to identify the structure of the unknown.

(c) Name the compound formed by oxidation of the unknown.



108. Describe a simple chemical test to tell the difference between $CH_3CH_2CH_2CH{=}CH_2$ and its isomer cyclopentane.

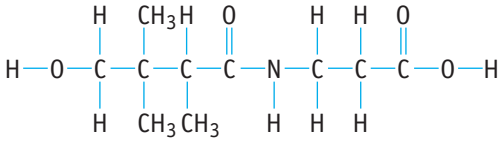
109. Describe a simple chemical test to tell the difference between 2-propanol and its isomer methyl ethyl ether.

110. ▲ An unknown ester has the formula $C_4H_8O_2$. Hydrolysis gives methanol as one product. Identify the ester, and write an equation for the hydrolysis reaction.

111. ▲ Addition of water to alkene X gives an alcohol Y. Oxidation of Y produces 3,3-dimethyl-2-pentanone. Identify X and Y, and write equations for the two reactions.

112. 2-Iodobenzoic acid, a tan, crystalline solid, can be prepared from 2-aminobenzoic acid. Other required reagents are $NaNO_2$ and KI (as well as HCl).

2-aminobenzoic acid 2-iodobenzoic acid



(a) If you use 4.0 g of 2-aminobenzoic acid, 2.2 g of $NaNO_2$, and 5.3 g of KI, what is the theoretical yield of 2-iodobenzoic acid?

(b) Are other isomers of 2-iodobenzoic acid possible?

(c) You titrate the product in a mixture of water and ethanol. If you use 15.62 mL of 0.101 M NaOH to titrate 0.399 g of the product, what is its molar mass? Is it in reasonable agreement with the theoretical molar mass?

113. The transesterification reaction between PET and CH_3OH forms dimethyl terephthalate and ethylene glycol. If the methanol used in this reaction is labeled with oxygen-18 (^{18}O), in which of the products will the label be found?

114. Vitamin B-5, pantothenic acid, has the structure shown below. Base hydrolysis of this compound followed by acidification gives two compounds. Draw their structures.

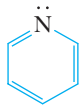
Vitamin B-5, pantothenic acid

Summary and Conceptual Questions

The following questions may use concepts from this and previous chapters.

115. Carbon atoms appear in organic compounds in several different ways with single, double, and triple bonds combining to give an octet configuration. Describe the various ways that carbon can bond to reach an octet, and give the name and draw the structure of a compound that illustrates that mode of bonding.

116. There is a high barrier to rotation around a carbon–carbon double bond, whereas the barrier to rotation around a carbon–carbon single bond is considerably smaller. Use the orbital overlap model of bonding (Chapter 9) to explain why there is restricted rotation around a double bond.



117. What important properties do the following characteristics impart to a polymer?

(a) Cross-linking in polyethylene

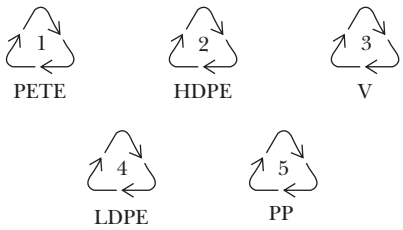
(b) The OH groups in polyvinyl alcohol

(c) Hydrogen bonding in a polyamide like nylon

118. One of the resonance structures for pyridine (C_5H_5N) is illustrated here. Draw another resonance structure for the molecule. Comment on the similarity between this compound and benzene.

Pyridine

119. Write balanced equations for the combustion of ethane gas and liquid ethanol (to give gaseous products).



(a) Calculate the enthalpy of combustion of each compound. Which has the more negative enthalpy change for combustion per gram?

(b) If ethanol is assumed to be partially oxidized ethane, what effect does this have on the enthalpy of combustion?

120. Plastics make up about 20% of the volume of landfills. There is, therefore, considerable interest in reusing or recycling these materials. To identify common plastics, a set of universal symbols is now used, five of which are illustrated here. They symbolize low- and high-density polyethylene, polyvinyl chloride, polypropylene, and polyethylene terephthalate.

(a) Tell which symbol belongs to which type of plastic.

(b) Find an item in the grocery or drug store made from each of these plastics. Properties of several plastics are listed in the table. Based on this information, describe how to separate samples of these plastics from one another.

Plastic	Density (g/cm^3)	Melting Point (°C)
Polypropylene	0.92	170
High-density polyethylene	0.97	135
Polyethylene terephthalate	1.34–1.39	245

121. ▲ Maleic acid is prepared by the catalytic oxidation of benzene. It is a dicarboxylic acid; that is, it has two carboxylic acid groups.

(a) Combustion of 0.125 g of the acid gives 0.190 g of CO_2 and 0.0388 g of H_2O. Calculate the empirical formula of the acid.

(b) A 0.261-g sample of the acid requires 34.60 mL of 0.130 M NaOH for complete titration (so that the H ions from both carboxylic acid groups are used). What is the molecular formula of the acid?

(c) Draw a Lewis structure for the acid.

(d) Describe the hybridization used by the C atoms.

(e) What are the bond angles around each C atom?

CHAPTER OUTLINE

24.1 Proteins

24.2 Carbohydrates

24.3 Nucleic Acids

24.4 Lipids and Cell Membranes

24.5 Metabolism

24.1 Proteins

Goals for Section 24.1

- Draw the Lewis structures for the most common naturally-occurring amino acids.
- Understand that under physiological conditions, amino acids exist as zwitterions in aqueous solution.
- Draw the Lewis structures for short polypeptides.
- Identify the categories of protein structure (primary, secondary, tertiary, and quaternary).

You are a marvelously complex biological organism, and so is every other living thing on Earth. What molecules are present in you, and what are their properties? How is genetic information passed from generation to generation? How does your body carry out the numerous reactions that are needed for life?

These questions and many others fall into the realm of biochemistry, a rapidly expanding area of science. As the name implies, biochemistry exists at the interface of two scientific disciplines: biology and chemistry. Biochemists tend to concentrate on the specific molecules involved in biological processes and on how chemical reactions occur in an organism (Figure 24.1). They use the strategies of chemistry to understand processes in living things.

The main goal of this chapter is to consider how chemistry is involved in answering important biological questions. To do so, we will examine four major classes of biological compounds: proteins, carbohydrates, nucleic acids, and lipids.

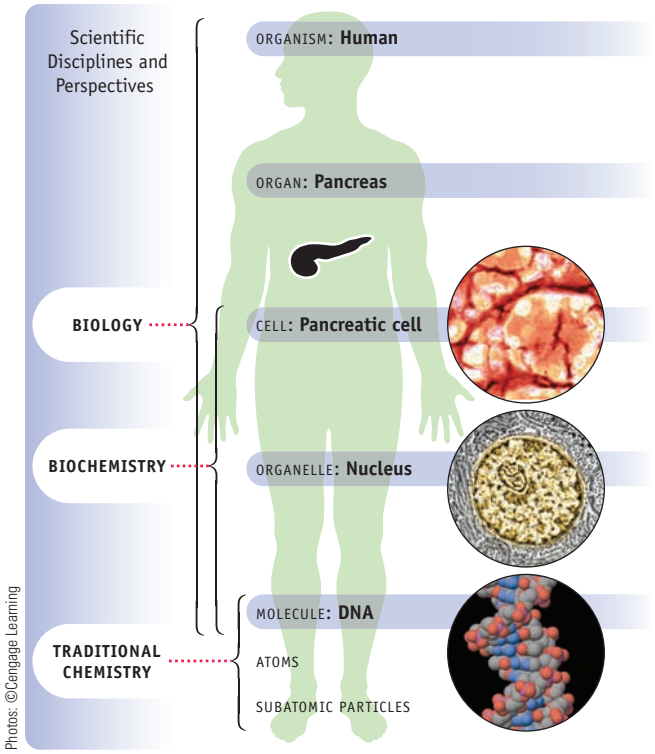

Figure 24.1 The human body with areas of interest to biologists, biochemists, and chemists.

◀ **CRISPR-Cas9 Complex.** The CRISPR-Cas9 complex (*A Closer Look: Genetic Engineering with CRISPR-Cas9*, page 1132) consists of a protein (white) and an RNA guide sequence (pink). This complex is able to cut DNA (green) at a particular sequence of nucleotides complementary to a portion of the guide RNA. In the drawing of the protein, the curly ribbons represent helices, and the arrows represent sheets formed by amino acids (Section 24.1).

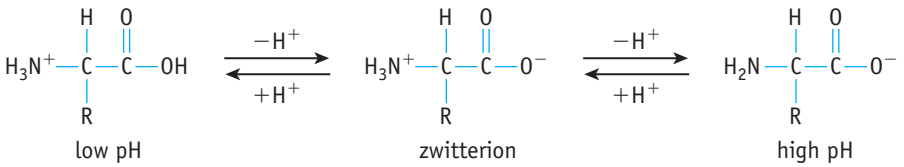
Amino Acids Are the Building Blocks of Proteins

Your body contains thousands of different proteins, and about 50% of the dry weight of your body consists of proteins. Proteins provide structural support (muscle, collagen), help organisms move (muscle), store and transport chemicals from one area to another (hemoglobin), regulate when certain chemical reactions will occur (hormones), and catalyze a host of chemical reactions (enzymes).



Proteins are condensation polymers (Section 23.5) formed from amino acids. **Amino acids** are organic compounds that contain an amino group ($—NH_2$) and a carboxylic acid group ($—CO_2H$)

Almost all amino acids that make up proteins are α-amino acids, in which the amino group is at one end of the molecule, the acid group is at the other end, and in between, a single carbon atom (the α-carbon) has attached to it a hydrogen atom and either another hydrogen atom or an organic group, denoted R. Naturally occurring proteins are predominantly built using 20 amino acids, which differ only in the identity of the organic group, R. These organic groups can be nonpolar (groups derived from alkanes or aromatic hydrocarbons) or polar (with alcohol, acidic, basic, or other polar functional groups) (Figure 24.2). Depending on which amino acids are present, a region in a protein may be nonpolar, very polar, or anything in between.

All α-amino acids, except glycine, have four different groups attached to the α-carbon. The α-carbon is thus a chiral center (Section 23.1), and two enantiomers exist. Interestingly, all of these amino acids occur in nature in a single enantiomeric form—the form with the L-configuration (*Applying Chemical Principles 23.1: An Awakening with L-DOPA*, page 1103).

Both the amino group and the carboxylic acid group can exist in two different states: an ionized form ($—NH_3^+$ and $—CO_2^-$) and an un-ionized form ($—NH_2$ and $—CO_2H$). At low pH, both groups will be in their protonated forms, that is, the amino group will be present as $—NH_3^+$ and the carboxylic acid group will be present as $—CO_2H$. As the pH is raised, the carboxylic acid group loses its proton and becomes the ionized form ($—CO_2^-$). The resulting species, which is the form prevalent in an aqueous environment at physiological pH (about 7.4), contains both a positive and a negative charge and is called a **zwitterion**. At higher pH values, the amino group loses its ionizable proton and becomes the un-ionized form ($—NH_2$).

The pH behavior of amino acids that have acidic or basic *R* groups is more complicated.

A condensation reaction between two amino acids results in the elimination of water and the formation of an amide linkage (Figure 24.3). The amide linkage in proteins is often referred to as a **peptide bond**, and the polymer (the protein) is called a **polypeptide**. The amide linkage is planar (Section 23.4), and both the carbon and the nitrogen atoms are sp^2 hybridized. There is partial double-bond character in the C—O and C—N bonds, leading to restricted rotation about the

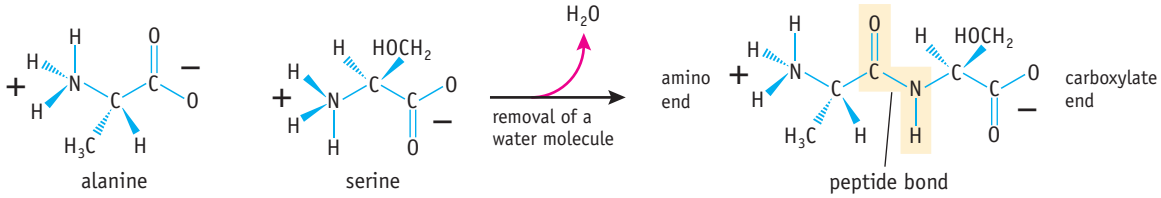

Figure 24.3 Formation of a peptide. Two α-amino acids condense to form an amide linkage, often called a *peptide bond*. Proteins are polypeptides, polymers consisting of many amino acid units linked through peptide bonds.

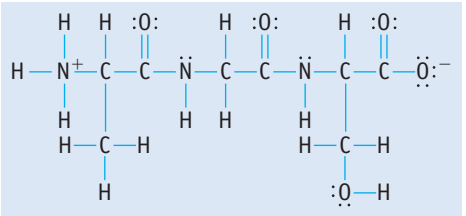
carbon–nitrogen bond. As a consequence, each peptide bond in a protein is rigid and planar, a feature that plays a role in determining its structure.

Proteins consist of one or more polypeptide chains that are often hundreds of amino acids long. Their molar masses are thus often thousands of grams per mole.

EXAMPLE 24.1



Drawing Peptide Structures

Problem Peptide and protein structures are drawn starting with the free amino group on the left and ending with the free carboxylic acid group on the right. Draw the Lewis structure for the tripeptide alanine-glycine-serine.

What Do You Know? You know the sequence of amino acids in the tripeptide, and that they are joined by amide linkages. The structures of the amino acids are listed in Figure 24.2.

Strategy Begin with the amino group of alanine on the left. Connect it via an amide linkage to glycine and then connect glycine to serine by another amide linkage.

SOLUTION The Lewis structure for this tripeptide is

Think about Your Answer A tripeptide contains three amino acids and two peptide bonds. The zwitterionic form of the tripeptide is shown as this is the form present at physiological pH.

Check Your Understanding

Draw the Lewis structure for the tripeptide glycine-phenylalanine-valine.

Protein Structure and Hemoglobin

With this basic understanding of amino acids and peptide bonds, let us examine some larger issues related to protein structure. One of the central tenets of biochemistry is that "structure determines function." In other words, what a molecule can do is determined by which atoms or groups of atoms are present and how they are arranged in space.

To simplify their discussions, biochemists describe proteins as having different structural levels. Each level of structure can be illustrated using hemoglobin.

Hemoglobin is the molecule in red blood cells that carries oxygen from the lungs to all of the body's other cells. It is a large iron-containing protein, made up of more than 10,000 atoms and having a molar mass of 64,500 g/mol. Hemoglobin consists of four polypeptide segments: two identical segments called the α subunits containing 141 amino acids each and two other segments called the β subunits containing 146 amino acids each. The β subunits are identical to each other but different from the α subunits. Each subunit contains an iron(II) ion locked inside an organic ion called a **heme** unit (Figure 24.4). The oxygen molecules transported by hemoglobin bind to these iron(II) ions.

Let us focus on the polypeptide part of hemoglobin (Figure 24.5). The first step in describing a structure is to identify how the atoms are covalently linked. This is called the **primary structure** of a protein, which is simply the sequence of amino acids linked by peptide bonds. For example, a glycine unit can be followed by an alanine, followed by a valine, and so on.

The remaining levels of structure all deal with noncovalent (nonbonding) interactions—that is, intermolecular forces—between amino acids in the protein. The **secondary structure** of a protein refers to hydrogen bonding networks formed between amide linkages in the protein backbone. (Figure 23.18 gives an example of interchain hydrogen bonding.) Specifically, the carbonyl group of one amide linkage interacts with the amino hydrogen of another amide. Some regular patterns, such as helices, sheets, and turns, often emerge as a result of hydrogen bonding. In hemoglobin, the amino acids in large portions of the polypeptide chains arrange themselves into many helical regions.

The **tertiary structure** of a protein refers to how the chain is folded, including how amino acids far apart in the sequence interact with each other. In other words, this structure deals with how the regions of the polypeptide chain fold into the overall three-dimensional structure.

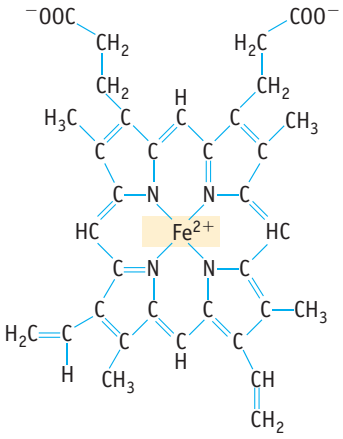

Figure 24.4 Heme. The heme unit in hemoglobin (and in myoglobin, a related protein) consists of an iron ion in the center of a porphyrin ring system. (For more information about the iron-containing heme group, see *A Closer Look: Hemoglobin: A Molecule with a Tetradentate Ligand*, page 1033.)

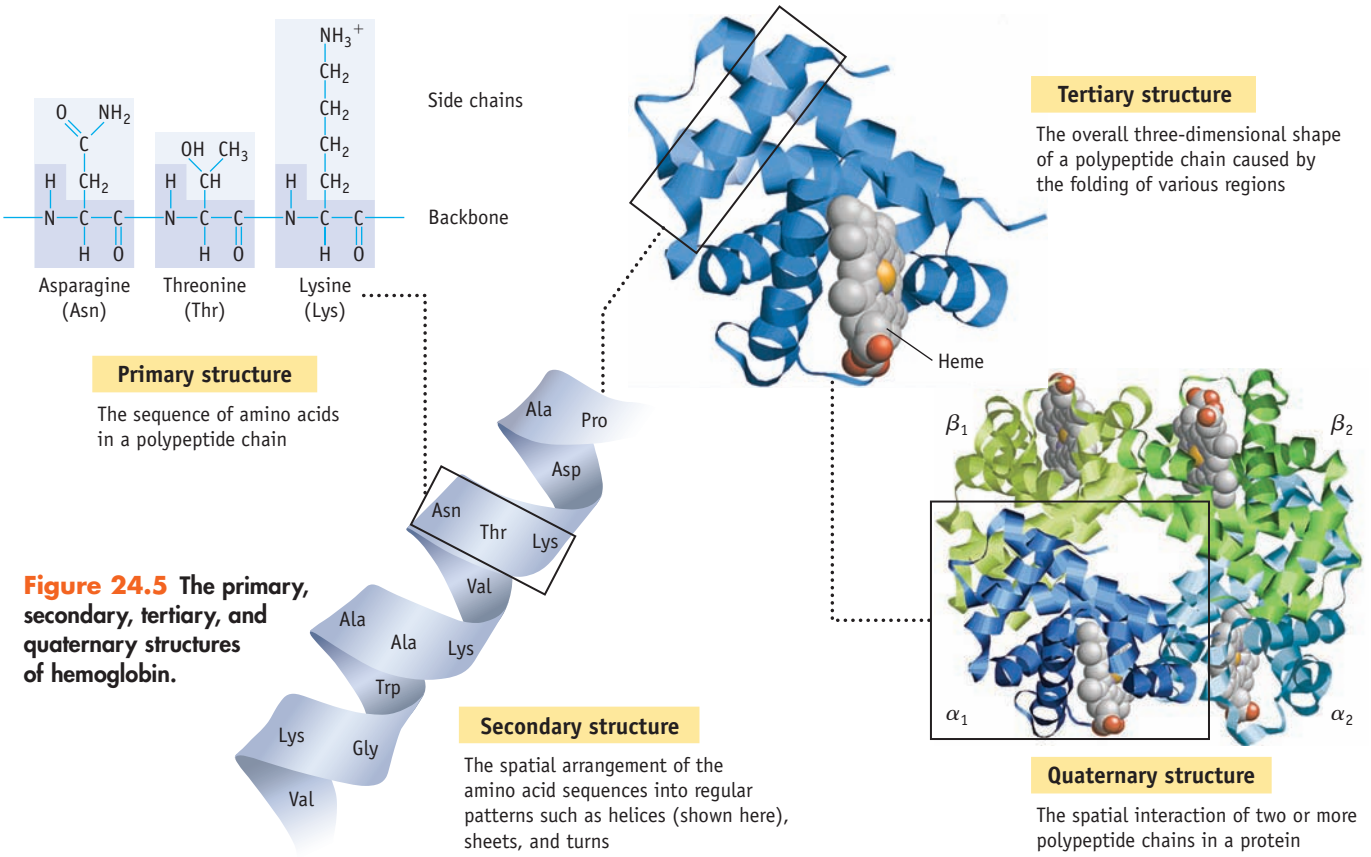

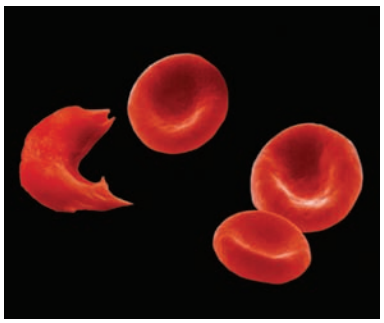

Figure 24.5 The primary, secondary, tertiary, and quaternary structures of hemoglobin.

Dr. Stanley Flegler/Visuals Unlimited, Inc.

(a)

(b)

Figure 24.6 Normal and sickled red blood cells. **(a)** Red blood cells are normally rounded in shape, but people afflicted with sickle cell anemia have cells with a characteristic "sickle" shape. **(b)** Sickle cell hemoglobin has a nonpolar region that can fit into a nonpolar cavity on another hemoglobin. Sickle cell hemoglobins can link together to form long chainlike structures.

For proteins consisting of only one chain, the tertiary structure is the highest level of structure present. In proteins consisting of more than one polypeptide chain, such as hemoglobin, there is a fourth level of structure, called the **quaternary structure**. It is concerned with how the different chains interact. The quaternary structure of hemoglobin shows how the four subunits are related to one another in the overall protein.

The subtleties of sequence, structure, and function are dramatically illustrated in the case of hemoglobin. Seemingly small changes in the amino acid sequence of hemoglobin and other molecules can be important in determining function, as is illustrated by the disease called *sickle cell anemia*. This disease, which is sometimes fatal, affects some individuals of African descent. Persons affected by this disease are anemic; that is, they have low red blood cell counts. In addition, many of their red blood cells are elongated and curved like a sickle instead of being round disks (Figure 24.6a). These elongated red blood cells are more fragile than normal blood cells and thus often break, leading to the anemia that is observed. The elongated cells also do not fit through the capillaries properly and so block the flow of blood, thereby decreasing the amount of oxygen that the individual's cells receive.

The cause of sickle cell anemia has been traced to a small structural difference in hemoglobin. In the β subunits of the hemoglobin in individuals carrying the sickle cell trait, a valine has been substituted for a glutamic acid. An amino acid in this position ends up on the surface of the protein, where it is exposed to the aqueous environment of the cell. Glutamic acid and valine are quite different from each other. The side chain in glutamic acid is ionic, whereas the side chain in valine is nonpolar. The nonpolar side chain on valine causes a nonpolar region to stick out from the molecule. When hemoglobin (normal or sickle cell) is in the deoxygenated state, it has a nonpolar cavity in another region. The nonpolar region around the valine on one sickle cell hemoglobin molecule fits nicely into this nonpolar cavity on another hemoglobin. The sickle cell hemoglobins thus link together, forming long chainlike structures (Figure 24.6b) that lead to the symptoms described.

Just one amino acid substitution in each β subunit causes sickle cell anemia! While other amino acid substitutions may not lead to such severe consequences, sequence, structure, and function are intimately linked and of crucial importance throughout biochemistry.

Enzyme Catalysis For an interesting example describing an experiment with the enzyme carbonic anhydrase, see Section 14.6 and *Applying Chemical Principles 14.1: Enzymes—Nature's Catalysts*, page 652.

Enzymes, Active Sites, and Lysozyme

Many reactions necessary for life occur too slowly on their own, so organisms speed them up to the appropriate level using biological catalysts called **enzymes**. Almost every metabolic reaction in a living organism requires an enzyme, and most of these enzymes are proteins. Enzymes are often able to speed up reaction rates tremendously, typically 10^7 to 10^{14} times faster than uncatalyzed rates.

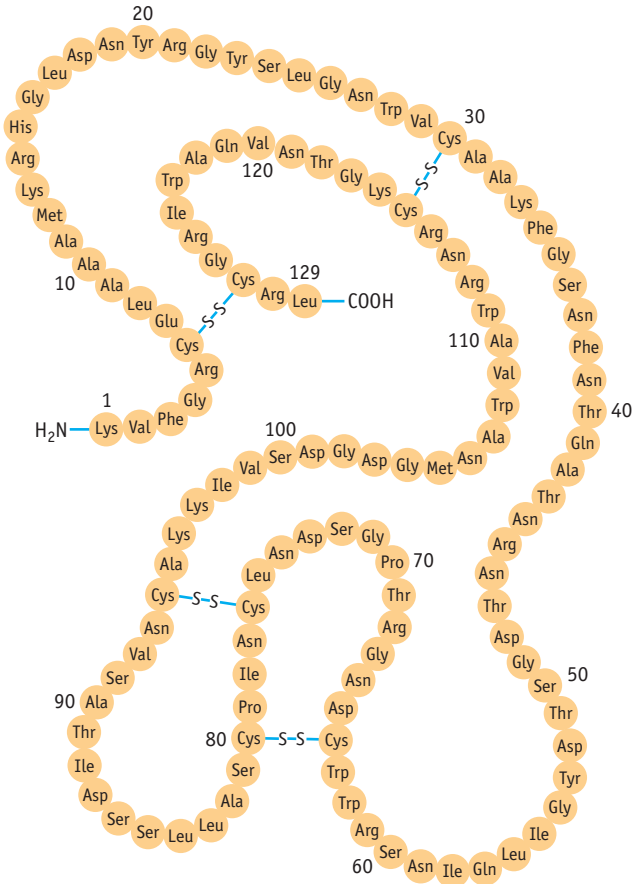
For an enzyme to catalyze a reaction, several key steps must occur:

1. A reactant (often called the **substrate**) must bind to the enzyme.
2. The chemical reaction must take place.
3. The product(s) of the reaction must leave the enzyme so that more substrate can bind and the process can be repeated.

Typically, enzymes are very specific; that is, only a limited number of compounds (often only one) serve as substrates for a given enzyme, and the enzyme catalyzes only one type of reaction. The place in the enzyme where the substrate binds and the reaction occurs is called the **active site**. The active site often consists of a cavity or cleft in the structure of the enzyme into which the substrate or part of the substrate can fit. The R groups of amino acids or the presence of metal ions in an active site are often important factors in binding a substrate and catalyzing a reaction.

Lysozyme is an enzyme that can be obtained from human mucus and tears and from other sources, such as egg whites. Alexander Fleming (1881–1955) (who later discovered penicillin) is said to have discovered its presence in mucus when he had a cold. He purposely allowed some of the mucus from his nose to drip onto a dish containing a bacteria culture and found that some of the bacteria died. The chemical in the mucus responsible for this effect was a protein. Fleming called it *lysozyme* because it is an enzyme that causes some bacteria to undergo lysis (rupture).



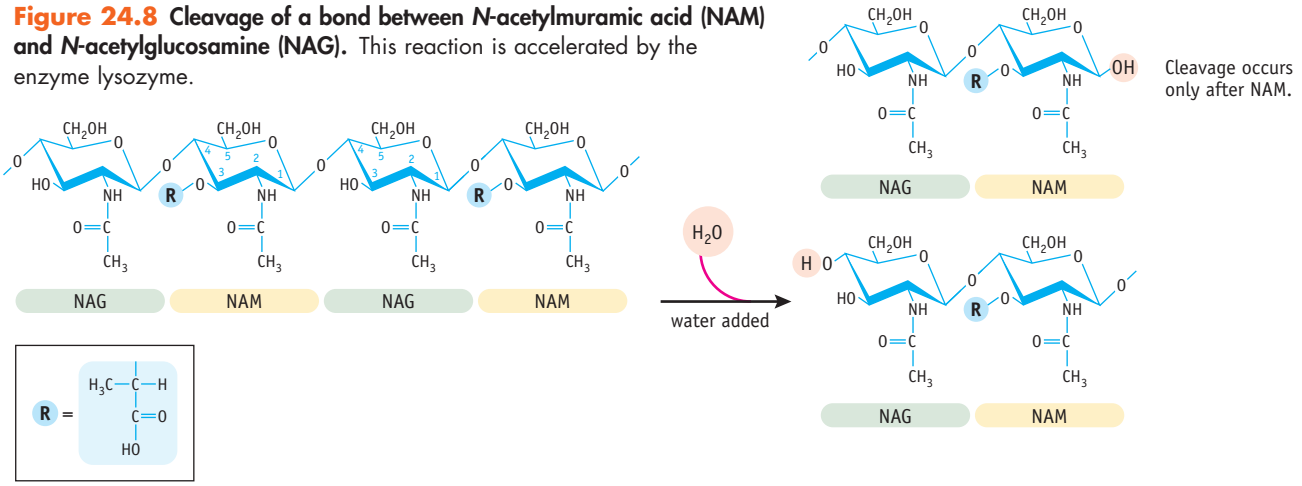


Figure 24.7 The primary structure of lysozyme. The cross-chain disulfide links (—S—S—) are links between cysteine amino acid residues.

Lysozyme is a protein containing 129 amino acids linked together in a single polypeptide chain (Figure 24.7). Its molar mass is 14,000 g/mol. As was true in the determination of the double-helical structure of DNA (pages 395–396), x-ray crystallography and model building were key techniques used in determining lysozyme's three-dimensional structure and method of action.

Lysozyme's antibiotic activity results from its catalysis of a reaction that breaks down the cell walls of some bacteria. These cell walls contain a **polysaccharide**, a polymer of sugar molecules. This polysaccharide is composed of two alternating sugars: *N*-acetylmuramic acid (NAM) and *N*-acetylglucosamine (NAG). Lysozyme speeds up the reaction that breaks the bond between carbon-1 of NAM and carbon-4 of NAG (Figure 24.8), thereby breaking down the cell wall.

Figure 24.8 Cleavage of a bond between *N*-acetylmuramic acid (NAM) and *N*-acetylglucosamine (NAG). This reaction is accelerated by the enzyme lysozyme.

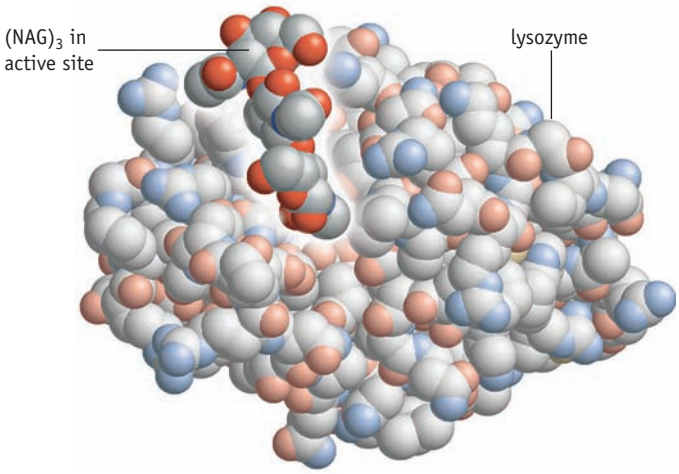

Figure 24.9 **Lysozyme with $(NAG)_3$ binds to the active site in lysozyme by means of intermolecular forces of attraction.**

Lysozyme also catalyzes the breakdown of polysaccharides containing only NAG, but it is not very effective in cleaving molecules consisting of only two or three NAG units [$(NAG)_3$]. In fact, these molecules act as inhibitors of the enzyme. Researchers surmised that the inhibition resulted from these small molecules binding to but not completely filling the active site in the enzyme. X-ray crystallography of crystals of lysozyme that had been treated with $(NAG)_3$ revealed that $(NAG)_3$ binds to a cleft in lysozyme (Figure 24.9).

This cleft has room for a total of six NAG units. Molecular models of the enzyme and $(NAG)_6$ showed that five of the six sugars fit nicely into the cleft but that the fourth sugar in the sequence did not fit well. To get this fourth sugar into the active site, its structure has to be distorted. Assuming that the bond cleaved is the one connecting this fourth sugar to the fifth sugar, this distortion is advantageous because it deforms the molecule to more closely resemble the transition state of the cleavage reaction, thus speeding up this reaction. Amino acids immediately around this location can also assist in the cleavage reaction. In addition, models showed that if an alternating sequence of NAM and NAG binds to the enzyme in this cleft, NAM must bind to this fourth sugar location in the active site because it cannot fit into the third sugar-binding site, whereas NAG can. Cleavage must therefore occur only between carbon-1 of NAM and carbon-4 of the following NAG, not the other way around—and this is exactly what occurs.

24.2 Carbohydrates

Goals for Section 24.2

- Draw the Lewis structures for commonly occurring mono-, di-, and polysaccharides.
- Identify the types of linkages between glucose subunits in common polysaccharides.

Carbohydrates, or sugars, constitute another major class of compounds found in living things. They serve as fuel for life's activities. Ribose and deoxyribose, two sugars, are components of the nucleic acids (Section 24.3) that store and translate the genetic information in our cells. Polymers of sugars, polysaccharides, serve as structural molecules in plants and bacteria. Finally, sugar molecules linked to other biomolecules are involved in cell-cell interactions.

Monosaccharides

Carbohydrates are polyhydroxy aldehydes or ketones. The open-chain structures of glucose, a polyhydroxy aldehyde or *aldose*, and of fructose, a polyhydroxy ketone or *ketose*, are shown in Figure 24.10. Both glucose and fructose are examples of **monosaccharides**, which are the simplest sugars. Monosaccharides usually have the general formula $C_x(H_2O)_x$, and it is from this formula that this class of compounds derives its name of carbohydrate, a combination of carbon and water. Thus, the formula of glucose, $C_6H_{12}O_6$, is equivalent to $C_6(H_2O)_6$.

The most abundant sugars in nature contain five or six carbon atoms and are referred to as *pentoses* and *hexoses*, respectively. Ribose and deoxyribose (Section 24.3), found in the nucleic acids RNA and DNA, are the most abundant pentoses in nature. By far, the most abundant six-carbon sugar containing an aldehyde group is glucose, and the most abundant six-carbon sugar containing a ketone group is fructose.

Almost all sugars are chiral, containing one or more carbon atoms with four different groups attached (Section 23.1). In the chain structure of glucose, for example, four of the carbon atoms are bonded to four different groups. In nature, glucose occurs in just one of its enantiomeric forms; thus a solution of glucose rotates polarized light. The structures shown in Figure 24.10 are the D-isomers of glucose and fructose.

D-glucose exists in three different isomeric forms in aqueous solutions. Two of the isomers contain six-member rings, and the third is the open chain structure (Figure 24.11). Notice that the two ring structures differ by the orientation of the hydroxyl group and hydrogen atom at C-1. In α-D-glucose, the hydroxyl group is pointing down (axial), whereas in β-D-glucose, it is pointing up (equatorial). In aqueous solution, the three different forms of glucose rapidly interconvert, but the three different forms are not present in equal amounts. The straight chain isomer makes up less than 1% of the molecules with the cyclic forms predominating and present in a 63%:37% ratio of β-D-glucose to α-D-glucose. The predominant structures of most monosaccharides in aqueous solution contain rings.

Knowing the structure of glucose allows one to predict some of its properties. With five polar —OH groups in the molecule, glucose is, not surprisingly, soluble in water. The aldehyde group is susceptible to chemical oxidation to form a carboxylic acid, and detection of glucose (in urine or blood) takes advantage of this fact. Diagnostic tests for glucose involve oxidation with subsequent detection of the products.

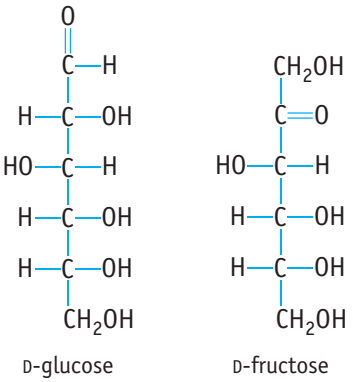

Figure 24.10 D-glucose and D-fructose. D-Glucose (an aldose) and D-fructose (a ketose) both have the molecular formula $C_6H_{12}O_6$. In D-sugars the hydroxyl group attached to the chiral carbon farthest from the carbonyl is shown on the right in this type of structure, whereas in L-sugars it is on the left.

D and L D and L are symbols historically used to identify absolute configurations of chiral species. They derive from dextro- (right) and levo- (left).

Disaccharides

When two sugar molecules join together to form a **disaccharide**, they do so by means of a condensation reaction, in which a water molecule is lost. The two sugars end up connected to each other by a bridging oxygen atom; this type of bond between two sugar molecules is called a **glycosidic bond**. Table sugar, sucrose (Figure 24.12a), is a disaccharide formed by the reaction of the hydroxyl group at position 1 in α-D-glucose with the hydroxyl group at position 2 of β-D-fructose. This type of linkage is referred to as an α,β-1,2 glycosidic bond.

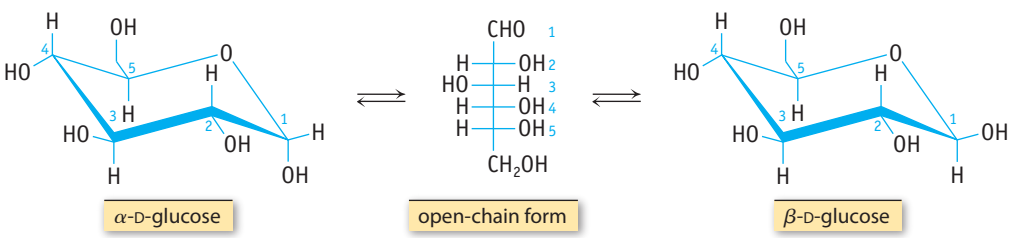

Figure 24.11 The straight-chain and ring forms of D-glucose.

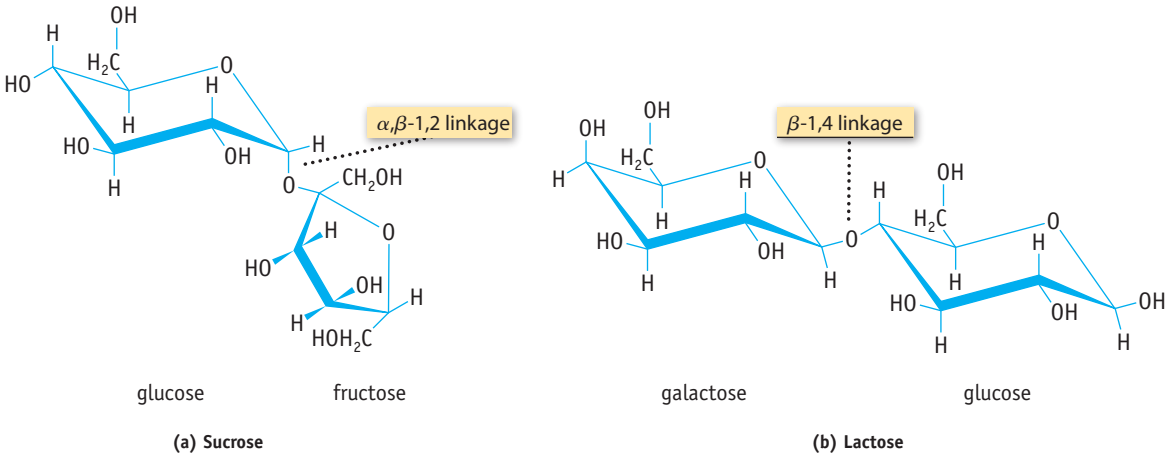

Figure 24.12 **The disaccharides sucrose and lactose.**

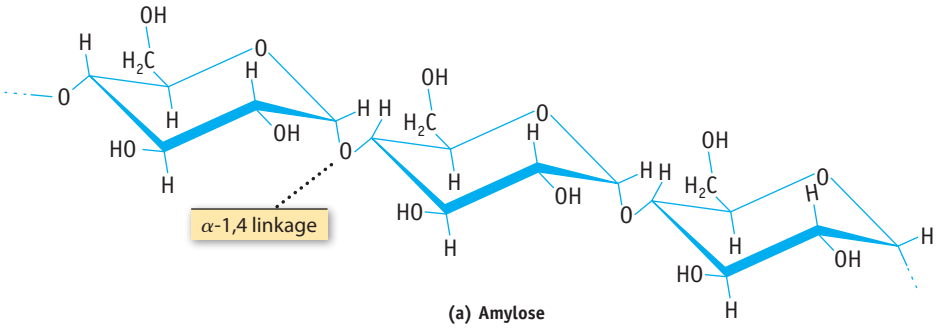
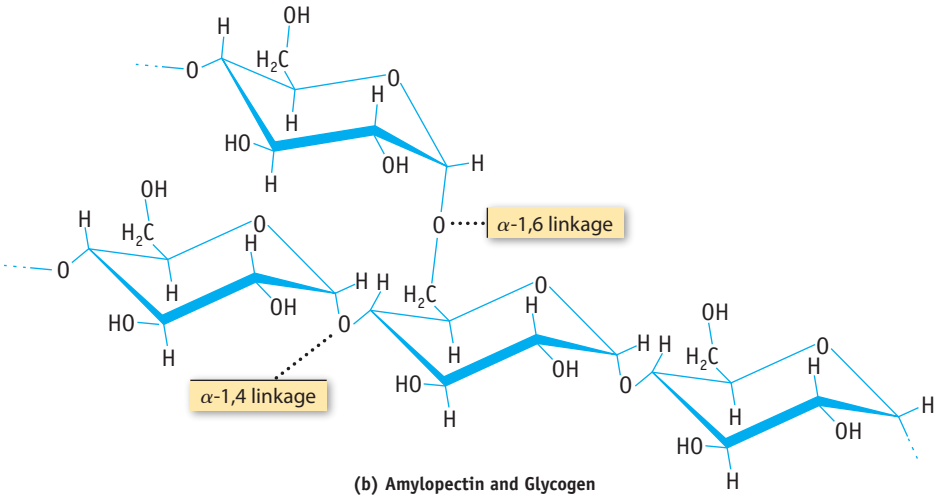
Another common disaccharide is lactose (Figure 24.12b), a sugar found in milk. This sugar contains another hexose called β-D-galactose, which is combined with D-glucose by means of a β-1,4 linkage. When milk is consumed, lactose is broken down into its monosaccharides by utilizing an enzyme called lactase. As many humans grow older, their ability to produce lactase and thus digest lactose decreases; they are said to become *lactose intolerant*. In such individuals, the lactose is instead fermented by bacteria in the digestive tract into lactic acid, producing methane gas and hydrogen gas in the process. These gases can cause discomfort and lead to flatulence. In addition, the lactic acid and any undigested lactose can sometimes lead to diarrhea. These symptoms can certainly be avoided if the affected person abstains from dairy products, but they can also be avoided if a supplement containing the enzyme lactase is consumed along with the dairy products.

Polysaccharides



Long polymers of sugars, **polysaccharides**, form when a large number of sugar molecules are joined by glycosidic bonds. In animal cells, excess glucose is stored as the polysaccharide *glycogen* (Figure 24.13). The basic structure of glycogen is a branched chain of glucose molecules. Within a chain, the linkages are all α-1,4 glycosidic bonds, and branch points to the chain occur by means of α-1,6 glycosidic bonds. Branch points occur every 10 or so glucose units in a chain.

Plant cells often store glucose in the form of starch. The chains in starch can range in size from molar masses of thousands to half a million or more. There are two main types of starch: *amylose starch* and *amylopectin starch*. Amylose starch contains linear chains of glucose molecules connected by means of α-1,4 glycosidic bonds. Amylopectin starch, like glycogen, is a branched chain of glucose molecules. The key difference is that the α-1,6 branch points in amylopectin occur less often than in glycogen, only every 30 or so glucose units.



Finally, the major structural molecule in plants, *cellulose*, is also a polysaccharide with chain lengths ranging from hundreds to many thousands of glucose units. The linkage between glucose molecules in cellulose is β-1,4 rather than α-1,4. This seemingly small change has a tremendous effect. Humans have enzymes that break down the α-1,4 linkages in starch but do not have an enzyme that breaks down the β-1,4 linkages between glucose molecules in cellulose. We can thus digest starch but cannot digest cellulose, and, when ingested, it passes through our systems unchanged as insoluble dietary fiber.

24.3 Nucleic Acids

Goals for Section 24.3

- Draw the Lewis structures for short strands of DNA and RNA.
- Predict the sequence of nucleotides complementary to a given strand of DNA.
- Predict the amino acid selected by a given sequence of three nucleotides in mRNA.

Nucleic Acid Structure

In the first half of the 20th century, researchers identified **deoxyribonucleic acid (DNA)** as the genetic material in cells. A close relative of DNA called **ribonucleic acid (RNA)** was also found in cells.

RNA and DNA are polymers (Figure 24.14). They consist of sugars having five carbon atoms (β-D-ribose in RNA and β-D-2-deoxyribose in DNA) that are

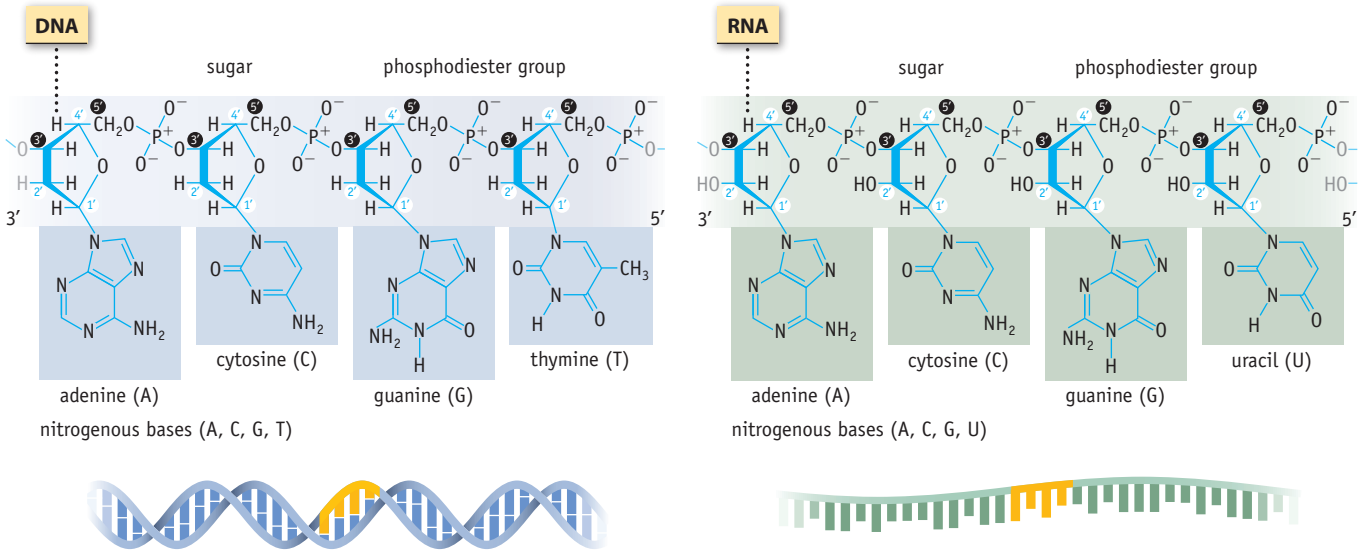

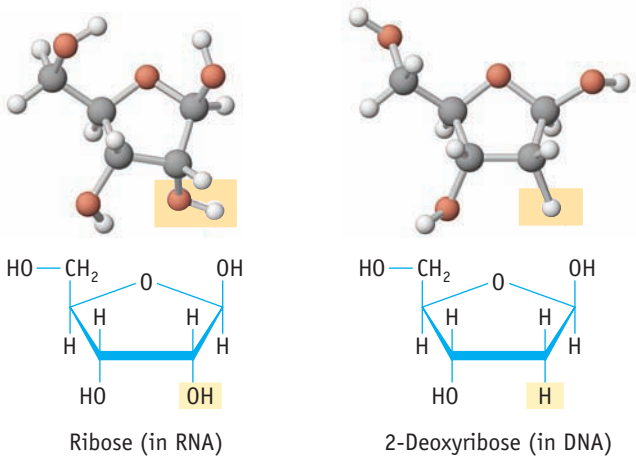

Figure 24.14 DNA and RNA.

Why Use the Primes in Numbering the Sugar Positions in DNA and RNA? In a nucleotide, there are two ring systems present: one in the nitrogenous base and one in the sugar. So that we can tell the difference between them, positions in the bases are numbered normally (1, 2, 3, etc.), whereas positions in the sugars are numbered using numbers followed by the prime symbol (1′, 2′, 3′, etc.).

connected by phosphodiester groups. At physiological pH, these phosphodiester linkages are in their ionized states with a net 1− charge per linkage. Thus, there is also a 1+ cation present per phosphodiester linkage (not shown in Figure 24.14). A phosphodiester group links the 3′ (pronounced "three prime") position of one sugar to the 5′ position of the next sugar. Attached at the 1′ position of each sugar is a nitrogen-containing (nitrogenous) base. The bases in DNA are adenine (A), cytosine (C), guanine (G), and thymine (T); in RNA, the nitrogenous bases are the same as in DNA, except that uracil (U) is used rather than thymine. A single sugar with a nitrogenous base attached is called a **nucleoside**. If a phosphate group is also attached, then the combination is called a **nucleotide** (Figure 24.15).

The principal chemical difference between RNA and DNA is the identity of the sugar.

Ribose has a hydroxyl group (—OH) at the 2 position, whereas 2-deoxyribose has only a hydrogen atom at this position. This seemingly small difference turns out to have profound effects. The polymer chain of RNA is cleaved many times faster than a corresponding chain of DNA under similar conditions due to the involvement of this hydroxyl group in the cleavage reaction. The greater stability of DNA contributes to it being a better repository for genetic information.

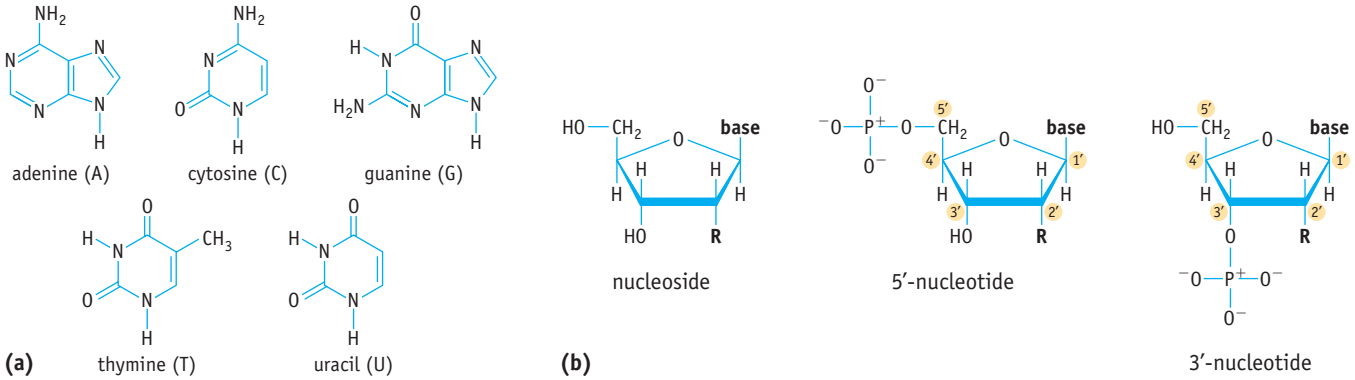

Figure 24.15 **Bases, nucleosides, and nucleotides.**

Storing Genetic Information

How does DNA store genetic information? DNA consists of a double helix (Figure 24.16). In this structure, one strand of DNA is paired with another strand running in the opposite direction. Thus, if one strand is viewed from the 5′-end to the 3′-end, the other strand will be lined up next to it such that it runs from the 3′-end to the 5′-end.

The key parts of the structure of DNA for storing genetic information are the nitrogenous bases. James Watson and Francis Crick (page 396) noticed that A can form two hydrogen bonds with T and that C can form three hydrogen bonds with G. The spacing between the two strands of the double helix is just right for either an A–T pair or for a C–G pair to fit, but other combinations (such as A–G) do not fit properly. Thus, if we know the identity of a nucleotide on one strand of the double helix, we can figure out which nucleotide must be bound to it on the other strand. The two strands are referred to as **complementary strands**.

If the two strands are separated from each other, a new complementary strand can be constructed for each of the original strands by placing a G wherever there is a C, a T wherever there is an A, and so forth. Through this process, called **replication**, the cell ends up with two identical double-stranded DNA molecules for each molecule of DNA initially present. When the cell divides, each of the two resulting cells gets one copy of each DNA molecule (Figure 24.17). In this way, genetic information is passed along from one generation to the next.

The Structure of DNA For more information about the structure of DNA, see *Chemical Bonding in DNA*, page 350, Section 8.10: *DNA, Revisited*, pages 395–396, and *A Closer Look: Hydrogen Bonding in Biochemistry*, page 500.

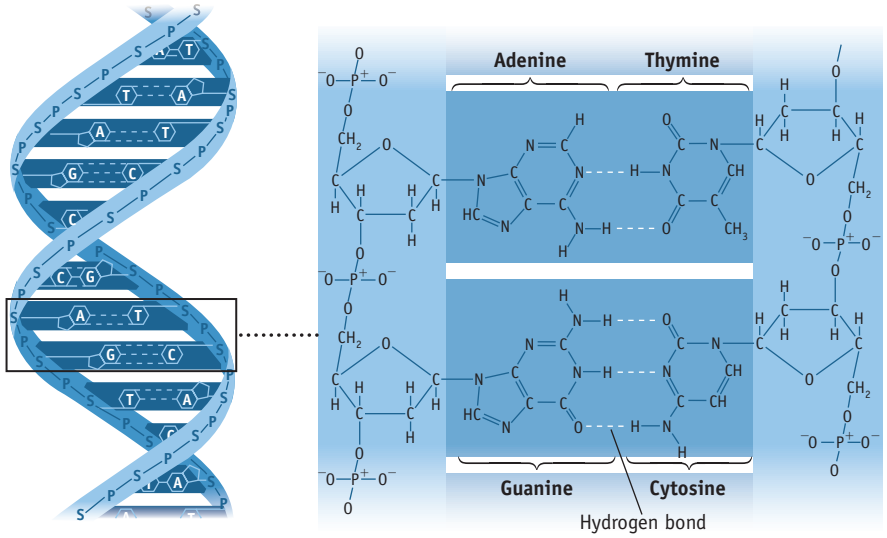

Figure 24.16 **Base pairs and complementary strands in DNA.** With the four bases in DNA, the usual pairings are adenine with thymine and cytosine with guanine. The pairing is promoted by hydrogen bonding.

Two strands of DNA. Each base is paired with its partner: adenine (A) with thymine (T), guanine (G) with cytosine (C).

The two DNA strands are separated from each other.

Two new complementary strands are built using the original strands.

Replication results in two identical double-stranded DNA molecules.

At this stage during cell division, the chromosomes containing the DNA have been duplicated, and the two sets have been separated.

Figure 24.17 The main steps in DNA replication. The products of this replication are two identical double-helical DNA molecules. When a cell divides, each resulting cell gets one set.

The power of DNA was demonstrated further in 2010 in an experiment conducted by researchers at the J. Craig Venter Institute. They designed a sequence of DNA with a little over 1 million base pairs that was similar to that of a species of bacteria, *Mycoplasma mycoides*. Beginning with chemically synthesized strands of DNA that were only about one thousand base pairs long, they constructed the overall desired DNA sequence. They then replaced the DNA in cells of another species of bacteria, *M. capricolum*, with this synthesized DNA. The resulting organisms could perform cell division and grew into colonies of bacteria. These bacteria had characteristics not of *M. capricolum* but of the modified *M. mycoides*. The synthetic DNA, designed and constructed by humans, was not only capable of carrying out the normal functions of DNA but had transformed one species into another!

EXAMPLE 24.2

Complementary Strands of DNA

Problem Nucleic acid sequences are usually written starting with the nucleotide on the 5′-end and proceeding to the 3′-end. A particular segment of a strand of DNA has the sequence AGTCCTCATG. What is the sequence of the complementary strand?

What Do You Know? You know the sequence of a segment of DNA and that in the complementary strand A will base pair with T, and C will base pair with G.

Strategy Write the sequence of DNA that is complementary to the given sequence by completing the base pairs (A with T and G with C). Make sure that in your final answer you list the sequence from the 5′-end to the 3′-end.

SOLUTION The given sequence and its complement are as follows:

Given sequence: 5′-AGTCCTCATG-3′

Complementary sequence: 3′-TCAGGAGTAC-5′

In order from the 5′-end to the 3′-end, this sequence is CATGAGGACT.

Think about Your Answer Knowing the sequence of one strand of DNA allows us to predict the sequence of DNA on the complementary strand.

Protein Synthesis

The sequence of nucleotides in a cell's DNA contains the instructions to make the proteins the cell needs. DNA is the information storage molecule. To use this information, the cell first makes a complementary copy of the required portion of the DNA using RNA. This step is called **transcription**. The molecule of RNA that results is called **messenger RNA (mRNA)** because it takes this message to where protein synthesis occurs in the cell. The cell uses the more rapidly cleaved RNA rather than DNA to carry out this function.

It makes sense to use DNA, the more stable molecule, to store the genetic information because the cell wants this information to be passed from generation to generation intact. Conversely, it makes sense to use RNA to send the message to make a particular protein. By using the less-stable RNA, the message will not be permanent but rather will be destroyed after a certain time, thus allowing the cell to turn off the synthesis of the protein.

Protein synthesis occurs in **ribosomes**, complex bodies in a cell consisting of a mixture of proteins and RNA, which bind to mRNA. The sequence of nucleotides in mRNA contains information about the order of amino acids in the desired protein. Following the signal in mRNA to start protein synthesis, every sequence of three nucleotides provides the code for an amino acid in the protein until the ribosome reaches the signal to stop (Table 24.1). These three-nucleotide sequences in mRNA are referred to as **codons**, and the correspondence between each codon and its message (start, add a particular amino acid, or stop) is referred to as the **genetic code**.

How is the genetic code used to make a protein? In the ribosome–mRNA complex, there are three neighboring binding sites, called the *A site*, the *P site*, and the *E site*. Each cycle that adds an amino acid to a growing protein begins with that part of the protein already constructed being located in the P site. The A site is where the next amino acid is brought in, and yet another type of RNA becomes involved at this point. This **transfer RNA (tRNA)** consists of a strand of RNA to which an amino acid can be attached (Figure 24.18). A strand of tRNA has a particular region that contains a sequence of three nucleotides that can attempt to form base pairs to a codon in the mRNA at the ribosome's A site. This three-nucleotide sequence in the tRNA is called the **anticodon**. Only if the base pairing between the codon and anticodon is complementary (for example, A with U) will the tRNA be able to bind to the mRNA–ribosome complex. Not only does the anticodon determine to which codon a

TABLE 24.1

Examples of the 64 Codons in the Genetic Code

Codon Base Sequence*	Amino Acid to Be Added

A CLOSER LOOK

Genetic Engineering with CRISPR-Cas9

Ever since Watson and Crick discovered the double helical structure of DNA, scientists have looked for ways to modify the DNA of an organism. For example, they might wish to learn more about what certain portions of the DNA do, to eliminate a faulty gene from being expressed, or to correct a gene to produce a healthy protein. In order to do these things, the DNA of an organism must often be cut at specific locations. Over the years, various proteins have been discovered and developed for this purpose, but very recently, a new and very powerful technique to do this has been found.

Russell, Peter J, Paul E. Herz & Beverly McMillan. Biology: The Dynamic Science, 4ed, 2017, Cengage Learning.

CRISPR-Cas9. A guide sequence of RNA is incorporated into the structure of the Cas9 protein. When a strand of DNA is encountered that is complementary to a portion of this guide sequence, both strands of the DNA are cut at the indicated locations.

This method is based on a process carried out by bacterial cells to protect themselves from invading bacteria or viruses to which that species of bacteria had been exposed sometime in the past. As a result of that past invasion, portions of the invader's DNA were introduced into the bacterial DNA. It was found that these bacteria have regions of DNA called clustered regularly interspaced palindromic repeats (CRISPRs). In these CRISPRs, there are multiple regions of 20–30 base pairs of DNA that arose from past invading species. When these segments of DNA are transcribed into RNA, the resulting short segments of RNA are joined with proteins such as the CRISPR-associated protein 9 (Cas9) and with another strand of RNA associated with the protein. When these protein-RNA hybrids come across DNA that is complementary to the CRISPR RNA, such as in an invading virus, the protein cuts both strands of the DNA, inactivating the invader and protecting the bacteria.

Since the discovery of this mechanism, scientists have found that they can combine the two types of RNA into a single strand of RNA, called the guide sequence, which has one part that is complementary to the DNA to be cut and one part that binds the RNA to the Cas9 protein. The key aspect of this CRISPR-Cas9 system is that the DNA to be cut can be programmed by simply incorporating the complementary RNA into the CRISPR-Cas9 system. Thus, scientists can choose to cut virtually any sequence of DNA using the appropriate RNA bound to the Cas9 protein. Once the DNA is cut, this causes DNA repair enzymes to rejoin the strands. In this process, the gene is either disrupted or replaced, perhaps with a new gene for a different protein.

CRISPR-Cas9 has already been used in a multitude of studies. The method has been used to edit the genomes of a wide range of cell types and organisms, including human cells in the laboratory. It holds the promise of being able to correct genetic mutations leading to disease. One major challenge that remains is how to get the molecular machinery for CRISPR-Cas9 into a complex living organism, such as a human being, and deliver it to the target cells. This is a problem being worked on by many scientists and companies around the world. Finally, there are also ethical issues that must be considered whenever it is proposed to change the genome of an organism, particularly when that organism is a human being.

particular strand of tRNA can bind, but it also determines which amino acid will be attached to the end of the tRNA molecule. Thus, a codon in the mRNA is complementary to a particular tRNA anticodon, which in turn specifies the correct amino acid.

The growing protein chain in the P site (Figure 24.19) reacts with the amino acid in the A site, resulting in the protein chain being elongated by one amino acid and moving the chain into the A site. The ribosome then moves down the mRNA chain, moving the tRNA along with the protein strand from the A site into the P site and exposing a new codon in the A site. The tRNA that had been in the P site and that no longer has an amino acid attached moves into the E site and then exits from the ribosome. The process is then repeated.

Converting the information from a nucleotide sequence in mRNA into an amino acid sequence in a protein is called **translation**. Protein synthesis thus consists of two main processes: transcription of the DNA's information into RNA, followed by translation of the RNA's message into the amino acid sequence of the protein. There is more involved, but the processes of transcription and translation as discussed here provide a basic introduction to this important topic.

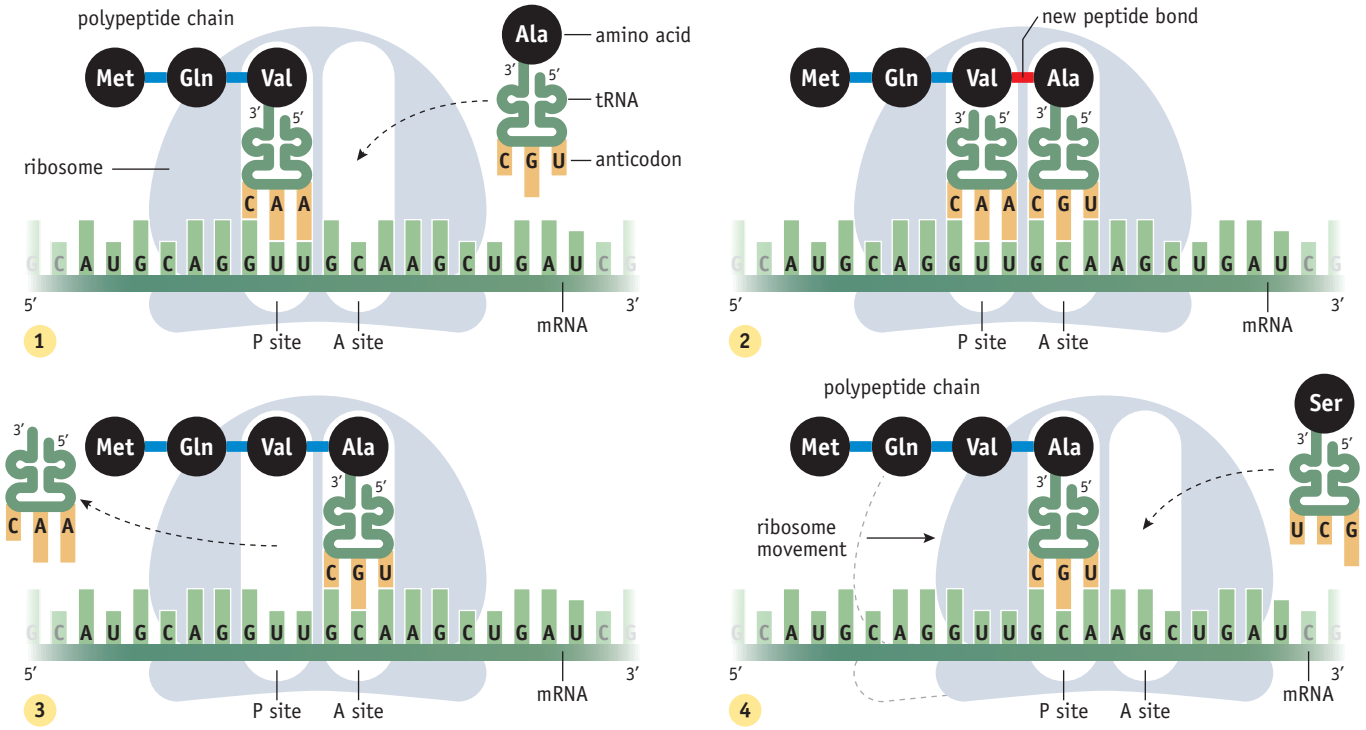

Figure 24.19 Protein synthesis. The tRNA with an anticodon complementary to the mRNA codon exposed in the A site of the ribosome brings the next amino acid to be added to the growing protein chain. After the new peptide bond is formed, the ribosome moves down the mRNA, exposing a new codon in the A site and transferring the previous tRNA and the protein chain to the P site.

EXAMPLE 24.3

Protein Synthesis

Problem A strand of DNA that codes for three amino acids in a protein has the following sequence: TTT TGC GTA. What is the sequence of amino acids that will result from this sequence?

What Do You Know? The sequence of DNA is given. The information in DNA is transcribed into mRNA and then translated by tRNA into the desired amino acid sequence. You know the rules for forming base pairs. The genetic code for some of the codons in mRNA is given in Table 24.1.

Strategy From the given DNA sequence, determine the sequence of mRNA that would be transcribed. Look at the sequence of mRNA in groups of three nucleotides, which correspond to the codons. Determine which amino acids correspond to these codons.

SOLUTION The given sequence of DNA and its complementary strand of mRNA are as follows:

Given sequence of DNA: 5′-TTT TGC GTA-3′

Complementary sequence of mRNA: 3′-AAA ACG CAU-5′

Thus the resulting strand of mRNA has the sequence 5′-UAC GCA AAA-3′. This strand of mRNA is divided into groups of three nucleotides each, corresponding to the codons in the mRNA. Based on Table 24.1 and reading from the 5′ end to the 3′ end, the amino acids selected by this sequence are tyrosine-alanine-lysine.

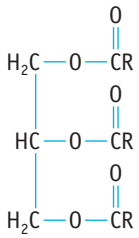
Check Your Understanding

What is the sequence of amino acids encoded by the DNA sequence TTG TGC TTT?

24.4 Lipids and Cell Membranes

Goals for Section 24.4



- Understand that lipids are not very soluble in water and that some lipids consist of molecules in which one end is polar and the other end is nonpolar.
- Recognize the ring system in steroids.
- Understand the structure of a lipid bilayer and how materials can be transported across the bilayer.

Lipids are the principal components of cell membranes and a repository of chemical energy in the form of fat. In addition, some of the chemical messengers called **hormones** are lipids.

Lipids include a wide range of compounds because classification of a compound as a lipid is based on its solubility rather than on a particular chemical functional group. A lipid is a compound that is at best slightly soluble in water but is soluble in organic solvents. Compounds in biological organisms that are nonpolar, or at least substantially nonpolar, have limited solubility in water (Section 13.2) and are therefore lipids.

A major category of lipids consists of molecules that have a polar end and a nonpolar end. The polar end provides the slight water affinity necessary for it to be compatible with being in the aqueous environment of the cell, but the nonpolar end greatly limits the water solubility. Many of these lipid components are fats, oils, fatty acids, or related to these compounds.

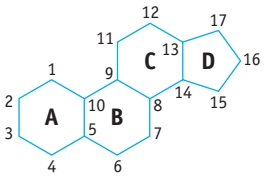
Fats and **oils** serve many functions in the body, a primary one being the storage of energy. Fats (solids) and oils (liquids) are triesters formed from glycerol (1,2,3-propanetriol) and three carboxylic acids that can be the same or different. Because they are triesters of glycerol, they are sometimes referred to as **triglycerides**.

Triglyceride. R = long chain fatty acid (Table 24.2)

The carboxylic acids in fats and oils are known as **fatty acids** and have a lengthy carbon chain, usually between 12 and 18 carbon atoms (Table 24.2). Fatty acids and triglycerides are lipids of the type where one end of the molecule is polar and the other end is nonpolar. The polar end in fatty acids is a carboxylic acid group, and the nonpolar end is a long hydrocarbon chain.

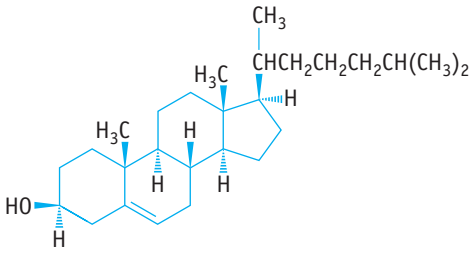
The hydrocarbon chains can be saturated (Section 23.2) or may include one or more double bonds. Saturated

TABLE 24.2 Common Fatty Acids



Name	Number of C Atoms	Formula
Saturated Acids		
Lauric	C_{12}	$CH_3(CH_2)_{10}CO_2H$
Myristic	C_{14}	$CH_3(CH_2)_{12}CO_2H$
Palmitic	C_{16}	$CH_3(CH_2)_{14}CO_2H$
Stearic	C_{18}	$CH_3(CH_2)_{16}CO_2H$
Unsaturated Acid		
Oleic	C_{18}	$CH_3(CH_2)_7CH{=}CH(CH_2)_7CO_2H$

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203



Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

compounds are more common in animal products while unsaturated fats and oils are more common in plants. In general, triglycerides containing saturated fatty acids are solids, and those containing unsaturated fatty acids are liquids at room temperature. The difference in melting point relates to the molecular structure. With only single bonds linking carbon atoms in saturated fatty acids, the hydrocarbon group is flexible, allowing the molecules to pack more closely together. This greater contact between the molecules leads to greater forces of attraction between the molecules and thus to higher melting points. The double bonds in unsaturated triglycerides, on the other hand, introduce kinks that make the hydrocarbon group less flexible; consequently, the molecules pack less tightly together, leading to smaller London dispersion forces and lower melting points.

Steroids are another category of lipids. Steroid molecules consist of four, joined hydrocarbon rings (Figure 24.20). Three of the rings contain six carbon atoms, and one contains five carbon atoms. Examples of steroids are the sex hormones testosterone, estradiol, and progesterone. Cholesterol (Figure 24.20) is also an important steroid. You may have heard of cholesterol because of its correlation with heart disease. While some cholesterol is necessary for humans, excess cholesterol can deposit in blood vessels, thus partially blocking them and causing the heart to work harder than it should.

The ring structure present in all steroids: three six member rings (A, B, and C) and one five-member ring (D).

cholesterol

Figure 24.20 Steroids.

The most prevalent molecules in most cell membranes are **phospholipids** (Figure 24.21a). These are similar to triglycerides in that they are based on glycerol. Two of the alcohol groups in glycerol are esterified to long-chain fatty acids. The third alcohol group is bonded to a phosphate that has another hydrocarbon chain attached. Phosphate groups are very polar. In phospholipid molecules, the phosphate end is sometimes called the "head," and the nonpolar hydrocarbon chains comprise the "tail."

When phospholipids are placed in water, they typically arrange themselves in a **bilayer structure** (Figure 24.21b). This is exactly the arrangement that phospholipids have in a cell membrane. Water is present on both the inside and the outside of the bilayer, corresponding to the inside and outside of the cell. In the outside layer of the membrane, the phospholipids line up alongside each other such that their polar heads face the aqueous environment outside the cell. Moving inward, next come the tails of these lipids. The phospholipids in the second layer align themselves so that their nonpolar tails are in contact with the outer layer's nonpolar tails.

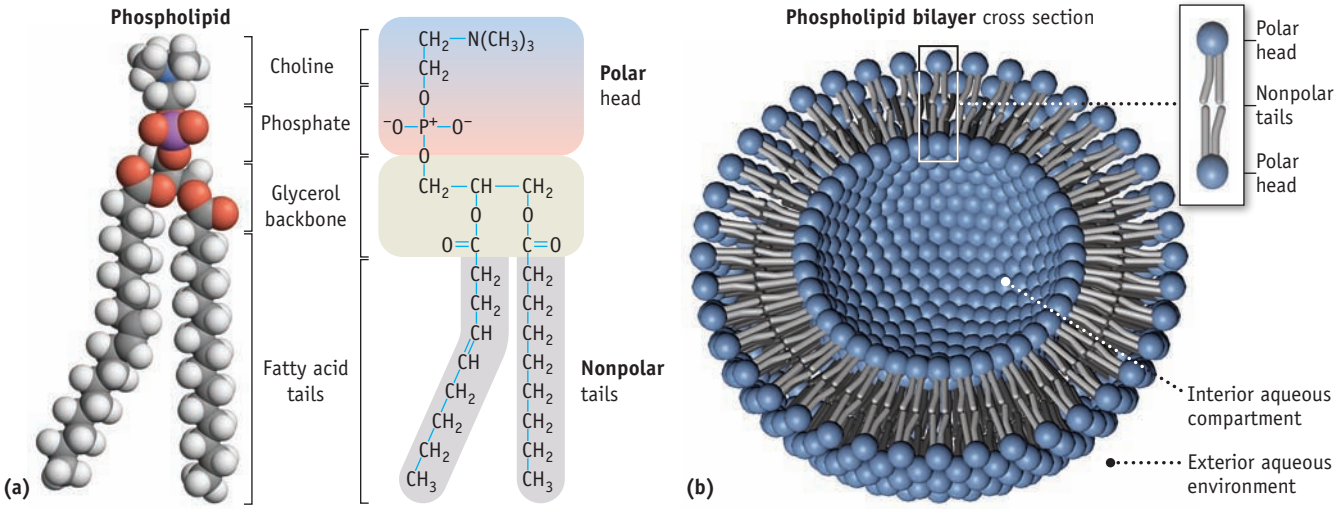


Figure 24.21 Phospholipids. **(a)** The structure of a phospholipid. **(b)** A cross-section of a phospholipid bilayer. The polar heads of the phospholipids are exposed to water, whereas the nonpolar tails are located in the interior of the bilayer.

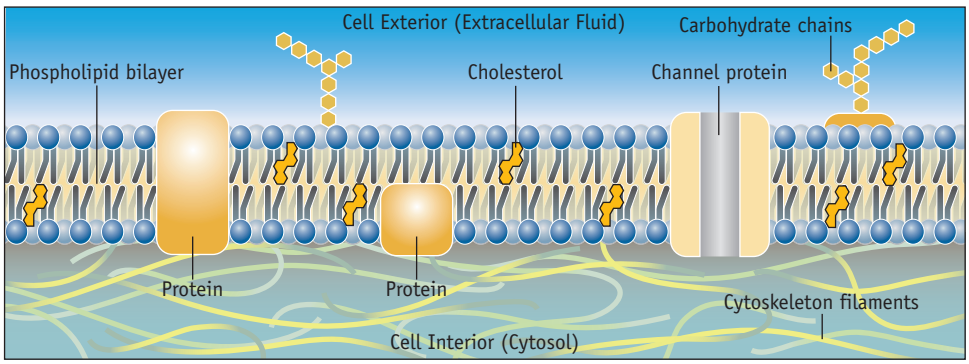

Figure 24.22 The fluid-mosaic model of cell membranes. A cell membrane is made up primarily of a phospholipid bilayer in which are embedded cholesterol, other lipids, and proteins. Movement within a layer occurs, but movement from one side of the bilayer to the other is rare.

Finally, the polar heads of the second layer face the aqueous environment inside the cell. The phospholipid bilayer nicely encloses the cell and provides a good barrier between the inside and the outside of the cell, due to the different solubility characteristics of the nonpolar region in the middle of the bilayer.

There are other molecules present in cell membranes. Cholesterol is an important part of animal cell membranes, helping to give the membranes greater rigidity. Some proteins in the cell membrane allow select materials to cross from one side of the membrane to the other (*transport proteins*). Others accept chemical signals from other cells or respond to materials in the cell's environment (*receptor proteins*). Finally, some enzymes are also associated with the membrane.

The overall model for a cell membrane is called the **fluid-mosaic model** (Figure 24.22). In this model, the membrane's structure is largely that of a phospholipid bilayer. Embedded in this bilayer are molecules such as cholesterol and proteins. Movement of all of these components within each layer of the bilayer occurs readily; the membrane is thus fluid to a certain extent. On the other hand, there is little movement of components, such as phospholipids, from one side of the membrane to the other. The "like dissolves like" observation provides the reason for this lack of exchange between layers. The head of a phospholipid in the outer layer, for example, would not be compatible with the very nonpolar region within the bilayer that the phospholipid would need to pass through in order to traverse from one side of the bilayer to the other.

A cell membrane serves as the boundary between the cell and the rest of the universe, but exchange of some materials between the cell and the outside world needs to occur. There are different mechanisms by which this happens (Figure 24.23). The simplest is *passive diffusion*. In this process, a molecule moves through the phospholipid bilayer from a region of higher concentration to a region of lower concentration, the natural direction of flow. Because the bilayer provides such a good barrier, only a few very small uncharged molecules (such as N_2, O_2, CO_2, and H_2O) can pass through the membrane this way. Many more species enter or leave the cell through a process called *facilitated diffusion*. In this process, ions or molecules still travel from a region of higher concentration to a region of lower concentration, but they do not pass directly through the bilayer. Instead, they pass through channels formed by proteins embedded in the cell membrane.

Sometimes, it is necessary for the cell to move species from a region of lower concentration to a region of higher concentration, the opposite direction that would normally occur on its own. The cell accomplishes this by means of *active transport*. This is again mediated by transport proteins in the cell membrane. Because the species of interest must move in the opposite direction than it would normally go, the cell must expend energy in order to make this occur.

Finally, cells sometimes transport materials into themselves by means of *endocytosis*. This process is usually mediated by a receptor protein. The species of interest (called the *substrate*) binds to the receptor protein. A portion of the cell membrane surrounds the receptor–substrate complex. This portion of the cell membrane is then broken off, bringing the complex into the cell.

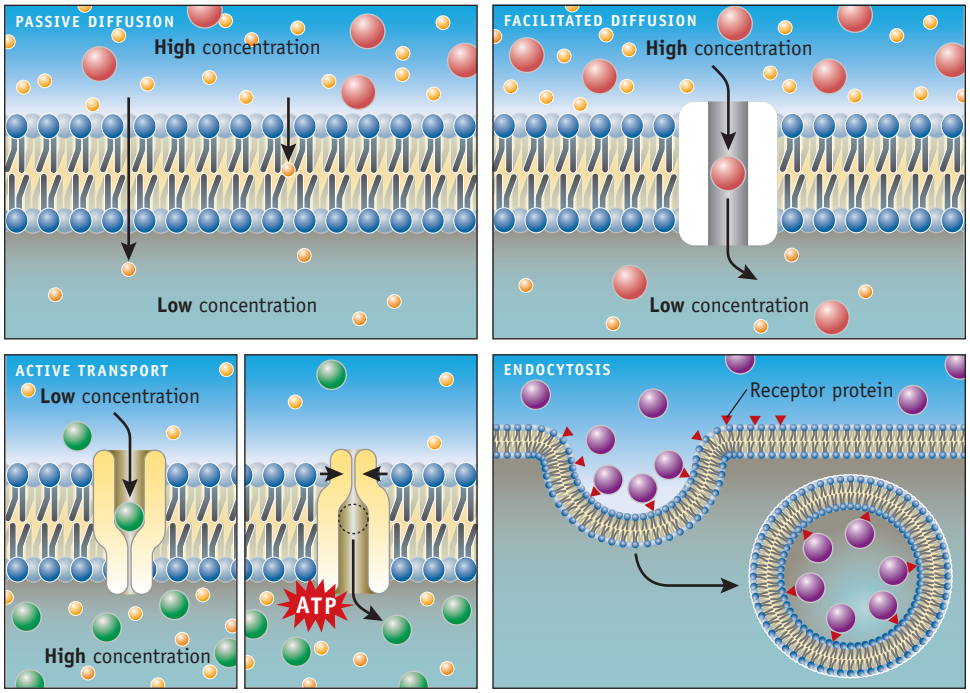

Figure 24.23 Transport of materials across a cell membrane.

24.5 Metabolism

Goals for Section 24.5

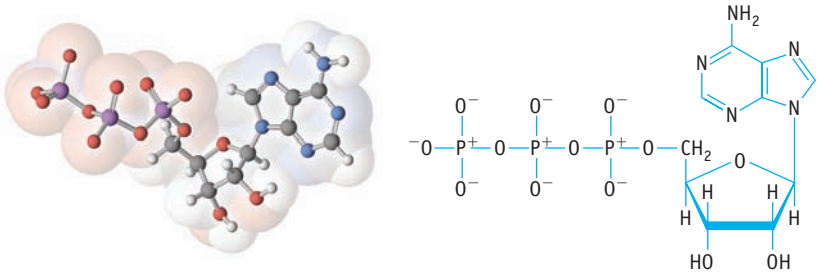
- Understand that coupling of ATP hydrolysis with a reactant-favored reaction can lead to a product-favored reaction.
- Recognize that NAD^+ and NADH are involved in biochemical redox reactions.
- Contrast the overall reactions for respiration and photosynthesis.
- Understand the absorption of light by chlorophyll.

Why do we eat? Some components of our food, such as water, are used directly in our bodies. We break down other chemicals to obtain the molecular building blocks we need to make the many chemicals in our bodies. Oxidation of foods also provides the energy we need to perform the activities of life. The many different chemical reactions that foods undergo in the body to provide energy and chemical building blocks fall into the area of biochemistry called **metabolism**.

Energy and ATP

Substances in food, such as carbohydrates and fats, are oxidized in metabolic processes. These oxidations are energetically favorable reactions, releasing large quantities of energy. For example, the oxidation of the sugar glucose ($C_6H_{12}O_6$) to form carbon dioxide and water is very exothermic.

$$C_6H_{12}O_6(s) + 6\ O_2(g) \rightarrow 6\ CO_2(g) + 6\ H_2O(\ell)$$



$$\Delta_r H° = -2803\ \text{kJ/mol-rxn}$$

However, rather than carry out this reaction in one rapid and exothermic step, a cell carries out a more controlled oxidation in a series of steps so that it can obtain the energy in small increments. In addition, it would be inefficient if every part of a cell needed to have all the mechanisms necessary to carry out the oxidation of every type of molecule used for energy. Instead, it carries out the oxidation of compounds such as glucose in one location and stores the energy in a small set of compounds that can be used almost anywhere in the cell.

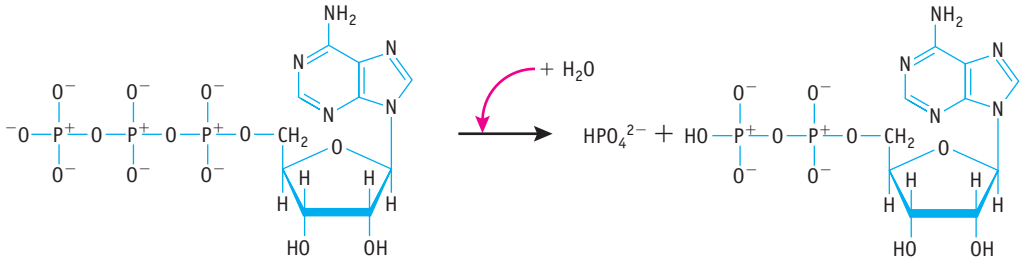
Figure 24.24 Adenosine-5′-triphosphate (ATP).

The principal compound used to perform this storage and transport of energy function is **adenosine 5′-triphosphate** (ATP). This ribonucleotide consists of a ribose molecule to which the nitrogenous base adenine is connected at the 1′ position and a triphosphate group is connected at the 5′ position (Figure 24.24). In aerobic respiration, the equivalent of 30–32 mol of ATP is typically produced per mole of glucose oxidized. Based on the ΔH values for the processes, a greater production of ATP might be expected, but the process is not completely efficient.

The hydrolysis of ATP to adenosine 5′-diphosphate (ADP) and the hydrogen phosphate ion (P_i) is an exothermic process that is product-favored at equilibrium (Figure 24.25).

$\Delta G°'$ For the definition of $\Delta G°'$, see *Applying Chemical Principles 18.1: Thermodynamics and Living Things*, page 843.

$$ATP + H_2O \rightarrow ADP + P_i \qquad \Delta_r H° \approx -24 \text{ kJ/mol-rxn } (\Delta_r G°' = -30.5 \text{ kJ/mol-rxn})$$



Why is this reaction exothermic? In this reaction, we must break two bonds, a P—O bond in ATP and an H—O bond in water. But we also form two new bonds: a P—O bond connecting the phosphate group being cleaved off the ATP with the OH of the original water and an H—O bond connecting the hydrogen from the water with the portion of the ATP that forms ADP. *In this overall process, more energy is released in forming these new bonds in the products than is required to break the necessary bonds in the reactants.*

In cells, many chemical processes that would be reactant-favored on their own are linked with the hydrolysis of ATP. The combination of an energetically unfavorable process with the energetically favorable hydrolysis of ATP can yield a process that is energetically favorable and product-favored at equilibrium. For example, most cells have a greater concentration of potassium ions and a smaller concentration of sodium ions inside them than are present outside them. The natural tendency, therefore, is for sodium ions to flow into the cell and for potassium ions to flow out. To maintain the correct concentrations, the cell must counteract this movement and pump sodium ions out of the cell and potassium ions into the cell. This requires energy. To accomplish this feat, the cell links this pumping process to the hydrolysis of ATP to ADP. The energy released from the hydrolysis reaction provides the energy to run a molecular pump (a transport protein) that moves the ions in the direction the cell needs.

Oxidation–Reduction and NADH

Cells also need compounds that can be used to carry out oxidation–reduction reactions. Just as ATP is a compound used in many biochemical reactions when energy

Figure 24.25 The exothermic conversion of adenosine-5′-triphosphate (ATP) to adenosine-5′-diphosphate (ADP).

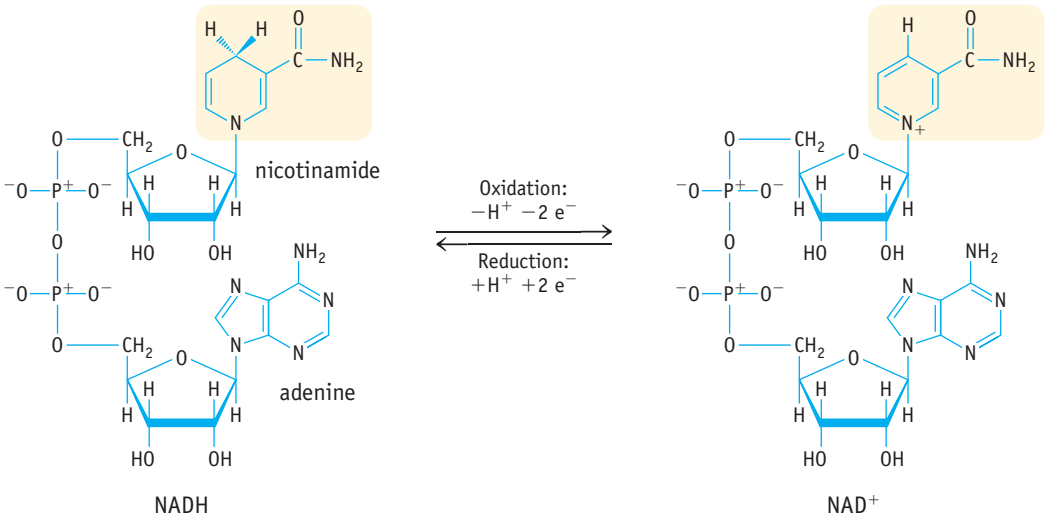

Figure 24.26 The structures of NADH and NAD^+.

is needed, so nature uses another small set of compounds to run many redox reactions. An important example is **nicotinamide adenine dinucleotide (NADH)**. This compound consists of two ribonucleotides joined at their 5′ positions via a diphosphate linkage. One of the nucleotides has adenine as its nitrogenous base, whereas the other has a nicotinamide ring (Figure 24.26). When NADH is oxidized, changes occur in the nicotinamide ring, such that the equivalent of a hydride ion (H^-) is lost. Because this hydride ion has two electrons associated with it, the nicotinamide ring loses two electrons in the process. The resulting species, referred to as NAD^+, is shown on the right in Figure 24.26.

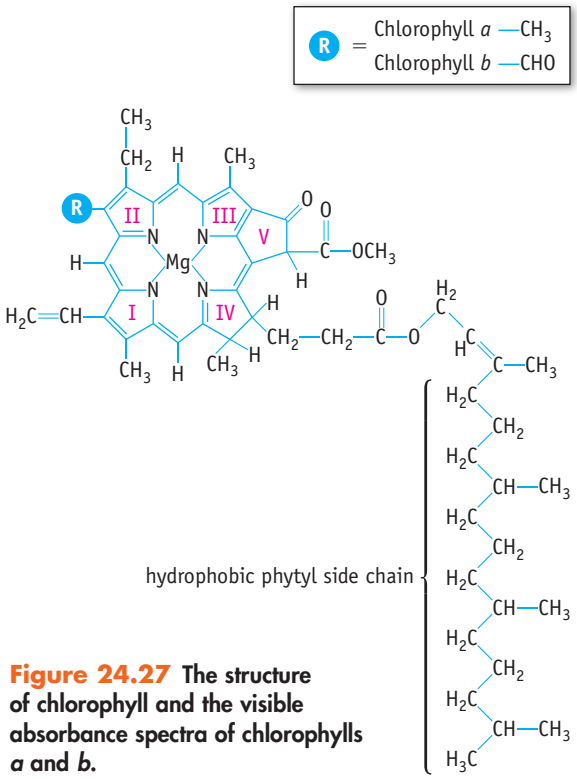
In many biochemical reactions, when a particular species needs to be reduced, it reacts with NADH. The NADH is oxidized to NAD^+, losing two electrons in the process, and the species of interest is reduced by gaining these electrons. If a species must be oxidized, the opposite process often occurs; that is, it reacts with NAD^+. The NAD^+ is reduced to NADH, and the species of interest is oxidized.

Respiration and Photosynthesis

In the process of **respiration**, a cell breaks down molecules such as glucose, oxidizing them to CO_2 and H_2O.

$$C_6H_{12}O_6(s) + 6\ O_2(g) \rightarrow 6\ CO_2(g) + 6\ H_2O(\ell)$$

The energy released in these reactions is used to generate the ATP needed by the cell. The sugars used in this process can be traced back to green plants, where sugars are made via the process of **photosynthesis**. In photosynthesis, plants carry out the reverse of glucose oxidation—that is, the synthesis of glucose from CO_2 and H_2O.



$$6\ CO_2(g) + 6\ H_2O(\ell) \rightarrow C_6H_{12}O_6(s) + 6\ O_2(g)$$

Green plants have found a way to use light to provide the energy needed to run this endothermic reaction.

The key molecule involved in trapping the energy from light in photosynthesis is chlorophyll. Green plants contain two types of chlorophyll: chlorophyll *a* and chlorophyll *b* (Figure 24.27). The absorbance spectra of chlorophyll *a* and chlorophyll *b* are also shown in Figure 24.27. Notice that these molecules absorb best in the blue-violet and red-orange regions of the visible spectrum. Not much light is absorbed in the green region. When white light shines on chlorophyll, red-orange and blue-violet light are absorbed by the chlorophyll; green light is reflected. We see the reflected light, so plants appear green to us. The light energy absorbed by the chlorophyll is used to drive the process of photosynthesis.

APPLYING CHEMICAL PRINCIPLES

24.1 Antisense Therapy

Much traditional research in finding new drugs focuses on discovering compounds that bind to proteins involved in a disease. A different approach is followed by what is called "antisense" therapy. Rather than proteins, antisense therapy focuses on nucleic acids, specifically the mRNA or even the DNA coding for the protein. A compound is introduced that is complementary to this strand and that will therefore bind to it, thus tying up the strand of nucleic acid so that it will not deliver its message to the ribosome in the case of mRNA or will not be transcribed in the case of DNA. The sequence of the targeted nucleic acid is referred to as the "sense" strand and the complementary strand, the drug, is referred to as the antisense strand.

In 2013, a drug produced by Isis Pharmaceuticals became the second antisense compound approved by the Food and Drug Administration for human use in the United States. The drug, called Kynamro, targets the mRNA for a protein involved in a rare condition that leads to very high levels of cholesterol called *homozygous familial hypercholesterolemia*. (The first compound ever approved was produced by Isis in the late 1990s but was not commercially successful.)

Nucleic acid strands with natural phosphodiester linkages are very susceptible to enzyme breakdown in the body and thus do not make good drug candidates. Kynamro uses a backbone that contains phosphorothioate groups (Figure) in which an oxygen attached to phosphorus is replaced by a sulfur atom. In addition,

Part of the sequence of the antisense drug, Kynamro.

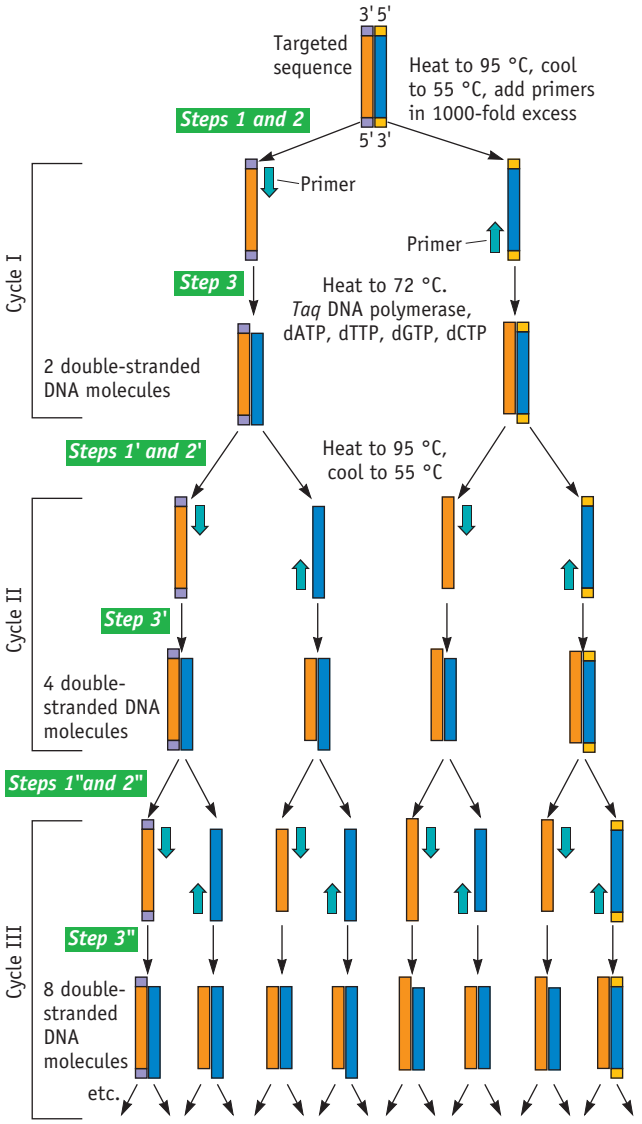
the drug uses deoxyribose sugars in some locations and modified ribose sugars in other locations. In these ribose sugars, the 2′-OH group has been replaced by a methoxyethyl group. Yet another modification is that a methyl group has been added to each of the cytosine and uracil bases in the compound.

Kynamro may be just the beginning of what is likely to be many more antisense treatments.

Questions:

1. Kynamro has the hydrogen bonding sequence: GCCU-CAGTCTGCTTCGCACC. What is the sequence of nucleotides in the targeted mRNA?
2. The formula of Kynamro is $C_{230}H_{305}N_{67}O_{122}P_{19}S_{19}Na_{19}$. How many nucleotides are present in one molecule of Kynamro?
3. What is the molecular geometry around the phosphorus atom in the phosphorothioate group?

24.2 Polymerase Chain Reaction



One night while driving to a cabin in Northern California, Kary Mullis, a chemist at the Cetus Corporation, was musing about how he might be able to develop a method to determine the sequence of a strand of DNA. As he worked on this problem, he realized that his musings had led him instead to a way to copy a sequence of DNA multiple times. Now called the *polymerase chain reaction* (PCR), the method allows one to amplify a segment of as little as a single copy of double-stranded DNA many times over in a relatively short period of time.

A piece of double-stranded DNA is heated to a temperature of around 95 °C. At this temperature, the hydrogen bonds holding the two strands together break, and the two strands separate from each other. The reaction mixture is then cooled to a lower temperature, around 55 °C. At this lower temperature, two small segments (usually 18–30 nucleotides long) of DNA called primers bind to the DNA, one primer per strand. One primer is complementary to the 3′-region of DNA to be amplified on one strand, and the other primer is complementary to the 3′-region of DNA to be amplified on the other strand. The temperature is then raised to around 72 °C where an enzyme called *Taq* polymerase becomes active. This polymerase, from a species of bacteria that lives at high temperature called *Thermus aquaticus (Taq)*, takes DNA nucleotide triphosphates (dATP, dGTP, dCTP, and dTTP) from the solution and adds them to the primers in the proper order so that new strands of DNA complementary to the original strands are produced. The process began with one double-stranded DNA, but two are now present at the end of the first cycle of PCR. The temperature is then raised again to 95 °C, and a new cycle is begun. After this second cycle, there will be four double-stranded DNAs present. After three cycles, the number will be eight, and so on with the amount of DNA growing exponentially. In this way, millions of copies of the original DNA can be made fairly quickly.

PCR has become commonplace in forensic science where it is used to amplify DNA found at a crime scene so that it can be tested against a suspect's DNA. It has also been used in tests for HIV infection, paternity tests, and for determining the DNA of organisms long extinct, as well as many other uses. Kary Mullis shared the Nobel Prize in Chemistry in 1993 for his work in developing this technique.

Questions:

1. Theoretically, how many copies of double-stranded DNA could be present after 20 cycles of PCR?
2. How does the fact that DNA molecules separate at 95 °C give evidence that the forces holding together DNA molecules are not covalent bonds?

PCR. Note that at the end of three cycles of PCR, eight copies of the segment of DNA exist.

3. Care must be exercised in selecting good primers to use in PCR.
   a. Why are primers often chosen that have a high number of cytosines and guanines in their sequences?
   b. Why would a primer sequence of CCCCCCCCCCGGGGGGGGGG not be a good choice?
   c. Why is a vast excess of primer used for the amount of DNA to be amplified?

CHAPTER GOALS REVISITED

The goals for this chapter are keyed to specific Study Questions to help you organize your review:

24.1 Proteins

- Draw the Lewis structures for the most common naturally-occurring amino acids. 1–4.
- Understand that under physiological conditions, amino acids exist as zwitterions in aqueous solution. 1, 2.
- Draw the Lewis structures for short polypeptides. 5–8.
- Identify the categories of protein structure (primary, secondary, tertiary, and quaternary). 9, 10.

24.2 Carbohydrates

- Draw the Lewis structures for commonly occurring mono-, di-, and polysaccharides. 11, 12.
- Identify the types of linkages between glucose subunits in common polysaccharides. 12.

24.3 Nucleic Acids

- Draw the Lewis structures for short strands of DNA and RNA. 15, 16.
- Predict the sequence of nucleotides complementary to a given strand of DNA. 17, 18.
- Predict the amino acid selected by a given sequence of three nucleotides in mRNA. 17, 18.

24.4 Lipids and Cell Membranes

- Understand that lipids are not very soluble in water and that some lipids consist of molecules in which one end is polar and the other end is nonpolar. 20.
- Recognize the ring system in steroids. 21, 22.
- Understand the structure of a lipid bilayer and how materials can be transported across the bilayer. 19.

24.5 Metabolism

- Understand that coupling of ATP hydrolysis with a reactant-favored reaction can lead to a product-favored reaction. 34.
- Recognize that NAD^+ and NADH are involved in biochemical redox reactions. 25, 26.
- Contrast the overall reactions for respiration and photosynthesis. 29, 33.
- Understand the absorption of light by chlorophyll. 29.

▲ denotes challenging questions. **Blue-numbered questions** have answers in Appendix N and fully worked solutions in the *Student Solutions Manual*.

Practicing Skills

Proteins

(See Section 24.1 and Example 24.1.)

1. (a) Draw the Lewis structure for the amino acid valine, showing the amino group and the carboxylic acid group in their un-ionized forms.
   (b) Draw the Lewis structure for the zwitterionic form of valine.
   (c) Which of these structures will be the predominant form at physiological pH?
2. (a) Draw the Lewis structure for the amino acid phenylalanine, showing the amino group and the carboxylic group in their un-ionized forms.
   (b) Draw the Lewis structure for the zwitterionic form of phenylalanine.
   (c) Which of these structures will be the predominant form at physiological pH?
3. Consider the amino acids alanine, leucine, serine, phenylalanine, lysine, and aspartic acid. Which have polar R groups, and which have nonpolar R groups?
4. Consider the amino acids arginine, cysteine, glutamine, isoleucine, threonine, and tryptophan. Which have polar R groups, and which have nonpolar R groups?
5. Draw Lewis structures for the two dipeptides that contain both alanine and glycine.
6. Do the amino acid sequences: valine-asparagine and asparagine-valine represent the same compound? Explain.
7. Draw the Lewis structure for the tripeptide serine-leucine-valine.
8. Draw the Lewis structure for the tripeptide tyrosine-histidine-glycine.
9. Identify the type of structure (primary, secondary, tertiary, or quaternary) that corresponds to the following statements.
   (a) This type of structure is the amino acid sequence in the protein.
   (b) This type of structure indicates how different peptide chains in the overall protein are arranged with respect to one another.
   (c) This type of structure refers to how the polypeptide chain is folded, including how amino acids that are far apart in the sequence end up in the overall molecule.
   (d) This type of structure deals with structures that arise from hydrogen bonding between amide groups in the protein's backbone.
10. The β-pleated sheet is a structure that commonly arises in proteins. Part of a β-pleated sheet is shown in the following figure. This type of structure is an example of which level of protein structure: primary, secondary, tertiary, or quaternary?

Carbohydrates

(See Section 24.2.)

11. Draw the structural formulas for α-D-glucose and β-D-glucose.
12. Draw the structural formula for two glucose molecules joined by a β-1,4 linkage.

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Nucleic Acids

(See Section 24.3 and Examples 24.2 and 24.3.)

13. (a) Draw the structural formula for the sugar β-D-ribose.

(b) Draw the structural formula for the nucleoside adenosine (it consists of β-D-ribose and adenine).

(c) Draw the structural formula for the nucleotide adenosine 5′-monophosphate.

14. (a) Draw the structural formula for the sugar β-D-2-deoxyribose.

(b) Draw the structural formula for the nucleoside deoxyadenosine (it consists of β-D-2-deoxyribose and adenine).

(c) Draw the structural formula for the nucleotide deoxyadenosine 5′-monophosphate.

15. Draw the structural formula for the tetranucleotide AUGC.

16. Draw the structural formula for the tetradeoxynucleotide CGTA.

17. Given the following nucleotide sequence in DNA: 5′—ACGCGATTC—3′:

(a) Determine the sequence of the complementary strand of DNA. Report this sequence by writing it from its 5′ end to its 3′ end.

(b) Write the sequence (5′–3′) for the strand of mRNA that would be complementary to the original strand of DNA.

(c) Assuming that this sequence is part of the coding sequence for a protein and that it is properly lined up so that the first codon of this sequence begins with the 5′ nucleotide of the mRNA, write the sequences for the three anticodons that would be complementary to this strand of mRNA.

(d) What sequence of amino acids is selected by this mRNA? (The complete genetic code is listed in several sites on the Internet.)

18. Given the following nucleotide sequence in DNA: 5′—TCGTAGGAT—3′:

(a) Determine the sequence of the complementary strand of DNA. Report this sequence by writing it from its 5′ end to its 3′ end.

(b) Write the sequence (5′–3′) for the strand of mRNA that would be complementary to the original strand of DNA.

(c) Assuming that this sequence is part of the coding sequence for a protein and that it is properly lined up so that the first codon of this sequence begins with the 5′ nucleotide of the mRNA, write the sequences for the three anticodons that would be complementary to this strand of mRNA.

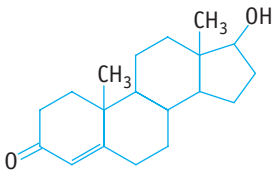
(d) What sequence of amino acids is selected by this mRNA? (The complete genetic code is listed in several sites on the Internet.)

Lipids and Cell Membranes

(See Section 24.4.)

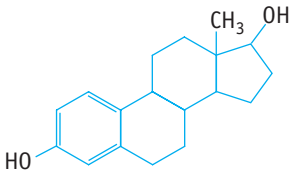
19. Sketch a section of a phospholipid bilayer in which you let a circle represent the polar head group and curvy lines represent the hydrocarbon tails. Label the regions of the bilayer as being polar or nonpolar.

20. If a drop of oleic acid is added to a dish of water, the oleic acid will spread out and form a layer that is one molecule thick on top of the water.



(a) Draw the Lewis structure for oleic acid.

(b) Label the region of the oleic acid molecule that is polar and the region that is nonpolar.



(c) In the layer of oleic acid that forms, which part of the oleic acid molecule points down into the water and which part points out of the water?

21. What structure do all steroids have in common?

22. The structures of the sex hormones testosterone (a male sex hormone) and estrogen (a female sex hormone) are shown below.

testosterone

estrogen (estradiol)

(a) Compare these two structures.

(b) Are these molecules steroids? Explain.

Metabolism

(See Section 24.5.)

23. The section about metabolism provided a value for $\Delta_r H°$ for the oxidation of one mole of glucose (−2803 kJ/mol-rxn). Using $\Delta_f H°$ values at 25 °C, verify that this is the correct value for the equation

$$C_6H_{12}O_6(s) + 6\ O_2(g) \rightarrow 6\ CO_2(g) + 6\ H_2O(\ell)$$

$$\Delta_f H°[C_6H_{12}O_6(s)] = -1273.3\ \text{kJ/mol}$$

24. The chemical equation for the fermentation of glucose into ethanol is

$$C_6H_{12}O_6(s) \rightarrow 2\ C_2H_5OH(\ell) + 2\ CO_2(g)$$

Using $\Delta_f H°$ values at 25 °C, calculate $\Delta_r H°$ for this reaction. (See Question 23 for $\Delta_f H°$ for glucose.)

25. Consider the following reaction:

$$NADH + H^+ + {}^1/_2\ O_2 \rightarrow NAD^+ + H_2O$$

(a) Which species (NADH, H^+, or O_2) undergoes oxidation?

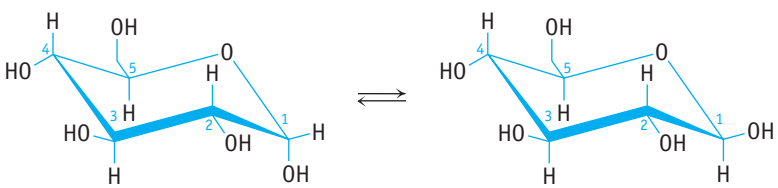
(b) Which species undergoes reduction?

(c) Which species is the oxidizing agent?

(d) Which species is the reducing agent?

26. The body processes ethanol by first converting it to acetaldehyde in a reaction catalyzed by the enzyme alcohol dehydrogenase.

$$CH_3CH_2OH + NAD^+ \xrightarrow{\text{alcohol dehydrogenase}} CH_3CHO + NADH + H^+$$



In the body, acetaldehyde can cause headaches and nausea and is one of the causes of hangovers. Eventually, the acetaldehyde is oxidized to the acetate ion and then converted to carbon dioxide and water. In the reaction of ethanol with NAD^+, which species (ethanol or NAD^+) undergoes oxidation? Which species undergoes reduction?

General Questions

These questions are not designated as to type or location in the chapter. They may combine several concepts.

27. Draw two Lewis structures for the dipeptide alanine-isoleucine that show the resonance structures of the amide linkage.

28. What is the equilibrium constant for the conversion of α-D-glucose to β-D-glucose in water at room temperature (assume that there is no glucose present in the open-chain structure)?

α-D-glucose
37%

β-D-glucose
63%

29. (a) Calculate the enthalpy change for the production of one mole of glucose by the process of photosynthesis at 25 °C. $\Delta_f H°$ [glucose(s)] = −1273.3 kJ/mol

$$6\ CO_2(g) + 6\ H_2O(\ell) \rightarrow C_6H_{12}O_6(s) + 6\ O_2(g)$$

(b) What is the enthalpy change involved in producing one molecule of glucose by this process?

(c) Chlorophyll molecules absorb light of various wavelengths. One wavelength absorbed is 650 nm. Calculate the energy of a photon of light having this wavelength.

(d) Assuming that all of this energy goes toward providing the energy required for the photosynthetic reaction, can the absorption of one photon at 650 nm lead to the production of one molecule of glucose, or must multiple photons be absorbed?

30. (a) According to the genetic code in Table 24.1, which amino acid is selected by the mRNA codon GAA?

(b) What is the sequence in the original DNA that led to this codon being present in the mRNA?

(c) If a mutation occurs in the DNA in which a G is substituted for the nucleotide at the second position of this coding region in the DNA, which amino acid will now be selected?

31. How many codons are possible? All of these codons are used in molecules of mRNA and there are only 20 amino acids normally encoded (plus start codons and stop codons). Is there exactly one codon per amino acid, must some codons select for more than one amino acid, or must there be some amino acids for which there is more than one codon?

32. There are $4^1 = 4$ mononucleotides of DNA, there are $4^2 = 16$ possible dinucleotides, and so on. If a segment of DNA were completely random, how many nucleotides long would it need to be in order to have one possible sequence for each person on Earth (currently about 7.5 billion people)?

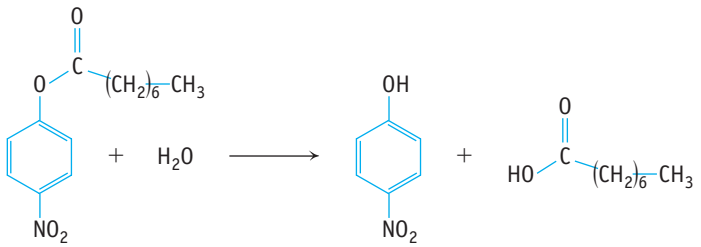
33. In the process of respiration

$$C_6H_{12}O_6(s) + 6\ O_2(g) \rightarrow 6\ CO_2(g) + 6\ H_2O(\ell)$$

which molecule undergoes oxidation? Which molecule undergoes reduction?

34. The first step of the metabolic process known as glycolysis is the conversion of glucose to glucose-6-phosphate. This process has a positive value for $\Delta_r G°'$.

$$\text{Glucose} + P_i \rightarrow \text{Glucose-6-phosphate} + H_2O \qquad \Delta_r G°' = +13.8\ \text{kJ/mol-rxn}$$



This reaction is coupled to the hydrolysis of ATP

$$\text{ATP} + H_2O \rightarrow \text{ADP} + P_i \qquad \Delta_r G°' = -30.5\ \text{kJ/mol-rxn}$$

What is the sum of these two equations and the value of $\Delta_r G°'$ for the coupled reaction? Is the coupled reaction product-favored at equilibrium?

In the Laboratory

35. The enzyme lipase catalyzes the hydrolysis of esters of fatty acids. The hydrolysis of *p*-nitrophenyloctanoate was followed by measuring the appearance of *p*-nitrophenol in the reaction mixture:

p-nitrophenol

The following data were obtained at 30 °C:

Substrate Concentration (mol/L)	Reaction Rate (mol/L · min)
1.0×10^{-5}	6.3×10^{-6}
1.4×10^{-5}	8.8×10^{-6}
2.0×10^{-5}	1.2×10^{-5}
5.0×10^{-5}	2.6×10^{-5}
6.7×10^{-5}	3.1×10^{-5}

This reaction obeys Michaelis-Menten kinetics (Section 14.6). Determine the value of Rate_{max} for this reaction using the method described in Study Question 14.45.

36. Insulin is a protein important in the metabolism of sugar. Its molar mass can be determined by means of an osmotic pressure experiment. A 50.0-mg sample of insulin was dissolved in enough water to make 100. mL of solution. This solution was determined to have an osmotic pressure of 21.8 mm H_2O. What is the molar mass of insulin? (Hint: The density of mercury is 13.6 g/mL.)

Summary and Conceptual Questions

The following questions may use concepts from this and previous chapters.

37. Which of the amino acids listed in Figure 24.2 is not chiral?

38. (a) What type of interaction holds DNA's double-helical strands together?

(b) Why would it not be good for DNA's double-helical strands to be held together by covalent bonds?

39. Do the DNA sequences ATGC and CGTA represent the same compound? Explain.

40. For many chemical reactions in the laboratory, a percent yield of the correct product of 95% is considered very good. Many biochemical reactions, however, require a much greater percent yield of the correct product.

(a) Assume that there is a process that replicates DNA with only 95% accuracy for each nucleotide added and that we wish to make complementary copies of identical strands of DNA 10 nucleotides long. What fraction of the molecules produced would have the correct sequence of nucleotides?

(b) Many naturally occurring DNA polymerases, enzymes that catalyze the replication of DNA, have an accuracy much greater, often being 99.999999% accurate. If an enzyme with this accuracy constructed a 10-nucleotide sequence of DNA, what fraction of the molecules would have the correct sequence?

41. (a) Describe what occurs in the process of transcription.

(b) Describe what occurs in the process of translation.

42. Which of the following statements is/are true?

(a) Breaking the P—O bond in ATP is an exothermic process.

(b) Making a new bond between the phosphorus atom in the phosphate group being cleaved off ATP and the OH group of water is an exothermic process.

(c) Breaking bonds is an endothermic process.

(d) The energy released in the hydrolysis of ATP may be used to run endothermic reactions in a cell.

CHAPTER OUTLINE

25.1 Natural Radioactivity

25.2 Nuclear Reactions and Radioactive Decay

25.3 Stability of Atomic Nuclei

25.4 Rates of Nuclear Decay

25.5 Artificial Nuclear Reactions

25.6 Nuclear Fission and Nuclear Fusion

25.7 Radiation Health and Safety

25.8 Applications of Nuclear Chemistry

25.1 Natural Radioactivity

Goal for Section 25.1

- Identify α, β, and γ radiation, the three major types of radiation in natural radioactive decay.

In the late 19th century, while studying radiation emanating from uranium and thorium, Ernest Rutherford (1871–1937) stated, "There are present at least two distinct types of radiation—one that is readily absorbed, which will be termed for convenience ***α* (alpha) radiation**, and the other of a more penetrative character, which will be termed ***β* (beta) radiation**." Subsequently, charge-to-mass ratio measurements showed that α radiation is composed of helium nuclei (He^{2+}) and β radiation is composed of electrons (e^-) (Table 25.1).

Discovery of Radioactivity The discovery of radioactivity by Henri Becquerel and the isolation of radium and polonium from pitchblende, a uranium ore, by Marie Curie were described in *Key Experiments: How Do We Know the Nature of the Atom and Its Components, page 66 and on page 72.*

TABLE 25.1 Characteristics of α, β, and γ Radiation

Name	Symbols	Charge	Mass (g/particle)
Alpha	${}^4_2\text{He}$, ${}^4_2\alpha$	2+	6.65×10^{-24}
Beta	${}^0_{-1}\text{e}$, ${}^0_{-1}\beta$	1−	9.11×10^{-28}
Gamma	γ	0	0

◀ Dr. Joanna Fowler, recipient of the National Medal of Science in 2008, spent her career at Brookhaven National Laboratory in New York. She was instrumental in developing radioactive tracers (based on ^{11}C and ^{18}F) for studying cancer using positron emission tomography (PET). She also used the radioactive isotopes to examine the brain, particularly when affected by addictive substances such as cocaine.

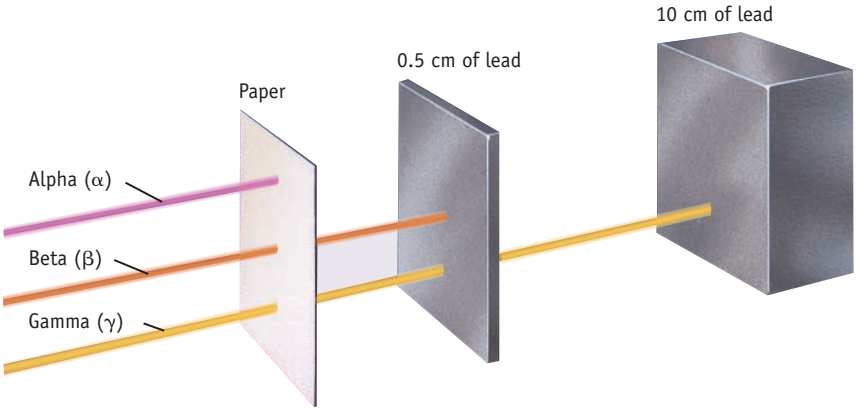

Figure 25.1 The relative penetrating ability of α, β, and γ radiation. Highly charged α particles interact strongly with matter and are stopped by a piece of paper. Beta particles, with less mass and a lower charge, interact to a lesser extent with matter and thus can penetrate farther. Gamma radiation is the most penetrating.

Common Symbols: α and β
Symbols used to represent alpha and beta particles do not include a plus or minus superscript.

A third type of radiation was later discovered by the French scientist Paul Villard (1860–1934); he named it **γ (gamma) radiation**, using the third letter in the Greek alphabet in keeping with Rutherford's scheme. Unlike α and β radiation, γ radiation is not affected by electric and magnetic fields. Rather, it is a form of electromagnetic radiation like x-rays but even more energetic.

Early studies measured the penetrating power of the three types of radiation (Figure 25.1). Alpha radiation is the least penetrating; it can be stopped by several sheets of ordinary paper or clothing. Beta particles can penetrate several millimeters of living bone or tissue, but about 0.5 cm of lead will stop the particles. Gamma radiation is the most penetrating. This type of radiation can pass completely through the human body, so thick layers of lead or concrete are required to shield the body from this radiation.

Alpha and β particles typically possess high kinetic energies. The energy of γ radiation is always very high. When α and β particles are stopped by a material, or when γ radiation is absorbed, the energy associated with the radiation is transferred to the material. This fact is important because the damage caused by radiation is related to the energy absorbed (Sections 25.7 and 25.8).

25.2 Nuclear Reactions and Radioactive Decay

Goals for Section 25.2

- Write balanced equations for nuclear reactions (alpha, beta, gamma and positron emission, electron capture, and fission).
- Recognize that radioactive isotopes decay by a series of nuclear reactions, called a radioactive decay series, eventually ending with a stable isotope.

Equations for Nuclear Reactions

In 1903, Rutherford and Frederick Soddy (1877–1956) proposed that radioactivity is the result of a natural change of an isotope of one element into an isotope of a different element. Such processes are called **nuclear reactions**.

Symbols Used in Nuclear Equations
The mass number is included on the element symbol as a superscript, and the atomic number is given as a subscript.

Consider a reaction in which radium-226 (the isotope of radium with mass number 226) emits an α particle to form radon-222. The equation for this reaction is

$$^{226}_{88}\text{Ra} \rightarrow {}^{4}_{2}\alpha + {}^{222}_{86}\text{Rn}$$

In a nuclear reaction, the sum of the mass numbers of reacting particles must equal the sum of the mass numbers of products. Furthermore, to maintain nuclear charge balance, the sum of the atomic numbers of the products must equal the sum

of the atomic numbers of the reactants. These principles are illustrated using the preceding nuclear equation:

	$^{226}_{88}$Ra RADIUM-226	→	$^{4}_{2}\alpha$ α PARTICLE	+	$^{222}_{86}$Rn RADON-222
Mass number: (protons + neutrons)	226	=	4	+	222
Atomic number: (protons)	88	=	2	+	86

Be sure to notice that α-particle emission causes a decrease of two units in atomic number and four units in the mass number.

Similarly, nuclear mass and nuclear charge balance accompany β-particle emission, as illustrated by the decomposition of uranium-239:

	$^{239}_{92}$U URANIUM-239	→	$^{0}_{-1}\beta$ β PARTICLE	+	$^{239}_{93}$Np NEPTUNIUM-239
Mass number: (protons + neutrons)	239	=	0	+	239
Atomic number: (protons)	92	=	−1	+	93

The β particle has a charge of 1−. For beta radiation, charge balance requires that the atomic number of the product be one unit greater than the atomic number of the reacting nucleus. The mass number does not change in this process.

How does a nucleus, composed of protons and neutrons, eject an electron? It is a complex process, but the net result is the conversion within the nucleus of a neutron to a proton and an electron.

$$\underset{\text{neutron}}{^{1}_{0}\text{n}} \longrightarrow \underset{\text{electron}}{^{0}_{-1}\text{e}} + \underset{\text{proton}}{^{1}_{1}\text{p}}$$

Notice that the mass and charge numbers balance in this equation.

What is the origin of the γ radiation that accompanies many nuclear reactions? Recall that a photon of visible light is emitted when an atom undergoes a transition from an excited electronic state to a lower energy state (Section 6.3). Gamma radiation similarly originates from transitions between nuclear energy levels. Nuclear reactions often result in the formation of a product nucleus in an excited nuclear state. One option is to return to the ground state by emitting a photon. The energy of γ radiation is a measure of the large energy difference between the energy levels in the nucleus.

Radioactive Decay Series

Several naturally occurring radioactive isotopes decay to form a product that is also radioactive. When this happens, the initial nuclear reaction is followed by a second nuclear reaction; if the situation is repeated, a third and a fourth nuclear reaction occur; and so on. Eventually, a nonradioactive isotope is formed to end the series. Such a sequence of nuclear reactions is called a **radioactive decay series**. In each step of this sequence, the reactant nucleus is called the *parent*, and the product is called the *daughter*.

Uranium-238, the most abundant of three naturally occurring uranium isotopes, is the origin of one of four radioactive decay series. One series begins with the loss of an α particle from $^{238}_{92}$U to form radioactive $^{234}_{90}$Th. Thorium-234 then decomposes by β emission to $^{234}_{91}$Pa, which emits a β particle to give $^{234}_{92}$U. Uranium-234 is an α emitter, forming $^{230}_{90}$Th. Further α and β emissions follow, until the series ends with formation of the stable, nonradioactive isotope, $^{206}_{82}$Pb. In all, this radioactive decay series converting $^{238}_{92}$U to $^{206}_{82}$Pb is made up of 14 decays, with eight α and six

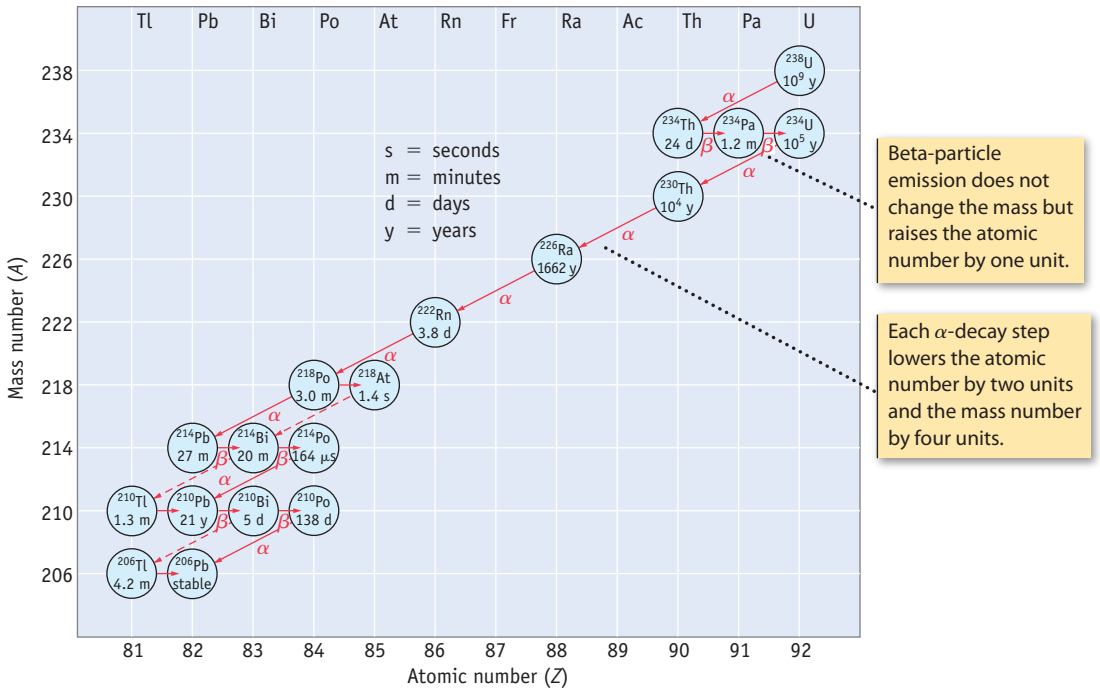

Figure 25.2 The uranium-238 radioactive decay series. The steps in this radioactive decay series are shown graphically in this plot of mass number versus atomic number. Half-lives of the isotopes are included on the chart. Notice that several of the isotopes in this series decompose by two different pathways.

β particles being emitted. The series is portrayed graphically in Figure 25.2. An equation can be written for each step in the sequence. Equations for the first four steps in the uranium-238 radioactive decay series are as follows:

Step 1. $^{238}_{92}\text{U} \longrightarrow {}^{234}_{90}\text{Th} + {}^{4}_{2}\alpha$

Step 2. $^{234}_{90}\text{Th} \longrightarrow {}^{234}_{91}\text{Pa} + {}^{0}_{-1}\beta$

Step 3. $^{234}_{91}\text{Pa} \longrightarrow {}^{234}_{92}\text{U} + {}^{0}_{-1}\beta$

Step 4. $^{234}_{92}\text{U} \longrightarrow {}^{230}_{90}\text{Th} + {}^{4}_{2}\alpha$

Uranium ore always contains trace quantities of the radioactive elements formed in the radioactive decay series. A significant development in nuclear chemistry was Marie Curie's discovery in 1898 of radium and polonium as trace components of pitchblende, a uranium ore. The amount of each of these elements is small because their isotopes have short half-lives. Consequently, Marie Curie was able to isolate only a single gram of radium from 7 tons of ore. It is a credit to her skills as a chemist that she extracted sufficient amounts of radium and polonium from uranium ore to identify these elements.

The uranium-238 radioactive decay series is also the source of the environmental hazard radon. Trace quantities of uranium are often present naturally in soil and rocks, and radon-222 is being continuously formed. Because radon is chemically inert, it is not trapped by chemical processes in soil or water and is free to seep into mines or into homes through pores in cement block walls, through cracks in the basement floor or walls, or around pipes. Because it is more dense than air, radon tends to collect in low spots, and its concentration can build up in the basement of a building if steps are not taken to remove it.

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

The major health hazard from radon, when it is inhaled by humans, arises not from radon itself but from its decomposition product, polonium.

$$^{222}_{86}\text{Rn} \longrightarrow {}^{218}_{84}\text{Po} + {}^{4}_{2}\alpha \qquad t_{1/2} = 3.82 \text{ days}$$

$$^{218}_{84}\text{Po} \longrightarrow {}^{214}_{82}\text{Pb} + {}^{4}_{2}\alpha \qquad t_{1/2} = 3.04 \text{ minutes}$$

Radon does not undergo chemical reactions or form compounds that can be taken up in the body. Polonium, however, is not chemically inert. Polonium-218 can lodge in body tissues, where it undergoes α decay to give lead-214, another radioactive isotope. The range of an α particle in body tissue is quite small, perhaps 0.7 mm. This is approximately the thickness of the epithelial cells of the lungs so α-particle radiation can seriously damage lung tissue.

Virtually every home in the United States has some level of radon, and kits can be purchased to test for the presence of this gas. If a significant amount of radon gas is detected in your home, you should take corrective actions such as sealing cracks around the foundation and in the basement. It may be reassuring to know that the health risks associated with radon are low. The likelihood of getting lung cancer from exposure to radon is about the same as the likelihood of dying in an accident in your home.

© Cengage Learning/Charles D. Winters

Radon detector. This kit is intended for use in the home to detect radon gas. The small device is placed in the home's basement for a given time period and is then sent to a laboratory to measure the amount of radon that might be present.

EXAMPLE 25.1

Radioactive Decay Series

Problem Another uranium radioactive decay series begins with $^{235}_{92}\text{U}$ and ends with $^{207}_{82}\text{Pb}$.

(a) How many α and β particles are emitted in this series?

(b) The first three steps of this series are (in order) α, β, and α emission. Write an equation for each of these steps.

What Do You Know? You are given the starting (long-lived radioactive) isotope and the final (stable) isotope. A series of α and β reactions is the link between these two species.

Strategy First, find the total change in atomic number and mass number. A combination of α and β particles is required that will decrease the total nuclear mass by 28 (235 − 207) and at the same time decrease the atomic number by 10 (92 − 82). Each equation must give symbols for the parent and daughter nuclei and the emitted particle. In the equations, the sums of the atomic numbers and mass numbers for reactants and products must be equal.

SOLUTION

(a) Mass declines by 28 mass units (235 − 207). Because a decrease of 4 mass units occurs with each α emission, 7 α particles must be emitted. Also, for each α emission, the atomic number decreases by 2. Emission of 7 α particles would cause the atomic number to decrease by 14, but the actual decrease in atomic number is 10 (92 − 82). This means that 4 β particles must also have been emitted because each β emission increases the atomic number of the product by one unit. Thus, the radioactive decay sequence involves emission of 7 α and 4 β particles.

(b) **Step 1.** $^{235}_{92}\text{U} \longrightarrow {}^{231}_{90}\text{Th} + {}^{4}_{2}\alpha$

Step 2. $^{231}_{90}\text{Th} \longrightarrow {}^{231}_{91}\text{Pa} + {}^{0}_{-1}\beta$

Step 3. $^{231}_{91}\text{Pa} \longrightarrow {}^{227}_{89}\text{Ac} + {}^{4}_{2}\alpha$

Think about Your Answer Because the mass number changes in these series only when an α particle is lost, all of the mass numbers in a given decay series are some multiple of four less than the first isotope in the series. For the series beginning with U-238, the mass numbers are in the series 238, 234, 230, . . . , 206. This series is sometimes called the *4n + 2 series* because each mass number (*M*) fits the equation $4n + 2 = M$, where *n* is an integer (*n* is 59 for the first member of this series and 51 for the last member). For the series headed by $^{235}_{92}U$, the mass numbers are 235, 231, 227, . . . , 207; this is the *4n + 3 series*.

Two other decay series are possible. One, called the *4n series* and beginning with ^{232}Th, is found in nature. The other, the $4n + 1$ series, is not found because no member of the series has a very long half-life. During the 4.5 billion years since this planet was formed, all radioactive members of the $4n + 1$ series have completely decayed to the end product, ^{209}Bi.

Check Your Understanding

(a) Six α and four β particles are emitted in the thorium-232 radioactive decay series before a stable isotope is reached. What is the final product in this series?

(b) The first three steps in the thorium-232 decay series (in order) are α, β, and β emission. Write an equation for each step.

Other Types of Radioactive Decay

Most naturally occurring radioactive elements decay by emission of α, β, and γ radiation. Other nuclear decay processes became known, however, when new radioactive elements were synthesized by artificial means. These include **positron** ($_{+1}^{0}\beta$) **emission** and **electron capture**.

Positrons Positrons were discovered by Carl Anderson (1905–1991) in 1932. The positron is one of a group of particles known as *antimatter*. If matter and antimatter particles collide, mutual annihilation occurs, with energy being emitted.

Positrons ($_{+1}^{0}\beta$) and electrons have the same mass but opposite charge. The positron is the antimatter analog to an electron. *Positron emission* by polonium-207, for example, results in the formation of bismuth-207.

	$^{207}_{84}Po$ POLONIUM-207	→	$_{+1}^{0}\beta$ POSITRON	+	$^{207}_{83}Bi$ BISMUTH-207
Mass number: (protons + neutrons)	207	=	0	+	207
Atomic number: (protons)	84	=	1	+	83

To retain charge balance, *positron decay results in a decrease in the atomic number.*

Neutrinos and Antineutrinos Beta particles having a wide range of energies are emitted. To balance the energy and momentum associated with β decay, it is necessary to postulate the concurrent emission of another particle, the *antineutrino*. Similarly, neutrino emission accompanies positron emission. Much study has gone into detecting neutrinos and antineutrinos. These particles do not have a charge. They are believed to have mass, but their mass is so small it has not been possible to measure it. Neutrinos and antineutrinos are not included when writing nuclear equations.

In *electron capture,* an extranuclear electron is captured by the nucleus. The mass number is unchanged, and *the atomic number is reduced by 1*. (In an old nomenclature, the innermost electron shell was called the *K shell,* and electron capture was called *K capture*.)

	$^{7}_{4}Be$ BERYLLIUM-7	+	$_{-1}^{0}e$ ELECTRON	→	$^{7}_{3}Li$ LITHIUM-7
Mass number: (protons + neutrons)	7	+	0	=	7
Atomic number: (protons)	4	+	−1	=	3

In summary, most unstable nuclei decay by one of four paths: α or β decay, positron emission, or electron capture. Gamma radiation often accompanies these processes. Section 25.6 introduces a fifth way that nuclei decompose, *fission*.

EXAMPLE 25.2

Nuclear Reactions

Problem Complete the following equations. Give the symbol, mass number, and atomic number of the product species.

(a) $^{37}_{18}\text{Ar} + {}^{0}_{-1}\text{e} \longrightarrow ?$

(b) $^{11}_{6}\text{C} \longrightarrow {}^{11}_{5}\text{B} + ?$

(c) $^{35}_{16}\text{S} \longrightarrow {}^{35}_{17}\text{Cl} + ?$

(d) $^{30}_{15}\text{P} \longrightarrow {}^{0}_{+1}\beta + ?$

What Do You Know? You are given the reactant and one of two products formed in these nuclear reactions. You know that both the masses and charges must balance in a balanced nuclear equation.

Strategy The missing product in each reaction can be determined by recognizing that the sums of mass numbers and atomic numbers for products and reactants must be equal. When you know the nuclear mass and nuclear charge of the product, you can identify it with the appropriate symbol.

SOLUTION

(a) This is an electron capture reaction. The product has a mass number of $37 + 0 = 37$ and an atomic number of $18 - 1 = 17$. Therefore, the symbol for the product is $^{37}_{17}\text{Cl}$.

(b) This missing particle has a mass of zero and a charge of 1+; these are the characteristics of a positron, $^{0}_{+1}\beta$. If this particle is included in the equation, the sums of the atomic numbers ($6 = 5 + 1$) and the mass numbers (11) on both sides of the equation are equal.

(c) A β particle, $^{0}_{-1}\beta$, is required to balance the mass numbers (35) and atomic numbers ($16 = 17 - 1$) in the equation.

(d) The product nucleus has mass number 30 and atomic number 14. This identifies the unknown as $^{30}_{14}\text{Si}$.

Think about Your Answer The product in each reaction is a stable isotope. As discussed in the next section, there is a narrow range of neutron-to-proton ratios for stable isotopes. Spontaneous nuclear reactions always occur in a way that moves either into or closer to the narrow range of stable isotopes.

Check Your Understanding

Indicate the symbol, the mass number, and the atomic number of the missing product in each of the following nuclear reactions.

(a) $^{13}_{7}\text{N} \longrightarrow {}^{13}_{6}\text{C} + ?$

(b) $^{41}_{20}\text{Ca} + {}^{0}_{-1}\text{e} \longrightarrow ?$

(c) $^{90}_{38}\text{Sr} \longrightarrow {}^{90}_{39}\text{Y} + ?$

(d) $^{22}_{11}\text{Na} \longrightarrow ? + {}^{0}_{+1}\beta$

25.3 Stability of Atomic Nuclei

Goals for Section 25.3

- Assess nuclear stability based on the numbers of neutrons and protons in a nucleus.
- Predict possible modes of decay of unstable nuclei based on n/p ratios.
- Calculate the mass defect for an isotope and from this determine the nuclear binding energy E_b and the binding energy per nucleon.

We can learn something about nuclear stability from Figure 25.3, a plot of the composition of the known isotopes of the elements. The horizontal axis represents the number of protons, and the vertical axis gives the number of neutrons. Each circle represents an isotope identified by the number of neutrons and protons contained in its nucleus. The black circles represent stable (nonradioactive) isotopes, 254 in number, and the red circles represent some of the known radioactive isotopes. For example, the three isotopes of hydrogen are $^{1}_{1}H$ and $^{2}_{1}H$ (neither is radioactive) and $^{3}_{1}H$ (tritium, radioactive). For lithium, the third element, isotopes are known with mass numbers 4, 5, 6, and 7. The isotopes with masses of 6 and 7 (shown in black) are stable, whereas the other two isotopes (in red) are radioactive.

Figure 25.3 gives us the following information about nuclear stability:

- Stable isotopes fall in a very narrow range called the **band of stability**. It is remarkable how few isotopes are stable.
- Only two stable isotopes ($^{1}_{1}H$ and $^{3}_{2}He$) have more protons than neutrons.
- Up to calcium ($Z = 20$), stable isotopes often have equal numbers of protons and neutrons or only one or two more neutrons than protons.
- Beyond calcium, the neutron-to-proton ratio is always greater than 1. As the mass increases, the band of stable isotopes deviates more and more from a 1 : 1 neutron-to-proton ratio (the line in Figure 25.3 for which n/p = 1).
- Beyond bismuth (83 protons and 126 neutrons), all isotopes are unstable and radioactive. The forces of attraction between nuclear particles are not strong enough to hold heavy nuclei together.
- Isotopes that fall farther from the band of stability tend to have shorter half-lives than do unstable isotopes nearer to the band of stability.
- Isotope stability is associated with even atomic numbers and even mass numbers. Among the stable isotopes, 148 have an even number of protons and neutrons, 53 have an even number of protons and an odd number of neutrons, and 48 have an odd number of protons and an even number of neutrons. Only five stable isotopes ($^{2}_{1}H$, $^{6}_{3}Li$, $^{10}_{5}B$, $^{14}_{7}N$, and $^{180}_{73}Ta$) have odd numbers of both protons and neutrons.

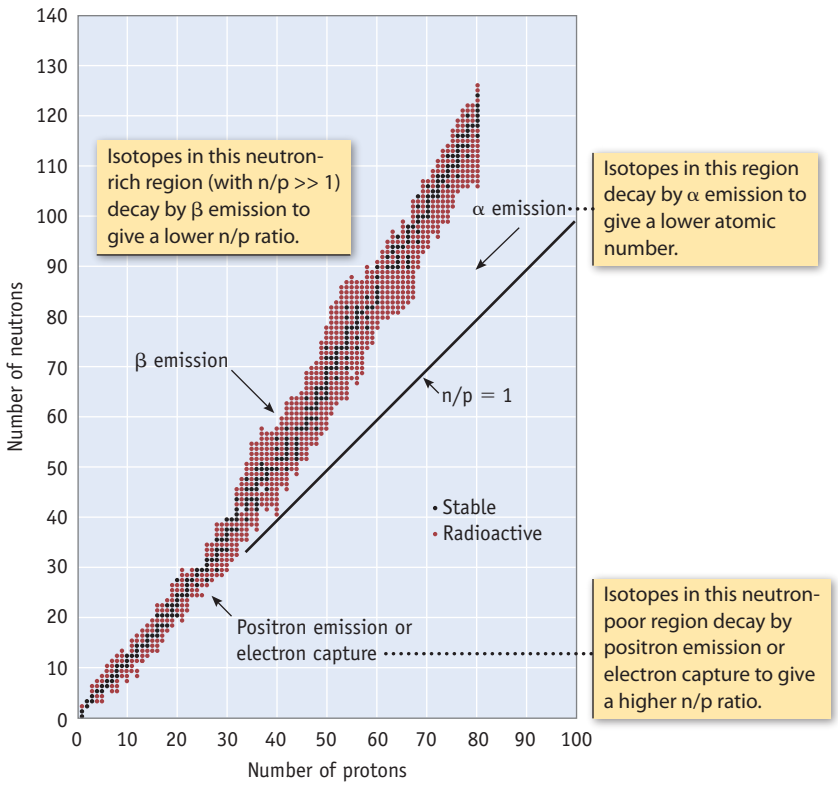

Figure 25.3 Stable and unstable isotopes. A graph of the number of neutrons (n) versus the number of protons (p) for stable (*black circles*) and radioactive (*red circles*) isotopes from hydrogen through mercury. This graph is used to assess criteria for nuclear stability and to predict modes of decay for unstable nuclei.

The Band of Stability and Radioactive Decay

Besides being a criterion for stability, the neutron-to-proton ratio can assist in predicting what type of radioactive decay will be observed. Unstable nuclei decay in a manner that brings them toward a stable neutron-to-proton ratio—that is, toward the band of stability.

- All elements beyond bismuth ($Z = 83$) are unstable. For an element beyond this atomic number, a process that decreases the atomic number is needed to reach the band of stability. Alpha emission is an effective way to do this because each emission decreases the atomic number by 2. For example, americium, the radioactive element used in smoke detectors, decays by α emission:

$$^{243}_{95}\text{Am} \longrightarrow {}^{4}_{2}\alpha + {}^{239}_{93}\text{Np}$$

- Beta emission occurs for isotopes that have a high neutron-to-proton ratio—that is, isotopes above the band of stability. With β decay, the atomic number increases by 1, and the mass number remains constant, resulting in a lower neutron-to-proton ratio:

$$^{60}_{27}\text{Co} \longrightarrow {}^{0}_{-1}\beta + {}^{60}_{28}\text{Ni}$$

- Isotopes with a low neutron-to-proton ratio, below the band of stability, decay by positron emission or by electron capture. Both processes lead to product nuclei with a lower atomic number and the same mass number and move the product closer to the band of stability:

$$^{13}_{7}\text{N} \longrightarrow {}^{0}_{+1}\beta + {}^{13}_{6}\text{C}$$

$$^{41}_{20}\text{Ca} + {}^{0}_{-1}\text{e} \longrightarrow {}^{41}_{19}\text{K}$$

EXAMPLE 25.3

Predicting Modes of Radioactive Decay

Problem Identify probable mode(s) of decay for each isotope and write an equation for the decay process.

(a) oxygen-15, $^{15}_{8}\text{O}$

(b) uranium-234, $^{234}_{92}\text{U}$

(c) fluorine-20, $^{20}_{9}\text{F}$

(d) manganese-56, $^{56}_{25}\text{Mn}$

What Do You Know? The possible modes of decomposition are α, β, or positron emission and electron capture. The preferred mode will give a more stable isotope and create a nucleus that is closer to the band of stability.

Strategy There are two main ideas to consider. First, if Z is greater than 83, then α decay is likely. Second, consider the n/p ratio. If the ratio is much greater than 1, then β decay is probable. If the ratio is less than 1, then positron emission or electron capture is the more likely process. It is not possible to choose between the latter two modes of decay without further information.

SOLUTION

(a) Oxygen-15 has 7 neutrons and 8 protons, so the neutron-to-proton (n/p) ratio is less than 1—too low for ^{15}O to be stable. Nuclei with too few neutrons are expected to decay by either positron emission or electron capture. In this instance, the process is $^{0}_{+1}\beta$ emission, and the equation is $^{15}_{8}\text{O} \longrightarrow {}^{0}_{+1}\beta + {}^{15}_{7}\text{N}$.

(b) Alpha emission is a common mode of decay for isotopes of elements with atomic numbers higher than 83. The decay of uranium-234 is one example:

$$^{234}_{92}\text{U} \longrightarrow {}^{230}_{90}\text{Th} + {}^{4}_{2}\alpha$$

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

(c) Fluorine-20 has 11 neutrons and 9 protons, a high *n/p* ratio. The ratio is lowered by β emission:

$$^{20}_{9}\text{F} \longrightarrow {}^{0}_{-1}\beta + {}^{20}_{10}\text{Ne}$$

(d) The mass number of ^{56}Mn is higher than the atomic weight of the element (54.85). This suggests that this radioactive isotope has an excess of neutrons (giving a high *n/p* ratio), in which case it would be expected to decay by β emission:

$$^{56}_{25}\text{Mn} \longrightarrow {}^{0}_{-1}\beta + {}^{56}_{26}\text{Fe}$$

Think about Your Answer Decomposition can occur by four possible paths, α and β emission, positron emission, and electron capture. Whether the decay follows beta emission or positron emission (or electron capture) is predicted by the neutron/proton ratio, relative to the *n/p* ratio in stable isotopes.

Check Your Understanding

Write an equation for the probable mode of decay for each of the following unstable isotopes, and write an equation for that nuclear reaction.

(a) silicon-32, $^{32}_{14}$Si

(b) titanium-45, $^{45}_{22}$Ti

(c) plutonium-239, $^{239}_{94}$Pu

(d) potassium-42, $^{42}_{19}$K

Nuclear Binding Energy

An atomic nucleus can contain as many as 83 protons and still be stable. For stability, nuclear binding (attractive) forces must be greater than the electrostatic repulsive forces between the closely packed protons in the nucleus. **Nuclear binding energy**, E_b, is defined as the energy required to separate the nucleus of an atom into protons and neutrons. For example, the nuclear binding energy for deuterium is the energy required to convert one mole of deuterium ($^{2}_{1}$H) nuclei into one mole of protons and one mole of neutrons.

$$^{2}_{1}\text{H} \longrightarrow {}^{1}_{1}\text{p} + {}^{1}_{0}\text{n} \qquad E_b = +2.15 \times 10^8 \text{ kJ/mol}$$

The positive sign for E_b indicates that energy is required for this process. A deuterium nucleus is more stable than an isolated proton and an isolated neutron, just as the H_2 molecule is more stable than two isolated H atoms. Recall, however, that the H—H bond energy is only 436 kJ/mol. The energy holding a proton and a neutron together in a deuterium nucleus, 2.15×10^8 kJ/mol, is about 500,000 times larger than the typical covalent bond energies.

To further understand nuclear binding energy, we turn to an experimental observation and a theory. The experimental observation is that the mass of a nucleus is *always* less than the sum of the masses of its constituent protons and neutrons. The theory is that the "missing mass," called the **mass defect**, is equated with the energy that holds the nuclear particles together.

The mass defect for deuterium is the difference between the mass of a deuterium nucleus and the sum of the masses of a proton and a neutron. Mass spectrometric measurements (Section 2.8) give the masses of these particles to a high level of accuracy, providing the numbers needed to carry out calculations of mass defects.

Masses of atomic nuclei are not generally listed in reference tables, but masses of atoms are. Nonetheless, calculation of the mass defect can be carried out using atom masses instead of masses of nuclei. (By using atomic masses, we are including in the calculation the masses of extranuclear electrons in the reactants and the products. However, because the same number of extranuclear electrons appears in

Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

products and reactants, this does not affect the result.) Thus, for one mole of deuterium nuclei, the mass defect is found as follows:

$$\underset{2.01410\ \text{g/mol}}{{}^{2}_{1}\text{H}} \longrightarrow \underset{1.007825\ \text{g/mol}}{{}^{1}_{1}\text{H}} + \underset{1.008665\ \text{g/mol}}{{}^{1}_{0}\text{n}}$$

$$\begin{aligned}\text{Mass defect} = \Delta m &= \text{mass of products} - \text{mass of reactants}\\ &= [1.007825\ \text{g/mol} + 1.008665\ \text{g/mol}] - 2.01410\ \text{g/mol}\\ &= 0.00239\ \text{g/mol}\end{aligned}$$

The relationship between mass and energy is given by Albert Einstein's 1905 theory of special relativity, which holds that mass and energy are different manifestations of the same quantity. Einstein showed that energy is equivalent to mass times the square of the speed of light; that is, $E = mc^2$. In the case of atomic nuclei, it is assumed that the missing mass (the mass defect, Δm) is equal to the binding energy holding the nucleus together.

$$E_b = (\Delta m)c^2 \tag{25.1}$$

If Δm is given in kilograms and the speed of light is given in meters per second, E_b will have units of joules (because 1 J = 1 kg · m^2/s^2). For the decomposition of one mole of deuterium nuclei to one mole of protons and one mole of neutrons, we have

$$\begin{aligned}E_b &= (2.39 \times 10^{-6}\ \text{kg/mol})(2.998 \times 10^{8}\ \text{m/s})^2\\ &= 2.15 \times 10^{11}\ \text{J/mol of } {}^{2}_{1}\text{H nuclei } (= 2.15 \times 10^{8}\ \text{kJ/mol of } {}^{2}_{1}\text{H nuclei})\end{aligned}$$

The nuclear stabilities of different elements are compared using the **binding energy per mole of nucleons**. (**Nucleon** is the general name given to nuclear particles—that is, protons and neutrons.) A deuterium nucleus contains two nucleons, so the binding energy per mole of nucleons, E_b/n, is 2.15×10^8 kJ/mol divided by 2, or 1.08×10^8 kJ/mol nucleon.

$$E_b/n = \left(\frac{2.15 \times 10^{8}\ \text{kJ}}{\text{mol } {}^{2}_{1}\text{H nuclei}}\right)\left(\frac{1\ \text{mol } {}^{2}_{1}\text{H nuclei}}{2\ \text{mol nucleons}}\right)$$

$$E_b/n = 1.08 \times 10^{8}\ \text{kJ/mol nucleons}$$

The binding energy per nucleon can be calculated for any atom whose mass is known. Then, to compare nuclear stabilities, binding energies per nucleon are plotted as a function of mass number (Figure 25.4). The greater the binding energy per nucleon, the greater the stability of the nucleus. Notice in Figure 25.4 that the point of maximum nuclear stability occurs at a mass of 56, that is, at iron in the periodic table.

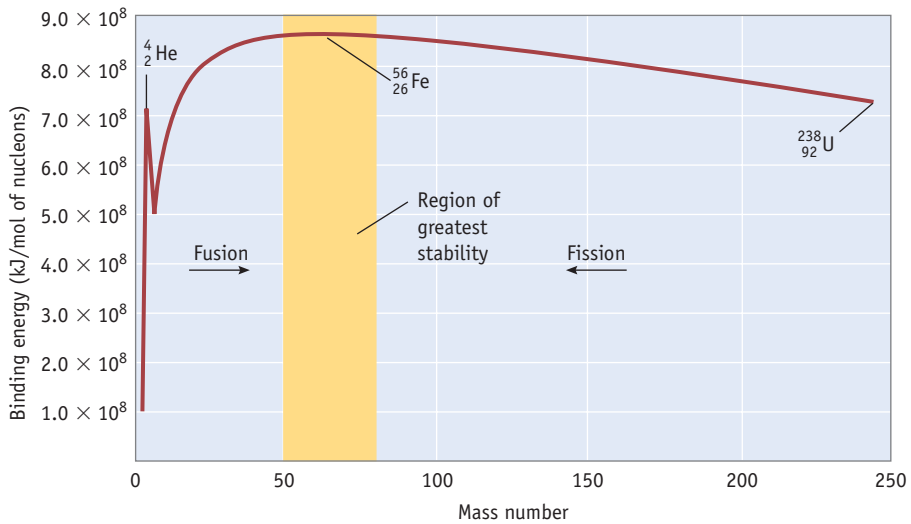

Figure 25.4 Relative stability of nuclei. Binding energy per nucleon for the most stable isotope of elements between hydrogen and uranium is plotted as a function of mass number. (Fission and fusion are discussed in Section 25.6.)

EXAMPLE 25.4

Nuclear Binding Energy

Problem Calculate the binding energy per mole of nucleons, E_b (in kJ/mol), and the binding energy per nucleon, E_b/n (in kJ/mol nucleon), for carbon-12.

What Do You Know? The mass of carbon-12 is, by definition, exactly 12 g/mol. You will need the molar masses of hydrogen atoms ($^1_1$H) and neutrons (1.007825 g/mol and 1.008665 g/mol, respectively), to determine the mass defect.

Strategy The mass defect is the difference between the mass of carbon-12 and the masses of 6 protons, 6 neutrons, and 6 electrons. The mass of 1 mol of protons and 1 mol of electrons can be taken into account by using the molar mass of $^1_1$H. Use the values given to calculate the mass defect (in g/mol). The binding energy is calculated from the mass defect using Equation 25.1.

SOLUTION The mass of $^1_1$H is 1.007825 g/mol, and the mass of $^1_0$n is 1.008665 g/mol. Carbon-12, $^{12}_6$C, is the standard for the atomic masses in the periodic table, and its mass is defined as exactly 12 g/mol.

$$\begin{aligned}\Delta m &= [(6 \times \text{mass } {}^1_1\text{H}) + (6 \times \text{mass } {}^1_0\text{n})] - \text{mass } {}^{12}_6\text{C} \\ &= [(6 \times 1.007825 \text{ g/mol}) + (6 \times 1.008665 \text{ g/mol})] - 12.000000 \text{ g/mol} \\ &= 9.8940 \times 10^{-2} \text{ g/mol}\end{aligned}$$

The binding energy is calculated using Equation 25.1. Using the mass in kilograms and the speed of light in meters per second gives the binding energy in joules:

$$\begin{aligned}E_b &= (\Delta m)c^2 \\ &= (9.8940 \times 10^{-5} \text{ kg/mol})(2.99792 \times 10^8 \text{ m/s})^2 \\ &= 8.89225 \times 10^{12} \text{ J/mol } (= 8.8923 \times 10^9 \text{ kJ/mol})\end{aligned}$$

The binding energy per nucleon, E_b/n, is determined by dividing the binding energy by 12 (the number of nucleons).

$$\frac{E_b}{n} = \frac{8.89225 \times 10^9 \text{ kJ/mol}}{12 \text{ mol nucleons/mol}}$$

$$= 7.4102 \times 10^8 \text{ kJ/mol nucleons}$$

Think about Your Answer The binding energy is a very large quantity of energy compared to those of ordinary chemical reactions. Compare binding energy to the very exothermic reaction of hydrogen and oxygen to form water vapor, for which $\Delta_r H°$ is only −242 kJ per mol of water vapor formed at 25 °C.

Check Your Understanding

Calculate the binding energy per nucleon, in kilojoules per mole, for lithium-6. The molar mass of $^6_3$Li is 6.015125 g/mol.

25.4 Rates of Nuclear Decay

Goals for Section 25.4

- Carry out calculations on rates of radioactive decay using equations defining first-order kinetics for these processes.
- Understand the process by which carbon-14 is used to date artifacts.

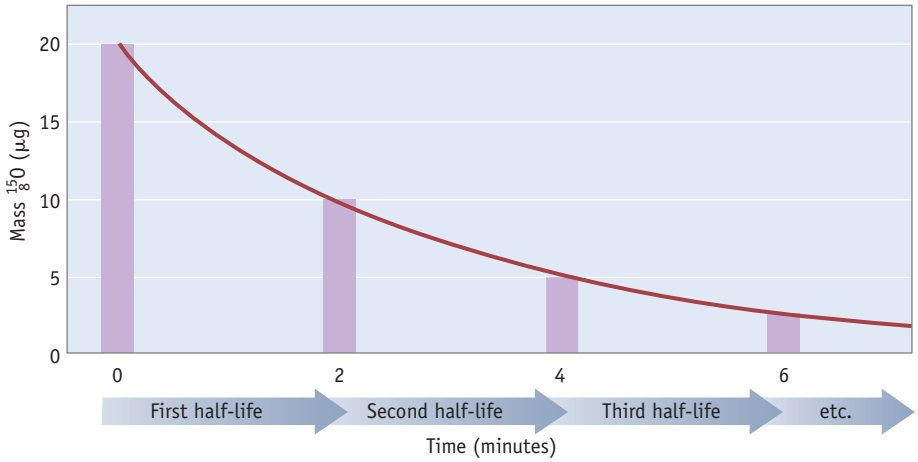

Figure 25.5 Decay of 20.0 μg of oxygen-15. After each half-life period of 2.0 minutes, the mass of oxygen-15 decreases by one half. (Oxygen-15 decays by positron emission.)

Half-Life

When a new radioactive isotope is identified, its *half-life* is usually determined. Half-life ($t_{1/2}$) is used in nuclear chemistry in the same way it is used when discussing the kinetics of first-order chemical reactions (Section 14.4): It is the time required for half of a sample to decay to products (Figure 25.5). Recall that for first-order kinetics the half-life is independent of the amount of sample.

Half-lives for radioactive isotopes cover a wide range of values. Uranium-238 has one of the longer half-lives, 4.47×10^9 years, a length of time close to the age of the Earth (estimated at $4.5–4.6 \times 10^9$ years). Thus, roughly half of the uranium-238 present when the planet was formed is still around. At the other end of the range of half-lives are isotopes such as copernicium-227 (element 112), which has a half-life of 240 microseconds ($1\ \mu s = 1 \times 10^{-6}$ s).

Half-life provides an easy way to estimate the time required before a radioactive element is no longer a health hazard. Strontium-90, for example, is a β-emitter with a half-life of 29.1 years. Significant quantities of strontium-90 were dispersed into the environment during atmospheric nuclear bomb tests in the 1950s and 1960s, and, from the half-life, we know that about one-fourth is still around. The health problems associated with strontium-90 arise because calcium and strontium have similar chemical properties. Strontium-90 is taken into the body and deposited in bone, taking the place of calcium. Radiation damage by strontium-90 (a β emitter) in bone has been directly linked to bone-related cancers.

EXAMPLE 25.5

Using Half-Life

Problem Radioactive iodine-131, used to treat hyperthyroidism, has a half-life of 8.04 days.

(a) If you have 8.8 μg (micrograms) of this isotope, what mass remains after 32.2 days?

(b) How long will it take for a sample of iodine-131 to decay to one eighth of its activity?

(c) Estimate the length of time necessary for the sample to decay to 10% of its original activity.

What Do You Know? The half-life of ^{131}I, 8.04 days, is given.

Strategy In part (a), determine how many half-lives have elapsed and use this information to determine how much iodine remains. In parts (b) and (c), use the fraction or percent of iodine remaining to estimate how many half-lives have elapsed.

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

SOLUTION

(a) The time elapsed, 32.2 days, is 4 half-lives (32.2/8.04 = 4). The amount of iodine-131 has decreased to 1/16 of the original amount [1/2 × 1/2 × 1/2 × 1/2 = $(1/2)^4$ = 1/16]. The amount of iodine remaining is 8.8 μg × $(1/2)^4$ or 0.55 μg.

(b) After 3 half-lives (24.12 days), the amount of iodine-131 remaining is 1/8 [= $(1/2)^3$] of the original amount. The amount remaining is 8.8 μg × $(1/2)^3$ = 1.1 μg.

(c) After 3 half-lives, 1/8 (12.5%) of the sample remains; after 4 half-lives, 1/16 (6.25%) remains. It will take between 3 and 4 half-lives, between 24.12 and 32.2 days, to decrease the amount of sample to 10% of its original value.

Think about Your Answer You will often find it useful to make approximations as we have done in (c). An exact time can be calculated from the first-order rate law (Equation 25.5).

Check Your Understanding

Tritium ($^3_1$H), a radioactive isotope of hydrogen, has a half-life of 12.3 years.

(a) Starting with 1.5 mg of this isotope, what mass (mg) remains after 49.2 years?

(b) How long will it take for a sample of tritium to decay to one eighth of its activity?

(c) Estimate the length of time necessary for the sample to decay to 1% of its original activity.

Kinetics of Nuclear Decay

The rate of nuclear decay is determined from measurements of the **activity** (A) of a sample. Activity refers to the number of disintegrations observed per unit of time, a quantity that can be measured readily with devices such as a Geiger–Müller counter (Figure 25.6). *Activity is proportional to the number of radioactive atoms present (N).*

$$A \propto N \tag{25.2}$$

If the number of radioactive nuclei N is reduced by half, the activity of the sample will be half as large. Doubling N will double the activity. This means that the rate of decomposition is first order with respect to N. Consequently, the equations describing rates of radioactive decay are the same as those used to describe the kinetics of

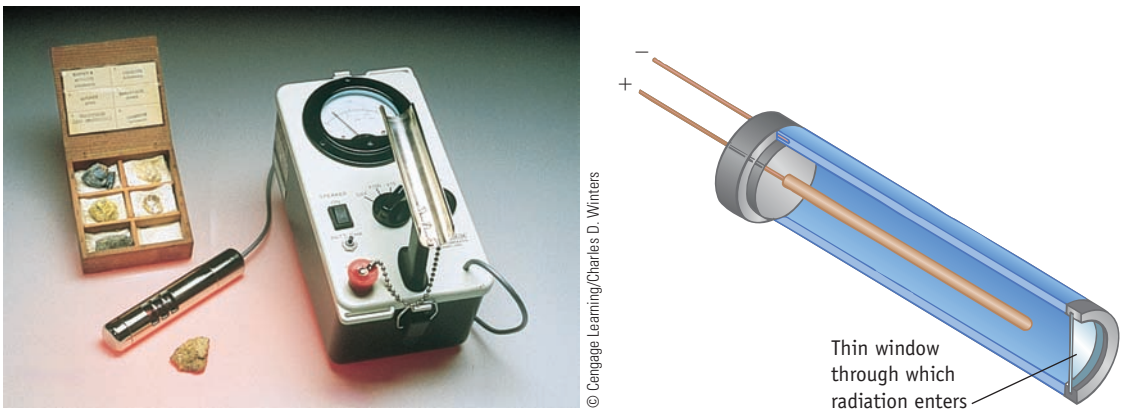

Figure 25.6 A Geiger–Müller counter. A charged particle (an α or β particle) or a gamma ray enters the gas-filled tube (diagram at the *right*) and ionizes the gas. The gaseous ions migrate to electrically charged electrodes and are recorded as a pulse of electric current. The current is amplified and used to operate a counter. A sample of carnotite, a mineral containing uranium oxide, is also shown in the photograph.

Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

first-order chemical reactions; the change in the number of radioactive atoms N per unit of time is proportional to N (Section 14.4)

$$\frac{\Delta N}{\Delta t} = -kN \tag{25.3}$$

The integrated rate equation can be written in two ways depending on the data used:

$$\ln\left(\frac{N}{N_0}\right) = -kt \tag{25.4}$$

or

$$\ln\left(\frac{A}{A_0}\right) = -kt \tag{25.5}$$

Here, N_0 and A_0 are the number of atoms and the initial activity of the sample, respectively, and N and A are the number of atoms and the activity of the sample after time t, respectively. Thus, N/N_0 is the fraction of atoms remaining after a given time (t), and A/A_0 is the fraction of the activity remaining after the same period. In these equations, k is the rate constant (decay constant) for the isotope in question. The relationship between half-life and the first-order rate constant is the same as seen with chemical kinetics (Equation 14.4):

$$t_{1/2} = \frac{0.693}{k} \tag{25.6}$$

Equations 25.3–25.6 are useful in several ways:

- If the activity (A) [which is proportional to the number of radioactive nuclei (N)] is measured in the laboratory over some period t, k can be calculated. The decay constant k can then be used to determine the half-life of the sample.
- If k is known, the fraction of a radioactive sample (N/N_0) still present after some time t has elapsed can be calculated.
- If k is known, the time required for that isotope to decay to a fraction of the original activity (A/A_0) can be calculated.

EXAMPLE 25.6

Kinetics of Radioactive Decay

Problem A sample of radon-222 has an initial α-particle activity (A_0) of 7.0×10^4 dps (disintegrations per second). After 6.6 days, its activity (A) is 2.1×10^4 dps. What is the half-life of radon-222?

What Do You Know? You are given the initial and final activities of the sample of ^{222}Rn and the time elapsed.

Strategy Values for A, A_0, and t are given. The problem can be solved using Equation 25.5 with k as the unknown. Once k is found, the half-life can be calculated using Equation 25.6.

SOLUTION

$$\ln(2.1 \times 10^4 \text{ dps}/7.0 \times 10^4 \text{ dps}) = -k\ (6.6 \text{ days})$$

$$\ln(0.300) = -k(6.6 \text{ days})$$

$$k = 0.182 \text{ days}^{-1}$$

From k we obtain $t_{1/2}$:

$$t_{1/2} = 0.693/0.182 \text{ days}^{-1} = 3.8 \text{ days}$$

Think about Your Answer Notice that the activity decreased to between one-half and one-fourth of its original value. The 6.6 days of elapsed time represents one full half-life and part of another half-life.

Check Your Understanding

(a) A sample of $Ca_3(PO_4)_2$ containing phosphorus-32 has an activity of 3.35×10^3 dpm. Exactly 2 days later, the activity is 3.18×10^3 dpm. Calculate the half-life of phosphorus-32.

(b) A highly radioactive sample of nuclear waste products with a half-life of 200. years is stored in an underground tank. How long will it take for the activity to diminish from an initial activity of 6.50×10^{12} dpm to a fairly harmless activity of 3.00×10^3 dpm?

Radiocarbon Dating

In certain situations, the age of a material can be determined based on the rate of decay of a radioactive isotope. The best-known example of this procedure is the use of carbon-14 to date historical artifacts.

Naturally-occurring carbon is primarily carbon-12 and carbon-13 with isotopic abundances of 98.9% and 1.1%, respectively. In addition, traces of a third isotope, carbon-14, are present to the extent of about 1 in 10^{12} atoms in atmospheric CO_2 and in living materials. Carbon-14 is a β emitter with a half-life of 5730 years. A 1-gram sample of carbon from living material will show about 14 disintegrations per minute, not a lot of radioactivity but nevertheless detectable by modern methods.

Carbon-14 is formed in the upper atmosphere by nuclear reactions initiated by neutrons in cosmic radiation:

$$^{14}_{7}\text{N} + {}^{1}_{0}\text{n} \rightarrow {}^{14}_{6}\text{C} + {}^{1}_{1}\text{H}$$

Once formed, carbon-14 is oxidized to $^{14}CO_2$. This product enters the carbon cycle, circulating through the atmosphere, oceans, and biosphere (Figure 25.7).

The usefulness of carbon-14 for dating comes about in the following way. Plants absorb CO_2 and convert it to organic compounds, thereby incorporating carbon-14 into living tissue. As long as a plant remains alive, this process will continue, and the percentage of carbon that is carbon-14 in the plant will equal the percentage in the atmosphere. When the plant dies, carbon-14 will no longer be taken up. Radioactive decay continues, however, with the carbon-14 activity decreasing over time. After 5730 years, the activity will be 7 dpm/g; after 11,460 years, it will be 3.5 dpm/g; and so on. By measuring the activity of a sample, and knowing the half-life of carbon-14, it is possible to calculate when a plant (or a plant-eating animal) died.

Oesper Collection in the History of Chemistry, University of Cincinnati

Willard Libby (1908–1980) Libby received the 1960 Nobel Prize in Chemistry for developing carbon-14 dating techniques. Carbon-14 dating is widely used in fields such as anthropology.

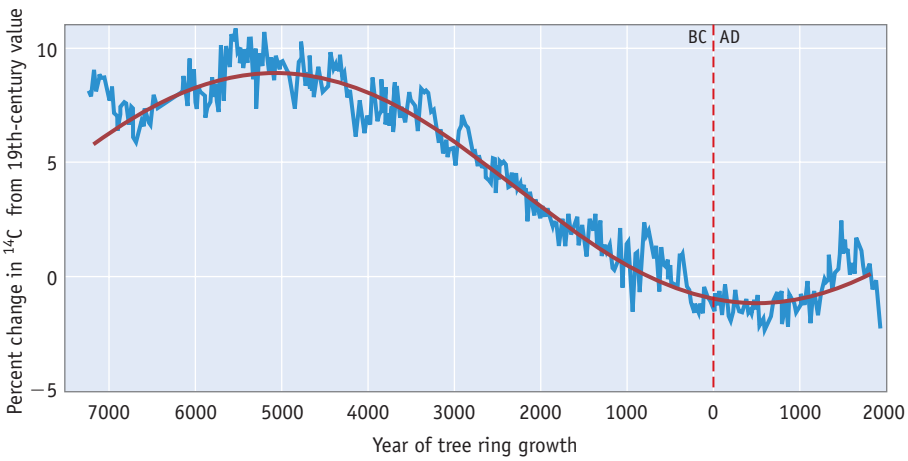

Figure 25.7 Variation of atmospheric carbon-14 activity. The amount of carbon-14 has changed with the variation in cosmic ray activity. To obtain the data for the pre-1990 part of the curve shown in this graph, scientists carried out carbon-14 dating of artifacts for which the age was accurately known (often through written records). Data for this figure were obtained using carbon-14 dating of tree rings.

As with all experimental procedures, carbon-14 dating has limitations. Although the procedure assumes that the amount of carbon-14 in the atmosphere hundreds or thousands of years ago was the same as it is now, in fact the percentage has varied by as much as 10% (Figure 25.7). Furthermore, it is not possible to use carbon-14 to date an object less than about 100 years old; the radiation level from carbon-14 will not change enough in this short time period to permit accurate detection of a difference from the initial value. In most instances, the accuracy of the measurement is only about ± 100 years. Finally, it is not possible to determine ages of objects much older than about 60,000 years. By then, after more than 10 half-lives, the ^{14}C radioactivity will have decreased virtually to zero. But for the span of time between 100 and 60,000 years, this technique has provided important information (Figure 25.8).

JEAN LOUIS PRADELS/MaxPPP/ RODEZ AVEYRON France/Newscom

Figure 25.8 The Iceman. Europe's oldest naturally preserved mummy was discovered in the ice of a glacier high in the Alps. Carbon-14 dating techniques allowed scientists to determine that he lived about 5300 years ago. See pages 1 and 102 for more information on the Iceman.

EXAMPLE 25.7

Radiochemical Dating

Problem To test the concept of carbon-14 dating, J. R. Arnold and W. F. Libby applied this technique to analyze samples of acacia and cyprus wood whose ages were already known. (The acacia wood, which was supplied by the Metropolitan Museum of Art in New York, came from the tomb of Zoser, the first Egyptian pharaoh to be entombed in a pyramid. The cyprus wood was from the tomb of Sneferu.) The average activity based on five determinations on one of these wood samples was 7.04 dpm per gram of carbon. Assume (as Arnold and Libby did) that the original activity of carbon-14, A_0, was 12.6 dpm per gram of carbon. Calculate the approximate age of the sample.

What Do You Know? You are given the initial and final ^{14}C activity. The first-order rate constant can be calculated from the half-life.

Strategy First, determine the rate constant for the decay of carbon-14 from its half-life ($t_{1/2}$ for ^{14}C is 5.73×10^3 years). Then, use Equation 25.5.

SOLUTION

$$k = 0.693/t_{1/2} = 0.693/5730 \text{ yr}$$

$$= 1.209 \times 10^{-4} \text{ yr}^{-1}$$

$$\ln(A/A_0) = -kt$$

$$\ln\left(\frac{7.04 \text{ dpm/g}}{12.6 \text{ dpm/g}}\right) = (-1.209 \times 10^{-4} \text{ yr}^{-1})t$$

$$t = 4.81 \times 10^3 \text{ yr}$$

The wood is about 4800 years old.

Think about Your Answer This problem uses real data from an early research paper in which the carbon-14 dating method was being tested. The age of the wood was known to be 4750 $\pm$ 250 years. (See J. R. Arnold and W. F. Libby: *Science,* Vol. 110, p. 678, 1949.)

Check Your Understanding

A sample of the inner part of a redwood tree felled in 1874 was shown to have ^{14}C activity of 9.32 dpm/g. Calculate the approximate age of the tree when it was cut down. Compare this age with that obtained from tree ring data, which estimated that the tree began to grow in 979 $\pm$ 52 BC. Use 13.4 dpm/g for the value of A_0.

Lawrence Berkeley Laboratory

Glenn T. Seaborg (1912–1999) Seaborg figured out that thorium and the elements that followed it fit under the lanthanides in the periodic table. For this insight, he and Edwin McMillan shared the 1951 Nobel Prize in Chemistry. Over a 21-year period, Seaborg and his colleagues synthesized 10 new transuranium elements. To honor Seaborg's scientific contributions, the name "seaborgium" was assigned to element 106 in 1997. It marked the first time an element was named for a living person.

25.5 Artificial Nuclear Reactions

Goals for Section 25.5

- Describe the experimental procedure used to carry out nuclear reactions.
- Describe procedures used to prepare new transuranic elements.

How many different isotopes are found on Earth? All of the stable isotopes occur naturally as well as a few unstable (radioactive) isotopes that have long half-lives; the best-known examples of the latter type are uranium-235, uranium-238, and thorium-232. Trace quantities of other radioactive isotopes with short half-lives are also present because they are being formed continuously by nuclear reactions. These include isotopes of radium, polonium, and radon, along with other elements produced in various radioactive decay series, and carbon-14, formed in a nuclear reaction initiated by cosmic radiation.

Naturally-occurring radioactive isotopes account for only a very small fraction of the currently known radioactive isotopes. The rest—several thousand—have been synthesized via artificial nuclear reactions, sometimes referred to as *transmutation*.

The first artificial nuclear reaction was identified by Rutherford about 90 years ago. Recall the classic experiment that led to the nuclear model of the atom (*Key Experiments: How Do We Know the Nature of the Atom and Its Components,* page 66) in which gold foil was bombarded with α particles. In the years following that experiment, Rutherford and his coworkers bombarded many other elements with α particles. In 1919, one of these experiments led to an unexpected result: When nitrogen atoms were bombarded with α particles, protons were detected among the products. Rutherford correctly concluded that a nuclear reaction had occurred. Nitrogen had undergone a *transmutation* to oxygen:

$$^{4}_{2}\text{He} + {}^{14}_{7}\text{N} \longrightarrow {}^{17}_{8}\text{O} + {}^{1}_{1}\text{H}$$

Discovery of Neutrons Neutrons had been predicted to exist for more than a decade before they were identified in 1932 by James Chadwick (1891–1974). Chadwick produced neutrons in a nuclear reaction between α particles and beryllium: $^{4}_{2}\alpha + {}^{9}_{4}\text{Be} \longrightarrow {}^{12}_{6}\text{C} + {}^{1}_{0}\text{n}$.

During the next decade, other nuclear reactions were discovered by bombarding other elements with α particles. Progress was slow, however, because in most cases α particles are simply scattered by target nuclei. The bombarding particles cannot get close enough to the nucleus to react because of the strong repulsive forces between the positively charged α particle and the positively charged atomic nucleus.

Two advances were made in 1932 that greatly extended nuclear reaction chemistry. The first involved the use of particle accelerators to create high-energy particles as projectiles. The second was the use of neutrons as the bombarding particles.

The α particles used in the early studies on nuclear reactions came from naturally radioactive materials such as uranium and had relatively low energies. Particles with higher energy were needed, so J. D. Cockcroft (1897–1967) and E. T. S. Walton (1903–1995), working in Rutherford's laboratory in Cambridge, England, turned to protons. Protons are formed when hydrogen atoms ionize in a cathode-ray tube, and it was known that they could be accelerated to higher energy by applying a high voltage. Cockcroft and Walton found that when energetic protons struck a lithium target, the following reaction occurs:

$$^{7}_{3}\text{Li} + {}^{1}_{1}\text{p} \longrightarrow 2\ {}^{4}_{2}\text{He}$$

Transuranium Elements in Nature Neptunium, plutonium, and americium were unknown prior to their preparation via nuclear reactions in the laboratory. Later, these elements were found to be present in trace quantities in uranium ores.

This was the first example of a reaction initiated by a particle that had been artificially accelerated to high energy. Since this experiment was done, the technique has been developed much further, and the use of particle accelerators in nuclear chemistry is now commonplace. Particle accelerators operate on the principle that a charged particle placed between charged plates will be accelerated to a high speed and high energy. Modern examples of this process are seen in the synthesis of the transuranium elements, as is described in more detail in *A Closer Look: The Search for New Elements* (page 1168).

Experiments using neutrons as bombarding particles were first carried out in both the United States and Great Britain in 1932. Nitrogen, oxygen, fluorine, and neon were bombarded with energetic neutrons, and α particles were detected among the products. Using neutrons made sense: Because neutrons have no charge, it was reasoned that these particles would not be repelled by the positively charged nuclear particles. Thus, neutrons did not need high energies to react.

In 1934, Enrico Fermi (1901–1954) and his coworkers showed that nuclear reactions using neutrons are more favorable if the neutrons have low energy. A low-energy neutron is simply captured by the nucleus, giving a product in which the mass number is increased by one unit. Because of the low energy of the bombarding particle, the product nucleus does not have sufficient energy to fragment in these reactions. The new nucleus is produced in an excited state, however; when the nucleus returns to the ground state, a γ ray is emitted. Reactions in which a neutron is captured and a γ ray is emitted are called **(n, γ) reactions**.

The (n, γ) reactions are the source of many of the radioisotopes used in medicine and chemistry. An example is radioactive phosphorus, $^{32}_{15}\text{P}$, which is used in chemical studies such as tracing the uptake of phosphorus in the body.

$$^{31}_{15}\text{P} + {}^{1}_{0}\text{n} \longrightarrow {}^{32}_{15}\text{P} + \gamma$$

The products of (n, γ) reactions provide a further access to new isotopes. Addition of a neutron to the nucleus raises the neutron-proton ratio (and often results in a change in the number of neutrons from even to odd) so that the resulting product is often unstable. With a higher n/p ratio the new isotopes are beta emitters which form an isotope of the element having the next atomic number. An example of this process is seen in the preparation of technetium-99m (*Applying Chemical Principles, 25.2: Technetium-99 and Medical Imaging*, page 1179).

Transuranium elements, elements with an atomic number greater than 92, were first made in a nuclear reaction sequence beginning with an (n, γ) reaction followed by beta decay. Scientists at the University of California at Berkeley bombarded uranium-238 with neutrons. Among the products identified were neptunium-239 and plutonium-239, which were formed when ^{239}U decayed by β emission.

$$^{238}_{92}\text{U} + {}^{1}_{0}\text{n} \longrightarrow {}^{239}_{92}\text{U}$$

$$^{239}_{92}\text{U} \longrightarrow {}^{239}_{93}\text{Np} + {}^{0}_{-1}\beta$$

$$^{239}_{93}\text{Np} \longrightarrow {}^{239}_{94}\text{Pu} + {}^{0}_{-1}\beta$$

A similar reaction sequence was used to make americium-241. Plutonium-239 was found to add two neutrons to form plutonium-241, which decays by β emission to give americium-241.

EXAMPLE 25.8

Nuclear Reactions

Problem Write equations for the nuclear reactions described below.

(a) Fluorine-19 undergoes an (n, γ) reaction to give a radioactive product that decays by β emission. (Write equations for both nuclear reactions.)

(b) When an atom of beryllium-9 (the only stable isotope of beryllium) reacts with an α particle emitted by a plutonium-239 atom, a neutron is ejected.

What Do You Know? Reactants and one of two products are given for each reaction.

Strategy The equations are written so that both mass and charge are balanced.

SOLUTION

(a) $^{19}_{9}\text{F} + {}^{1}_{0}\text{n} \rightarrow {}^{20}_{9}\text{F} + \gamma$

$^{20}_{9}\text{F} \rightarrow {}^{20}_{10}\text{Ne} + {}^{0}_{-1}\beta$

(b) $^{239}_{94}\text{Pu} \rightarrow {}^{235}_{92}\text{U} + {}^{4}_{2}\alpha$

$^{4}_{2}\alpha + {}^{9}_{4}\text{Be} \rightarrow {}^{12}_{6}\text{C} + {}^{1}_{0}\text{n}$

Think about Your Answer Both answers involve neutrons. The equation given for part (a), an (n, γ) reaction, illustrates a process that is easy to carry out. In a lab, the neutrons might be produced in a small device called a *Pu-Be neutron source*. The answer to part (b) describes the nuclear reactions in such a device.

Check Your Understanding

Technetium is one of the two elements with atomic numbers less than 83 for which there is no stable isotope (promethium, element 61, is the other). Nevertheless, technetium is a very important element because of its extensive use in medical imaging (page 1179). It is produced in a two-step process. First, ^{98}Mo undergoes an (n, γ) reaction; then, the resulting unstable isotope decomposes to ^{99}Tc. Write equations for these two reactions.

A CLOSER LOOK

The Search for New Elements

By 1936, guided first by Mendeleev's predictions and later by atomic theory, chemists had identified all but two of the elements with atomic numbers between 1 and 92. These two gaps in the periodic table were filled when radioactive technetium and promethium were identified in 1937 and 1942, respectively. From this point onward, all new elements to be discovered came from artificial nuclear reactions. The first success in the search for elements with atomic numbers higher than 92 came with the 1940 discovery of neptunium and plutonium.

Since 1950, laboratories in the United States (Lawrence Berkeley National Laboratory), Russia (Joint Institute for Nuclear Research at Dubna, near Moscow), and Europe (Institute for Heavy Ion Research at Darmstadt, Germany) have competed to make new elements. Syntheses of new transuranium elements use a standard methodology. An element of fairly high atomic number is bombarded with a beam of high-energy particles. Initially, neutrons were used; later, helium nuclei and then larger nuclei such as ^{11}B and ^{12}C were used; and, more recently, highly charged ions of elements such as calcium, chromium, cobalt, and zinc have been chosen. The bombarding particle fuses with the nucleus of the target atom, forming a new nucleus that lasts for a short time before decomposing. New elements are detected by their decomposition products, a signature of particles with specific masses and energies.

By using bigger particles and higher energies, the list of known elements reached 106 by the end of the 1970s. To further extend the search, Russian scientists used a new idea: Precisely matching the energy of the bombarding particle with the energy required to fuse the nuclei. This technique enabled the synthesis of elements 107, 108, and 109 in Darmstadt in the early 1980s, and the synthesis of elements 110, 111, and 112 in the following decade. Lifetimes of these elements were in the millisecond range; copernicium-277, $^{277}_{112}$Cn, for example, has a half-life of 240 μs.

Yet another breakthrough was needed to extend the list further. Scientists have long known that isotopes with specific so-called *magic numbers* of neutrons and protons are more stable. Elements with 2, 8, 20, 50, and 82 protons are members of this category, as are elements with 126 neutrons. The magic numbers correspond to filled shells in the nucleus. Their significance is analogous to the significance of filled shells for electronic structure. Theory had predicted that the next magic numbers would be 114 protons and 184 neutrons. Using this information, researchers discovered element 114 in early 1999. The Dubna group reporting this discovery found that the mass 289 isotope had an exceptionally long half-life, about 20 seconds. Element 114 was recently named flerovium, Fl, after the name of the laboratory in Dubna, Russia.

Element 116 was also discovered in 1999. About 35 atoms of this element were obtained; the longest-lived isotope, with mass number 293, had a half-life of about 60 ms. As research progressed, element 113 was discovered in 2003 by workers in Russia and Japan, and several atoms of element 118 were discovered in 2006 by bombarding atoms of ^{249}Cf with nuclei of ^{48}Ca. Finally, the discovery of element 117 was announced in April 2010 by an international team in Dubna, Russia. They obtained 6 atoms of the element by bombarding ^{249}Bk with ^{48}Ca nuclei.

The right to name new elements goes to the labs that discovered them. In December, 2016, the International Union of Pure and Applied Chemistry (IUPAC) accepted the names proposed for the remaining four unnamed elements. They are:

Element 113, Nihonium, Nh, after the Japanese word for Japan

Element 115, Moscovium, Mc, after Moscow

Element 117, Tennessine, Ts, after Tennessee

25.6 Nuclear Fission and Nuclear Fusion

Goal for Section 25.6

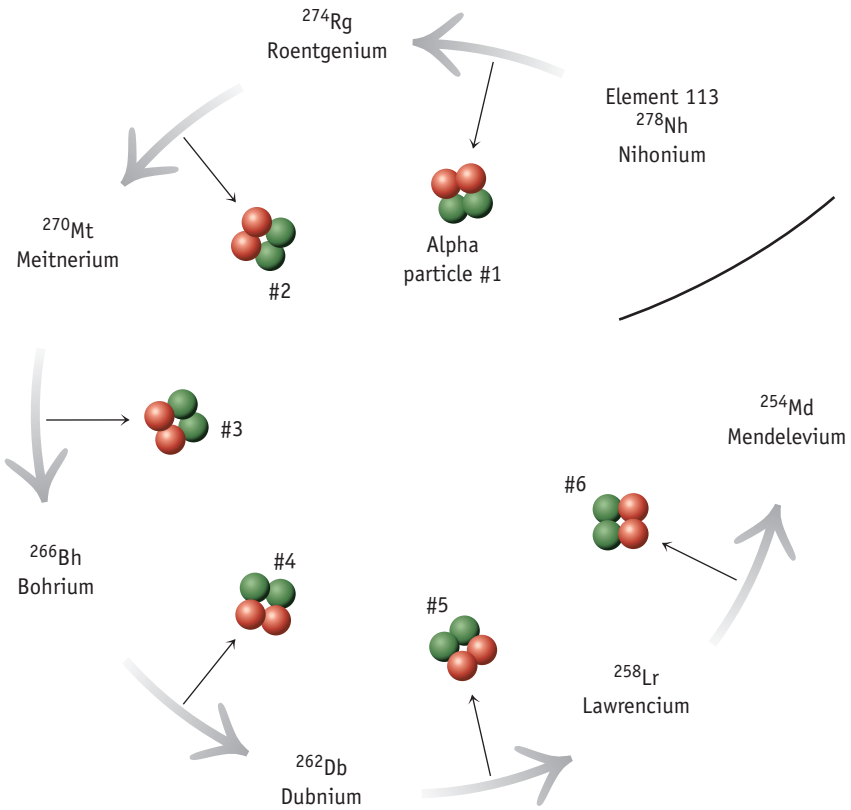
- Describe nuclear chain reactions, nuclear fission, and nuclear fusion.

In 1938, two chemists, Otto Hahn (1879–1968) and Fritz Strassman (1902–1980), isolated and identified barium in a sample of uranium that had been bombarded with neutrons. How was barium formed? The answer—that the uranium nucleus had split into smaller pieces in a process we now call **nuclear fission**—was one of the most significant scientific discoveries of the 20th century.

The details of nuclear fission were unraveled through the work of a number of scientists. They determined that a uranium-235 nucleus initially captured a neutron to form uranium-236. This isotope then underwent nuclear fission to produce two new nuclei, one with a mass around 140 and the other with a mass around 90, along with several neutrons (Figure 25.9). The nuclear reactions that led to formation of barium when a sample of ^{235}U was bombarded with neutrons are

$$^{235}_{92}U + {}^{1}_{0}n \rightarrow {}^{236}_{92}U$$

$$^{236}_{92}U \rightarrow {}^{141}_{56}Ba + {}^{92}_{36}Kr + 3\ {}^{1}_{0}n$$



Element 118, Oganesson, Og, after Yuri Oganessian, a Russian scientist

Element 117 was the second element to be named after a state (the first was Cf, Californium), and element 118 was the second element to be named after a living scientist. (The first was seaborgium, Sb, element 106, named for Glenn Seaborg.) Notice the endings for elements 117 and 118 match the endings on other elements in their representative groups in the periodic table (fluorine, chlorine, bromine, iodine, astatine, tennessine; and argon, krypton, xenon, radon, oganesson). With this action all the elements from 1 to 118 have been assigned official names.

An important question is how scientists can be sure of the identity of a new element. Element 113 (nihonium, Nh), for example, is produced by the collision of atoms of ^{209}Bi and ^{70}Zn. The process gives an atom of element 113, ^{278}Nh, and a neutron.

$$^{209}_{83}Bi + {}^{70}_{30}Zn \rightarrow {}^{278}_{113}Nh + {}^{1}_{0}n$$

The atom then decays to give six alpha particles and atoms of six well-known elements, the last of which is mendelevium. The scientists observed, for example, that lawrencium-258 decayed in the final step by emitting an alpha particle to give mendelevium-254. The observed half-life of this decay was 3.9 s, which corresponds to the known value for ^{254}Md.

Identifying Element 113, ^{278}Nh. Scientists at the Riken Nishina Center for Accelerator-Based Science in Japan first produced atoms of ^{278}Nh in an accelerator. The atom decayed by emitting six alpha particles to finally give ^{254}Md. Element 113 was confirmed when the measured half-lives in each of the last five steps agreed with known half-lives for these isotopes.

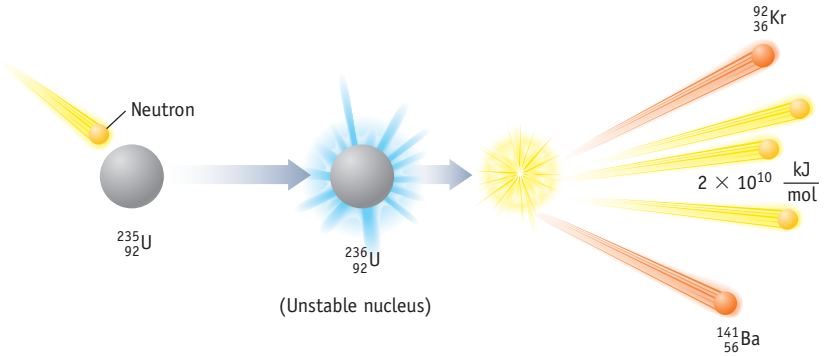

Figure 25.9 Nuclear fission. Neutron capture by $^{235}_{92}U$ produces $^{236}_{92}U$. This isotope undergoes fission, which yields several fragments along with several neutrons. These neutrons initiate further nuclear reactions by adding to other $^{235}_{92}U$ nuclei. The process is highly exothermic, producing about 2×10^{10} kJ/mol.

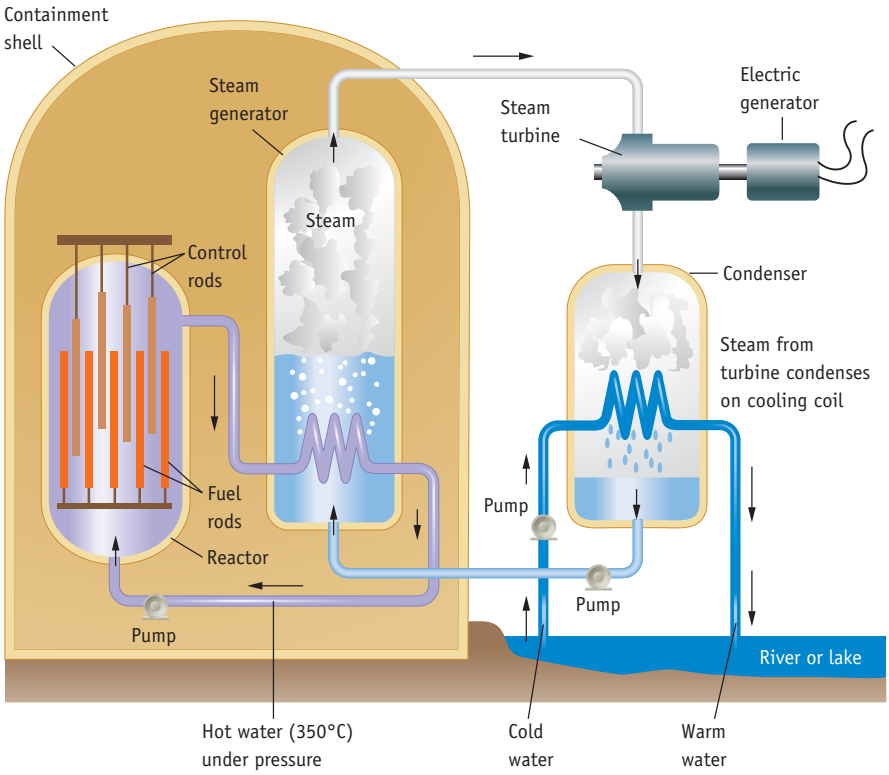
Central Press/Getty Images



Lise Meitner (1878–1968) Meitner and her nephew, Otto Frisch, also a physicist, published a paper in 1939 that was the first to use the term *nuclear fission*. Element number 109 is named *meitnerium* to honor Meitner's contributions. The leader of the team that discovered this element said that "She should be honored as the most significant woman scientist of [the 20th] century."

An important aspect of fission reactions is that they produce more neutrons than are used to initiate the process. Under the right circumstances, these neutrons then serve to continue the reaction. If one or more of these neutrons is captured by another ^{235}U nucleus, a further reaction can occur, releasing still more neutrons. This sequence repeats over and over. Such a mechanism, in which each step generates a reactant to continue the reaction, is called a **chain reaction**.

A nuclear fission chain reaction has three general steps:

1. *Initiation*. The reaction of a single atom is needed to start the chain. Following absorption of a neutron to form uranium-236, the reaction is initiated by decomposition of this atom.
2. *Propagation*. Absorption of neutrons and splitting of uranium atoms repeats over and over, with each step yielding more product. The fission of ^{236}U releases neutrons that initiate the fission of other uranium atoms.
3. *Termination*. Eventually, the chain will end. Termination could occur if the reactant (^{235}U) is used up or if the neutrons that continue the chain escape from the sample without being captured by ^{235}U.

A nuclear reactor uses the energy generated by fission as heat (Figure 25.10). To harness the energy, it is necessary to control the rate at which a fission reaction

Shipman, James T. Jerry D. Wilson, Charles A. Higgins, and Omar J. Torres. An Introduction to Physical Science, 14ed, 2016, Cengage Learning.

Figure 25.10 Schematic of a nuclear power plant. The heat from the fission reaction is used to generate steam, which in turn powers a turbine.

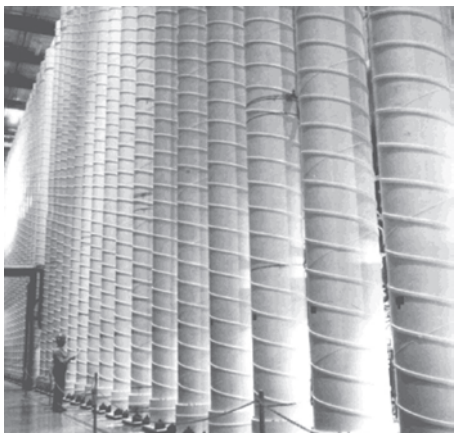
occurs. This is managed by balancing the propagation and termination steps to limiting the number of neutrons available. This is accomplished by using cadmium rods to absorb neutrons in a nuclear reactor. By withdrawing or inserting the rods, the number of neutrons available to propagate the chain can be changed, and the rate of the fission reaction (and the rate of energy production) can be increased or decreased.

Uranium-235 and plutonium-239 are the fissionable isotopes most commonly used in power reactors. Natural uranium contains only 0.72% of uranium-235; more than 99% of the natural element is uranium-238. The percentage of uranium-235 in natural uranium is too small to sustain a chain reaction, however, so the uranium used for nuclear fuel must be enriched in this isotope. One way to do so is by gaseous centrifugation (Figure 25.11).

Plutonium, which occurs naturally in trace quantities, must be made by a nuclear reaction. The raw material for this nuclear synthesis is the more abundant uranium isotope, ^{238}U. Addition of a neutron to ^{238}U gives ^{239}U, which, as noted earlier, undergoes two β emissions to form ^{239}Pu.



In 2017 there were 62 commercial nuclear power plants in the United States located in 30 states with almost 100 reactors. There are also more than 400 worldwide. About 20% of this country's electricity (and 17% of the world's energy) comes from nuclear power (Chapter 20). Although one might imagine that nuclear energy would be called upon to meet the ever-increasing needs of society, there is reluctance to move in this direction. Among other things, the disasters at Chernobyl (in the former Soviet Union) in 1986, Three Mile Island (in Pennsylvania) in 1979, and the Fukushima power plant in Japan (which was damaged by a tsunami in 2011) have sensitized the public to the issue of safety.

The cost to construct a nuclear power plant (measured in terms of dollars per kilowatt-hour of power) is considerably more than the cost for a natural gas–powered facility, and there are severe regulatory restrictions. Disposal of highly radioactive nuclear waste is yet another thorny problem, with 20 metric tons of waste being generated per year at each reactor.

In addition to technical problems, nuclear energy production brings with it significant geopolitical security concerns. The process for enriching uranium for use in a reactor is the same process used for generating weapons-grade uranium. Also, some nuclear reactors are designed so that one by-product of their operation is the isotope plutonium-239, which can be removed and used in a nuclear weapon. Despite these problems, nuclear fission is an important part of the energy profile in a number of countries. For example, about 75% of power production in France and 25% in Japan is nuclear generated.

Nuclear Power According to the *Bulletin of Atomic Scientists*, 41 nations since 1951 have been involved in the construction of 754 nuclear reactors. At the beginning of 2017, 55 reactors were under construction in 13 countries. Almost all of the activity is in Asia (34), Eastern Europe (10), and the Middle East (4).

Nuclear Weaponry, Power, and Related Topics. In 1946 Albert Einstein said that "The unleashed power of the atom has changed everything save our modes of thinking and we thus drift toward unparalleled catastrophe." To follow this highly significant topic, the best source to use is *The Bulletin of Atomic Scientists* (thebulletin.org). The *Bulletin* discusses not only topics related to nuclear weapons, power, and chemistry but also energy-related topics.

Oak Ridge National Laboratory

Separation of uranium isotopes for use in atomic weaponry or in nuclear power plants is done with gas centrifuges.

In a **nuclear fusion** reaction, several small nuclei react to form a larger nucleus and generate tremendous amounts of energy. An example is the fusion of deuterium and tritium nuclei to form $^{4}_{2}\text{He}$ and a neutron:

$$^{2}_{1}\text{H} + {}^{3}_{1}\text{H} \longrightarrow {}^{4}_{2}\text{He} + {}^{1}_{0}\text{n} \qquad \Delta E = -1.7 \times 10^{9}\ \text{kJ/mol}$$

a reaction that provides the energy of our Sun and other stars.

Scientists have long dreamed of being able to harness fusion to provide power. To do so, a temperature of 10^6 to 10^7 K, like that in the interior of the Sun, would be required to bring the positively charged nuclei together with enough energy to overcome nuclear repulsions. At the very high temperatures needed for a fusion reaction, matter does not exist as atoms or molecules; instead, matter is in the form of a *plasma* made up of unbound nuclei and electrons.

Three critical requirements must be met before nuclear fusion could become a viable energy source. First, the temperature must be high enough for fusion to occur. (The fusion of deuterium and tritium, for example, requires a temperature of 10^7 K or more.) Second, the plasma must be confined long enough to release a net output of energy. Third, the energy must be recovered in some usable form.

Harnessing a nuclear fusion reaction for a peaceful use has not yet been achieved. Nevertheless, many attractive features encourage continuing research in this field. The hydrogen used as "fuel" is cheap and available in almost unlimited amounts. As a further benefit, most radioisotopes produced by fusion have short half-lives, so they remain a radiation hazard for only a short time.

25.7 Radiation Health and Safety

Goal for Section 25.7

- Describe the units used to measure levels of radiation (curie, becquerel), the amount of energy absorbed by human tissue (rad, gray), and the damage to human tissue (rem, sievert).

Units for Measuring Radiation

Several units of measurement are used to describe levels and doses of radioactivity. In the United States, the degree of radioactivity is often measured in **curies** (Ci). Less commonly used in the United States is the SI unit, the **becquerel** (Bq). Both units measure the number of disintegrations per second; 1 Ci is 3.7×10^{10} dps (disintegrations per second), while 1 Bq represents 1 dps. The curie and the becquerel are used to report the amount of radioactivity when multiple kinds of unstable nuclei are decaying and to report amounts necessary for medical purposes.

Names for Units of Radiation The roentgen (R), an older unit of radiation, was named for Wilhelm Roentgen (1845–1923), who first produced and detected x radiation. Element 111 has been named roentgenium in his honor. The curie is named for Marie Curie (1867–1934, page 72), who is also honored by the name given element 96. The becquerel is named for Henri Becquerel (1852–1908), and the sievert is named for a Swedish physicist, Rolf Sievert (1896–1966).

By itself, the amount of radioactivity does not provide a good measure of the amount of energy in the radiation or the amount of damage that the radiation can cause to living tissue. Two additional kinds of information are necessary. The first is the amount of energy absorbed; the second is the effectiveness of the particular kind of radiation in causing tissue damage. The amount of energy absorbed by living tissue is measured in **rads**. *Rad* is an acronym for "radiation absorbed dose." One rad represents 0.01 J of energy absorbed per kilogram of tissue. Its SI equivalent is the **gray** (Gy); 1 Gy denotes the absorption of 1 J per kilogram of tissue.

Different forms of radiation cause different amounts of biological damage. The amount of damage depends on how strongly a form of radiation interacts with matter. Alpha particles cannot penetrate the body any farther than the outer layer of skin. If α particles are emitted within the body, however, they will cause between 10 and 20 times the amount of damage done by γ rays, which can go entirely through a human body without being stopped. In determining the amount of biological damage to living tissue, differences in damaging power are accounted for using a "quality factor." This quality factor has been set at 1 for β and γ radiation, 5 for

low-energy protons and neutrons, and 20 for α particles or high-energy protons and neutrons.

Biological damage is quantified in a unit called the **rem** (an acronym for "roentgen equivalent man"). A dose of radiation in rem is determined by multiplying the energy absorbed in rads by the quality factor for that kind of radiation. The rad and the rem are very large in comparison to normal exposures to radiation, so it is more common to express exposures in millirems (mrem). The SI equivalent of the rem is the **sievert** (Sv), determined by multiplying the dose in grays by the quality factor.

Radiation: Doses and Effects

Exposure to a small amount of radiation is unavoidable. Earth is constantly being bombarded with radioactive particles from outer space. There is also some exposure to radioactive elements that occur naturally on Earth, including ^{14}C, ^{40}K (a radioactive isotope that occurs naturally in 0.0117% abundance), ^{238}U, and ^{232}Th. Radioactive elements in the environment that were created artificially (in the fallout from nuclear bomb tests, for example) also contribute to this exposure. For some people, medical procedures using radioisotopes are a significant contributor.

The average dose of background radioactivity to which a person in the United States is exposed is about 200 mrem per year (Table 25.2). Well over half of that amount comes from natural sources over which we have no control. Of the 60–70 mrem per year exposure that comes from artificial sources, nearly 90% is delivered in medical procedures such as x-ray examinations and radiation therapy. Considering the controversy surrounding nuclear power, it is interesting to note that less than 0.5% of the total annual background dose of radiation the average person receives can be attributed to the nuclear power industry.

Describing the biological effects of a dose of radiation precisely is not a simple matter. The amount of damage done depends not only on the kind of radiation and

A CLOSER LOOK

A Real-Life Spy Thriller

On November 1, 2006, a Russian living in London, Alexander Litvinenko, suddenly fell ill and went to the hospital. He died three weeks later of radiation poisoning induced by polonium-210.

Litvinenko had been an officer in the Russian Federal Service (FSB), formerly called the KGB. However, he had left Russia to avoid prosecution and sought political asylum in the United Kingdom. There he supported a Russian oligarch, Boris Berezonsky, in his campaign against the Russian goverment. In his books Litvinenko alledged, among other things, that Vladimir Putin had come to power through a coup d'etat organized by the FSB.

On October 31, 2006, Litvinenko met with two other former KGB officers, one of whom was the bodyguard of ex-Prime Minister Yegor Gaidar (who is also thought to have been a poisoning victim in November 2006). It is thought that these two agents put a tiny amount of polonium-210 in Litvinenko's tea.

Litvinenko's symptoms suggested that he was given about 10 micrograms of polonium-210. The radiation from this sample would have been about 2 GBq or 50 mCi, about 200 times the lethal dose of the radionuclide. Polonium-210 is an alpha emitter. Alpha particles can be stopped even by a piece of paper, but if ingested they can produce significant damage to living cells.

After he died investigators examined the car in which he had ridden after apparently ingesting the polonium and found it was so radioactive it was unusable. His home was so contaminated that his family could not return for months.

There is a great deal of evidence pointing to the Russian FSB agents as the murderers. After it was determined that Litvinenko died of polonium poisoning, investigators found radioactivity on the aircraft the two agents used flying from Moscow to London. (Because ^{210}Po is an alpha emitter, one could carry a dilute solution of a polonium compound in a vial in a pocket, even through airport security.) It was found in the agent's hotel room, and it was on a tea cup in the bar where they had met with Litvinenko. Not only did this point to these agents, but, it is also the case that, though legal production of ^{210}Po had stopped in most countries, it continued in Russia.

Polonium-210 is made by bombarding ^{209}Bi with neutrons. This produces ^{210}Bi, which decays by beta emission to ^{210}Po. This isotope decays by alpha emission to stable ^{206}Pb with a half-life of 138 days.

Atomic Bomb Tests The first atomic bomb test (Trinity) occurred in New Mexico on July 16, 1945. Since then, well over 1300 nuclear test explosions were carried out in the atmosphere, underground, and underwater. Radioactive remnants from those explosions are with us today. North Korea continues to test weapons.

the amount of energy absorbed, but also on the particular tissues exposed and the rate at which the dose builds up. Information is more accurate when dealing with single, large doses than it is for the effects of chronic, smaller doses of radiation. A great deal has been learned about the effects of radiation on the human body by studying the survivors of the bombs dropped over Japan in World War II and the workers exposed to radiation from the reactor disaster at Chernobyl. From studies of the health of these survivors, we have learned that the effects of radiation are not generally observable below a single dose of 25 rem. At the other extreme, a single dose of >200 rem will be fatal to about half the population (Table 25.3).

TABLE 25.3 Effects of a Single Dose of Radiation

Dose (rem)	Effect
0–25	No effect observed
26–50	Small decrease in white blood cell count
51–100	Significant decrease in white blood cell count, lesions
101–200	Loss of hair, nausea
201–500	Hemorrhaging, ulcers, death in 50% of population
500	Death

25.8 Applications of Nuclear Chemistry

Goal for Section 25.8

- Recognize some uses of radioactive isotopes in science and medicine.

We tend to think about nuclear chemistry in terms of power plants and bombs. In truth, radioactive elements are now used in many areas of science and medicine, and they are of ever-increasing importance to our lives. Because describing all of their uses would take several books, we have selected just a few examples to illustrate the diversity of applications of radioactivity.

Nuclear Medicine: Medical Imaging

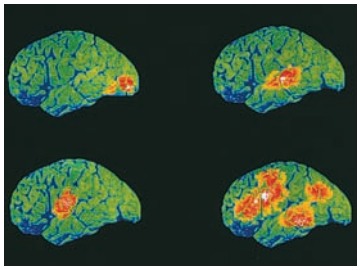
Diagnostic procedures using nuclear chemistry are essential in medical imaging, the creation of images of specific parts of the body. There are three principal components to constructing a radioisotope-based image:

- A radioactive isotope, administered as the element or incorporated into a compound that concentrates the radioactive isotope in the tissue to be imaged
- A method of detecting the type of radiation involved
- A computer to assemble the information from the detector into a meaningful image

The choice of a radioisotope and the manner in which it is administered are determined by the tissue in question. A compound containing the isotope must be absorbed more by the target tissue than by the rest of the body. Table 25.4 lists radioisotopes that are commonly used in nuclear imaging processes, their half-lives, and the tissues they are used to image. All the isotopes in Table 25.4 are γ emitters because γ radiation is preferred for imaging; it is less damaging to the body in small doses than either α or β radiation.

Technetium-99m is used in more than 85% of the diagnostic scans done in hospitals each year (*Applying Chemical Principles, 25.2: Technetium-99m and Medical Imaging,* page 1179). The "m" stands for *metastable,* a term used to identify an excited state of the nucleus that exists for a finite period of time. Recall that atoms in excited electronic states emit visible, infrared, and ultraviolet radiation (Chapter 6). Similarly, a nucleus in an excited state gives up its excess energy, but in this case a much higher energy is involved, and the emission occurs as γ radiation.

Another medical imaging technique based on nuclear chemistry is *positron emission tomography* (PET). In PET, an isotope that decays by positron emission is incorporated into a carrier compound and given to the patient. The emitted positron travels no more than a few millimeters before undergoing matter–antimatter annihilation.



$$ {}^{0}_{+1}\beta + {}^{0}_{-1}e \rightarrow 2\gamma $$

TABLE 25.4 Radioisotopes Used in Medical Diagnostic Procedures

Radioisotope	Half-Life (h)	Imaging
^{99m}Tc	6.0	Thyroid, brain, kidneys
^{201}Tl	73.0	Heart
^{123}I	13.2	Thyroid
^{67}Ga	78.2	Various tumors and abscesses
^{18}F	1.8	Brain, sites of metabolic activity

WDCN/Univ. College London/Science Source

Figure 25.12 PET scans of the brain. These scans show the left side of the brain; *red* indicates an area of highest activity. *(upper left) Sight* activates the visual area in the occipital cortex at the back of the brain. *(upper right) Hearing* activates the auditory area in the superior temporal cortex of the brain. *(lower left) Speaking* activates the speech centers in the insula and motor cortex. *(lower right) Thinking* about verbs, and speaking them, generates high activity, including in the hearing, speaking, temporal, and parietal areas. (See the photo of Dr. Joanna Fowler on page 1148, a pioneer in this area.)

The two emitted γ rays travel in opposite directions. By determining where high numbers of γ rays are being emitted, one can construct a map showing where the positron emitter is located in the body.

An isotope often used in PET is ^{15}O. A patient is given gaseous O_2 that contains ^{15}O. This isotope travels throughout the body in the bloodstream, allowing images of the brain and bloodstream to be obtained (Figure 25.12 and page 1148). Because positron emitters are typically very short-lived, PET facilities must be located near a cyclotron where the radioactive nuclei are prepared and then immediately incorporated into a carrier compound.

Nuclear Medicine: Radiation Therapy

To treat most cancers, it is necessary to use radiation that can penetrate the body to the location of the tumor. Gamma radiation from a cobalt-60 source is commonly used. Unfortunately, the penetrating ability of γ rays makes it virtually impossible to destroy diseased tissue without also damaging healthy tissue in the process. Nevertheless, this technique is a regularly sanctioned procedure, and its successes are well known.

Analytical Methods: The Use of Radioactive Isotopes as Tracers

Radioactive isotopes can be used to help determine the fate of compounds in the body or in the environment. In biology, for example, scientists can use radioactive isotopes to measure the uptake of nutrients. Plants take up phosphorus-containing compounds from the soil through their roots. By adding a small amount of radioactive ^{32}P, a β emitter with a half-life of 14.3 days, to fertilizer and then measuring the rate at which the radioactivity appears in the leaves, plant biologists can determine the rate at which phosphorus is taken up. The outcome can assist scientists in identifying hybrid strains of plants that can absorb phosphorus quickly, resulting in faster-maturing crops, better yields per acre, and more food or fiber at less expense.

To measure pesticide levels, a pesticide can be tagged with a radioisotope and then applied to a test field. By counting the disintegrations of the radioactive tracer, information can be obtained about how much pesticide accumulates in the soil, is taken up by the plant, and is carried off in runoff surface water. After these tests are completed, the radioactive isotope decays to harmless levels in a few days or a few weeks because of the short half-lives of the isotopes used.

Analytical Methods: Isotope Dilution

Imagine, for the moment, that you wanted to estimate the volume of blood in an animal subject. How might you do this? Obviously, draining the blood and measuring its volume in volumetric glassware is not a desirable option.

One technique uses a method called *isotope dilution*. In this process, a small amount of radioactive isotope is injected into the bloodstream. After a period of time to allow the isotope to become distributed throughout the body, a blood sample is taken and its radioactivity measured. The calculation used to determine the total blood volume is illustrated in the next example.

EXAMPLE 25.9

Analysis Using Radioisotopes

Problem A 1.00-mL solution containing 0.240 μCi of tritium is injected into a dog's bloodstream. After a period of time to allow the isotope to be dispersed, a 1.00-mL sample of blood is drawn. The radioactivity of this sample is found to be 4.3×10^{-4} μCi/mL. What is the total volume of blood in the dog?

What Do You Know? You know the concentration (activity) and volume of a concentrated solution and you then measure the concentration of the dilute solution. The unknown is the volume of the dilute solution.

Strategy In this problem, we relate the activity of the sample (in Ci) to the amount of the radioisotope present. The total amount of solute is 0.240 μCi, and the concentration (measured on the small sample of blood) is 4.3×10^{-4} μCi/mL. The unknown is the total volume of blood, *V*.

SOLUTION The blood contains a total of 0.240 μCi of radioactive material. Exactly 1.00 mL containing this amount was injected. After dilution in the bloodstream, 1.00 mL of blood, representative of the total volume *V*, is found to have an activity of 4.3×10^{-4} μCi/mL.

$$(0.240\ \mu\text{Ci/mL})(1.00\ \text{mL}) = (4.3 \times 10^{-4}\ \mu\text{Ci/mL})(V)$$

$$V = 560\ \text{mL}$$

Think about Your Answer This is solved as a classic dilution problem, where $C_{dil} \times V_{dil} = C_{conc} \times V_{conc}$.

Check Your Understanding

To measure the solubility for $PbCrO_4$ you mix a small amount of a lead(II) salt having radioactive ^{212}Pb with a lead salt containing 0.0100 g of lead. To this mixture you add enough K_2CrO_4 to completely precipitate the lead(II) ions as $PbCrO_4$. The supernatant solution still contains a trace of lead, of course, and when you evaporate 10.00 mL of this solution to solid $PbCrO_4$, you find a radioactivity that is 4.17×10^{-5} of what it is for the pure ^{212}Pb salt. Calculate the solubility of $PbCrO_4$ in mol/L. (Adapted from C. E. Housecraft and A. G. Sharpe, *Inorganic Chemistry*, Pearson, 3rd edition, 2008, p. 84.)

Food Science: Food Irradiation

Refrigeration, canning, and chemical additives provide significant protection in terms of food preservation, but in some parts of the world these procedures are unavailable, and stored-food spoilage may claim as much as 50% of the food crop. Irradiation with γ rays from sources such as ^{60}Co and ^{137}Cs is an option for prolonging the shelf life of foods. Relatively low levels of radiation retard the growth of organisms, such as bacteria, molds, and yeasts, that can cause food spoilage. After irradiation, milk in a sealed container has a minimum shelf life of 3 months without refrigeration. Chicken normally has a 3-day refrigerated shelf life; after irradiation, it may have a 3-week refrigerated shelf life.

Higher levels of radiation, in the 1- to 5-Mrad (1 Mrad = 1×10^6 rad) range, will kill every living organism. Foods irradiated at these levels will keep indefinitely when sealed in plastic or aluminum-foil packages. Ham, beef, turkey, and corned beef sterilized by radiation have been used on many Space Shuttle flights, for example. An astronaut said, "The beautiful thing was that it didn't disturb the taste, which made the meals much better than the freeze-dried and other types of foods we had."

"Radura." This international symbol called the "radura" should appear on the packaging of produce (fruits, vegetables, meat) that has been irradiated. See the EPA website for more information: https://www3.epa.gov/radtown/food-irradiation.html

An argument favoring this technique is that radiation is less harmful than other methodologies for food preservation. This type of sterilization offers greater safety to food workers because it lessens chances of exposure to harmful chemicals, and it protects the environment by avoiding contamination of water supplies with toxic chemicals. This said, the public has not readily accepted this procedure, the general concern being safety.

Food irradiation is commonly used in European countries, Canada, and Mexico. Its use in the United States is currently regulated by the U.S. Food and Drug Administration (FDA) and Department of Agriculture (USDA). Among the foods that have been approved for irradiation are eggs, beef and pork, poultry, shellfish, crustaceans (such as shrimp), shellfish, fresh fruits and vegetables, and lettuce and spinach.

APPLYING CHEMICAL PRINCIPLES

25.1 A Primordial Nuclear Reactor

In 1972, a French scientist noticed that the uranium taken from a mine in Oklo, Gabon, West Africa, was strangely deficient in ^{235}U. Uranium exists in nature as two principal isotopes, ^{238}U (99.274% abundant) and ^{235}U (0.720% abundant). ^{235}U most readily undergoes nuclear fission and is used to fuel nuclear power plants around the world. But the ^{235}U found in the Oklo mines was less abundant than expected, only 0.717% abundant. Based on this tiny discrepancy, and other evidence, scientists concluded that "natural" fission process occurred in the bed of uranium ore nearly 2 billion years ago.

But intriguing questions remained: Why could fission occur to a significant extent in this natural deposit of uranium and why didn't the "reactor" explode? Apparently, there must have been a moderator of neutron energy and a regulation mechanism. In a modern nuclear power reactor, control rods slow down the neutrons from nuclear fission so that they can induce fission in other ^{235}U nuclei. Without a moderator, the neutrons just fly off.

The reason the Oklo reactor did not explode is that water could have also been the moderator. As the fission process heated the water, it boiled off as steam. This caused the fission to stop, but it began again when more water seeped in. Scientists now believe this natural reactor would turn on for about 30 minutes and then shut down for several hours before turning on again. There is evidence this natural reactor functioned intermittently for about 1 million years, until the concentration of uranium isotopes was too low to keep the reaction going.

Questions:

1. There are two major isotopes of uranium, ^{235}U (half-life 7.038×10^9 yr, 0.720%) and ^{238}U (half-life 4.468×10^{10} yr, 99.274%). What was the relative abundance of ^{235}U two billion years (2.0×10^9 years) ago?
2. Rates of decomposition can be measured based on decompositions per min. What is the ratio of the rates of decomposition of the two major uranium isotopes (rate for ^{238}U /rate for ^{235}U)?
3. Uranium-235 is an alpha emitter. Write an equation for the nuclear decay process.
4. Calculate the molar mass (atomic weight) of naturally occurring uranium from the masses of the two major isotopes of uranium (^{235}U = 235.0409; ^{238}U = 238.0508) and their natural abundances.

Courtesy of Francois Gauthier-Lafaye

The natural nuclear reactor in Oklo, Gabon (West Africa). Nearly 2 billion years ago, a natural formation containing uranium oxide (the yellow material) underwent fission that started and stopped over a period of a million years.

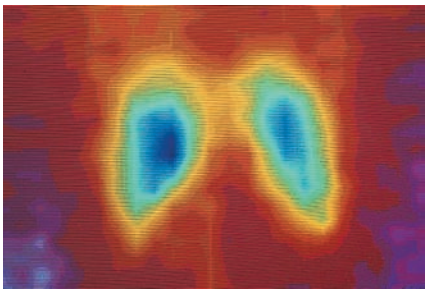
25.2 Technetium-99m and Medical Imaging

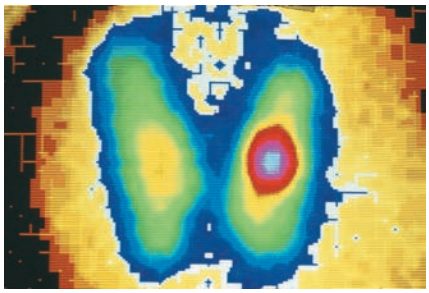
Technetium was the first element to be made artificially. One might think that this would make the element a chemical rarity, but it is not. Technetium is the product of nuclear reactions that can be done in a laboratory. As a consequence it has been readily available and even inexpensive (about $60 per gram). This has also led to widespread use in medical diagnosis, and it is now used all over the world in evaluations of the thyroid gland, the heart, kidneys, and lungs.

Technetium-99m is formed when molybdenum-99 decays by β emission. Technetium-99m (^{99m}Tc) then decays to its ground state (forming ^{99}Tc) with a half-life of 6.01 hours, giving off a 140-KeV γ ray in the process. (Technetium-99 is also radioactive, decaying to stable ^{99}Ru with a half-life of 2.1×10^5 years.)



Molydenum-99 is not a component of naturally occurring molybdenum. It is made in an (n, γ) reaction from molybdenum-98 (23.8% abundant in naturally occurring samples of the element). Nuclear power reactors utilizing U-235 provide the source of neutrons for this synthesis. But there was a problem with this route beginning about 2010 when the main reactors producing the molybdenum (in Canada and The Netherlands) had to be closed for repairs. Because technetium is so important worldwide for medical procedures, scientists immediately began looking for new sources.

Technetium-99m is produced in hospitals using a molybdenum–technetium generator. Shielded in lead, the generator contains the isotope ^{99}Mo in the form of the molybdate ion, MoO_4^{2-}, adsorbed on a column of alumina, Al_2O_3. The MoO_4^{2-} ion is continually converted into the pertechnetate ion, $^{99m}TcO_4^-$ by β emission. When it is needed, the $^{99m}TcO_4^-$ is washed from the column using a saline solution. Technetium-99m may be used directly as the pertechnetate ion (as $NaTcO_4$) or converted into other compounds. The pertechnetate ion or radiopharmaceuticals made from it are administered intravenously to the patient. Such small quantities are needed that 1 μg (microgram) of technetium-99m is sufficient for the average hospital's daily imaging needs.



One use of ^{99m}Tc is for imaging the thyroid gland. Because I^-(aq) and TcO_4^-(aq) ions have very similar sizes, the thyroid will (mistakenly) take up TcO_4^-(aq) along with iodide ion. This uptake concentrates ^{99m}Tc in the thyroid and allows a physician to obtain images such as the one shown here.

Questions:

1. Write an equation for the β decay of ^{99}Mo to ^{99}Tc.
2. What is the oxidation number of Tc in the pertechnetate ion? What is the electron configuration of a Tc^{n+} ion with a charge equal to this oxidation number? Should the TcO_4^- ion be paramagnetic or diamagnetic?
3. What amount of $NaTcO_4$ is there in 1.0 μg of the salt? What mass of Tc?
4. If you have 1.0 μg of Tc, what mass remains at the end of 24 hours?
5. ^{99}Tc decays to ^{99}Ru. What particle is produced in this decay?
6. Speculate on the reason the TcO_4^- ion is held less strongly to a column of Al_2O_3 than in the MoO_4^{2-} ion.

(a) Healthy human thyroid gland.

Photos: CNRI/Science Photo Library/ Science Source

(b) Thyroid gland showing effect of hyperthyroidism.

Thyroid imaging with technetium-99m. The radioactive isotope ^{99m}Tc concentrates in sites of high activity. Images of this gland, which is located at the base of the neck, were obtained by recording γ-ray emission after the patient was given radioactive technetium-99m. Current technology creates a computer color-enhanced scan.

25.3 The Age of Meteorites

Meteorites have a significant value for collectors, but they are also of scientific interest. Meteorites are generally regarded as some of the oldest materials in the solar system. And this raises the obvious question: How is the age of a meteorite determined? By age, we are referring to the time since the meteor condensed to a solid, locking the components into a solid matrix so they cannot escape. There are a number of methods to measure the age of a meteor, all involving the decay of long-lived radioactive elements.

One dating procedure involves vaporizing samples of the material and measuring the amounts of ^{86}Sr, ^{87}Sr, and ^{87}Rb by mass spectrometry. Both ^{86}Sr and ^{87}Sr are stable isotopes. The rubidium isotope, which decays to ^{87}Sr, has a half-life of 4.88×10^{10} years. The amount of ^{87}Sr measured includes the amount of ^{87}Sr initially present ($^{87}Sr_0$) when the meteorite was formed plus the amount formed by decay of ^{87}Rb. The ^{86}Sr remains constant and is used as a check on the original amounts of the other isotopes. The three measured amounts

Meteorites. Meteorites are materials that originate in outer space and survive the fall to the Earth's surface. They can be large or small, but as they enter Earth's atmosphere they are warmed to a high temperature by friction in the atmosphere and emit light, forming a fireball. There are three general categories: stony meteorites, which are silicate minerals; iron meteorites, largely composed of iron and nickel; and stony-iron meteorites. (See the photo of an iron meteorite, Figure 7.6.)

are related by an equation (which can be derived from the first-order rate law):

$$[^{87}Sr/^{86}Sr] = (e^{kt} - 1)\,[^{87}Rb/^{86}Sr] + [^{87}Sr_0/^{86}Sr]$$

The equation has the form of the equation of a straight line, $y = mx + b$. Multiple samples are analyzed from each meteorite. The amounts of each isotope may vary between samples, but a graph of $[^{87}Sr/^{86}Sr]$ versus $[^{87}Rb/^{86}Sr]$ will give a straight line with a slope $m = (e^{kt} - 1)$ and a y-intercept of $[^{87}Sr_0/^{86}Sr]$. The symbol k refers to the rate constant for the radioactive decomposition. This method is called *isochron dating*.

Questions:

1. Write a balanced equation for the radioactive decomposition of ^{87}Rb.
2. The decomposition of ^{87}Rb occurs by which of the following processes?
   a. alpha emission
   b. beta emission
   c. gamma emission
   d. electron capture
   e. positron emission
3. Determine the rate constant for the radioactive decay of ^{87}Rb.
4. The oldest dated meteorites have ages of about 4.5 billion years. What fraction of the initial ^{87}Rb has decayed?
5. The relative abundances of ^{86}Sr, ^{87}Sr, and ^{87}Rb were measured for four samples of a meteorite; the results were tabulated below. Make a strontium-rubidium isochron plot of these data, then use the slope of the line to determine the age of the meteorite.

Relative Abundance

Sample #	^{86}Sr	^{87}Sr	^{87}Rb
1	1.000	0.819	0.839
2	1.063	0.855	0.506
3	0.950	0.824	1.929
4	1.011	0.809	0.379

6. Derive the equation given in the text for $[^{87}Sr/^{86}Sr]$. (*Hint:* Start with the rate equation in the form $[^{87}Rb_0] = [^{87}Rb]\,e^{kt}$.)

CHAPTER GOALS REVISITED

The goals for this chapter are keyed to specific Study Questions to help you organize your review.

25.1 Natural Radioactivity

- Identify α, β, and γ radiation, the three major types of radiation in natural radioactive decay. 1, 2.

25.2 Nuclear Reactions and Radioactive Decay

- Write balanced equations for nuclear reactions (alpha, beta, gamma and positron emission, electron capture, and fission). 11,14, 21, 23.
- Recognize that radioactive isotopes decay by a series of nuclear reactions, called a radioactive decay series, eventually ending with a stable isotope. 9, 10, 25, 26.

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

25.3 Stability of Atomic Nuclei

- Assess nuclear stability based on the numbers of neutrons and protons in a nucleus. **3, 4.**
- Predict possible modes of decay of unstable nuclei based on n/p ratios. **27, 29.**
- Calculate the mass defect for an isotope and from this determine the nuclear binding energy E_b and the binding energy per nucleon. **33, 35.**

25.4 Rates of Nuclear Decay

- Carry out calculations on rates of radioactive decay using equations defining first order kinetics for these processes. **39, 41, 43.**
- Understand the process by which carbon-14 is used to date artifacts. **7, 8, 65.**

25.5 Artificial Nuclear Reactions

- Describe the experimental procedure used to carry out nuclear reactions. **5, 6.**
- Describe procedures used to prepare new transuranic elements. **49, 50.**

25.6 Nuclear Fission and Nuclear Fusion

- Describe nuclear chain reactions, nuclear fission, and nuclear fusion. **11–14.**

25.7 Radiation Health and Safety

- Describe the units used to measure levels of radiation (curie, becquerel), the amount of energy absorbed by human tissue (rad, gray), and the damage to human tissue (rem, sievert). **15.**

25.8 Applications of Nuclear Chemistry

- Recognize some uses of radioactive isotopes in science and medicine. **17, 69, 70, 73.**

KEY EQUATIONS

Equation 25.1 (page 1159): The equation relating interconversion of mass (m) and energy (E). This equation is applied in the calculation of binding energy (E_b) for nuclei.

$$E_b = (\Delta m)c^2$$

Equation 25.2 (page 1162): The activity of a radioactive sample (A) is proportional to the number of radioactive atoms (N).

$$A \propto N$$

Equation 25.3 (page 1163): The change in the number of radioactive elements with time is equal to the product of the rate constant (k, decay constant) and number of atoms present (N).

$$\Delta N/\Delta t = -kN$$

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Equation 25.4 (page 1163): The rate law for nuclear decay based on number of radioactive atoms initially present (N_0) and the number N after time t.

$$\ln(N/N_0) = -kt$$

Equation 25.5 (page 1163): The rate law for nuclear decay based on the measured activity of a sample (A).

$$\ln(A/A_0) = -kt$$

Equation 25.6 (page 1163): The relationship between the half-life and the rate constant for a nuclear decay process.

$$t_{1/2} = 0.693/k$$

STUDY QUESTIONS

▲ denotes challenging questions. **Blue-numbered questions** have answers in Appendix N and fully worked solutions in the *Student Solutions Manual*.

Practicing Skills

Important Concepts

1. Rank the three types of natural radiation (α, β, γ):
   (a) In order of increasing mass
   (b) In order of increasing penetrating power
2. What information was used to identify α and β particles?
3. A graph of binding energy per nucleon is shown in Figure 25.4. Explain how the data used to construct this graph were obtained.
4. How is Figure 25.3 used to predict the type of decomposition for unstable (radioactive) isotopes?
5. Outline how the synthesis of new isotopes is carried out in the laboratory. Why are neutrons so effective when used as a bombarding particle?
6. Cobalt-60, used as a source of high-energy gamma radiation in medical procedures, is made in a nuclear reactor by neutron irradiation of cobalt-59. Write an equation for this reaction.
7. Describe the process that uses carbon-14 for estimating the ages of archeological artifacts.
8. Explain why carbon-14 dating is limited to the range of 100 to about 60,000 years.
9. How many alpha and beta emissions occur in the uranium-238 radioactive decay series ending with lead-206?
10. The uranium-235 radioactive decay series includes 7 alpha emissions and 4 beta emissions. Identify the stable isotope at the end of this series.
11. Chain reactions occur in a series of steps described as initiation, propagation, and termination. Describe each of these steps for the fission of uranium-235.
12. The fission of uranium-235 releases 2×10^{10} kJ/mol. Calculate the quantity of mass converted to energy in this process.
13. In a nuclear reactor, what is a moderator and what is its function?
14. Identify the other element generated in the reaction $^{235}\text{U} + {}^{1}\text{n} \rightarrow {}^{141}\text{Ba} + 2\ {}^{1}\text{n} + ?$
15. What are the units associated with each of the following: (a) curie (b) rad
16. The interaction of radiation with matter has both positive and negative consequences. Discuss briefly the hazards of radiation and the way that radiation can be used in medicine.
17. What are the essential criteria for a radioactive isotope to be used for medical imaging?
18. Write equations that describe the preparation of technetium-99m from molybdenum-98.
19. Oxygen-15 is used in the medical procedure called positron emission tomography. This isotope is prepared on a cyclotron from irradiation of nitrogen-14 with deuterium nuclei. It decays to nitrogen-15 by positron emission, and the positrons are annihilated when they collide with electrons, forming two gamma rays. Write equations for the three reactions described here.
20. What are the advantages and disadvantages of food preservation using radiation?

Nuclear Reactions

(See Section 25.2 and Examples 25.1 and 25.2.)

21. Complete the following nuclear equations. Write the mass number and atomic number for the remaining particle, as well as its symbol.

(a) $^{54}_{26}\text{Fe} + {}^{4}_{2}\text{He} \longrightarrow 2\ {}^{1}_{0}\text{n} + ?$

(b) $^{27}_{13}\text{Al} + {}^{4}_{2}\text{He} \longrightarrow {}^{30}_{15}\text{P} + ?$

(c) $^{32}_{16}\text{S} + {}^{1}_{0}\text{n} \longrightarrow {}^{1}_{1}\text{H} + ?$

(d) $^{96}_{42}\text{Mo} + {}^{2}_{1}\text{H} \longrightarrow {}^{1}_{0}\text{n} + ?$

(e) $^{98}_{42}\text{Mo} + {}^{1}_{0}\text{n} \longrightarrow {}^{99}_{43}\text{Tc} + ?$

(f) $^{18}_{9}\text{F} \longrightarrow {}^{18}_{8}\text{O} + ?$

22. Complete the following nuclear equations. Write the mass number, atomic number, and symbol for the remaining particle.

(a) $^{9}_{4}\text{Be} + ? \longrightarrow {}^{6}_{3}\text{Li} + {}^{4}_{2}\text{He}$

(b) $? + {}^{1}_{0}\text{n} \longrightarrow {}^{24}_{11}\text{Na} + {}^{4}_{2}\text{He}$

(c) $^{40}_{20}\text{Ca} + ? \longrightarrow {}^{40}_{19}\text{K} + {}^{1}_{1}\text{H}$

(d) $^{241}_{95}\text{Am} + {}^{4}_{2}\text{He} \longrightarrow {}^{243}_{97}\text{Bk} + ?$

(e) $^{246}_{96}\text{Cm} + {}^{12}_{6}\text{C} \longrightarrow 4\ {}^{1}_{0}\text{n} + ?$

(f) $^{238}_{92}\text{U} + ? \longrightarrow {}^{249}_{100}\text{Fm} + 5\ {}^{1}_{0}\text{n}$

23. Complete the following nuclear equations. Write the mass number, atomic number, and symbol for the remaining particle.

(a) $^{111}_{47}\text{Ag} \longrightarrow {}^{111}_{48}\text{Cd} + ?$

(b) $^{87}_{36}\text{Kr} \longrightarrow {}^{0}_{-1}\beta + ?$

(c) $^{231}_{91}\text{Pa} \longrightarrow {}^{227}_{89}\text{Ac} + ?$

(d) $^{230}_{90}\text{Th} \longrightarrow {}^{4}_{2}\text{He} + ?$

(e) $^{82}_{35}\text{Br} \longrightarrow {}^{82}_{36}\text{Kr} + ?$

(f) $? \longrightarrow {}^{24}_{12}\text{Mg} + {}^{0}_{-1}\beta$

24. Complete the following nuclear equations. Write the mass number, atomic number, and symbol for the remaining particle.

(a) $^{19}_{10}\text{Ne} \longrightarrow {}^{0}_{+1}\beta + ?$

(b) $^{59}_{26}\text{Fe} \longrightarrow {}^{0}_{-1}\beta + ?$

(c) $^{40}_{19}\text{K} \longrightarrow {}^{0}_{-1}\beta + ?$

(d) $^{37}_{18}\text{Ar} + {}^{0}_{-1}\text{e}$ (electron capture) $\longrightarrow ?$

(e) $^{55}_{26}\text{Fe} + {}^{0}_{-1}\text{e}$ (electron capture) $\longrightarrow ?$

(f) $^{26}_{13}\text{Al} \longrightarrow {}^{25}_{12}\text{Mg} + ?$

25. The uranium-235 radioactive decay series, beginning with $^{235}_{92}\text{U}$ and ending with $^{207}_{82}\text{Pb}$, occurs in the following sequence: α, β, α, β, α, α, α, α, β, β, α. Write an equation for each step in this series.

26. The thorium-232 radioactive decay series, beginning with $^{232}_{90}\text{Th}$ and ending with $^{208}_{82}\text{Pb}$, occurs in the following sequence: α, β, β, α, α, α, α, β, β, α. Write an equation for each step in this series.

Nuclear Stability and Nuclear Decay

(See Section 25.3 and Examples 25.3 and 25.4.)

27. What particle is emitted in the following nuclear reactions? Write an equation for each reaction.

(a) Gold-198 decays to mercury-198.

(b) Radon-222 decays to polonium-218.

(c) Cesium-137 decays to barium-137.

(d) Indium-110 decays to cadmium-110.

28. What is the product of the following nuclear decay processes? Write an equation for each process.

(a) Gallium-67 decays by electron capture.

(b) Potassium-38 decays with positron emission.

(c) Technetium-99m decays with γ emission.

(d) Manganese-56 decays by β emission.

29. Predict the probable mode of decay for each of the following radioactive isotopes, and write an equation to show the products of decay.

(a) bromine-80 (c) cobalt-61

(b) californium-240 (d) carbon-11

30. Predict the probable mode of decay for each of the following radioactive isotopes, and write an equation to show the products of decay.

(a) manganese-54 (c) silver-110

(b) americium-241 (d) mercury-197m

31. (a) Which of the following nuclei decay by $^{0}_{-1}\beta$ decay?

^{3}H ^{16}O ^{20}F ^{13}N

(b) Which of the following nuclei decays by $^{0}_{+1}\beta$ decay?

^{238}U ^{19}F ^{22}Na ^{24}Na

32. (a) Which of the following nuclei decay by $^{0}_{-1}\beta$ decay?

^{1}H ^{23}Mg ^{32}P ^{20}Ne

(b) Which of the following nuclei decay by $^{0}_{+1}\beta$ decay?

^{235}U ^{35}Cl ^{38}K ^{24}Na

33. Boron has two stable isotopes, ^{10}B and ^{11}B. Calculate the binding energies per mole of nucleons of these two nuclei. The required masses (in g/mol) are $^{1}_{1}\text{H} = 1.00783$, $^{1}_{0}\text{n} = 1.00867$, $^{10}_{5}\text{B} = 10.01294$, and $^{11}_{5}\text{B} = 11.00931$.

34. Calculate the binding energy in kilojoules per mole of nucleons of P for the formation of ^{30}P and ^{31}P. The required masses (in g/mol) are $^{1}_{1}\text{H} = 1.00783$, $^{1}_{0}\text{n} = 1.00867$, $^{30}_{15}\text{P} = 29.97832$, and $^{31}_{15}\text{P} = 30.97376$.

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

35. Calculate the binding energy per mole of nucleons for calcium-40, and compare your result with the value in Figure 25.4. Masses needed for this calculation are (in g/mol) $^{1}_{1}H = 1.00783$, $^{1}_{0}n = 1.00867$, and $^{40}_{20}Ca = 39.96259$.

36. Calculate the binding energy per mole of nucleons for iron-56. Masses needed for this calculation (in g/mol) are $^{1}_{1}H = 1.00783$, $^{1}_{0}n = 1.00867$, and $^{56}_{26}Fe = 55.9349$. Compare the result of your calculation to the value for iron-56 in the graph in Figure 25.4.

37. Calculate the binding energy per mole of nucleons for $^{16}_{8}O$. Masses needed for this calculation are $^{1}_{1}H = 1.00783$, $^{1}_{0}n = 1.00867$, and $^{16}_{8}O = 15.99492$.

38. Calculate the binding energy per mole of nucleons for nitrogen-14. The mass of nitrogen-14 is 14.003074.

Rates of Radioactive Decay

(See Section 25.4 and Examples 25.5–25.7.)

39. Copper(II) acetate containing ^{64}Cu is used to study brain tumors. This isotope has a half-life of 12.7 hours. If you begin with 25.0 μg of ^{64}Cu, what mass remains after 63.5 hours?

40. Gold-198 is used in the diagnosis of liver problems. The half-life of ^{198}Au is 2.69 days. If you begin with 2.8 μg of this gold isotope, what mass remains after 10.8 days?

41. Iodine-131 is used to treat thyroid cancer.
    (a) The isotope decays by β-particle emission. Write a balanced equation for this process.
    (b) Iodine-131 has a half-life of 8.04 days. If you begin with 2.4 μg of radioactive ^{131}I, what mass remains after 40.2 days?

42. Phosphorus-32 is used in the form of Na_2HPO_4 in the treatment of chronic myeloid leukemia, among other things.
    (a) The isotope decays by β-particle emission. Write a balanced equation for this process.
    (b) The half-life of ^{32}P is 14.3 days. If you begin with 4.8 μg of radioactive ^{32}P in the form of Na_2HPO_4, what mass remains after 28.6 days (about 1 month)?

43. Gallium-67 ($t_{1/2}$ = 78.25 hours) is used in the medical diagnosis of certain kinds of tumors. If you ingest a compound containing 0.015 mg of this isotope, what mass (in milligrams) remains in your body after 13 days? (Assume none is excreted.)

44. Iodine-131 ($t_{1/2}$ = 8.04 days), a β emitter, is used to treat thyroid cancer.
    (a) Write an equation for the decomposition of ^{131}I.
    (b) If you ingest a sample of NaI containing ^{131}I, how much time is required for the activity to decrease to 35.0% of its original value?

45. Radon has been the focus of much attention recently because it is often found in homes. Radon-222 emits α particles and has a half-life of 3.82 days.
    (a) Write a balanced equation to show this process.
    (b) How long does it take for a sample of ^{222}Rn to decrease to 20.0% of its original activity?

46. Strontium-90 is a hazardous radioactive isotope that resulted from atmospheric testing of nuclear weapons. A sample of strontium carbonate containing ^{90}Sr is found to have an activity of 1.0×10^3 dpm. One year later, the activity of this sample is 975 dpm.
    (a) Calculate the half-life of strontium-90 from this information.
    (b) How long will it take for the activity of this sample to drop to 1.0% of the initial value?

47. Radioactive cobalt-60 is used extensively in nuclear medicine as a γ-ray source. It is made by a neutron capture reaction from cobalt-59 and is a β emitter; β emission is accompanied by strong γ radiation. The half-life of cobalt-60 is 5.27 years.
    (a) How long will it take for a cobalt-60 source to decrease to one eighth of its original activity?
    (b) What fraction of the activity of a cobalt-60 source remains after 1.0 year?

48. Scandium occurs in nature as a single isotope, scandium-45. Neutron irradiation produces scandium-46, a β emitter with a half-life of 83.8 days. If the initial activity is 7.0×10^4 dpm, draw a graph showing disintegrations per minute as a function of time during a period of 1 year.

Nuclear Reactions

(See Section 25.5 and Example 25.9.)

49. Americium-240 is made by bombarding plutonium-239 with α particles. In addition to ^{240}Am, the products are a proton and two neutrons. Write a balanced equation for this process.

50. There are two isotopes of americium, both with half-lives sufficiently long to allow the handling of large quantities. Americium-241, with a half-life of 432 years, is an α emitter used in smoke detectors. The isotope is formed from ^{239}Pu by absorption of two neutrons followed by emission of a β particle. Write a balanced equation for this process.

51. The superheavy element ^{287}Fl (element 114) was made by firing a beam of ^{48}Ca ions at ^{242}Pu. Three neutrons were ejected in the reaction. Write a balanced nuclear equation for the synthesis of ^{287}Fl.

52. To synthesize the heavier transuranium elements, a nucleus must be bombarded with a relatively large particle. If you know the products are californium-246 and four neutrons, with what particle would you bombard uranium-238 atoms?

53. Deuterium nuclei ($^{2}_{1}$H) are particularly effective as bombarding particles to carry out nuclear reactions. Complete the following equations:

(a) $^{114}_{48}\text{Cd} + {}^{2}_{1}\text{H} \longrightarrow \text{?} + {}^{1}_{1}\text{H}$

(b) $^{6}_{3}\text{Li} + {}^{2}_{1}\text{H} \longrightarrow \text{?} + {}^{1}_{0}\text{n}$

(c) $^{40}_{20}\text{Ca} + {}^{2}_{1}\text{H} \longrightarrow {}^{38}_{19}\text{K} + \text{?}$

(d) $\text{?} + {}^{2}_{1}\text{H} \longrightarrow {}^{65}_{30}\text{Zn} + \gamma$

54. Some important discoveries in scientific history that contributed to the development of nuclear chemistry are listed below. Briefly, describe each discovery, identify prominent scientists who contributed to it, and comment on the significance of the discovery to the development of this field.

(a) 1896, the discovery of radioactivity

(b) 1898, the identification of radium and polonium

(c) 1919, the first artificial nuclear reaction

55. Boron is an effective absorber of neutrons. When boron-10 is bombarded by neutrons, an α particle is emitted. Write an equation for this nuclear reaction.

56. Some of the reactions explored by Ernest Rutherford (pages 67 and 1166) and others are listed below. Identify the unknown species in each reaction.

(a) $^{14}_{7}\text{N} + {}^{4}_{2}\text{He} \longrightarrow {}^{17}_{8}\text{O} + \text{?}$

(b) $^{9}_{4}\text{Be} + {}^{4}_{2}\text{He} \longrightarrow \text{?} + {}^{1}_{0}\text{n}$

(c) $\text{?} + {}^{4}_{2}\text{He} \longrightarrow {}^{30}_{15}\text{P} + {}^{1}_{0}\text{n}$

(d) $^{239}_{94}\text{Pu} + {}^{4}_{2}\text{He} \longrightarrow \text{?} + {}^{1}_{0}\text{n}$

General Questions

These questions are not designated as to type or location in the chapter. They may combine several concepts.

57. ▲ A technique to date geological samples uses rubidium-87, a long-lived radioactive isotope of rubidium ($t_{1/2} = 4.8 \times 10^{10}$ years). Rubidium-87 decays by β emission to strontium-87. If rubidium-87 is part of a rock or mineral, then strontium-87 will remain trapped within the crystalline structure of the rock. The age of the rock dates back to the time when the rock solidified. Chemical analysis of the rock gives the amounts of ^{87}Rb and ^{87}Sr. From these data, the fraction of ^{87}Rb that remains can be calculated. Suppose analysis of a stony meteorite determined that 1.8 mmol of ^{87}Rb and 1.6 mmol of ^{87}Sr (the portion of ^{87}Sr formed by decomposition of ^{87}Rb) were present. Estimate the age of the meteorite. (*Hint:* The amount of ^{87}Rb at t_0 is moles ^{87}Rb + moles ^{87}Sr.)

58. Tritium, $^{3}_{1}$H, is one of the nuclei used in fusion reactions. This isotope is radioactive, with a half-life of 12.3 years. Like carbon-14, tritium is formed in the upper atmosphere from cosmic radiation, and it is found in trace amounts on Earth. To obtain the amounts required for a fusion reaction, however, it must be made via a nuclear reaction. The reaction of $^{6}_{3}$Li with a neutron produces tritium and an α particle. Write an equation for this nuclear reaction.

59. Phosphorus occurs in nature as a single isotope, phosphorus-31. Neutron irradiation of phosphorus-31 produces phosphorus-32, a β emitter with a half-life of 14.28 days. Assume you have a sample containing phosphorus-32 that has a rate of decay of 3.2×10^6 dpm. Draw a graph showing disintegrations per minute as a function of time during a period of 1 year.

60. In June 1972, natural fission reactors, which operated billions of years ago, were discovered in Oklo, Gabon (page 1178). At present, natural uranium contains 0.72% ^{235}U. How many years ago did natural uranium contain 3.0% ^{235}U, the amount needed to sustain a natural reactor? ($t_{1/2}$ for ^{235}U is 7.04×10^8 years.)

61. If a shortage in worldwide supplies of fissionable uranium arose, it would be possible to use other fissionable nuclei. Plutonium, one such fuel, can be made in "breeder" reactors that manufacture more fuel than they consume. The sequence of reactions by which plutonium is made is as follows:

(a) A ^{238}U nucleus undergoes an (n, γ) reaction to produce ^{239}U.

(b) ^{239}U decays by β emission ($t_{1/2} = 23.5$ min) to give an isotope of neptunium.

(c) This neptunium isotope decays by β emission to give a plutonium isotope.

(d) The plutonium isotope is fissionable. On collision of one of these plutonium isotopes with a neutron, fission occurs, with at least two neutrons and two other nuclei as products.

Write an equation for each of the nuclear reactions.

62. When a neutron is captured by an atomic nucleus, energy is released as γ radiation. This energy can be calculated based on the change in mass in converting reactants to products.

For the nuclear reaction ${}^{6}_{3}\text{Li} + {}^{1}_{0}\text{n} \longrightarrow {}^{7}_{3}\text{Li} + \gamma$:

(a) Calculate the energy evolved in this reaction (per atom). Masses needed (in g/mol) are ${}^{6}_{3}\text{Li} = 6.01512$, ${}^{1}_{0}\text{n} = 1.00867$, and ${}^{7}_{3}\text{Li} = 7.01600$.n

(b) Use the answer in part (a) to calculate the wavelength of the γ rays emitted in the reaction.

63. The synthesis of livermorium:

(a) Lv-296 is made from the collision of a relatively light atom with curium-248. What is the lighter particle?

(b) Lv-296 is not stable, decaying to Lv-293. What particles are emitted in this process?

64. Some important discoveries in scientific history that contributed to the development of nuclear chemistry are listed below. Briefly, describe each discovery, identify prominent scientists who contributed to it, and comment on the significance of the discovery to the development of this field.

(a) 1905, theory of special relativity

(b) 1932, (n, γ) reactions

(c) 1939, fission reactions

In the Laboratory

65. A piece of charred bone found in the ruins of a Native American village has a ${}^{14}\text{C}/{}^{12}\text{C}$ ratio that is 72% of the ratio found in living organisms. Calculate the age of the bone fragment. ($t_{1/2}$ for ${}^{14}\text{C}$ is 5.73×10^3 years.)

66. A sample of wood from a Thracian chariot found in an excavation in Bulgaria has a ${}^{14}\text{C}$ activity of 11.2 dpm/g. Estimate the age of the chariot and the year it was made. ($t_{1/2}$ for ${}^{14}\text{C}$ is 5.73×10^3 years, and the activity of ${}^{14}\text{C}$ in living material is 14.0 dpm/g.)

67. The isotope of polonium that was most likely isolated by Marie Curie in her pioneering studies is polonium-210. A sample of this element was prepared in a nuclear reaction. Initially, its activity (α emission) was 7840 dpm. Measuring radioactivity over time produced the data below. Determine the half-life of polonium-210.

Activity (dpm)	Time (days)
7840	0
7570	7
7300	14
5920	56
5470	72

68. Sodium-23 (in a sample of NaCl) is subjected to neutron bombardment in a nuclear reactor to produce ${}^{24}\text{Na}$. When removed from the reactor, the sample is radioactive, with β activity of 2.54×10^4 dpm. The decrease in radioactivity over time was studied, producing the following data:

Activity (dpm)	Time (hours)
2.54×10^4	0
2.42×10^4	1
2.31×10^4	2
2.00×10^4	5
1.60×10^4	10
1.01×10^4	20

(a) Write equations for the neutron capture reaction and for the reaction in which the product of this reaction decays by β emission.

(b) Determine the half-life of sodium-24.

69. The age of minerals can sometimes be determined by measuring the amounts of ${}^{206}\text{Pb}$ and ${}^{238}\text{U}$ in a sample. This determination assumes that all of the ${}^{206}\text{Pb}$ in the sample comes from the decay of ${}^{238}\text{U}$. The date obtained identifies when the rock solidified. Assume that the ratio of ${}^{206}\text{Pb}$ to ${}^{238}\text{U}$ in an igneous rock sample is 0.33. Calculate the age of the rock. ($t_{1/2}$ for ${}^{238}\text{U}$ is 4.5×10^9 years.)

70. To measure the volume of the blood system of an animal, the following experiment was done. A 1.0-mL sample of an aqueous solution containing tritium, with an activity of 2.0×10^6 dps, was injected into the animal's bloodstream. After time was allowed for complete circulatory mixing, a 1.0-mL blood sample was withdrawn and found to have an activity of 1.5×10^4 dps. What was the volume of the circulatory system? (The half-life of tritium is 12.3 years, so this experiment assumes that only a negligible amount of tritium has decayed in the time of the experiment.)

Summary and Conceptual Questions

The following questions may use concepts from this and previous chapters.

71. The average energy output of a good grade of coal is 2.6×10^7 kJ/ton. Fission of 1 mol of ${}^{235}\text{U}$ releases 2.1×10^{10} kJ. Find the number of tons of coal needed to produce the same energy as 1 lb of ${}^{235}\text{U}$. (See Appendix C for conversion factors.)

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

72. Collision of an electron and a positron results in formation of two γ rays. In the process, their masses are converted completely into energy.

(a) Calculate the energy evolved from the annihilation of an electron and a positron, in kilojoules per mole.

(b) Using Planck's equation (Equation 6.2), determine the frequency of the γ rays emitted in this process.

73. The principle underlying the isotope dilution method of analysis can be applied to many kinds of problems. Suppose that you, a marine biologist, want to estimate the number of fish in a lake. You release 1000 tagged fish, and after allowing an adequate amount of time for the fish to disperse evenly in the lake, you catch 5250 fish and find that 27 of them have tags. How many fish are in the lake?

74. ▲ Radioactive isotopes are often used as "tracers" to follow an atom through a chemical reaction. The following is an example of this process: Acetic acid reacts with methanol, CH_3OH, by eliminating a molecule of H_2O to form methyl acetate, $CH_3CO_2CH_3$. Explain how you would use the radioactive isotope ^{15}O to show whether the oxygen atom in the water product comes from the —OH of the acid or the —OH of the alcohol.

75. ▲ Radioactive decay series begin with a very long-lived isotope. For example, the half-life of ^{238}U is 4.5×10^9 years. Each series is identified by the name of the long-lived parent isotope of highest mass.

(a) The uranium-238 radioactive decay series is sometimes referred to as the $4n + 2$ series because the masses of all 13 members of this series can be expressed by the equation $M = 4n + 2$, where M is the mass number and n is an integer. Explain why the masses are correlated in this way.

(b) Two other radioactive decay series identified in minerals in the Earth's crust are the thorium-232 series and the uranium-235 series. Do the masses of the isotopes in these series conform to a simple mathematical equation? If so, identify the equation.

(c) Identify the radioactive decay series to which each of the following isotopes belongs: $^{226}_{88}Ra$, $^{215}_{86}At$, $^{228}_{90}Th$, $^{210}_{83}Bi$.

(d) Evaluation reveals that one series of elements, the $4n + 1$ series, is not present in the Earth's crust. Speculate why.

76. ▲ The thorium decay series includes the isotope $^{228}_{90}Th$. Determine the sequence of nuclei on going from $^{232}_{90}Th$ to $^{228}_{90}Th$.

77. ▲ The last unknown element between bismuth and uranium was discovered by Lise Meitner (1878–1968) and Otto Hahn (1879–1968) in 1918. They obtained ^{231}Pa by chemical extraction of pitchblende, in which its concentration is about 1 ppm (part per million). This isotope, an α emitter, has a half-life of 3.27×10^4 years.

(a) Which radioactive decay series (the uranium-235, uranium-238, or thorium-232 series) contains ^{231}Pa as a member?

(b) Suggest a possible sequence of nuclear reactions starting with the long-lived isotope that eventually forms this isotope.

(c) What quantity of ore would be required to isolate 1.0 g of ^{231}Pa, assuming 100% yield?

(d) Write an equation for the radioactive decay process for ^{231}Pa.

78. ▲ You might wonder how it is possible to determine the half-life of long-lived radioactive isotopes such as ^{238}U. With a half-life of more than 10^9 years, the radioactivity of a sample of uranium will not measurably change in your lifetime. In fact, you can calculate the half-life using the mathematics governing first-order reactions.

It can be shown that a 1.0-mg sample of ^{238}U decays at the rate of 12 α emissions per second. Set up a mathematical equation for the rate of decay, $\Delta N/\Delta t = -kN$, where N is the number of nuclei in the 1.0-mg sample and $\Delta N/\Delta t$ is 12 dps. Solve this equation for the rate constant for this process, and then relate the rate constant to the half-life of the reaction. Carry out this calculation, and compare your result with the literature value, 4.5×10^9 years.

79. ▲ Marie and Pierre Curie isolated radium and polonium from uranium ore (pitchblende, which contains ^{238}U and ^{235}U). Which of the following isotopes of radium and polonium can be found in the uranium ore? (*Hint:* Consider both the isotope half-lives and the decay series starting with ^{238}U and ^{235}U.)

Isotope	Half-Life
^{226}Ra	1620 y
^{225}Ra	14.8 d
^{228}Ra	6.7 y
^{216}Po	0.15 s
^{210}Po	138.4 d

APPENDIX

A

Using Logarithms and Solving Quadratic Equations

An introductory chemistry course requires basic algebra plus a knowledge of (1) exponential (or scientific) notation, (2) logarithms, and (3) quadratic equations. The use of exponential notation was reviewed on pages 37–38, and this appendix reviews the last two topics.

A.1 Logarithms

Two types of logarithms are used in this text: (1) common logarithms (abbreviated log) whose base is 10 and (2) natural logarithms (abbreviated ln) whose base is e (= 2.71828):

$$\log x = n, \text{ where } x = 10^n$$
$$\ln x = m, \text{ where } x = e^m$$

Most equations in chemistry and physics were developed in natural, or base e, logarithms, and we follow this practice in this text. The relation between log and ln is

$$\ln x = 2.303 \log x$$

Despite the different bases of the two logarithms, they are used in the same manner. What follows is largely a description of the use of common logarithms.

A common logarithm is the power to which you must raise 10 to obtain the number. For example, the log of 100 is 2, since you must raise 10 to the second power to obtain 100. Other examples are

$$\log 1000 = \log (10^3) = 3$$
$$\log 10 = \log (10^1) = 1$$
$$\log 1 = \log (10^0) = 0$$
$$\log 0.1 = \log (10^{-1}) = -1$$
$$\log 0.0001 = \log (10^{-4}) = -4$$

To obtain the common logarithm of a number other than a simple power of 10, you must resort to a log table or an electronic calculator. For example,

$$\log 2.10 = 0.322, \text{ which means that } 10^{0.322} = 2.10$$
$$\log 5.16 = 0.713, \text{ which means that } 10^{0.713} = 5.16$$
$$\log 3.125 = 0.4949, \text{ which means that } 10^{0.4949} = 3.125$$

To check this on many calculators, enter the number, and then press the "log" key. You should make sure that you understand how to use your particular calculator.

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

To obtain the natural logarithm ln of the numbers shown here, use a calculator having this function. Enter each number, and press "ln:"

$$\ln 2.10 = 0.742, \text{ which means that } e^{0.742} = 2.10$$
$$\ln 5.16 = 1.641, \text{ which means that } e^{1.641} = 5.16$$

To find the common logarithm of a number greater than 10 or less than 1 with a log table, first express the number in scientific notation. Then find the log of each part of the number and add the logs. For example,

$$\begin{aligned}\log 241 &= \log (2.41 \times 10^2) = \log 2.41 + \log 10^2 \\ &= 0.382 + 2 = 2.382 \\ \log 0.00573 &= \log (5.73 \times 10^{-3}) = \log 5.73 + \log 10^{-3} \\ &= 0.758 + (-3) = -2.242\end{aligned}$$

Significant Figures and Logarithms

Notice that the mantissa has as many significant figures as the number whose log was found.

Logarithms and Nomenclature
The number to the left of the decimal in a logarithm is called the **characteristic**, and the number to the right of the decimal is the **mantissa**.

Obtaining Antilogarithms

If you are given the logarithm of a number and find the number from it, you have obtained the "antilogarithm," or "antilog," of the number. Two common procedures used by electronic calculators to do this are as follows:

Procedure A	Procedure B
1. Enter the value of the log or ln.	1. Enter value of the log or ln.
2. Press 2ndF.	2. Press INV.
3. Press 10^x or e^x.	3. Press log or ln x.

Make sure you can properly perform this operation on your calculator by working the following examples:

1. Find the number whose log is 5.234:
   Recall that $\log x = n$, where $x = 10^n$. In this case, $n = 5.234$. Find the value of 10^n, the antilog. In this case,
   $$10^{5.234} = 10^{0.234} \times 10^5 = 1.71 \times 10^5$$
   Notice that the characteristic (5) sets the decimal point; it is the power of 10 in the exponential form. The mantissa (0.234) gives the value of the number x, 1.71 in this case.
2. Find the number whose log is -3.456:
   $$10^{-3.456} = 10^{0.544} \times 10^{-4} = 3.50 \times 10^{-4}$$
   Notice here that -3.456 is expressed as the sum of -4 and $+0.544$.

Mathematical Operations Using Logarithms

Because logarithms are exponents, operations involving them follow the same rules used for exponents. Thus, multiplying two numbers can be done by adding logarithms:

$$\log xy = \log x + \log y$$

For example, we multiply 563 by 125 by adding their logarithms and finding the antilogarithm of the result:

$$\begin{aligned}\log 563 &= 2.751 \\ \log 125 &= \underline{2.097} \\ \log xy &= 4.847 \\ xy &= 10^{4.848} = 10^{0.848} \times 10^4 = 7.04 \times 10^4\end{aligned}$$

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

One number (x) can be divided by another (y) by subtraction of their logarithms:

$$\log \frac{x}{y} = \log x - \log y$$

For example, to divide 125 by 742,

$$\begin{aligned} \log 125 &= 2.097 \\ -\log 742 &= \underline{2.870} \\ \log \frac{x}{y} &= -0.773 \end{aligned}$$

$$\frac{x}{y} = 10^{-0.773} = 10^{0.227} \times 10^{-1} = 1.68 \times 10^{-1}$$

Similarly, powers and roots of numbers can be found using logarithms.

$$\log x^y = y(\log x)$$

$$\log \sqrt[y]{x} = \log x^{1/y} = \frac{1}{y} \log x$$

As an example, find the fourth power of 5.23. We first find the log of 5.23 and then multiply it by 4. The result, 2.874, is the log of the answer. Therefore, we find the antilog of 2.874:

$$\begin{aligned} (5.23)^4 &= ? \\ \log (5.23)^4 &= 4 \log 5.23 = 4(0.719) = 2.874 \\ (5.23)^4 &= 10^{2.874} = 748 \end{aligned}$$

As another example, find the fifth root of 1.89×10^{-9}:

$$\sqrt[5]{1.89 \times 10^{-9}} = (1.89 \times 10^{-9})^{1/5} = ?$$

$$\log (1.89 \times 10^{-9})^{1/5} = \frac{1}{5} \log(1.89 \times 10^{-9}) = \frac{1}{5}(-8.724) = -1.745$$

The answer is the antilog of -1.745:

$$(1.89 \times 10^{-9})^{1/5} = 10^{-1.745} = 1.80 \times 10^{-2}$$

A.2 Quadratic Equations

Algebraic equations of the form $ax^2 + bx + c = 0$ are called **quadratic equations**. The coefficients a, b, and c may be either positive or negative. The two roots of the equation may be found using the *quadratic formula:*

$$x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$$

As an example, solve the equation $5x^2 - 3x - 2 = 0$. Here $a = 5$, $b = -3$, and $c = -2$. Therefore,

$$x = \frac{3 \pm \sqrt{(-3)^2 - 4(5)(-2)}}{2(5)}$$

$$= \frac{3 \pm \sqrt{9 - (-40)}}{10} = \frac{3 \pm \sqrt{49}}{10} = \frac{3 \pm 7}{10}$$

$$= 1 \text{ and } -0.4$$

How do you know which of the two roots is the correct answer? Mathematically, both roots are possible, but in chemistry problems you have to decide in each case

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

which root has physical significance. It is *usually* true in this course, however, that negative values are not significant.

When you have solved a quadratic expression, you should always check your values by substitution into the original equation. In the previous example, we find that $5(1)^2 - 3(1) - 2 = 0$ and that $5(-0.4)^2 - 3(-0.4) - 2 = 0$.

The most likely place you will encounter quadratic equations is in the chapters on chemical equilibria, particularly in Chapters 15 through 17. Here, you will often be faced with solving an equation such as

$$1.8 \times 10^{-4} = \frac{x^2}{0.0010 - x}$$

This equation can certainly be solved using the quadratic formula (to give $x = 3.4 \times 10^{-4}$). You may find the **method of successive approximations** to be especially convenient, however. Here we begin by making a reasonable approximation of x. This approximate value is substituted into the original equation, which is then solved to give what is hoped to be a more correct value of x. This process is repeated until the answer converges on a particular value of x—that is, until the value of x derived from two successive approximations is the same.

Step 1: First, assume that x is so small that $(0.0010 - x) \approx 0.0010$. This means that

$$x^2 = 1.8 \times 10^{-4}\ (0.0010)$$
$$x = 4.2 \times 10^{-4}\ \text{(to 2 significant figures)}$$

Step 2: Substitute the value of x from Step 1 into the denominator of the original equation, and again solve for x:

$$x^2 = 1.8 \times 10^{-4}(0.0010 - 0.00042)$$
$$x = 3.2 \times 10^{-4}$$

Step 3: Repeat Step 2 using the value of x found in that step:

$$x = \sqrt{1.8 \times 10^{-4}(0.0010 - 0.00032)} = 3.5 \times 10^{-4}$$

Step 4: Continue repeating the calculation, using the value of x found in the previous step:

$$x = \sqrt{1.8 \times 10^{-4}(0.0010 - 0.00035)} = 3.4 \times 10^{-4}$$

Step 5:

$$x = \sqrt{1.8 \times 10^{-4}(0.0010 - 0.00034)} = 3.4 \times 10^{-4}$$

Here, we find that iterations after the fourth step give the same value for x, indicating that we have arrived at a valid answer (and the same one obtained from the quadratic formula).

Here are some final thoughts on using the method of successive approximations. First, in some cases the method does not work. Successive steps may give answers that are random or that diverge from the correct value. In Chapters 15 through 17, you confront quadratic equations of the form $K = x^2/(C - x)$. The method of successive approximations works as long as $K < 4C$ (assuming one begins with $x = 0$ as the first guess, that is, $K \approx x^2/C$). This is always going to be true for weak acids and bases (the topic of Chapters 16 and 17), but it may *not* be the case for problems involving gas phase equilibria (Chapter 15), where K can be quite large.

Second, values of K in the equation $K = x^2/(C - x)$ are usually known only to two significant figures. We are therefore justified in carrying out successive steps until two answers are the same to two significant figures.

Finally, we highly recommend this method of solving quadratic equations, especially those in Chapters 16 and 17. If your calculator has a memory function, successive approximations can be carried out easily and rapidly.

APPENDIX

B*

Some Important Physical Concepts

B.1 Matter

The tendency to maintain a constant velocity is called *inertia*. Thus, unless acted on by an unbalanced force, a body at rest remains at rest, and a body in motion remains in motion with uniform velocity. Matter is anything that exhibits inertia; the quantity of matter is its mass.

B.2 Motion

Motion is the change of position or location in space. Objects can have the following classes of motion:

- Translation occurs when the center of mass of an object changes its location. Example: a car moving on the highway.
- Rotation occurs when each point of a moving object moves in a circle about an axis through the center of mass. Examples: a spinning top, a rotating molecule.
- Vibration is a periodic distortion and then recovery of original shape. Examples: a struck tuning fork, a vibrating molecule.

B.3 Force and Weight

Force is that which changes the velocity of a body; it is defined as

$$\text{Force} = \text{mass} \times \text{acceleration}$$

The SI unit of force is the **newton**, N, whose dimensions are kilograms times meter per second squared ($kg \cdot m/s^2$). A newton is therefore the force needed to change the velocity of a mass of 1 kilogram by 1 meter per second in a time of 1 second.

Because the Earth's gravity is not the same everywhere, the weight (a force) corresponding to a given mass is not a constant. At any given spot on Earth, gravity is

*Adapted from F. Brescia, J. Arents, H. Meislich, et al.: *General Chemistry,* 5th ed. Philadelphia: Harcourt Brace, 1988.

constant, however, and therefore weight is proportional to mass. When a balance tells us that a given sample (the "unknown") has the same weight as another sample (the "weights," as given by a scale reading or by a total of counterweights), it also tells us that the two masses are equal. The balance is therefore a valid instrument for measuring the mass of an object independently of slight variations in the force of gravity.

B.4 Pressure†

Pressure is force per unit area. The SI unit, called the *pascal*, Pa, is

$$1 \text{ pascal} = \frac{1 \text{ newton}}{\text{m}^2} = \frac{1 \text{ kg} \cdot \text{m/s}^2}{\text{m}^2} = \frac{1 \text{ kg}}{\text{m} \cdot \text{s}^2}$$

The International System of Units also recognizes the bar, which is 10^5 Pa and which is close to standard atmospheric pressure (Table 1).

Chemists also express pressure in terms of the heights of liquid columns, especially water and mercury. This usage is not completely satisfactory because the pressure exerted by a given column of a given liquid is not a constant but depends on the temperature (which influences the density of the liquid) and the location (which influences the magnitude of the force exerted by gravity). Such units are therefore not part of the SI, and their use is now discouraged. The older units are still used in books and journals, however, and chemists must be familiar with them.

The pressure of a liquid or a gas depends only on the depth (or height) and is exerted equally in all directions. At sea level, the pressure exerted by the Earth's atmosphere supports a column of mercury about 0.76 m (76 cm, or 760 mm) high.

One **standard atmosphere** (atm) is the pressure exerted by exactly 76 cm of mercury at 0 °C (density, 13.5951 g/cm^3) and at standard gravity, 9.80665 m/s^2. The **bar** is equivalent to 0.9869 atm. One **torr** is the pressure exerted by exactly 1 mm of mercury at 0 °C and standard gravity.

TABLE 1 Pressure Conversions

From	To	Multiply By
atmosphere	mm Hg	760 mm Hg/atm (exactly)
atmosphere	lb/in^2	14.6960 lb/(in^2 · atm)
atmosphere	kPa	101.325 kPa/atm
bar	Pa	10^5 Pa/bar (exactly)
bar	lb/in^2	14.5038 lb/(in^2 · bar)
mm Hg	torr	1 torr/mm Hg (exactly)

B.5 Energy and Power

The SI unit of energy is the product of the units of force and distance, or kilograms times meter per second squared (kg · m/s^2) times meters (× m), which is kg · m^2/s^2; this unit is called the **joule**, J. The joule is thus the work done when a force of 1 newton acts through a distance of 1 meter.

†See Section 10.1.

Work may also be done by moving an electric charge in an electric field. When the charge being moved is 1 coulomb (C) and the potential difference between its initial and final positions is 1 volt (V), the work is 1 joule. Thus,

$$1 \text{ joule} = 1 \text{ coulomb volt (CV)}$$

Another unit of electric work that is not part of the International System of Units but is still in use is the **electron volt**, eV, which is the work required to move an electron against a potential difference of 1 volt. (It is also the kinetic energy acquired by an electron when it is accelerated by a potential difference of 1 volt.) Because the charge on an electron is 1.602×10^{-19} C, we have

$$1 \text{ eV} = 1.602 \times 10^{-19} \text{ CV} \times \frac{1 \text{ J}}{1 \text{ CV}} = 1.602 \times 10^{-19} \text{ J}$$

If this value is multiplied by Avogadro's number, we obtain the energy involved in moving 1 mol of electron charges (1 faraday) in a field produced by a potential difference of 1 volt:

$$1 \frac{\text{eV}}{\text{particle}} = \frac{1.602 \times 10^{-19} \text{ J}}{\text{particle}} \times \frac{6.022 \times 10^{23} \text{ particles}}{\text{mol}} \times \frac{1 \text{ kJ}}{1000 \text{ J}} = 96.49 \text{ kJ/mol}$$

Power is the amount of energy delivered per unit time. The SI unit is the watt, W, which is 1 joule per second. One kilowatt, kW, is 1000 W. Watt-hours and kilowatt-hours are therefore units of energy (Table 2). For example, 1000 watt-hours, or 1 kilowatt-hour, is

$$1.0 \times 10^3 \text{ W} \cdot \text{h} \times \frac{1 \text{ J}}{1 \text{ W} \cdot \text{s}} \times \frac{3.6 \times 10^3 \text{ s}}{1 \text{ h}} = 3.6 \times 10^6 \text{ J}$$

C.1 Fundamental Units of the SI System

The metric system was begun by the French National Assembly in 1790 and has undergone many modifications. The International System of Units or *Système International* (SI), which represents an extension of the metric system, was adopted by the 11th General Conference of Weights and Measures in 1960. It is constructed from seven base units, each of which represents a particular physical quantity (Table 4).

TABLE 4 SI Fundamental Units

Physical Quantity	Name of Unit	Symbol
Length	meter	m
Mass	kilogram	kg
Time	second	s
Temperature	kelvin	K
Amount of substance	mole	mol
Electric current	ampere	A
Luminous intensity	candela	cd

The first five units listed in Table 4 are particularly useful in general chemistry and are defined as follows:

1. The *meter* was redefined in 1960 to be equal to 1,650,763.73 wavelengths of a certain line in the emission spectrum of krypton-86.
2. The *kilogram* represents the mass of a platinum–iridium block kept at the International Bureau of Weights and Measures at Sèvres, France.
3. The *second* was redefined in 1967 as the duration of 9,192,631,770 periods of a certain line in the microwave spectrum of cesium-133.
4. The *kelvin* is 1/273.16 of the temperature interval between absolute zero and the triple point of water.
5. The *mole* is the amount of substance that contains as many entities as there are atoms in exactly 0.012 kg of carbon-12 (12 g of ^{12}C atoms).

C.2 Prefixes Used with Traditional Metric Units and SI Units

Decimal fractions and multiples of metric and SI units are designated by using the prefixes listed in Table 5. Those most commonly used in general chemistry appear in italics.

TABLE 5 Traditional Metric and SI Prefixes

Factor	Prefix	Symbol	Factor	Prefix	Symbol
10^{12}	tera	T	10^{-1}	*deci*	d
10^{9}	giga	G	10^{-2}	*centi*	c
10^{6}	mega	M	10^{-3}	*milli*	m
10^{3}	*kilo*	k	10^{-6}	micro	μ
10^{2}	hecto	h	10^{-9}	*nano*	n
10^{1}	deka	da	10^{-12}	*pico*	p
			10^{-15}	femto	f
			10^{-18}	atto	a

C.3 Derived SI Units

In the International System of Units, all physical quantities are represented by appropriate combinations of the base units listed in Table 4. A list of the derived units frequently used in general chemistry is given in Table 6.

TABLE 6 Derived SI Units

Physical Quantity	Name of Unit	Symbol	Definition
Area	square meter	m^2	
Volume	cubic meter	m^3	
Density	kilogram per cubic meter	kg/m^3	
Force	newton	N	$kg \cdot m/s^2$
Pressure	pascal	Pa	N/m^2
Energy	joule	J	$kg \cdot m^2/s^2$
Electric charge	coulomb	C	$A \cdot s$
Electric potential difference	volt	V	$J/(A \cdot s)$

TABLE 7 Common Units of Mass and Weight

1 pound = 453.39 grams
1 kilogram = 1000 grams = 2.205 pounds
1 gram = 1000 milligrams
1 gram = 6.022×10^{23} atomic mass units
1 atomic mass unit = 1.6605×10^{-24} gram
1 short ton = 2000 pounds = 907.2 kilograms
1 long ton = 2240 pounds
1 metric tonne = 1000 kilograms = 2205 pounds

E

A Brief Guide to Naming Organic Compounds

It seems a daunting task to devise a systematic procedure that gives each organic compound a unique name, but that is what has been done. A set of rules was developed to name organic compounds by the International Union of Pure and Applied Chemistry (IUPAC). The IUPAC nomenclature allows chemists to write a name for any compound based on its structure or to identify the formula and structure for a compound from its name. In this book, we have generally used the IUPAC nomenclature scheme when naming compounds.

In addition to the systematic names, many compounds have common names. The common names came into existence before the nomenclature rules were developed, and they have continued in use. For some compounds, these names are so well entrenched that they are used most of the time. One such compound is acetic acid, which is almost always referred to by that name and not by its systematic name, ethanoic acid.

The general procedure for systematic naming of organic compounds begins with the nomenclature for hydrocarbons. Other organic compounds are then named as derivatives of hydrocarbons. Nomenclature rules for simple organic compounds are given in the following section.

E.1 Hydrocarbons

Alkanes

The names of alkanes end in "-ane." When naming a specific alkane, the root of the name identifies the longest carbon chain in the compound. Specific substituent groups attached to this carbon chain are identified by name and position.

Alkanes with chains of one to ten carbon atoms are given in Table 23.2. After the first four compounds, the names derive from Greek and Latin numbers—pentane, hexane, heptane, octane, nonane, decane—and this regular naming continues for higher alkanes. For substituted alkanes, the substituent groups on a hydrocarbon chain must be identified both by a name and by the position of substitution; this information precedes the root of the name. The position is indicated by a number that refers to the carbon atom to which the substituent is attached. (Numbering of the carbon atoms in a chain should begin at the end of the carbon chain that allows the substituent groups to have the lowest numbers.)

Names of hydrocarbon substituents are derived from the name of the hydrocarbon. The group $—CH_3$, derived by taking a hydrogen from methane, is called the *methyl group*; the $—C_2H_5$ group is the *ethyl group*. The nomenclature scheme is easily extended to derivatives of hydrocarbons with other substituent groups such as

—Cl (chloro), —NO_2 (nitro), —CN (cyano), —D (deuterio), and so on (Table 13). If two or more of the same substituent groups occur, the prefixes "di-," "tri-," and "tetra-" are added. When different substituent groups are present, they are generally listed in alphabetical order.

TABLE 13 Names of Common Substituent Groups

Formula	Name	Formula	Name
—CH_3	methyl	—D	deuterio
—C_2H_5	ethyl	—Cl	chloro
—$CH_2CH_2CH_3$	propyl (*n*-propyl)	—Br	bromo
—$CH(CH_3)_2$	1-methylethyl (isopropyl)	—F	fluoro
—$CH{=}CH_2$	ethenyl (vinyl)	—CN	cyano
—C_6H_5	phenyl	—NO_2	nitro
—OH	hydroxo		
—NH_2	amino		

Example:

Step	Information to Include	Contribution to Name
1	An alkane	Name will end in "-ane"
2	Longest chain is 7 carbons	Name as a *heptane*
3	—CH_3 group at carbon 3	3-*methyl*
4	—C_2H_5 group at carbon 5	5-*ethyl*
Name:	5-ethyl-3-methylheptane	

Cycloalkanes are named based on the ring size and by adding the prefix "cyclo"; for example, the cycloalkane with a six-member ring of carbons is called *cyclohexane.*

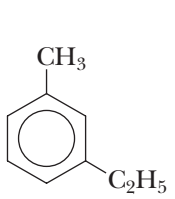
Alkenes

Alkenes have names ending in "-ene." The name of an alkene must specify the length of the carbon chain and the position of the double bond (and when appropriate, the configuration, either *cis* or *trans*). As with alkanes, both identity and position of substituent groups must be given. The carbon chain is numbered from the end that gives the double bond the lowest number.

Compounds with two double bonds are called *dienes,* and they are named similarly—specifying the positions of the double bonds and the name and position of any substituent groups.

For example, the compound $H_2C{=}C(CH_3)CH(CH_3)CH_2CH_3$ has a five-carbon chain with a double bond between carbon atoms 1 and 2 and methyl groups on carbon atoms 2 and 3. Its name using IUPAC nomenclature is **2,3-dimethyl-1**-pentene. The compound $CH_3CH{=}CHCCl_3$ with a *cis* configuration around the double bond is named **1,1,1-trichloro-*cis*-2-butene**. The compound $H_2C{=}C(Cl)CH{=}CH_2$ is **2-chloro-1,3-butadiene**.

Alkynes



The naming of alkynes is similar to the naming of alkenes, except that *cis–trans* isomerism isn't a factor. The ending "-yne" on a name identifies a compound as an alkyne.

Benzene Derivatives

The carbon atoms in the six-member ring are numbered 1 through 6, and the name and position of substituent groups are given. The two examples shown here are **1-ethyl-3-methylbenzene** and **1,4-diaminobenzene**.

1-ethyl-3-methylbenzene

1,4-diaminobenzene

E.2 Derivatives of Hydrocarbons

The names for alcohols, aldehydes, ketones, and acids are based on the name of the hydrocarbon with an appropriate suffix to denote the class of compound, as follows:

- **Alcohols:** Substitute "-ol" for the final "-e" in the name of the hydrocarbon, and designate the position of the —OH group by the number of the carbon atom. For example, $CH_3CH_2CHOHCH_3$ is named as a derivative of the 4-carbon hydrocarbon butane. The —OH group is attached to the second carbon, so the name is **2-butanol**.
- **Aldehydes:** Substitute "-al" for the final "-e" in the name of the hydrocarbon. The carbon atom of an aldehyde is, by definition, carbon-1 in the hydrocarbon chain. For example, the compound $CH_3CH(CH_3)CH_2CH_2CHO$ contains a 5-carbon chain with the aldehyde functional group being carbon-1 and the $—CH_3$ group at position 4; thus, the name is **4-methylpentanal**.
- **Ketones:** Substitute "-one" for the final "-e" in the name of the hydrocarbon. The position of the ketone functional group (the carbonyl group) is indicated by the number of the carbon atom. For example, the compound $CH_3COCH_2CH(C_2H_5)CH_2CH_3$ has the carbonyl group at the 2 position and an ethyl group at the 4 position of a 6-carbon chain; its name is **4-ethyl-2-hexanone**.
- **Carboxylic acids (organic acids):** Substitute "-oic" for the final "-e" in the name of the hydrocarbon. The carbon atoms in the longest chain are counted beginning with the carboxylic carbon atom. For example, *trans*-$CH_3CH{=}CHCH_2CO_2H$ is named as a derivative of *trans*-3-pentene—that is, ***trans*-3-pentenoic acid**.

An **ester** is named as a derivative of the alcohol and acid from which it is made. The name of an ester is obtained by splitting the formula RCO_2R' into two parts, the $RCO_2—$ portion and the —R′ portion. The —R′ portion comes from the alcohol and is identified by the hydrocarbon group name; derivatives of ethanol, for example, are called *ethyl* esters. The acid part of the compound is named by dropping the "-oic" ending for the acid and replacing it by "-oate." The compound $CH_3CH_2CO_2CH_3$ is named **methyl propanoate**.

Notice that an anion derived from a carboxylic acid by loss of the acidic proton is named the same way. Thus, $CH_3CH_2CO_2^-$ is the **propanoate anion**, and the sodium salt of this anion, $Na(CH_3CH_2CO_2)$, is **sodium propanoate**.

Ni^{2+}	$NiCO_3$	1.4×10^{-7}
	$Ni(OH)_2$	5.5×10^{-16}
Ag^+	*AgBr	5.4×10^{-13}
	*$AgBrO_3$	5.4×10^{-5}
	$AgCH_3CO_2$	1.9×10^{-3}
	AgCN	6.0×10^{-17}
	Ag_2CO_3	8.5×10^{-12}
	*$Ag_2C_2O_4$	5.4×10^{-12}
	*AgCl	1.8×10^{-10}
	Ag_2CrO_4	1.1×10^{-12}
	*AgI	8.5×10^{-17}
	AgSCN	1.0×10^{-12}
	*Ag_2SO_4	1.2×10^{-5}
Sr^{2+}	$SrCO_3$	5.6×10^{-10}
	SrF_2	4.3×10^{-9}
	$SrSO_4$	3.4×10^{-7}
Tl^+	TlBr	3.7×10^{-6}
	TlCl	1.9×10^{-4}
	TlI	5.5×10^{-8}
Zn^{2+}	$Zn(OH)_2$	3×10^{-17}
	$Zn(CN)_2$	8.0×10^{-12}

The values reported in this table were taken from J. A. Dean: *Lange's Handbook of Chemistry,* 15th ed. New York: McGraw-Hill Publishers, 1999. Values have been rounded off to two significant figures.

*Calculated solubility from these K_{sp} values will match experimental solubility for this compound within a factor of 2. Experimental values for solubilities are given in R. W. Clark and J. M. Bonicamp: *Journal of Chemical Education,* Vol. 75, p. 1182, 1998.

TABLE 18B

Modified K'_{sp} Values* for Some Metal Sulfides at 25 °C

Substance	K'_{sp}
HgS (red)	4×10^{-54}
HgS (black)	2×10^{-53}
CuS	6×10^{-37}
PbS	3×10^{-28}
CdS	8×10^{-28}
SnS	1×10^{-26}
FeS	6×10^{-19}

*The equilibrium constant values for these metal sulfides refers to the equilibrium $MS(s) + H_2O(\ell) \rightleftharpoons M^{2+}(aq) + OH^-(aq) + HS^-(aq)$; see R. J. Myers, *Journal of Chemical Education,* Vol. 63, p. 687, 1986.

K

Formation Constants for Some Complex Ions in Aqueous Solution at 25 °C

TABLE 19 Formation Constants for Some Complex Ions in Aqueous Solution at 25 °C*

Formation Equilibrium	K_f
$Ag^+ + 2\ Br^- \rightleftharpoons [AgBr_2]^-$	2.1×10^7
$Ag^+ + 2\ Cl^- \rightleftharpoons [AgCl_2]^-$	1.1×10^5
$Ag^+ + 2\ CN^- \rightleftharpoons [Ag(CN)_2]^-$	1.3×10^{21}
$Ag^+ + 2\ S_2O_3^{2-} \rightleftharpoons [Ag(S_2O_3)_2]^{3-}$	2.9×10^{13}
$Ag^+ + 2\ NH_3 \rightleftharpoons [Ag(NH_3)_2]^+$	1.1×10^7
$Al^{3+} + 6\ F^- \rightleftharpoons [AlF_6]^{3-}$	6.9×10^{19}
$Al^{3+} + 4\ OH^- \rightleftharpoons [Al(OH)_4]^-$	1.1×10^{33}
$Au^+ + 2\ CN^- \rightleftharpoons [Au(CN)_2]^-$	2.0×10^{38}
$Cd^{2+} + 4\ CN^- \rightleftharpoons [Cd(CN)_4]^{2-}$	6.0×10^{18}
$Cd^{2+} + 4\ NH_3 \rightleftharpoons [Cd(NH_3)_4]^{2+}$	1.3×10^7
$Co^{2+} + 6\ NH_3 \rightleftharpoons [Co(NH_3)_6]^{2+}$	1.3×10^5
$Cu^+ + 2\ CN^- \rightleftharpoons [Cu(CN)_2]^-$	1.0×10^{24}
$Cu^+ + 2\ Cl^- \rightleftharpoons [CuCl_2]^-$	3.2×10^5
$Cu^{2+} + 4\ NH_3 \rightleftharpoons [Cu(NH_3)_4]^{2+}$	2.1×10^{13}
$Fe^{2+} + 6\ CN^- \rightleftharpoons [Fe(CN)_6]^{4-}$	1.0×10^{35}
$Hg^{2+} + 4\ Cl^- \rightleftharpoons [HgCl_4]^{2-}$	1.2×10^{15}
$Ni^{2+} + 4\ CN^- \rightleftharpoons [Ni(CN)_4]^{2-}$	2.0×10^{31}
$Ni^{2+} + 6\ NH_3 \rightleftharpoons [Ni(NH_3)_6]^{2+}$	5.5×10^8
$Zn^{2+} + 4\ OH^- \rightleftharpoons [Zn(OH)_4]^{2-}$	4.6×10^{17}
$Zn^{2+} + 4\ NH_3 \rightleftharpoons [Zn(NH_3)_4]^{2+}$	2.9×10^9

*Data reported in this table are taken from J. A. Dean: *Lange's Handbook of Chemistry,* 15th ed. New York: McGraw-Hill Publishers, 1999.

Standard Reduction Potentials in Aqueous Solution at 25 °C

TABLE 21 Standard Reduction Potentials in Aqueous Solution at 25 °C

Acidic Solution	Standard Reduction Potential $E°$ (volts)
$F_2(g) + 2\ e^- \longrightarrow 2\ F^-(aq)$	2.87
$Co^{3+}(aq) + e^- \longrightarrow Co^{2+}(aq)$	1.82
$Pb^{4+}(aq) + 2\ e^- \longrightarrow Pb^{2+}(aq)$	1.8
$H_2O_2(aq) + 2\ H^+(aq) + 2\ e^- \longrightarrow 2\ H_2O$	1.77
$NiO_2(s) + 4\ H^+(aq) + 2\ e^- \longrightarrow Ni^{2+}(aq) + 2\ H_2O$	1.7
$PbO_2(s) + SO_4^{2-}(aq) + 4\ H^+(aq) + 2\ e^- \longrightarrow PbSO_4(s) + 2\ H_2O$	1.685
$Au^+(aq) + e^- \longrightarrow Au(s)$	1.68
$2\ HClO(aq) + 2\ H^+(aq) + 2\ e^- \longrightarrow Cl_2(g) + 2\ H_2O$	1.63
$Ce^{4+}(aq) + e^- \longrightarrow Ce^{3+}(aq)$	1.61
$NaBiO_3(s) + 6\ H^+(aq) + 2\ e^- \longrightarrow Bi^{3+}(aq) + Na^+(aq) + 3\ H_2O$	≈1.6
$MnO_4^-(aq) + 8\ H^+(aq) + 5\ e^- \longrightarrow Mn^{2+}(aq) + 4\ H_2O$	1.51
$Au^{3+}(aq) + 3\ e^- \longrightarrow Au(s)$	1.50
$ClO_3^-(aq) + 6\ H^+(aq) + 5\ e^- \longrightarrow \frac{1}{2}\ Cl_2(g) + 3\ H_2O$	1.47
$BrO_3^-(aq) + 6\ H^+(aq) + 6\ e^- \longrightarrow Br^-(aq) + 3\ H_2O$	1.44
$Cl_2(g) + 2\ e^- \longrightarrow 2\ Cl^-(aq)$	1.36
$Cr_2O_7^{2-}(aq) + 14\ H^+(aq) + 6\ e^- \longrightarrow 2\ Cr^{3+}(aq) + 7\ H_2O$	1.33
$N_2H_5^+(aq) + 3\ H^+(aq) + 2\ e^- \longrightarrow 2\ NH_4^+(aq)$	1.24
$MnO_2(s) + 4\ H^+(aq) + 2\ e^- \longrightarrow Mn^{2+}(aq) + 2\ H_2O$	1.23
$O_2(g) + 4\ H^+(aq) + 4\ e^- \longrightarrow 2\ H_2O$	1.229
$Pt^{2+}(aq) + 2\ e^- \longrightarrow Pt(s)$	1.2
$IO_3^-(aq) + 6\ H^+(aq) + 5\ e^- \longrightarrow \frac{1}{2}\ I_2(aq) + 3\ H_2O$	1.195
$ClO_4^-(aq) + 2\ H^+(aq) + 2\ e^- \longrightarrow ClO_3^-(aq) + H_2O$	1.19
$Br_2(\ell) + 2\ e^- \longrightarrow 2\ Br^-(aq)$	1.08
$AuCl_4^-(aq) + 3\ e^- \longrightarrow Au(s) + 4\ Cl^-(aq)$	1.00

APPENDIX

N

Answers to Study Questions, Check Your Understanding, and Applying Chemical Principles Questions

Chapter 1

Check Your Understanding

1.1 P_4 is an element; CO is a compound.

1.2 Vinegar is more dense than olive oil.

1.3 Intensive properties: boiling point, hardness, number of atoms per volume of solution. Extensive properties: volume of solution, number of atoms.

1.4 Physical changes: melting butter, dissolving sugar. Chemical change: burning wood.

Applying Chemical Principles

1.1 CO_2 in the Oceans

1. Carbon dioxide
2. Calcium: Ca; copper: Cu; manganese: Mn; iron: Fe
3. Most dense: copper, least dense: calcium
4. Elements: calcium, carbon, oxygen
   Compound name: calcium carbonate

Study Questions

1.1 (a) hypothesis
(b) law
(c) theory

1.3 Meeting today's economic and environmental needs while preserving the options of future generations to meet theirs.

1.5 See bulleted list on page 5: To a greater or lesser extent, the new procedure applies all of these principles.

1.7 (a) C, carbon
(b) K, potassium
(c) Cl, chlorine
(d) P, phosphorus
(e) Mg, magnesium
(f) Ni, nickel

1.9 (a) Ba, barium
(b) Ti, titanium
(c) Cr, chromium
(d) Pb, lead
(e) As, arsenic
(f) Zn, zinc

1.11 (a) Na (element) and NaCl (compound)
(b) Sugar (compound) and carbon (element)
(c) Gold (element) and gold chloride (compound)

1.13 The preparation of 27 g of water requires 3 g of hydrogen gas and 24 g of oxygen gas. The law of definite proportions, sometimes called the law of constant composition, is used to solve this problem.

1.15 (a) Physical property
(b) Chemical property
(c) Chemical property
(d) Physical property
(e) Physical property
(f) Physical property

1.17 (a) Physical (colorless liquid) and chemical (burns in air)
(b) Physical (shiny metal, orange-red) and chemical (reacts with bromine)

1.19 Mechanical energy is used to move the lever, which in turn moves gears. The device produces electrical energy and radiant energy.

1.21 (a) Kinetic energy
(b) Potential energy
(c) Potential energy
(d) Potential energy

1.23 1500 J; law of conservation of energy.

1.25 (a) Qualitative: blue-green color, solid physical state
Quantitative: density = 2.65 g/cm^3 and mass = 2.5 g
(b) Density, physical state, and color are intensive properties, whereas mass is an extensive property.
(c) Volume = 0.94 cm^3

1.27 Observation c is a chemical property.

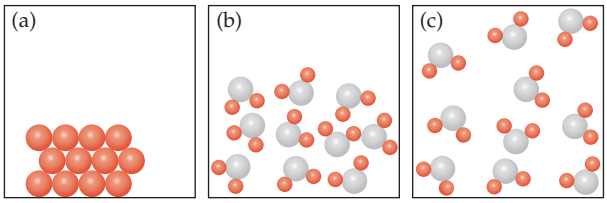
Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. WCN 02-200-203

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

1.29 Calcium, Ca; fluorine, F

The crystals are cubic in shape because the atoms are arranged in cubic structures.

1.31 The water can be removed by boiling the solution until all of the water evaporates. The solid that remains is salt, NaCl.



1.33 Physical changes: a, b, d
Chemical changes: c

1.35 The macroscopic view is the photograph of NaCl, and the particulate view is the drawing of the ions in a cubic arrangement. The structure of the compound at the particulate level determines the properties that are observed at the macroscopic level.

1.37 The density of the plastic is less than that of CCl_4, so the plastic will float on the liquid CCl_4. Aluminum is more dense than CCl_4, so aluminum will sink when placed in CCl_4.

1.39 (a) Mixture
(b) Mixture
(c) Element
(d) Compound

1.41

1.43 The three liquids will form three separate layers with hexane on the top, water in the middle, and perfluorohexane on the bottom. The HDPE will float at the interface of the hexane and water layers. The PVC will float at the interface of the water and perfluorohexane layers. The Teflon will sink to the bottom of the cylinder.

1.45 HDPE will float in ethylene glycol, water, acetic acid, and glycerol.

1.47 Milk is mostly water. When water freezes its density decreases, so for a given mass of water, the volume increases considerably. The increased volume means that the frozen water expands out of the bottle.

1.49 If too much sugar is excreted, the density of the urine would be higher than normal. If too much water is excreted, the density would be lower than normal.

1.51 (a) Solid potassium metal reacts with liquid water to produce gaseous hydrogen and a homogeneous mixture (solution) of potassium hydroxide in liquid water.
(b) The reaction is a chemical change.
(c) The reactants are potassium and water. The products are hydrogen gas and a water (aqueous) solution of potassium hydroxide. Heat and light are also evolved.
(d) Among the qualitative observations are (i) the reaction is violent, and (ii) heat and light (a purple flame) are produced.

1.53 The balloons containing helium and neon will float in air.

1.55 Physical change

1.57 (a) Gold = Au, silver = Ag, and copper = Cu
(b) No, gold is not the most dense element. Iridium Ir, is slightly more dense (22.65 g/cm^3).
(c) Mass gold = 0.75×5.58 g = 4.2 g
(d) Mass loss = (6.15 mg/ring)(1 g/1000 mg) $(5.6 \times 10^7$ couples)(2 rings/couple) = 6.89×10^5 g = 6.9×10^5 g
Value lost = $(6.89 \times 10^5$ g)(1 troy oz/31.1 g) (\$1620/1 troy oz) = $\$3.6 \times 10^7$ (or 36 million dollars)

Chapter 1-LR

Check Your Understanding

LR-1. 0.154 nm (1 m/10^9 nm)(10^{12} pm/1 m) = 154 pm

0.154 nm (1 m/10^9 nm)(100 cm/1 m) = 1.54×10^{-8} cm

LR-2. Average for Balance 1 is 5.02 g; average for Balance 2 is 4.97 g. Percent error for Balance 1 = ((5.018 g − 5.000 g)/5.000 g) × 100% = 0.35%; percent error for Balance 2 = ((4.968 g − 5.000 g)/5.000 g) × 100% = − 0.65%. Balance 1 is sightly more accurate.

LR-3. $x = 3.9 \times 10^5$. The difference between 110.7 and 64 is 47. Dividing 47 by 0.056 and 0.00216 gives an answer with two significant figures.

LR-4. (19,320 kg/m^3)(10^3 g/1 kg)(1 m^3/10^6 cm^3) = 19.32 g/cm^3

LR-5. Change all dimensions to centimeters: 7.6 m = 760 cm; 2.74 m = 274 cm; 0.13 mm = 0.013 cm.

Volume of paint = (760 cm)(274 cm)(0.013 cm) = 2.71×10^3 cm^3

Volume (L) = (2.71×10^3 cm^3)(1 L/10^3 cm^3) = 2.7 L

Mass = (2.71×10^3 cm^3)(0.914 g/cm^3) = 2.5×10^3 g

Applying Chemical Principles

1 Out of Gas!

1. Fuel density in kg/L: (1.77 lb/L)(0.4536 kg/lb) = 0.8029 kg/L = 0.803 kg/L

2. Mass of fuel already in tank: 7682 L(0.8029 kg/L) = 6168 kg

Mass of fuel needed: 22,300 kg − 6,168 kg = 16,130 kg = 16,100 kg (answer to three significant figures)

Volume of fuel needed: 16,130 kg(1 L/0.8029 kg) = 20,100 L

2 Ties in Swimming and Significant Figures

1. Rate = 50.00 m/20.91 s = 2.3912 m/s; distance traveled in exactly 0.001 s = 2.3912 m/s × 0.001 s = 0.0023912 m = 2.3912 mm (= 2.4 mm)
2. 30. mm(0.001 s/2.3912 mm) = 0.0125 s = 0.013 s
3. 3 cm/5000. cm × 100% = 0.06%

Study Questions

1. 298 K

3. (a) 289 K
   (b) 97 °C
   (c) 310 K (3.1×10^2 K)

5. 42,195 m; 26.219 miles

7. 5.3 cm^2; 5.3×10^{-4} m^2

9. 250. cm^3; 0.250 L, 2.50×10^{-4} m^3; 0.250 dm^3

11. 2.52×10^3 g

13. 555 g

15. (c) zinc

17. 5.0×10^6 J

19. 170 kcal is equivalent to 710 kJ, which is considerably greater than 280 kJ.

21. (a) Method A with all data included: average = 2.4 g/cm^3

    Method B with all data included: average = 3.480 g/cm^3

    For B, the 5.811 g/cm^3 data point can be excluded because it is more than twice as large as all other points for Method B. Using only the first three points, average = 2.703 g/cm^3

    (b) Method A: error = 0.3 g/cm^3 or about 10%

    Method B: error = 0.001 g/cm^3 or about 0.04%

    (c) Method A: standard deviation = 0.2 g/cm^3

    Method B (including all data points): standard deviation = 1.554 g/cm^3

    Method B (excluding the 5.811 g/cm^3 data point): standard deviation = 0.002 g/cm^3

    (d) Method B's average value is both more precise and more accurate so long as the 5.811 g/cm^3 data point is excluded.

23. (a) 5.4×10^{-2} g, two significant figures
    (b) 5.462×10^3 g, four significant figures
    (c) 7.92×10^{-4} g, three significant figures
    (d) 1.6×10^3 mL, two significant figures

25. (a) 9.44×10^{-3}
    (b) 5694
    (c) 11.9
    (d) 0.122

27. 

    Slope: 0.1637 g/kernel

    The slope represents the average mass of a popcorn kernel.

    Mass of 20 popcorn kernels = 3.370 g

    There are 127 kernels in a sample with a mass of 20.88 g.

29. (a) y = −4.00x + 20.00
    (b) y = −4.00

31. C = 0.0823

33. T = 295

35. 0.197 nm; 197 pm

37. (a) 7.5×10^{-6} m; (b) 7.5×10^3 nm; (c) 7.5×10^6 pm

39. 50. mg procaine hydrochloride

41. The volume of the marbles is 99 mL − 61 mL = 38 mL. This yields a density of 2.5 g/cm^3.

43. (a) 0.178 nm^3; 1.78×10^{-22} cm^3
    (b) 3.87×10^{-22} g
    (c) 9.68×10^{-23} g

45. Your normal body temperature (about 98.6 °F) is 37 °C. As this is higher than gallium's melting point, the metal will melt in your hand.

47. (a) 15%
    (b) 3.63×10^3 kernels

49. 8.0×10^4 kg of sodium fluoride per year

51. 245 g sulfuric acid

53. (a) 272 mL ice
    (b) The ice cannot be contained in the can.

55. 7.99 g/cm^3

57. (a) 8.7 g/cm^3
    (b) The metal is probably cadmium, but the calculated density is close to that of cobalt, nickel, and copper. Further testing should be done on the metal.

59. 0.0927 cm

61. (a) 1.143×10^{21} atoms; 76.4% of the lattice is filled with atoms; 23.6% of the lattice is open space.

Atoms are spheres. When spheres are packed together, they touch only at certain points, therefore leaving spaces in the structure.

(b) Four atoms

63. (d) Al, aluminum

65.

When absorbance = 0.635, concentration = 2.55×10^{-3} g/L = 2.55×10^{-3} mg/mL

67. Average = 5.24%, standard deviation = 0.05%

Seven of the ten values fall within the region $5.19 \leq x \leq 5.29$

Chapter 2

Check Your Understanding

2.1 (1) Mass number with 26 protons and 30 neutrons is 56

(2) (59.930788 u)(1.661×10^{-24} g/u) = 9.955×10^{-23} g

(3) ^{64}Zn has 30 protons, 30 electrons, and (64 − 30) = 34 neutrons.

2.2 Use Equation 2.2 for the calculation.

Atomic mass = (34.96885)(75.77/100) + (36.96590)(24.23/100) = 35.45. (Accuracy is limited by the value of the percent abundance to four significant figures.)

2.3 Use Equation 2.2 for the calculation. Let x = percent abundance of ^{20}Ne and y = percent abundance of ^{22}Ne.

20.1797 u = $(x/100)(19.992435\text{ u}) + (0.27/100)(20.993843\text{ u}) + (y/100)(21.991383\text{ u})$

Because all the percent abundances must sum to 100%, $y = 100 - x - 0.27 = 99.73 - x$.

20.1797 u = $(x/100)(19.992435\text{ u}) + (0.27/100)(20.993843\text{ u}) + [(99.73 - x)/100](21.991383\text{ u})$

$x = 90.5$; therefore the percent abundance of ^{20}Ne = 90.5% and the percent abundance of ^{22}Ne = 9.2%.

2.4 (a) (1) NaF: 1 Na^+ and 1 F^- ion. (2) $Cu(NO_3)_2$: 1 Cu^{2+} and 2 NO_3^- ions. (3) $NaCH_3CO_2$: 1 Na^+ and 1 $CH_3CO_2^-$ ion.

2.5 (a) Na_2S, Na_3PO_4, BaS, $Ba_3(PO_4)_2$
(b) $FeCl_2$, $FeCl_3$

2.6 $(2.6 \times 10^{24}\text{ atoms})(1\text{ mol}/6.022 \times 10^{23}\text{ atoms})(197.0\text{ g Au}/1\text{ mol}) = 850\text{ g Au}$

2.7 Molar mass $H_3C_6H_5O_7 = 8(1.01) + 6(12.01) + 7(16.00) = 192.14$ g/mol

$(454\text{ g } H_3C_6H_5O_7)(1\text{ mol } H_3C_6H_5O_7/192.14\text{ g } H_3C_6H_5O_7) = 2.363\text{ mol } H_3C_6H_5O_7 = 2.36\text{ mol } H_3C_6H_5O_7$

$(2.363\text{ mol } H_3C_6H_5O_7)(6.022 \times 10^{23}\text{ molecules}/1\text{ mol}) = 1.423 \times 10^{24}\text{ molecules } H_3C_6H_5O_7 = 1.42 \times 10^{24}\text{ molecules } H_3C_6H_5O_7$

$(1.423 \times 10^{24}\text{ molecules } H_3C_6H_5O_7)(6\text{ atoms C}/1\text{ molecule } H_3C_6H_5O_7) = 8.54 \times 10^{24}\text{ atoms C}$

2.8 (1) 1.00 mol $(NH_4)_2CO_3$ (molar mass 96.09 g/mol) has 28.0 g of N (29.1%), 8.06 g of H (8.39%), 12.0 g of C (12.5%), and 48.0 g of O (50.0%)

(2) 454 g C_8H_{18} (1 mol C_8H_{18}/114.2 g) (8 mol C/1 mol C_8H_{18})(12.01 g C/1 mol C) = 382 g C

2.9 (1) C_5H_4

(2) $C_2H_4O_2$

(3) (88.17 g C)(1 mol C/12.011 g C) = 7.3408 mol C

(11.83 g H)(1 mol H/1.008 g H) = 11.736 mol H

11.736 mol H/7.3408 mol C = 1.6 mol H/1 mol C = (8/5); (mol H/1 mol C) = 8 mol H/5 mol C

The empirical formula is C_5H_8. The molar mass, 68.11 g/mol, closely matches this formula, so C_5H_8 is also the molecular formula.

(4) (78.90 g C)(1 mol C/12.011 g C) = 6.5690 mol C

(10.59 g H)(1 mol H/1.008 g H) = 10.505 mol H

(10.51 g O)(1 mol O/16.00 g O) = 0.65688 mol O

10.505 mol H/0.65688 mol O = 16 mol H/1 mol O

6.5690 mol C/0.65688 mol O = 10 mol C/1 mol O

The empirical formula is $C_{10}H_{16}O$.

2.10 (1.25 g Ga)(1 mol Ga/69.72 g Ga) = 0.01793 mol Ga

1.68 g product − 1.25 g Ga = 0.43 g O

(0.43 g O)(1 mol O/16.00 g O) = 0.0269 mol O

Mole ratio = 0.0269 mol O/0.01793 mol Ga = 1.5 mol O/1.0 mol Ga = 3.0 mol O/2.0 mol Ga

Empirical formula = Ga_2O_3

2.11 Mass of water lost on heating is 0.235 g − 0.128 g = 0.107 g; 0.128 g $NiCl_2$ remain

(0.107 g H_2O)(1 mol H_2O/18.016 g H_2O) = 0.005939 mol H_2O
(0.128 g $NiCl_2$)(1 mol $NiCl_2$/129.6 g $NiCl_2$) = 0.0009877 mol $NiCl_2$

Mole ratio = 0.005939 mol H_2O/0.0009877 mol $NiCl_2$ = 6.01: Therefore $x = 6$

The formula for the hydrate is $NiCl_2 \cdot 6\ H_2O$.

2.12 (a) $m/Z = 270$: $P^{79}Br^{79}Br^{81}Br$
$m/Z = 272$: $P^{79}Br^{81}Br^{81}Br$

(b) There are a total of eight ways to make PBr_3 molecules using the two isotopes of bromine. One configuration contains only ^{79}Br atoms and has a mass of 268 u. Likewise, there is one configuration that contains only ^{81}Br and has a mass of 274 u. Of the remaining six configurations, three contain two ^{79}Br atoms and one ^{81}Br atom. The other three configurations contain one ^{79}Br atom and two ^{81}Br atoms. Because the isotopes of bromine are present in approximately equal percentages, each configuration has approximately an equal probability. Thus, there is a one in eight chance (12.5%) that a given molecule contains only ^{79}Br and a one in eight chance (12.5%) that a molecule contains only ^{81}Br. The probability is three times greater—three of eight configurations or 37.5% chance—that a molecule contains two atoms of one isotope and one atom of the other. Thus, the two peaks at 270 and 272 should be approximately three times larger than those at 268 and 274.

Applying Chemical Principles

2.1 Using Isotopes: Ötzi, the Iceman of the Alps

1. ^{18}O: 18 − 8 = 10 neutrons
^{204}Pb: 204 − 82 = 122 neutrons
^{206}Pb: 206 − 82 = 124 neutrons

2. 15.9993 u

2.2 Arsenic, Medicine, and the Formula of Compound 606

1. Amount As: 19.024 g As × (1 mol As/74.9216 g As) = 0.253919 mol As

Amount Cu: 48.407 g Cu × (1 mol Cu/63.546 g Cu) = 0.761763 mol Cu

Amount S: 32.569 g S × (1 mol S/32.066 g S) = 1.01569 mol S

Mole ratio Cu/As: 0.761763 mol Cu/0.253919 mol As = 3.0000 mol Cu/1 mol As

Mole ratio S/As: 1.01569 mol S/0.253919 mol As = 4.0000 mol S/1 mol As

Empirical formula: Cu_3AsS_4

2. Amount C: 39.37 g C × (1 mol C/12.011 g C) = 3.2778 mol C

Amount H: 3.304 g H × (1 mol H/1.0079 g H) = 3.2781 mol H

Amount O: 8.741 g O × (1 mol O/15.999 g O) = 0.54635 mol O

Amount N: 7.652 g N × (1 mol N/14.007 g N) = 0.54629 mol N

Amount As: 40.932 g As × (1 mol As/74.9216 g As) = 0.546331 mol As

Mole ratio C/O and H/O: 3.2778 mol C/0.54629 mol O = 6.000 mol C/1 mol O. A similar calculation yields 6.000 mol H/1 mol O.

Mole ratio N/O and As/O: 0.54629 mol N/0.54635 mol O = 1.000 mol N/1 mol O. A similar calculation yields 1.000 mol As/1 mol O.

Empirical formula: C_6H_6AsNO

Molar mass of C_6H_6AsNO: 183.0 g/mol

Compound 1: 549/183.0 = 3.00; therefore, the molecular formula is $C_{18}H_{18}As_3N_3O_3$.

Compound 2: 915/183.0 = 5.00; therefore, the molecular formula is $C_{30}H_{30}As_5N_5O_5$.

2.3 Argon—An Amazing Discovery

1. Volume = mass/density = (0.20389 g/1.25718 g/L) (1000 cm^3/L) = 162.18 cm^3

2. (0.2096)(1.42952 g/L) + (0.7811)(1.25092 g/L) + (0.00930)x = 1.29327 g/L; x = 1.78 g/L

3. % Abundance ^{40}Ar = 100 − 0.337 − 0.063 = 99.600%
(0.337/100)(35.967545 u) + (0.063/100)(37.96732 u) + (99.600/100)x = 39.948 u
Atomic mass of ^{40}Ar = 39.963 u

4. (4.0 m)(5.0 m)(2.4 m)(1 L/10^{-3} m^3) = 4.8 × 10^4 L
(4.8 × 10^4 L)(1.78 g/L)(1 mol/39.948 g)
(6.022 × 10^{23} atoms/mol) = 1.3 × 10^{27} atoms

Study Questions

2.1 Atoms contain the following fundamental particles: protons (+1 charge), neutrons (zero charge), and electrons (−1 charge). Protons and neutrons are in the nucleus of an atom. Electrons are the least massive of the three particles.

2.3 The electron cloud would extend around 1 × 10^{-13} cm = 1 fm.

2.5 (a) $^{27}_{12}Mg$
(b) $^{48}_{22}Ti$
(c) $^{62}_{30}Zn$

2.7

Element	Electrons	Protons	Neutrons
^{24}Mg	12	12	12
^{119}Sn	50	50	69
^{232}Th	90	90	142
^{13}C	6	6	7
^{63}Cu	29	29	34
^{205}Bi	83	83	122

2.9 mass p/mass e = 1.672622×10^{-24} g/9.109383×10^{-28} g = 1836.15. The proton is more than 1800 times heavier than the electron. Thomson's estimate was off by a factor of 2.

2.11 Gamma rays (γ) have no charge and so are unaffected by the electric field. Alpha particles (α) are positively charged and attracted to the negative plate, and beta particles (β) are negatively charged and attracted to the positive plate. Beta particles are more affected by the electric field because they are lighter than alpha particles. (Alpha particles are He^+ ions, whereas beta particles are electrons.)

2.13 $^{16}O/^{12}C = 1.3329$

2.15 $^{57}_{27}Co$, $^{58}_{27}Co$, $^{60}_{27}Co$

2.17 Protium: one proton, one electron
Deuterium: one proton, one neutron, one electron
Tritium: one proton, two neutrons, one electron

2.19 ^{205}Tl is more abundant than ^{203}Tl. The atomic mass of thallium is closer to 205 than to 203.

2.21 (0.0750)(6.015121) + (0.9250)(7.016003) = 6.94

2.23 ^{69}Ga, 60.12%; ^{71}Ga, 39.88%

2.25

	Symbol	Atomic No.	Atomic Mass	Group	Period	
Titanium	Ti	22	47.867	4B(IUPAC 4)	4	Metal
Thallium	Tl	81	204.3833	3A(IUPAC 13)	6	Metal

2.27 Eight elements: periods 2 and 3. 18 elements: periods 4 and 5. 32 elements: periods 6 and 7.

2.29 (a) Nonmetals: C, Cl
(b) Main group elements: C, Ca, Cl, Cs
(c) Lanthanides: Ce
(d) Transition elements: Cr, Co, Cd, Ce, Cm, Cu, Cf
(e) Actinides: Cm, Cf
(f) Gases: Cl

2.31 Metals: Na, Ni, Np
Metalloids: None in this list
Nonmetals: N, Ne

2.33 Molecular formula: HNO_3.
Structural formula:

The structure around the N atom is flat. The O atoms are arranged around the N atoms at the corners of a triangle. The hydrogen atom is connected to one of the oxygen atoms.

2.35 (a) Mg^{2+}
(b) Zn^{2+}
(c) Ni^{2+}
(d) Ga^{3+}

2.37 (a) Ba^{2+}
(b) Ti^{4+}
(c) PO_4^{3-}
(d) HCO_3^-
(e) S^{2-}
(f) ClO_4^-
(g) Co^{2+}
(h) SO_4^{2-}

2.39 K loses one electron per atom to form a K^+ ion. It has the same number of electrons as an Ar atom.

2.41 Ba^{2+} and Br^- ions. The compound's formula is $BaBr_2$.

2.43 (a) Two K^+ ions and one S^{2-} ion
(b) One Co^{2+} ion and one SO_4^{2-} ion
(c) One K^+ ion and one MnO_4^- ion
(d) Three NH_4^+ ions and one PO_4^{3-} ion
(e) One Ca^{2+} ion and two ClO^- ions
(f) One Na^+ ion and one $CH_3CO_2^-$ ion

2.45 Co^{2+} gives CoO and Co^{3+} gives Co_2O_3.

2.47 (a) $AlCl_2$ should be $AlCl_3$ (based on an Al^{3+} ion and three Cl^- ions).
(b) KF_2 should be KF (based on a K^+ ion and an F^- ion).
(c) Ga_2O_3 is correct.
(d) MgS is correct.

2.49 (a) Potassium sulfide
(b) Cobalt(II) sulfate
(c) Ammonium phosphate
(d) Calcium hypochlorite

2.51 (a) $(NH_4)_2CO_3$
(b) CaI_2
(c) $CuBr_2$
(d) $AlPO_4$
(e) $AgCH_3CO_2$

2.53 Compounds with Na^+: Na_2CO_3 (sodium carbonate) and NaI (sodium iodide). Compounds with Ba^{2+}: $BaCO_3$ (barium carbonate) and BaI_2 (barium iodide).

2.55 The force of attraction is stronger in NaF than in NaI because the distance between ion centers is smaller in NaF (235 pm) than in NaI (322 pm).

Number of O atoms = 2.26×10^{25} atoms

2.77 4×10^{21} molecules

2.79 (a) 86.60% Pb and 13.40% S
(b) 81.71% C and 18.29% H
(c) 79.96% C, 9.394% H, and 10.65% O

2.81 66.46% copper in CuS. 15.0 g of CuS is needed to obtain 10.0 g of Cu.

2.83 $C_4H_6O_4$

2.85 (a) CH, 26.0 g/mol; C_2H_2
(b) CHO, 116.1 g/mol; $C_4H_4O_4$
(c) CH_2, 112.2 g/mol, C_8H_{16}

2.87 Empirical formula, CH; molecular formula, C_2H_2

2.89 Empirical formula, C_3H_4; molecular formula, C_9H_{12}

2.91 Empirical and molecular formulas are both $C_8H_8O_3$

2.93 XeF_2

2.95 $MgSO_4 \cdot 2\ H_2O$

2.97 (a) 14 = N^+, 16 = O^+, 30 = NO^+, 46 = NO_2^+
(b) This is evidence for the ONO structure. Ions are associated with fragments of the molecule when bonds are broken. If the structure had been OON, then ions of mass 32, corresponding to O_2^+, would be expected; their absence suggests that OON is the wrong structure.

2.99 (a) m/Z = 50 is $^{12}C^1H_3{}^{35}Cl^+$; m/Z = 52 is $^{12}C^1H_3{}^{37}Cl^+$ The height of the line at m/Z = 52 is about 1/3 the height of the line at m/Z = 50 because the abundance of ^{37}Cl is about 1/3 that of ^{35}Cl.
(b) $^{13}C^1H_3{}^{35}Cl^+$ (a small portion of this peak is also due to $^{12}C^2H^1H_2{}^{35}Cl^+$)

2.101

Symbol	^{58}Ni	^{33}S	^{20}Ne	^{55}Mn
Protons	28	16	10	25
Neutrons	30	17	10	30
Electrons	28	16	10	25
Name	Nickel	Sulfur	Neon	Manganese

2.103

S	**N**
B	**I**

2.105 (a) 1.0552×10^{-22} g for 1 Cu atom
(b) 6.3×10^{-22} dollars for 1 Cu atom

2.107 (a) Strontium
(b) Zirconium
(c) Carbon
(d) Arsenic
(e) Iodine
(f) Magnesium
(g) Krypton
(h) Sulfur
(i) Germanium or arsenic

2.109 (a) 0.25 mol U
(b) 0.50 mol Na
(c) 10 atoms of Fe

2.111 40.157 g H_2 (b) < 103.0 g C (c) < 182 g Al (f) < 210 g Si (d) < 212.0 g Na (e) < 351 g Fe (a) < 650 g Cl_2 (g)

2.113 (a) Atomic mass of O = 15.873 u; Avogadro's number = 5.9802×10^{23} particles per mole
(b) Atomic mass of H = 1.00798 u; Avogadro's number = 6.0279×10^{23} particles per mole

2.115 $(NH_4)_2CO_3$, $(NH_4)_2SO_4$, $NiCO_3$, $NiSO_4$

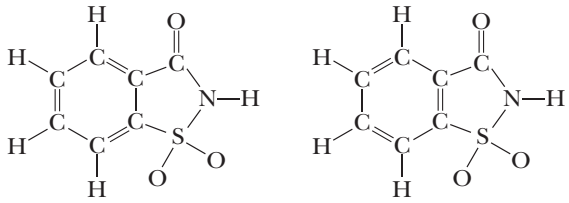
2.117 All of these compounds have one atom of some element plus three Cl atoms. The highest mass percent of chlorine will occur in the compound having the lightest central element. Here, that element is B, so BCl_3 should have the highest mass percent of Cl (90.77%).

2.119 The molar mass of adenine ($C_5H_5N_5$) is 135.13 g/mol. 3.0×10^{23} molecules represents 67 g. Thus, 3.0×10^{23} molecules of adenine has a larger mass than 40.0 g of the compound.



2.121 1.7×10^{21} molecules of water

2.123 245.75 g/mol. Mass percent: 25.86% Cu, 22.80% N, 5.742% H, 13.05% S, and 32.55% O. In 10.5 g of compound there are 2.72 g Cu and 0.770 g H_2O.

2.125 Empirical formula of malic acid: $C_4H_6O_5$

2.127 $Fe_2(CO)_9$

2.129 (a) $C_7H_5NO_3S$

(b) 6.82×10^{-4} mol saccharin
(c) 21.9 mg S

2.131 (a) NaClO, ionic
(b) BI_3
(c) $Al(ClO_4)_3$, ionic
(d) $Ca(CH_3CO_2)_2$, ionic
(e) $KMnO_4$, ionic
(f) $(NH_4)_2SO_3$, ionic
(g) KH_2PO_4, ionic
(h) S_2Cl_2
(i) ClF_3
(j) PF_3

2.133 (a) Empirical formula = molecular formula = CF_2O_2
(b) Empirical formula = C_5H_4; molecular formula = $C_{10}H_8$

2.135 Empirical formula and molecular formula = $C_5H_{14}N_2$

2.137 $C_9H_7MnO_3$

2.139 68.42% Cr; 1.2×10^3 kg Cr_2O_3

2.141 Empirical formula = ICl_3; molecular formula = I_2Cl_6

2.143 7.35 kg of iron

2.145 (d) Na_2MoO_4

2.147 5.52×10^{-4} mol $C_{21}H_{15}Bi_3O_{12}$; 0.346 g Bi

2.149 The molar mass of the compound is 154 g/mol. The unknown element is carbon.

2.151 $n = 2.19 \times 10^3$

2.153 (a) 2.3×10^{14} g/cm^3
(b) 3.34×10^{-3} g/cm^3
(c) The nucleus is much more dense than the space occupied by the electrons.

2.155 (a) 0.0130 mol Ni
(b) NiF_2
(c) Nickel(II) fluoride

2.157 Volume = 3.0 cm^3; length of side = 1.4 cm

2.159 Formula is $MgSO_4 \cdot 7\ H_2O$

2.161 SnI_4

2.163 (c) The calculated mole ratio is 0.78 mol H_2O per mol $CaCl_2$. The student should heat the crucible again and then reweigh it. More water might be driven off.

2.165 Required data: density of iron (d), molar mass of iron (b), Avogadro's number (c)

$$1.00\ \text{cm}^3\left(\frac{7.87\ \text{g}}{1\ \text{cm}^3}\right)\left(\frac{1\ \text{mol}}{55.85\ \text{g}}\right)\left(\frac{6.022 \times 10^{23}\ \text{atoms}}{1\ \text{mol}}\right) = 8.49 \times 10^{22}\ \text{atoms Fe}$$

2.167 (a) Barium would be more reactive than calcium, so a more vigorous evolution of hydrogen should occur.
(b) Reactivity generally increases on descending the periodic table, at least for Groups 1A and 2A.

Chapter 3

Check Your Understanding

3.1 (a) $2\ C_4H_{10}(g) + 13\ O_2(g) \rightarrow 8\ CO_2(g) + 10\ H_2O(g)$
(b) $2\ C_3H_7BO_3(\ell) + 8\ O_2(g) \rightarrow 6\ CO_2(g) + 7\ H_2O(g) + B_2O_3(s)$

3.2 (a) $LiNO_3$ is soluble and gives $Li^+(aq)$ and $NO_3^-(aq)$ ions.
(b) $CaCl_2$ is soluble and gives $Ca^{2+}(aq)$ and $Cl^-(aq)$ ions.
(c) $Cu(OH)_2$ is not water soluble.
(d) $NaCH_3CO_2$ is soluble and gives $Na^+(aq)$ and $CH_3CO_2^-(aq)$ ions.

3.3 (a) $Na_2CO_3(aq) + CuCl_2(aq) \rightarrow 2\ NaCl(aq) + CuCO_3(s)$
(b) No reaction; no insoluble compound is produced.
(c) $NiCl_2(aq) + 2\ KOH(aq) \rightarrow Ni(OH)_2(s) + 2\ KCl(aq)$

3.4 (a) $3\ CaCl_2(aq) + 2\ Na_3PO_4(aq) \rightarrow Ca_3(PO_4)_2(s) + 6\ NaCl(aq)$
$3\ Ca^{2+}(aq) + 2\ PO_4^{3-}(aq) \rightarrow Ca_3(PO_4)_2(s)$
(b) $FeCl_3(aq) + 3\ KOH(aq) \rightarrow Fe(OH)_3(s) + 3\ KCl(aq)$
$Fe^{3+}(aq) + 3\ OH^-(aq) \rightarrow Fe(OH)_3(s)$
(c) $Pb(NO_3)_2(aq) + 2\ KCl(aq) \rightarrow PbCl_2(s) + 2\ KNO_3(aq)$
$Pb^{2+}(aq) + 2\ Cl^-(aq) \rightarrow PbCl_2(s)$

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

3.5 (a) $H_3PO_4(aq) + H_2O(\ell) \rightarrow H_3O^+(aq) + H_2PO_4^-(aq)$
(b) Acting as an acid:
$H_2PO_4^-(aq) + H_2O(\ell) \rightleftharpoons HPO_4^{2-}(aq) + H_3O^+(\ell)$
Acting as a base:
$H_2PO_4^-(aq) + H_2O(\ell) \rightleftharpoons H_3PO_4(aq) + OH^-(aq)$
Because $H_2PO_4^-(aq)$ can react as a Brønsted acid and as a base, it is said to be amphiprotic.

3.6 $Mg(OH)_2(s) + 2\ HCl(aq) \rightarrow MgCl_2(aq) + 2\ H_2O(\ell)$
Net ionic equation:
$Mg(OH)_2(s) + 2\ H_3O^+(aq) \rightarrow Mg^{2+}(aq) + 4\ H_2O(\ell)$

3.7 $BaCO_3(s) + 2\ HNO_3(aq) \rightarrow Ba(NO_3)_2(aq) + CO_2(g) + H_2O(\ell)$
Barium carbonate and nitric acid produce barium nitrate, carbon dioxide, and water.

3.8 (a) Fe in Fe_2O_3, +3; (b) S in H_2SO_4, +6;
(c) C in CO_3^{2-}, +4; (d) N in NO_2^+, +5

3.9 Dichromate ion is the oxidizing agent and is reduced. (Cr with a +6 oxidation number is reduced to Cr^{3+} with a +3 oxidation number.) Ethanol is the reducing agent and is oxidized. (The C atoms in ethanol have an oxidation number of −2. The oxidation number is 0 in acetic acid.)

3.10 (a) Gas-forming reaction:
$CuCO_3(s) + H_2SO_4(aq) \rightarrow CuSO_4(aq) + H_2O(\ell) + CO_2(g)$
Net ionic equation:
$CuCO_3(s) + 2\ H_3O^+(aq) \rightarrow Cu^{2+}(aq) + 3\ H_2O(\ell) + CO_2(g)$
(b) Oxidation–reduction reaction:
$4\ Ga(s) + 3\ O_2(g) \rightarrow 2\ Ga_2O_3(s)$
(c) Acid–base reaction:
$Ba(OH)_2(s) + 2\ HNO_3(aq) \rightarrow Ba(NO_3)_2(aq) + 2\ H_2O(\ell)$
Net ionic equation:
$Ba(OH)_2(s) + 2\ H_3O^+(aq) \rightarrow Ba^{2+}(aq) + 4\ H_2O(\ell)$
(d) Precipitation reaction:
$CuCl_2(aq) + (NH_4)_2S(aq) \rightarrow CuS(s) + 2\ NH_4Cl(aq)$
Net ionic equation:
$Cu^{2+}(aq) + S^{2-}(aq) \rightarrow CuS(s)$

Applying Chemical Principles

3.1 Superconductors

1. In this case, because you know that Cu has an implied subscript of 1, divide the number of moles of each element determined by the number of moles of Cu.
$x = 0.15$; Formula = $La_{1.85}Ba_{0.15}CuO_4$
2. Y, 13.4%; Ba, 41.3%; Cu, 28.7%; O, 16.7%
3. One formula unit of the compound contains two Cu^{2+} ions and one Cu^{3+} ion.
4. $Y_2O_3 + 4\ BaCO_3 + 6\ CuO \rightarrow 2\ YBa_2Cu_3O_{6.5} + 4\ CO_2$
(The value of x is 0.5.)
5. 0.011 g O_2

3.2 Sequestering Carbon Dioxide

1. $Ca^{2+}(aq) + H_2CO_3(aq) + 2\ H_2O(\ell) \rightarrow CaCO_3(s) + 2\ H_3O^+(aq)$
2. 6 protons, 8 neutrons, and 6 electrons

3.3 Black Smokers and Volcanoes

1. Cations: calcium ion, Ca^{2+}; manganese(II) ion, Mn^{2+}; iron(II) ion, Fe^{2+}; nickel(II) ion, Ni^{2+}. Anions: sulfate ion, SO_4^{2-}; sulfide ion, S^{2-}.
2. Sulfide ion, S^{2-}, oxidation number is −2. Sulfate ion, SO_4^{2-}, oxidation number is +6.

Study Questions

3.1 Reactants: phosphorus (P_4) and oxygen (O_2); product: tetraphosphorus decaoxide (P_4O_{10}). The stoichiometric coefficients are 1, 5, 1; s and g indicate states of matter: s = solid, g = gas.

3.3 48,000 molecules of Cl_2

3.5 0.57 g of oxygen

3.7 **(a)** $2\ Al(s) + Fe_2O_3(s) \rightarrow 2\ Fe(\ell) + Al_2O_3(s)$
So much energy is released as heat in this reaction that the iron formed is in the liquid state.
(b) $C(s) + H_2O(g) \rightarrow CO(g) + H_2(g)$
(c) $SiCl_4(\ell) + 2\ Mg(s) \rightarrow Si(s) + 2\ MgCl_2(s)$

3.9 (a) $4\ Cr(s) + 3\ O_2(g) \rightarrow 2\ Cr_2O_3(s)$
(b) $Cu_2S(s) + O_2(g) \rightarrow 2\ Cu(s) + SO_2(g)$
(c) $C_6H_5CH_3(\ell) + 9\ O_2(g) \rightarrow 4\ H_2O(\ell) + 7\ CO_2(g)$

3.11 (a) $Fe_2O_3(s) + 3\ Mg(s) \rightarrow 3\ MgO(s) + 2\ Fe(s)$
Reactants = iron(III) oxide, magnesium
Products = magnesium oxide, iron
(b) $AlCl_3(s) + 3\ NaOH(aq) \rightarrow Al(OH)_3(s) + 3\ NaCl(aq)$
Reactants = aluminum chloride, sodium hydroxide
Products = aluminum hydroxide, sodium chloride
(c) $2\ NaNO_3(s) + H_2SO_4(aq) \rightarrow Na_2SO_4(s) + 2\ HNO_3(aq)$
Reactants = sodium nitrate, sulfuric acid
Products = sodium sulfate, nitric acid
(d) $NiCO_3(s) + 2\ HNO_3(aq) \rightarrow Ni(NO_3)_2(aq) + CO_2(g) + H_2O(\ell)$
Reactants = nickel(II) carbonate, nitric acid
Products = nickel(II) nitrate, carbon dioxide, water

3.13 (a) and (c) are true; (b) is false.

3.15 The reaction involving HCl is more product-favored at equilibrium.

3.17 Electrolytes are compounds whose aqueous solutions conduct electricity. Given an aqueous solution containing a strong electrolyte and another aqueous solution containing a weak electrolyte at the same concentration, the solution containing the strong electrolyte (such as NaCl) will conduct electricity much better than the one containing the weak electrolyte (such as acetic acid).

3.19 (a) $CuCl_2$
(b) $AgNO_3$
(c) All are water-soluble.

3.21 (a) K^+ and OH^- ions
(b) K^+ and SO_4^{2-} ions
(c) Li^+ and NO_3^- ions
(d) NH_4^+ and SO_4^{2-} ions

3.23 (a) Soluble, Na^+ and CO_3^{2-} ions
(b) Soluble, Cu^{2+} and SO_4^{2-} ions
(c) Insoluble
(d) Soluble, Ba^{2+} and Br^- ions

3.25 $CdCl_2(aq) + 2\ NaOH(aq) \rightarrow Cd(OH)_2(s) + 2\ NaCl(aq)$

$Cd^{2+}(aq) + 2\ OH^-(aq) \rightarrow Cd(OH)_2(s)$

3.27 (a) $NiCl_2(aq) + (NH_4)_2S(aq) \rightarrow NiS(s) + 2\ NH_4Cl(aq)$

$Ni^{2+}(aq) + S^{2-}(aq) \rightarrow NiS(s)$

(b) $3\ Mn(NO_3)_2(aq) + 2\ Na_3PO_4(aq) \rightarrow Mn_3(PO_4)_2(s) + 6\ NaNO_3(aq)$

$3\ Mn^{2+}(aq) + 2\ PO_4^{3-}(aq) \rightarrow Mn_3(PO_4)_2(s)$

3.29 $HNO_3(aq) + H_2O(\ell) \rightarrow H_3O^+(aq) + NO_3^-(aq)$

3.31 $H_2C_2O_4(aq) + H_2O(\ell) \rightarrow H_3O^+(aq) + HC_2O_4^-(aq)$

$HC_2O_4^-(aq) + H_2O(\ell) \rightarrow H_3O^+(aq) + C_2O_4^{2-}(aq)$

3.33 $MgO(s) + H_2O(\ell) \rightarrow Mg(OH)_2(s)$

3.35 (a) Acetic acid reacts with magnesium hydroxide to give magnesium acetate and water.

$2\ CH_3CO_2H(aq) + Mg(OH)_2(s) \rightarrow Mg(CH_3CO_2)_2(aq) + 2\ H_2O(\ell)$

(b) Perchloric acid reacts with ammonia to give ammonium perchlorate

$HClO_4(aq) + NH_3(aq) \rightarrow NH_4ClO_4(aq)$

3.37 $Ba(OH)_2(aq) + 2\ HNO_3(aq) \rightarrow Ba(NO_3)_2(aq) + 2\ H_2O(\ell)$

3.39 $HNO_3(aq) + H_2O(\ell) \rightleftharpoons H_3O^+(aq) + NO_3^-(aq)$
Brønsted acids: $HNO_3(aq)$ and $H_3O^+(aq)$
Brønsted bases: $H_2O(\ell)$ and $NO_3^-(aq)$

HNO_3 is a strong acid; therefore, this reaction is product-favored at equilibrium.

3.41 $H_2O(\ell) + HBr(aq) \rightleftharpoons H_3O^+(aq) + Br^-(aq)$
Water accepts H^+ from HBr(aq)

$H_2O(\ell) + NH_3(aq) \rightleftharpoons OH^-(aq) + NH_4^+(aq)$
Water donates H^+ to $NH_3(aq)$

3.43 (a) $(NH_4)_2CO_3(aq) + Cu(NO_3)_2(aq) \rightarrow CuCO_3(s) + 2\ NH_4NO_3(aq)$

$CO_3^{2-}(aq) + Cu^{2+}(aq) \rightarrow CuCO_3(s)$

(b) $Pb(OH)_2(s) + 2\ HCl(aq) \rightarrow PbCl_2(s) + 2\ H_2O(\ell)$

$Pb(OH)_2(s) + 2\ H_3O^+(aq) + 2\ Cl^-(aq) \rightarrow PbCl_2(s) + 4\ H_2O(\ell)$

(c) $BaCO_3(s) + 2\ HCl(aq) \rightarrow BaCl_2(aq) + H_2O(\ell) + CO_2(g)$

$BaCO_3(s) + 2\ H_3O^+(aq) \rightarrow Ba^{2+}(aq) + 3\ H_2O(\ell) + CO_2(g)$

(d) $2\ CH_3CO_2H(aq) + Ni(OH)_2(s) \rightarrow Ni(CH_3CO_2)_2(aq) + 2\ H_2O(\ell)$

$2\ CH_3CO_2H(aq) + Ni(OH)_2(s) \rightarrow Ni^{2+}(aq) + 2\ CH_3CO_2^-(aq) + 2\ H_2O(\ell)$

3.45 (a) $AgNO_3(aq) + KI(aq) \rightarrow AgI(s) + KNO_3(aq)$

$Ag^+(aq) + I^-(aq) \rightarrow AgI(s)$

(b) $Ba(OH)_2(aq) + 2\ HNO_3(aq) \rightarrow Ba(NO_3)_2(aq) + 2\ H_2O(\ell)$

$OH^-(aq) + H_3O^+(aq) \rightarrow 2\ H_2O(\ell)$

(c) $2\ Na_3PO_4(aq) + 3\ Ni(NO_3)_2(aq) \rightarrow Ni_3(PO_4)_2(s) + 6\ NaNO_3(aq)$

$2\ PO_4^{3-}(aq) + 3\ Ni^{2+}(aq) \rightarrow Ni_3(PO_4)_2(s)$

3.47 (a) $HNO_2(aq) + OH^-(aq) \rightarrow NO_2^-(aq) + H_2O(\ell)$
(b) $Ca(OH)_2(s) + 2\ H_3O^+(aq) \rightarrow Ca^{2+}(aq) + 4\ H_2O(\ell)$

3.49 $FeCO_3(s) + 2\ HNO_3(aq) \rightarrow Fe(NO_3)_2(aq) + CO_2(g) + H_2O(\ell)$

Iron(II) carbonate reacts with nitric acid to give iron(II) nitrate, carbon dioxide, and water.

3.51 $(NH_4)_2S(aq) + 2\ HBr(aq) \rightarrow 2\ NH_4Br(aq) + H_2S(g)$

Ammonium sulfide reacts with hydrobromic acid to give ammonium bromide and hydrogen sulfide.

3.53 (a) Br = +5 and O = −2
(b) C = +3 and O = −2
(c) F = −1
(d) Ca = +2 and H = −1
(e) H = +1, Si = +4, and O = −2
(f) H = +1, S = +6, and O = −2

3.55 (a) Oxidation–reduction reaction
Zn is oxidized from 0 to +2, and N in NO_3^- is reduced from +5 to +4 in NO_2.
(b) Acid–base reaction
(c) Oxidation–reduction reaction
Calcium is oxidized from 0 to +2 in $Ca(OH)_2$, and H is reduced from +1 in H_2O to 0 in H_2.

3.57 (a) O_2 is the oxidizing agent (as it always is), so C_2H_4 is the reducing agent. In this process, C_2H_4 is oxidized, and O_2 is reduced.
(b) Si is oxidized from 0 in Si to +4 in $SiCl_4$. Cl_2 is reduced from 0 in Cl_2 to −1 in Cl^-. Si is the reducing agent, and Cl_2 is the oxidizing agent.

3.59 (a) Acid–base

$Ba(OH)_2(aq) + 2\ HCl(aq) \rightarrow BaCl_2(aq) + 2\ H_2O(\ell)$

(b) Gas-forming

$2\ HNO_3(aq) + CoCO_3(s) \rightarrow Co(NO_3)_2(aq) + H_2O(\ell) + CO_2(g)$

(c) Precipitation

$2\ Na_3PO_4(aq) + 3\ Cu(NO_3)_2(aq) \rightarrow Cu_3(PO_4)_2(s) + 6\ NaNO_3(aq)$

3.61 (a) Precipitation

$MnCl_2(aq) + Na_2S(aq) \rightarrow MnS(s) + 2\ NaCl(aq)$

$Mn^{2+}(aq) + S^{2-}(aq) \rightarrow MnS(s)$

(b) Precipitation

$K_2CO_3(aq) + ZnCl_2(aq) \rightarrow ZnCO_3(s) + 2\ KCl(aq)$

$CO_3^{2-}(aq) + Zn^{2+}(aq) \rightarrow ZnCO_3(s)$

3.63 (a) $CuCl_2(aq) + H_2S(aq) \rightarrow CuS(s) + 2\ HCl(aq)$; precipitation

(b) $H_3PO_4(aq) + 3\ KOH(aq) \rightarrow 3\ H_2O(\ell) + K_3PO_4(aq)$

acid–base

(c) $Ca(s) + 2\ HBr(aq) \rightarrow H_2(g) + CaBr_2(aq)$

oxidation–reduction and gas-forming

(d) $MgCl_2(aq) + 2\ NaOH(aq) \rightarrow Mg(OH)_2(s) + 2\ NaCl(aq)$

precipitation

3.65 (a) $Ca(OH)_2(s) + 2\ HBr(aq) \rightarrow 2\ H_2O(\ell) + CaBr_2(aq)$

(b) $MgCO_3(s) + 2\ HNO_3(aq) \rightarrow Mg(NO_3)_2(aq) + CO_2(g) + H_2O(\ell)$

(c) $BaCl_2(aq) + Na_2SO_4(aq) \rightarrow BaSO_4(s) + 2\ NaCl(aq)$

(d) $NH_3(g) + H_2O(\ell) \rightarrow NH_4^+(aq) + OH^-(aq)$

3.67 (a) $CO_2(g) + 2\ NH_3(g) \rightarrow NH_2CONH_2(s) + H_2O(\ell)$

(b) $UO_2(s) + 4\ HF(aq) \rightarrow UF_4(s) + 2\ H_2O(\ell)$

$UF_4(s) + F_2(g) \rightarrow UF_6(s)$

(c) $TiO_2(s) + 2\ Cl_2(g) + 2\ C(s) \rightarrow TiCl_4(\ell) + 2\ CO(g)$

$TiCl_4(\ell) + 2\ Mg(s) \rightarrow Ti(s) + 2\ MgCl_2(s)$

3.69 (a) NaBr, KBr, or other alkali metal bromides; Group 2A bromides; other metal bromides except AgBr, Hg_2Br_2, and $PbBr_2$

(b) $Al(OH)_3$ and transition metal hydroxides

(c) Alkaline earth carbonates ($CaCO_3$) or transition metal carbonates ($NiCO_3$)

(d) Metal nitrates are generally water-soluble [e.g., $NaNO_3$, $Ni(NO_3)_2$].

(e) CH_3CO_2H, other acids containing the $—CO_2H$ group

3.71 Water soluble: $Cu(NO_3)_2$, $CuCl_2$. Water insoluble: $CuCO_3$, $Cu_3(PO_4)_2$

3.73 $2\ H_3O^+(aq) + Mg(OH)_2(s) \rightarrow 4\ H_2O(\ell) + Mg^{2+}(aq)$

Spectator ion, NO_3^-. Acid–base reaction.

3.75 (a) Cl_2 is reduced (to Cl^-) and Br^- is oxidized (to Br_2).

(b) Cl_2 is the oxidizing agent and Br^- is the reducing agent.

3.77 (a) $MgCO_3(s) + 2\ H_3O^+(aq) \rightarrow CO_2(g) + Mg^{2+}(aq) + 3\ H_2O(\ell)$

Chloride ion (Cl^-) is the spectator ion.

(b) Gas-forming reaction

3.79 (a) H_2O, NH_3, NH_4^+, and OH^- (and a trace of H_3O^+)
weak Brønsted base

(b) H_2O, CH_3CO_2H, $CH_3CO_2^-$, and H_3O^+ (and a trace of OH^-)
weak Brønsted acid

(c) H_2O, Na^+, and OH^- (and a trace of H_3O^+)
strong Brønsted base

(d) H_2O, H_3O^+, and Br^- (and a trace of OH^-)
strong Brønsted acid

3.81 (a) $K_2CO_3(aq) + 2\ HClO_4(aq) \rightarrow 2\ KClO_4(aq) + CO_2(g) + H_2O(\ell)$

gas-forming

Potassium carbonate and perchloric acid react to form potassium perchlorate, carbon dioxide, and water.

$CO_3^{2-}(aq) + 2\ H_3O^+(aq) \rightarrow CO_2(g) + 3\ H_2O(\ell)$

(b) $FeCl_2(aq) + (NH_4)_2S(aq) \rightarrow FeS(s) + 2\ NH_4Cl(aq)$

precipitation

Iron(II) chloride and ammonium sulfide react to form iron(II) sulfide and ammonium chloride.

$Fe^{2+}(aq) + S^{2-}(aq) \rightarrow FeS(s)$

(c) $Fe(NO_3)_2(aq) + Na_2CO_3(aq) \rightarrow FeCO_3(s) + 2\ NaNO_3(aq)$

precipitation

Iron(II) nitrate and sodium carbonate react to form iron(II) carbonate and sodium nitrate

$Fe^{2+}(aq) + CO_3^{2-}(aq) \rightarrow FeCO_3(s)$

(d) $3\ NaOH(aq) + FeCl_3(aq) \rightarrow 3\ NaCl(aq) + Fe(OH)_3(s)$

precipitation

Sodium hydroxide and iron(III) chloride react to form sodium chloride and iron(III) hydroxide.

$3\ OH^-(aq) + Fe^{3+}(aq) \rightarrow Fe(OH)_3(s)$

3.83 (a) NaOH
(b) $MgCl_2$
(c) KI
(d) NH_4Cl

3.85 (a) NH_3
(b) CH_3CO_2H, HF

3.87 $2\ H_3O^+(aq) + S^{2-}(aq) \rightarrow H_2S(g) + 2\ H_2O(\ell)$

$H_2S(g) + Pb^{2+}(aq) + 2\ H_2O(\ell) \rightarrow PbS(s) + 2\ H_3O^+(aq)$

3.89 (a) Reactants: Na(+1), I(−1), H(+1), S(+6), O(−2), Mn(+4)

Products: Na(+1), S(+6), O(−2), Mn(+2), I(0), H(+1)

(b) The oxidizing agent is MnO_2, and NaI is oxidized. The reducing agent is NaI, and MnO_2 is reduced.

(c) Based on the picture, the reaction is product-favored.

(d) Sodium iodide, sulfuric acid, and manganese(IV) oxide react to form sodium sulfate, manganese(II) sulfate, iodine, and water.

3.91 Among the reactions that could be used are the following:

$MgCO_3(s) + 2\ HCl(aq) \rightarrow MgCl_2(aq) + CO_2(g) + H_2O(\ell)$

$MgS(s) + 2\ HCl(aq) \rightarrow MgCl_2(aq) + H_2S(g)$

$MgSO_3(s) + 2\ HCl(aq) \rightarrow MgCl_2(aq) + SO_2(g) + H_2O(\ell)$

In each case, the resulting solution could be evaporated to obtain the desired magnesium chloride.

3.93 The Ag^+ was reduced (to silver metal), and the glucose was oxidized (to $C_6H_{12}O_7$). The Ag^+ is the oxidizing agent, and the glucose is the reducing agent.

3.95 Weak electrolyte test: Compare the conductivity of a solution of lactic acid and that of an equal concentration of a strong acid. The conductivity of the lactic acid solution should be significantly less.

Reversible reaction: The fact that lactic acid is an electrolyte indicates that the reaction proceeds in the forward direction. To test whether the ionization is reversible, one could prepare a solution containing as much lactic acid as it will hold and then add a strong acid (to provide H_3O^+). If the reaction proceeds in the reverse direction, this will cause some lactic acid to precipitate.

3.97 (a) Several precipitation reactions are possible:

i. $BaCl_2(aq) + H_2SO_4(aq) \rightarrow BaSO_4(s) + 2\ HCl(aq)$

ii. $BaCl_2(aq) + Na_2SO_4(aq) \rightarrow BaSO_4(s) + 2\ NaCl(aq)$

iii. $Ba(OH)_2(aq) + H_2SO_4(aq) \rightarrow BaSO_4(s) + 2\ H_2O(\ell)$

(b) Gas-forming reaction:

$BaCO_3(s) + H_2SO_4(aq) \rightarrow BaSO_4(s) + CO_2(g) + H_2O(\ell)$

3.99 $NiC_8H_{14}N_4O_4$

3.101 (a) Reactants: As: +3; S: −2; N: +5

Products: As: +5; S: 0; N: +2

(b) Ag_3AsO_4

Chapter 4

Check Your Understanding

4.1 $(454\ g\ C_3H_8)(1\ mol\ C_3H_8/44.10\ g\ C_3H_8) = 10.29\ mol\ C_3H_8$

$10.29\ mol\ C_3H_8\ (5\ mol\ O_2/1\ mol\ C_3H_8)(32.00\ g\ O_2/1\ mol\ O_2) = 1650\ g\ O_2$

$(10.29\ mol\ C_3H_8)(3\ mol\ CO_2/1\ mol\ C_3H_8)(44.01\ g\ CO_2/1\ mol\ CO_2) = 1360\ g\ CO_2$

$(10.29\ mol\ C_3H_8)(4\ mol\ H_2O/1\ mol\ C_3H_8)(18.02\ g\ H_2O/1\ mol\ H_2O) = 742\ g\ H_2O$

4.2 $(50.0\ g\ Al)(1\ mol\ Al/26.98\ g\ Al)(2\ mol\ Fe/2\ mol\ Al)(55.85\ g\ Fe/1\ mol\ Fe) = 104\ g\ Fe$

$(50.0\ g\ Fe_2O_3)(1\ mol\ Fe_2O_3/159.7\ g\ Fe_2O_3)(2\ mol\ Fe/1\ mol\ Fe_2O_3)(55.85\ g\ Fe/1\ mol\ Fe) = 35.0\ g\ Fe$

The mass of iron that can be produced from the Fe_2O_3 is less than that predicted from Al, so the limiting reactant is Fe_2O_3.

The mass of iron produced is that predicted by the limiting reactant, 35.0 g Fe.

4.3 $(0.143\ g\ O_2)(1\ mol\ O_2/32.00\ g\ O_2)(3\ mol\ TiO_2/3\ mol\ O_2)(79.87\ g\ TiO_2/1\ mol\ TiO_2) = 0.3569\ g\ TiO_2$

Percent TiO_2 in sample = (0.3569 g/2.367 g)(100%) = 15.1%

4.4 $(1.612\ g\ CO_2)(1\ mol\ CO_2/44.010\ g\ CO_2)(1\ mol\ C/1\ mol\ CO_2) = 0.036628\ mol\ C$

$(0.7425\ g\ H_2O)(1\ mol\ H_2O/18.015\ g\ H_2O)(2\ mol\ H/1\ mol\ H_2O) = 0.082431\ mol\ H$

$0.082431\ mol\ H/0.036628\ mol = 2.250\ H/1\ C = 9\ H/4\ C$

The empirical formula is C_4H_9, which has a molar mass of 57 g/mol. This is one half of the measured value of molar mass, so the molecular formula is C_8H_{18}.

4.5 $(0.240\ g\ CO_2)(1\ mol\ CO_2/44.01\ g\ CO_2)\ (1\ mol\ C/1\ mol\ CO_2)(12.01\ g\ C/1\ mol\ C) = 0.06549\ g\ C$

$(0.0982\ g\ H_2O)(1\ mol\ H_2O/18.02\ g\ H_2O)(2\ mol\ H/1\ mol\ H_2O)(1.008\ g\ H/1\ mol\ H) = 0.01099\ g\ H$

Mass O (by difference) = $0.1342\ g - 0.06549\ g - 0.01099\ g = 0.05772\ g$

$Amount\ C = 0.06549\ g(1\ mol\ C/12.01\ g\ C) = 0.005453\ mol\ C$

$Amount\ H = 0.01099\ g\ H(1\ mol\ H/1.008\ g\ H) = 0.01090\ mol\ H$

$Amount\ O = 0.05772\ g\ O(1\ mol\ O/16.00\ g\ O) = 0.003608\ mol\ O$

To find a whole-number ratio, divide each value by 0.003608; this gives 1.51 mol C:3.02 mol H:1 mol O. Multiply each value by 2, and round off to 3 mol C:6 mol H:2 mol O. The empirical formula is $C_3H_6O_2$; given the molar mass of 74.1, this is also the molecular formula.

4.6 (26.3 g)(1 mol $NaHCO_3$/84.01 g $NaHCO_3$) = 0.3131 mol $NaHCO_3$

0.3131 mol $NaHCO_3$/0.200 L = 1.57 M

Ion concentrations: $[Na^+] = [HCO_3^-] = 1.57$ M

4.7 (2.00 M)(V_{conc}) = (1.00 M)(0.250 L); V_{conc} = 0.125 L

To prepare the solution, measure accurately 125 mL of 2.00 M NaOH into a 250-mL volumetric flask, and add water to give a total volume of 250 mL.

4.8 (a) pH = $-\log(2.6 \times 10^{-2})$ = 1.59
(b) $-\log[H^+] = 3.80$; $[H^+] = 1.6 \times 10^{-4}$ M

4.9 HCl is the limiting reactant.

(0.350 mol HCl/1 L)(0.0750 L)(1 mol CO_2/2 mol HCl)(44.01 g CO_2/1 mol CO_2) = 0.578 g CO_2

4.10 (0.953 mol NaOH/1 L)(0.02833 L NaOH) = 0.02700 mol NaOH

(0.02700 mol NaOH)(1 mol CH_3CO_2H/1 mol NaOH) = 0.02700 mol CH_3CO_2H

(0.02700 mol CH_3CO_2H)(60.05 g/mol) = 1.62 g CH_3CO_2H

0.02700 mol CH_3CO_2H/0.0250 L = 1.08 M

4.11 (0.100 mol HCl/1 L)(0.02967 L) = 0.002967 mol HCl

(0.002967 mol HCl)(1 mol NaOH/1 mol HCl) = 0.002967 mol NaOH

0.002967 mol NaOH/0.02500 L = 0.119 M NaOH

4.12 Moles acid = moles base = (0.323 mol/L)(0.03008 L) = 9.716×10^{-3} mol

Molar mass = 0.856 g acid/9.716×10^{-3} mol acid = 88.1 g/mol

4.13 (0.196 mol $Na_2S_2O_3$/1 L)(0.02030 L) = 0.003979 mol $Na_2S_2O_3$

(0.003979 mol $Na_2S_2O_3$)(1 mol I_2/2 mol $Na_2S_2O_3$) = 0.001989 mol I_2

0.001989 mol I_2 is in excess and was not used in the reaction with ascorbic acid.

I_2 originally added = (0.0520 mol I_2/1 L)(0.05000 L) = 0.002600 mol I_2

I_2 used in reaction with ascorbic acid = 0.002600 mol − 0.001989 mol = 6.11×10^{-4} mol I_2

(6.11×10^{-4} mol I_2)(1 mol $C_6H_8O_6$/1 mol I_2)(176.1 g/1 mol) = 0.11 g $C_6H_8O_6$

4.14 A Beer's Law plot of the calibration data was constructed by plotting concentration of Cu^{2+} along the *x*-axis and the absorbance along the *y*-axis. The equation for the best-fit line is $y = 13.0x + 0.011$.

Substituting the absorbance for the solution of unknown concentration yields

$$0.418 = 13.0x + 0.011$$

$$x = 0.0315$$

Thus the concentration of Cu^{2+} in the solution of unknown concentration is 0.0315 M.

Applying Chemical Principles

4.1 Green Chemistry and Atom Economy

1. Reactant molecules contain 5 C, 10 H, 3 O. Combined molar mass = 118.1 g/mol

Desired product (methyl methacrylate) contains 5 C, 8 H, 2 O. Molar mass = 100.1 g/mol

% Atom economy = (100.1/118.1) × 100 = 84.75%

4.2 Forensic Chemistry—Food Tampering

1. Step 1: Calculate the amount of I_2 in solution from titration data.

Amount I_2 = (0.0425 mol $S_2O_3^{2-}$/L)(0.0253 L)(1 mol I_2/2 mol $S_2O_3^{2-}$) = 5.376×10^{-4} mol I_2

Step 2: Calculate the amount of NaClO present based on the amount of I_2 formed, and from that value calculate the mass of NaClO.

Mass NaClO = 5.376×10^{-4} mol I_2 (1 mol HClO/1 mol I_2)(1 mol NaClO/1 mol HClO)(74.44 g NaClO/1 mol NaClO) = 0.0400 g NaClO

4.3 How Much Salt Is There in Seawater?

1. Step 1: Calculate the amount of Cl^- in the diluted solution from titration data.

Mol Cl^- in 50 mL of dilute solution = mol Ag^+ = (0.100 mol/L)(0.02625 L) = 2.625×10^{-3} mol Cl^-

Step 2: Calculate the concentration of Cl^- in the dilute solution.

Concentration of Cl^- in dilute solution = 2.625×10^{-3} mol/0.0500 L = 5.250×10^{-2} M

Step 3: Calculate the concentration of Cl^- in seawater.

Seawater was initially diluted to one hundredth its original concentration. Thus, the concentration of Cl^- in seawater (undiluted) = 5.25 M.

4.4 The Martian

1. (d) Molar mass of H_2O, 18.0 g/mol

2. (d) 2 mol H_2O/1 mol O_2

3. (b) 1.28 L

1.00×10^3 mL O_2(1.14 g O_2/1 mL O_2)(1 mol O_2/32.00 g O_2)(2 mol H_2O/1 mol O_2)(18.0 g H_2O/1 mol H_2O)(1 mL H_2O/1.00 g H_2O)(1 L/1000 mL) = 1.28 L

4. 1.0×10^3 mL N_2H_4(1.02 g N_2H_4/1 mL N_2H_4)(1 mol N_2H_4/32.05 g N_2H_4)(2 mol H_2O/1 mol N_2H_4)(18.0 g H_2O/1 mol H_2O)(1 mL/1.00 g H_2O)(1 L/1000 mL) = 1.1 L H_2O

Notice the similarity of these two calculations. In both cases one mole of the starting material led to two moles of product. The molar masses were the same. The only factor making a difference in the final volume is the density. Thinking at the particulate level: the volume of a liquid will depend on the size of individual molecules and how well they pack together.

Study Questions

4.1 6.0 mol Al and 340 g Fe

4.3 22.7 g Br_2; 25.3 g Al_2Br_6

4.5 (a) CO_2, carbon dioxide, and H_2O, water
(b) $CH_4(g) + 2\ O_2(g) \rightarrow CO_2(g) + 2\ H_2O(\ell)$
(c) 102 g O_2
(d) 128 g products

4.7

Equation	$2\ PbS(s) + 3\ O_2(g)$	$\rightarrow$	$2\ PbO(s) + 2\ SO_2(g)$	
Initial (mol)	2.50	3.75	0	0
Change (mol)	−2.50	$-\frac{3}{2}(2.50) = -3.75$	$+\frac{2}{2}(2.50) = +2.50$	$+\frac{2}{2}(2.50) = +2.50$
Final (mol)	0	0	2.50	2.50

The amounts table shows that 2.50 mol of PbS requires $\frac{3}{2}(2.50) = 3.75$ mol of O_2 and produces 2.50 mol of PbO and 2.50 mol of SO_2.

4.9 (a) Balanced equation: $4\ Cr(s) + 3\ O_2(g) \rightarrow 2\ Cr_2O_3(s)$
(b) 0.175 g of Cr is equivalent to 0.003366 mol Cr.

Equation	$4\ Cr(s)$ +	$3\ O_2(g)$	$\rightarrow$	$2\ Cr_2O_3(s)$
Initial (mol)	0.003366	0.002524 mol		0
Change (mol)	−0.003366	$-\frac{3}{4}(0.003366) = -0.002524$		$+\frac{2}{4}(0.003366) = +0.00168$
Final (mol)	0	0		0.001683

The 0.001683 mol Cr_2O_3 produced corresponds to 0.256 g Cr_2O_3.
(c) 0.0808 g O_2

4.11 0.106 mol of Na_2SO_4 and 0.624 mol of C are mixed. Sodium sulfate is the limiting reactant. Therefore, 0.106 mol of Na_2S is formed, or 8.2 g.

4.13 (a) F_2 is the limiting reactant.
(b) 12 mol SF_6

4.15 (a) CH_4 is the limiting reactant.
(b) 375 g H_2
(c) Excess H_2O = 1390 g

4.17 (a) Fe_2O_3 is the limiting reactant.
(b) 6.99 g Fe produced
(c) 16.6 g of aluminum remains
(d) Amounts table

Equation	$Fe_2O_3(s) + 2\ Al(s)$	$\rightarrow$	$2\ Fe(\ell) + Al_2O_3(g)$	
Initial (mol)	0.06262	0.7412	0	0
Change (mol)	−0.06262	−0.1252	+0.1252	+0.06262
Final (mol)	0	0.6160	0.1252	0.06262

4.19 (332 g CH_3OH/407 g)100% = 81.6%

4.21 (a) 14.3 g $Cu(NH_3)_4SO_4$
(b) 88.3% yield

4.23 110 g CH_4 required

4.25 91.9% $CuSO_4 \cdot 5\ H_2O$

4.27 84.3% $CaCO_3$

4.29 13.8% NiS

4.31 Empirical formula = CH

4.33 (a) Empirical formula = C_5H_4;
(b) Molecular formula = $C_{10}H_8$

4.35 Empirical formula = CH_3O
molecular formula = $C_2H_6O_2$

4.37 $Ni(CO)_4$

4.39 $[Na_2CO_3] = 0.254$ M; $[Na^+] = 0.508$ M; $[CO_3^{2-}] = 0.254$ M

4.41 0.494 g $KMnO_4$

4.43 5.08×10^3 mL

4.45 (a) 0.50 M NH_4^+ and 0.25 M SO_4^{2-}
(b) 0.246 M Na^+ and 0.123 M CO_3^{2-}
(c) 0.056 M H_3O^+ and 0.056 M NO_3^-

4.47 A mass of 1.06 g of Na_2CO_3 is required. After weighing out this quantity of Na_2CO_3, transfer it to a 500.-mL volumetric flask. Rinse any solid from the neck of the flask while filling the flask with distilled water. Dissolve the solute in water. Add water until the bottom of the meniscus of the water is at the top of the scribed mark on the neck of the flask. Thoroughly mix the solution.

4.49 0.0750 M

4.51 Method (a) is correct. Method (b) gives an acid concentration of 0.15 M.

4.53 0.00340 M

4.55 $[H_3O^+] = 10^{-pH} = 4.0 \times 10^{-4}$ M; the solution is acidic.

4.57 HNO_3 is a strong acid, so $[H_3O^+] = 0.0013$ M. pH = 2.89.

4.59

	pH	$[H_3O^+]$	Acidic/Basic
(a)	1.00	0.10 M	Acidic
(b)	10.50	3.2×10^{-11} M	Basic
(c)	4.89	1.3×10^{-5} M	Acidic
(d)	7.64	2.3×10^{-8} M	Basic

4.61 268 mL

4.63 210 g NaOH and 190 g Cl_2

4.65 174 mL of $Na_2S_2O_3$ solution

4.67 1.50×10^3 mL of $Pb(NO_3)_2$ solution

4.69 44.6 mL

4.71 1.052 M HCl

4.73 104 g/mol

4.75 12.8% Fe

4.77

(a) Slope = 1.2×10^5 M^{-1}; y-intercept = 0.18 M
(b) 3.0×10^{-6} M

4.79 (a) Products = $CO_2(g)$ and $H_2O(g)$
(b) $2\ C_6H_6(\ell) + 15\ O_2(g) \rightarrow 12\ CO_2(g) + 6\ H_2O(g)$
(c) 49.28 g O_2
(d) 65.32 g products (= sum of C_6H_6 mass and O_2 mass)

4.81 0.28 g arginine, 0.21 g ornithine

4.83 (a) Titanium(IV) chloride, water, titanium(IV) oxide, hydrogen chloride
(b) 4.60 g H_2O
(c) 10.2 TiO_2, 18.6 g HCl

4.85 8.33 g NaN_3

4.87 Mass percent saccharin = 75.92%

4.89 SiH_4

4.91 C_3H_2O

4.93 1.85 kg H_2SO_4

4.95 The calculated molar mass of the metal is 1.2×10^2 g/mol. The metal is probably tin (118.67 g/mol).

4.97 479 kg Cl_2

4.99 66.5 kg CaO

4.101 1.27 g C_4H_8 (44.4%) and 1.59 g C_4H_{10} (55.6%)

4.103 62.2% Cu_2S and 26.8% CuS

4.105 Acetic acid is the limiting reactant. 1.54 g of $NaCH_3CO_2$ produced.

4.107 3.13 g $Na_2S_2O_3$, 96.8%

4.109 (a) pH = 0.979
(b) $[H_3O^+]$ = 0.0028 M; the solution is acidic.
(c) $[H_3O^+] = 2.1 \times 10^{-10}$ M; the solution is basic.
(d) The new solution's concentration is 0.102 M HCl; the pH = 0.990

4.111 The concentration of hydrochloric acid is 2.92 M; the pH is −0.465

4.113 1.56 g of $CaCO_3$ required; 1.00 g $CaCO_3$ remains; 1.73 g $CaCl_2$ produced.

4.115 Volume of water in the pool = 7.6×10^4 L

4.117 (a) Au, gold, has been oxidized and is the reducing agent.
O_2, oxygen, has been reduced and is the oxidizing agent.
(b) 26 L NaCN solution

4.119 % Atom economy = 49.81%

4.121 The concentration of Na_2CO_3 in the first solution prepared is 0.0275 M, in the second solution prepared the concentration of Na_2CO_3 is 0.00110 M.

4.123 (a) $Ag^+(aq) + Cl^-(aq) \rightarrow AgCl(s)$
(b) Balanced equation:
$2\ AgNO_3(aq) + K_2CrO_4(aq) \rightarrow 2\ KNO_3(aq) + Ag_2CrO_4(s)$
Net ionic equation:
$2\ Ag^+(aq) + CrO_4^{2-}(aq) \rightarrow Ag_2CrO_4(s)$
(c) $[Cl^-] = 5.30 \times 10^{-4}$ mol/L = 18.8 mg/L. This concentration is sufficient to promote oyster growth.

4.125 (a) First reaction: oxidizing agent = Cu^{2+} and reducing agent = I^-. Second reaction: oxidizing agent = I_3^- and reducing agent = $S_2O_3^{2-}$.
(b) 67.3% copper

4.127 $x = 6$; $Cr(NH_3)_6Cl_3$.

4.129 11.48% 2,4-D

4.131 3.3 mol H_2O/mol $CaCl_2$

4.133 (a) Slope = 2.06×10^5; y-intercept = 0.024
(b) 1.20×10^{-4} g/L
(c) 0.413 mg PO_4^{3-}

4.135 The total mass of the beakers and products after reaction is equal to the total mass before the reaction (167.170 g) because no gases were produced in the reaction and there is conservation of mass in chemical reactions.

4.137 The balanced chemical equation indicates that the stoichiometric ratio of HCl to Zn is 2 mol HCl/1 mol Zn. In each reaction, there is 0.100 mol of HCl present. In reaction 1, there is 0.107 mol of Zn present. This gives a 0.93 mol HCl/mol Zn ratio, indicating that HCl is the limiting reactant. In reaction 2, there is 0.050 mol of Zn, giving a 2.0 mol HCl/mol Zn ratio. This indicates that the two reactants are present in exactly the correct stoichiometric ratio. In reaction 3, there is 0.020 mol of Zn, giving a 5.0 mol HCl/mol Zn ratio. This indicates that the HCl is present in excess and that the zinc is the limiting reactant.

4.139 If both students base their calculations on the amount of HCl solution pipeted into the flask (20 mL), then the second student's result will be (e), the same as the first student's. However, if the HCl concentration is calculated using the diluted solution volume, student 1 will use a volume of 40 mL, and student 2 will use a volume of 80 mL in the calculation. The second student's result will be (c), half that of the first student's.

4.141 (a) % Atom economy = 44.15%
(b) Theoretical yield of maleic anhydride = 1.26×10^3 g; % yield = 77.4%

The theoretical yield of carbon dioxide from 1.00 kg of benzene is 1.13 kg.

Chapter 5

Check Your Understanding

5.1 $C = 59.8 \text{ J}/[(25.0 \text{ g})(1.00 \text{ K})] = 2.39 \text{ J/g} \cdot \text{K}$

5.2 $(15.5 \text{ g})(C_{metal})(18.9 \text{ °C} - 100.0 \text{ °C}) + (55.5 \text{ g})(4.184 \text{ J/g} \cdot \text{K})(18.9 \text{ °C} - 16.5 \text{ °C}) = 0$

$C_{metal} = 0.44 \text{ J/g} \cdot \text{K}$

5.3 1.00 L (1000 mL/1 L)(0.7849 g/cm^3) = 784.9 g

Heat liquid from 25.0 °C to 78.3 °C.

$\Delta T = 78.3 \text{ °C} - 25.0 \text{ °C} = 53.3 \text{ °C} = 53.3 \text{ K}$

$q = (2.44 \text{ J/g} \cdot \text{K})(784.9 \text{ g})(53.3 \text{ K}) = 1.021 \times 10^5 \text{ J} = 102.1 \text{ kJ}$

Boil the liquid.

$q = 38.56 \text{ kJ/mol}\ (784.9 \text{ g})(1 \text{ mol}/46.08 \text{ g}) = 656.8 \text{ kJ}$

Total = 102.1 kJ + 656.8 kJ = 759 kJ

5.4 Energy transferred as heat from tea + energy as heat expended to melt ice = 0.

$(250 \text{ g})(4.2 \text{ J/g} \cdot \text{K})(273.2 \text{ K} - 291.4 \text{ K}) + x \text{ g } (333 \text{ J/g}) = 0$

$x = 57.4 \text{ g} = 57 \text{ g}$

57 g of ice melts with energy supplied by cooling 250 g of tea from 18.2 °C (291.4 K) to 0 °C (273.2 K).

Mass of ice remaining = mass of ice initially − mass of ice melted

Mass of ice remaining = 75 g − 57.4 g = 18 g

5.5 The volume change is $(-0.65 \text{ L})(1 \text{ m}^3/1000 \text{ L}) = -6.5 \times 10^{-4} \text{ m}^3$. Work, $w_p = -P\Delta V = -(1.01 \times 10^5 \text{ kg/m} \cdot \text{s}^2)(-6.5 \times 10^{-4} \text{ m}^3) = 65.7 \text{ J}$ (work done on the system by the surroundings).

Heat (485 J) is transferred from system; q_p for system = −485 J.

$\Delta U = q_p + w_p = -485 \text{ J} + 65.7 \text{ J} = -419 \text{ J}$

5.6 $(15.0 \text{ g } C_2H_6)(1 \text{ mol } C_2H_6/30.07 \text{ g } C_2H_6) = 0.4988 \text{ mol } C_2H_6$

$\Delta H° = 0.4988 \text{ mol } C_2H_6(1 \text{ mol-rxn}/2 \text{ mol } C_2H_6)(-2857.3 \text{ kJ/mol-rxn}) = -713 \text{ kJ}$

5.7 Mass of final solution = 400. g

$\Delta T = 27.78 \text{ °C} - 25.10 \text{ °C} = 2.68 \text{ °C} = 2.68 \text{ K}$

Amount of HCl used = amount of NaOH used = $C \times V = (0.400 \text{ mol/L}) \times 0.200 \text{ L} = 0.0800 \text{ mol}$

Energy transferred as heat by acid−base reaction + energy gained as heat to warm solution = 0

$q_{rxn} + (4.20 \text{ J/g} \cdot \text{K})(400. \text{ g})(2.68 \text{ K}) = 0$

$q_{rxn} = -4.502 \times 10^3 \text{ J}$

This represents the energy transferred as heat in the reaction of 0.0800 mol HCl.

Energy transferred as heat per mole = $\Delta_r H$ = −4.502 kJ/0.0800 mol HCl = −56.3 kJ/mol HCl

5.8 (a) Energy evolved as heat in reaction + energy as heat absorbed by H_2O + energy as heat absorbed by bomb = 0

$q_{rxn} + (1.50 \times 10^3 \text{ g})(4.20 \text{ J/g} \cdot \text{K})(27.32 \text{ °C} - 25.00 \text{ °C}) + (837 \text{ J/K})(27.32 \text{ °C} - 25.00 \text{ °C}) = 0$

$q_{rxn} = -16{,}560 \text{ J} = -16{,}600 \text{ J}$ (energy evolved as heat in burning 1.0 g sucrose)

(b) Energy evolved as heat per mole = (−16.56 kJ/g sucrose)(342.3 g sucrose/1 mol sucrose) = −5670 kJ/mol sucrose

5.9 $C(s) + O_2(g) \rightarrow CO_2(g)$ $\quad \Delta_r H°_1 = -393.5 \text{ kJ}$

$2\,[S(s) + O_2(g) \rightarrow SO_2(g)]$ $\quad \Delta_r H° = 2\,\Delta_r H°_2 = 2(-296.8) = -593.6 \text{ kJ}$

$CO_2(g) + 2\,SO_2(g) \rightarrow CS_2(g) + 3\,O_2(g)$ $\quad \Delta_r H° = -\Delta_r H°_3 = +1103.9 \text{ kJ}$

Net: $C(s) + 2\,S(s) \rightarrow CS_2(g)$

$\Delta_r H°_{net} = -393.5 \text{ kJ} + (-593.6 \text{ kJ}) + 1103.9 \text{ kJ} = +116.8 \text{ kJ}$

5.10 $\Delta_r H° = (6 \text{ mol } CO_2/\text{mol-rxn})\Delta_f H°[CO_2(g)] + (3 \text{ mol } H_2O/\text{mol-rxn})\Delta_f H°[H_2O(\ell)] - \{(1 \text{ mol } C_6H_6/1 \text{ mol-rxn})\Delta_f H°[C_6H_6(\ell)] + (^{15}/_2 \text{ mol } O_2/\text{mol-rxn})\Delta_f H°[O_2(g)]\}$

$= (6 \text{ mol/mol-rxn})(-393.5 \text{ kJ/mol}) + (3 \text{ mol/mol-rxn})(-285.8 \text{ kJ/mol}) - (1 \text{ mol/mol-rxn})(+49.0 \text{ kJ/mol}) - (^{15}/_2 \text{ mol/mol-rxn})(0 \text{ kJ/mol})$

$= -3267.4 \text{ kJ/mol-rxn}$

Applying Chemical Principles

5.1 Gunpowder

1. (a) $\Delta_r H° = (1 \text{ mol } K_2S/\text{mol-rxn})[\Delta_f H°(K_2S)] + (1 \text{ mol } N_2/\text{mol-rxn})[\Delta_f H°(N_2)] + (3 \text{ mol } CO_2/\text{mol-rxn})[\Delta_f H°(CO_2)] - \{(2 \text{ mol } KNO_3/\text{mol-rxn})[\Delta_f H°(KNO_3)] + (3 \text{ mol C/mol-rxn})[\Delta_f H°(C)] + (1 \text{ mol S/mol-rxn})[\Delta_f H°(S)]$

$\Delta_r H° = (1 \text{ mol/mol-rxn})(-376.6 \text{ kJ/mol}) + (1 \text{ mol/mol-rxn})(0 \text{ kJ/mol}) + (3 \text{ mol/mol-rxn})(-393.5 \text{ kJ/mol}) - \{(2 \text{ mol/mol-rxn})(-494.6 \text{ kJ/mol}) + (3 \text{ mol/mol-rxn})(0 \text{ kJ/mol}) + (1 \text{ mol/mol-rxn})(0 \text{ kJ/mol})$

$\Delta_r H° = -567.9 \text{ kJ/mol-rxn}$

(b) $\Delta H° = 1.00 \text{ g black powder}$ (1 mol black power/270.31 g black power)(1 mol-rxn/1 mol black powder)(−567.9 kJ/mol-rxn) = −2.10 kJ

2. $q = -[(4.184 \text{ J/g} \cdot \text{K})(1.200 \times 10^3 \text{ g})(1.32 \text{ K}) + (691 \text{ J/K})(1.32 \text{ K})] = -7.540 \times 10^3 \text{ J}$

$-7.540 \times 10^3 \text{ J}/0.725 \text{ g} = -1.04 \times 10^4 \text{ J/g}$ guncotton

3. (a) $4\ C_3H_5N_3O_9(\ell) \rightarrow 12\ CO_2(g) + 6\ N_2(g) + 10\ H_2O(g) + O_2(g)$

(b) $(-6.23\ kJ/1.00\ g\ C_3H_5N_3O_9)(227.09\ g\ C_3H_5N_3O_9/1\ mol\ C_3H_5N_3O_9)(4\ mol\ C_3H_5N_3O_9/1\ mol\text{-}rxn) = -5659\ kJ/mol\text{-}rxn$

$-5659\ kJ/mol\text{-}rxn = (12\ mol\ CO_2/mol\text{-}rxn)(-393.5\ kJ/mol\ CO_2) + (6\ mol\ N_2/mol\text{-}rxn)(0\ kJ/mol\ N_2) + (10\ mol\ H_2O/mol\text{-}rxn)(-241.8\ kJ/mol\ H_2O) + (1\ mol\ O_2/mol\text{-}rxn)(0\ kJ/mol\ O_2) - 4\Delta_fH°[C_3H_5N_3O_9]$

$\Delta_fH°[C_3H_5N_3O_9] = -3.70 \times 10^2\ kJ/mol$

5.2 The Fuel Controversy—Alcohol and Gasoline

In the following, we assume water vapor, $H_2O(g)$, is formed upon oxidation.

1. Burning ethanol: $C_2H_5OH(\ell) + 3\ O_2(g) \rightarrow 2\ CO_2(g) + 3\ H_2O(g)$

$\Delta_rH° = (2\ mol\ CO_2/mol\text{-}rxn)[\Delta_fH°(CO_2)] + (3\ mol\ H_2O/mol\text{-}rxn)[\Delta_fH°(H_2O)] - (1\ mol\ C_2H_5OH/mol\text{-}rxn)[\Delta_fH°(C_2H_5OH)]$

$\Delta_rH° = (2\ mol\ CO_2/mol\text{-}rxn)[-393.5\ kJ/mol\ CO_2] + (3\ mol\ H_2O/mol\text{-}rxn)[-241.8\ kJ/mol\ H_2O] - (1\ mol\ C_2H_5OH/mol\text{-}rxn)[-277.0\ kJ/mol\ C_2H_5OH)] = -1235.4\ kJ/mol\text{-}rxn$

1 mol ethanol per 1 mol-rxn; therefore, q per mol is -1235.4 kJ/mol

q per gram: $(-1235.4\ kJ/mol)(1\ mol\ C_2H_5OH/46.07\ g\ C_2H_5OH) = -26.82\ kJ/g\ C_2H_5OH$

Burning octane: $C_8H_{18}(\ell) + 12.5\ O_2(g) \rightarrow 8\ CO_2(g) + 9\ H_2O(g)$

$\Delta_rH° = (8\ mol\ CO_2/mol\text{-}rxn)[\Delta_fH°(CO_2)] + (9\ mol\ H_2O/mol\text{-}rxn)[\Delta_fH°(H_2O)] - (1\ mol\ C_8H_{18}/mol\text{-}rxn)[\Delta_fH°(C_8H_{18})]$

$\Delta_rH° = (8\ mol\ CO_2/mol\text{-}rxn)[-393.5\ kJ/mol\ CO_2] + (9\ mol\ H_2O/mol\text{-}rxn)[-241.8\ kJ/mol\ H_2O] - (1\ mol\ C_8H_{18}/mol\text{-}rxn)[-250.1\ kJ/mol\ C_8H_{18})] = -5074.1\ kJ/mol\text{-}rxn$

1 mol octane per mol-rxn; therefore, q per mol octane is -5074.1 kJ/mol

q per gram: $-5074.1\ kJ/1\ mol\ C_8H_{18}$ $(1\ mol\ C_8H_{18}/114.2\ g\ C_8H_{18}) = -44.43\ kJ/g\ C_8H_{18}$

Octane provides more energy per mol and per gram than ethanol.

2. For ethanol, per liter: $q = (-26.82\ kJ/g)(785\ g/L) = 2.105 \times 10^4\ kJ/L = -2.11 \times 10^4\ kJ/L$

For octane, per liter: $q = (-44.43\ kJ/g)(699\ g/L) = 3.106 \times 10^4\ kJ/L = -3.11 \times 10^4\ kJ/L$

Octane produces almost 50% more energy per liter of fuel.

3. Mass of CO_2 per liter of ethanol $= 1.000$ L $(785\ g\ C_2H_5OH/L)(1\ mol\ C_2H_5OH/46.07\ g\ C_2H_5OH)(2\ mol\ CO_2/1\ mol\ C_2H_5OH)(44.01\ g\ CO_2/1\ mol\ CO_2) = 1.500 \times 10^3\ g\ CO_2 = 1.50 \times 10^3\ g\ CO_2$

Mass of CO_2 per liter of octane $=$ $1.000\ L\ (699\ g\ C_8H_{18}/L)(1\ mol\ C_8H_{18}/114.2\ g\ C_8H_{18})(8\ mol\ CO_2/1\ mol\ C_8H_{18})(44.01\ g\ CO_2/1\ mol\ CO_2) = 2.16 \times 10^3\ g\ CO_2$

4. Volume of ethanol needed to obtain 3.11×10^4 kJ of energy from oxidation: $(2.105 \times 10^4\ kJ/L\ C_2H_5OH)(x) = 3.106 \times 10^4$ kJ (where x is volume of ethanol)

Volume of ethanol $= x = 1.475$ L

Mass of CO_2 produced by burning 1.475 L of ethanol $= (1.500 \times 10^3\ g\ CO_2/L\ C_2H_5OH)(1.475\ L\ C_2H_5OH) = 2.21 \times 10^3\ g\ CO_2$

To obtain the same amount of energy, slightly more CO_2 is produced by burning ethanol than by burning octane.

5. Your car will travel about 50% farther on a liter of octane, and it will produce slightly less CO_2 emissions, than if you burned 1.0 L of ethanol.

Study Questions

5.1 The system is the part of the universe being studied. The surroundings are everything else in the universe that can exchange matter and/or energy with the system. A system and its surroundings are said to be in thermal equilibrium if they can exchange energy with each other but are at the same temperature; therefore, there is no net transfer of energy as heat from one to the other.

5.3 (a) Exothermic; q_{sys} is negative
(b) Endothermic; q_{sys} is positive
(c) Endothermic; q_{sys} is positive
(d) Endothermic; q_{sys} is positive

5.5 0.140 J/g · K

5.7 2.44 kJ

5.9 32.8 °C

5.11 20.7 °C

5.13 $T_{initial} = 37.4$ °C

5.15 0.40 J/g · K

5.17 330 kJ

5.19 49.3 kJ

5.21 273 J

5.23 9.97×10^5 J

5.25 $w = -P\Delta V = 126$ J

5.27 $\Delta V = 4.42$ L

5.29 $\Delta U = 433$ J

5.31 $V_{final} = 2.6$ L

5.33 Reaction is exothermic because $\Delta_rH°$ is negative. The heat evolved is 2.38 kJ.

5.47 0.236 J/g · K

5.49 (a) $\Delta_r H° = -126$ kJ/mol-rxn

(b)

5.51 $\Delta_r H° = +90.3$ kJ/mol-rxn

5.53 $C(s) + 2\ H_2(g) + 1/2\ O_2(g) \rightarrow CH_3OH(\ell)$

$\Delta_f H° = -238.4$ kJ/mol

5.55 (a) $2\ Cr(s) + 3/2\ O_2(g) \rightarrow Cr_2O_3(s)$

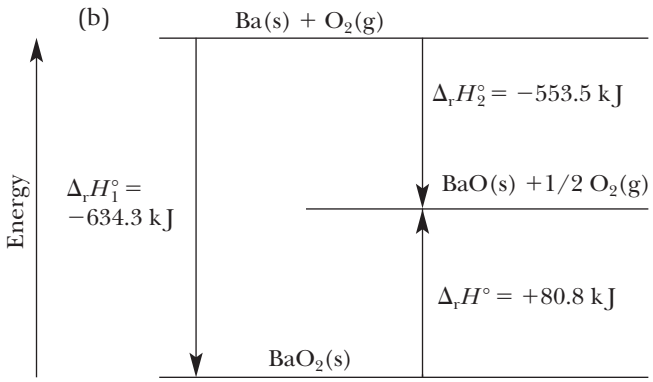
$\Delta_f H° = -1134.7$ kJ/mol

(b) 2.4 g is equivalent to 0.046 mol of Cr. This will produce 26 kJ of energy transferred as heat.

5.57 (a) $\Delta H° = -24$ kJ for 1.0 g of phosphorus

(b) $\Delta H° = -18$ kJ for 0.20 mol NO

(c) $\Delta H° = -16.9$ kJ for the formation of 2.40 g of NaCl(s)



(d) $\Delta H° = -1.8 \times 10^3$ kJ for the oxidation of 250 g of iron

5.59 (a) $\Delta_r H° = -906.2$ kJ

(b) The heat evolved is 133 kJ for the oxidation of 10.0 g of NH_3.

5.61 (a) $\Delta_r H° = +161.6$ kJ/mol-rxn; the reaction is endothermic.

(b)

5.63 $\Delta_f H° = +77.7$ kJ/mol for naphthalene

5.65 (a) Exothermic: a process in which energy is transferred as heat from a system to its surroundings. (The combustion of methane is exothermic.)

Endothermic: a process in which energy is transferred as heat from the surroundings to the system. (Ice melting is endothermic.)

(b) System: the object or collection of objects being studied. (A chemical reaction—the system—taking place inside a calorimeter—the surroundings.)

Surroundings: everything outside the system that can exchange mass or energy with the system. (The calorimeter and everything outside the calorimeter comprise the surroundings.)

(c) Specific heat capacity: the quantity of energy that must be transferred as heat to raise the temperature of 1 gram of a substance 1 kelvin. (The specific heat capacity of water is 4.184 J/g · K.)

(d) State function: a quantity that is characterized by changes that do not depend on the path chosen to go from the initial state to the final state. (Enthalpy and internal energy are state functions.)

(e) Standard state: the most stable form of a substance in the physical state that exists at a pressure of 1 bar and at a specified temperature. (The standard state of carbon at 25 °C is graphite.)

(f) Enthalpy change, ΔH: the energy transferred as heat at constant pressure. (The enthalpy change for melting ice at 0 °C is 6.00 kJ/mol.)

(g) Standard enthalpy of formation: the enthalpy change for the formation of 1 mol of a compound in its standard state directly from the component elements in their standard states. ($\Delta_f H°$ for liquid water is −285.83 kJ/mol.)

5.67 (a) System: reaction between methane and oxygen

Surroundings: the furnace and the rest of the universe. Energy is transferred as heat from the system to the surroundings.

(b) System: water drops

Surroundings: skin and the rest of the universe

Energy is transferred as heat from the surroundings to the system

(c) System: water

Surroundings: freezer and the rest of the universe

Energy is transferred as heat from the system to the surroundings.

(d) System: reaction of aluminum and iron(III) oxide

Surroundings: flask, laboratory bench, and rest of the universe

Energy is transferred as heat from the system to the surroundings.

5.69 Standard state of oxygen is gas, $O_2(g)$.

$O_2(g) \rightarrow 2\ O(g)$, $\Delta_r H° = +498.34$ kJ/mol-rxn, endothermic

$3/2\ O_2(g) \rightarrow O_3(g)$, $\Delta_r H° = +142.67$ kJ/mol-rxn

5.71 (a) Energy is transferred as heat from the surroundings to the system and as work done by the system.

(b) Energy is transferred as heat from the surroundings to the system and as work done by the system.

5.73 $\Delta H° = -0.627$ kJ

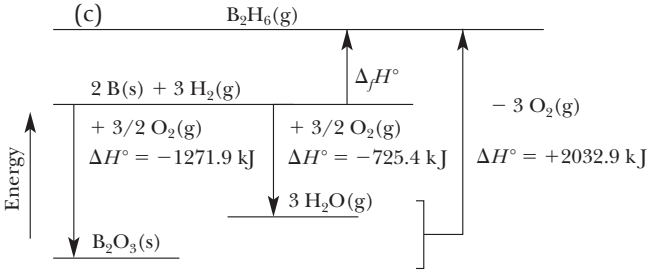
5.75 $C_{Ag} = 0.24$ J/g · K

5.77 Mass of ice melted = 75.4 g

5.79 Final temperature = 278 K (5 °C)

5.81 (a) When summed, the following equations give the balanced equation for the formation of $B_2H_6(g)$ from the elements.

$2\ B(s) + 3/2\ O_2(g) \rightarrow B_2O_3(s)$ $\quad \Delta_rH° = -1271.9$ kJ



$3\ H_2(g) + 3/2\ O_2(g) \rightarrow 3\ H_2O(g)$ $\quad \Delta_rH° = -725.4$ kJ

$B_2O_3(s) + 3\ H_2O(g) \rightarrow B_2H_6(g) + 3\ O_2(g)$ $\quad \Delta_rH° = +2032.9$ kJ

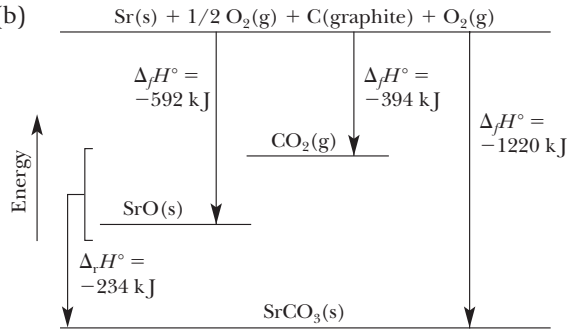
$2\ B(s) + 3\ H_2(g) \rightarrow B_2H_6(g)$ $\quad \Delta_rH° = +35.6$ kJ

(b) The enthalpy of formation of $B_2H_6(g)$ is +35.6 kJ/mol.

(c)

(d) The formation of $B_2H_6(g)$ is endothermic.

5.83 (a) $\Delta_rH° = +131.31$ kJ
(b) Endothermic
(c) 1.0932×10^7 kJ



5.85 Assuming $CO_2(g)$ and $H_2O(\ell)$ are the products of combustion:

$\Delta_rH°$ for isooctane is −5461.3 kJ/mol or −47.81 kJ per gram.

$\Delta_rH°$ for liquid methanol is −726.77 kJ/mol or −22.682 kJ per gram.

5.87 (a) Adding the equations as they are given in the question results in the desired equation for the formation of $SrCO_3(s)$. The calculated $\Delta_rH° = -1220.$ kJ/mol.

(b)

5.89 $\Delta_rH° = -305.3$ kJ

5.91 $\Delta_rH° = -1235.4$ kJ/mol-rxn;
$\Delta H°$ for 100.0 g of $C_2H_5OH = -2682$ kJ (−2680 kJ to three significant figures)

5.93 $C_{Pb} = 0.121$ J/g · K

5.95 $\Delta_rH = -69$ kJ/mol AgCl

5.97 36.0 kJ evolved per mol of NH_4NO_3

5.99 The standard enthalpy change, $\Delta_rH°$, is −352.88 kJ/mol-rxn. The quantity of magnesium needed is 0.43 g.

5.101 (a) Exothermic
(b) Exothermic

5.103 The enthalpy change for each of the following three reactions is known or can be measured by calorimetry. The three equations sum to give the enthalpy of formation of $CaSO_4(s)$.

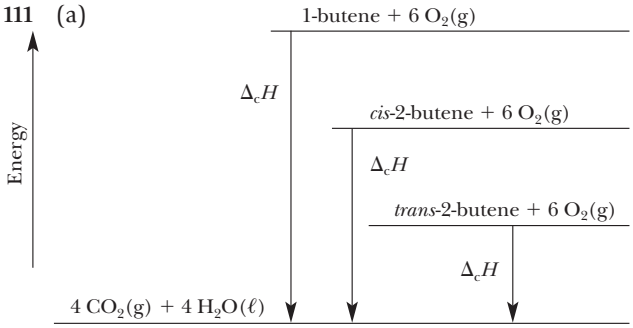
$Ca(s) + 1/2\ O_2(g) \rightarrow CaO(s)$ $\quad \Delta_rH° = \Delta_fH° = -635.09$ kJ

$1/8\ S_8(s) + 3/2\ O_2(g) \rightarrow SO_3(g)$ $\quad \Delta_rH° = \Delta_fH° = -395.77$ kJ

$CaO(s) + SO_3(g) \rightarrow CaSO_4(s)$ $\quad \Delta_rH° = -402.7$ kJ

$Ca(s) + 1/8\ S_8(s) + 2\ O_2(g) \rightarrow CaSO_4(s)$ $\quad \Delta_rH° = \Delta_fH° = -1433.6$ kJ

5.105



Metal	Molar Heat Capacity (J/mol · K)
Al	24.2
Fe	25.1
Cu	24.5
Au	25.4

All the metals have a molar heat capacity of 24.8 ± 0.5 J/mol · K. Therefore, assuming the molar heat capacity of Ag is 24.8 J/mol · K, its specific heat capacity is 0.230 J/g · K. This is very close to the experimental value of 0.236 J/g · K.

5.107 120 g of CH_4 required (assuming $H_2O(g)$ as product)

5.109 1.6×10^{11} kJ released to the surroundings. This is equivalent to 3.8×10^4 tons of dynamite.

5.111 (a)

(b) *cis*-2-butene: $\Delta_f H° = -7.6$ kJ/mol
trans-2-butene: $\Delta_f H° = -10.8$ kJ/mol
1-butene: $\Delta_f H° = -0.6$ kJ/mol

(c)

(d) −3.4 kJ/mol-rxn

5.113 (a) −726 kJ/mol Mg
(b) 25.0 °C

5.115 (a) Methane
(b) Methane
(c) −279 kJ
(d) $CH_4(g) + 1/2\ O_2(g) \rightarrow CH_3OH(\ell)$

5.117 (a) Metal heated = 100.0 g of Al; metal cooled = 50.0 g of Au; final temperature = 26 °C
(b) Metal heated = 50.0 g of Zn; metal cooled = 50.0 g of Al; final temperature = 21 °C

5.119 $w = -(1.0\ L \cdot atm)(0.36\ L - 0\ L)$
$= -0.36\ L\ atm = -36\ J$

Thus, 36 J of work is done by the system on the surroundings.

Chapter 6

Check Your Understanding

6.1 (a) Highest frequency, violet; lowest frequency, red
(b) The wavelength of radiation in a microwave oven is shorter than the FM radio wavelength.
(c) The wavelength of x-rays is shorter than the wavelength of ultraviolet light.
(d) $\lambda = 5.10 \times 10^{-7}$ m
$\nu = c/\lambda = (2.998 \times 10^8\ m/s^{-1})/(5.10 \times 10^{-7}\ m)$
$= 5.88 \times 10^{14}\ s^{-1}$

6.2 $\nu = c/\lambda = (2.998 \times 10^8\ m/s)/(4.05 \times 10^{-7}\ m) = 7.402 \times 10^{14}\ s^{-1}$
$E = N_A h\nu = (6.022 \times 10^{23}\ photons/mole)(6.626 \times 10^{-34}\ J\ s/photon)(7.402 \times 10^{14}\ s^{-1})$
$E = 295{,}000$ J/mol (= 295 kJ/mol)

6.3 (a) E (per atom) $= -Rhc/n^2$
$= (-2.179 \times 10^{-18})/(3^2)$ J/atom
$= -2.4211 \times 10^{-19}$ J/atom
$= -2.421 \times 10^{-19}$ J/atom
(b) E (per mol) $= (-2.4211 \times 10^{-19}\ J/atom)(6.022 \times 10^{23}\ atoms/mol)(1\ kJ/10^3\ J)$
$= -145.8$ kJ/mol

6.4 The least energetic line is from the electron transition from $n = 2$ to $n = 1$.

$\Delta E = -Rhc[1/1^2 - 1/2^2]$
$= -(2.179 \times 10^{-18}\ J/atom)(3/4)$
$= -1.6343 \times 10^{-18}$ J/atom

The photon emitted thus has $E_{photon} = 1.634 \times 10^{-18}$ J

$\nu = E_{photon}/h$
$= (1.6343 \times 10^{-18}\ J)/(6.626 \times 10^{-34}\ J \cdot s)$
$= 2.4664 \times 10^{15}\ s^{-1} = 2.466 \times 10^{15}\ s^{-1}$

$\lambda = c/\nu = (2.998 \times 10^8\ m/s^{-1})/(2.4664 \times 10^{15}\ s^{-1})$
$= 1.216 \times 10^{-7}$ m (or 121.6 nm)

6.5 First, calculate the velocity of the neutron:

$\nu = [2E/m]^{1/2} = [2(6.21 \times 10^{-21}\ kg \cdot m^2\ s^{-2})/(1.675 \times 10^{-27}\ kg)]^{1/2}$
$= 2723\ m \cdot s^{-1}$

Use this value in the de Broglie equation:

$\lambda = h/m\nu = (6.626 \times 10^{-34}\ kg \cdot m^2\ s^{-2} \cdot s)/[(1.675 \times 10^{-27}\ kg)\ (2723\ m\ s^{-1})]$
$= 1.45 \times 10^{-10}$ m = 0.145 nm

Applying Chemical Principles

6.1 Sunburn, Sunscreens, and Ultraviolet Radiation

1. Visible light has the longer wavelength. UV light has the higher frequency and the higher energy per photon.

2. Red light

$E = (6.626 \times 10^{-34}\ J \cdot s)(2.998 \times 10^8\ m/s)/(7.00 \times 10^{-7}\ m)$
$= 2.84 \times 10^{-19}$ J/photon

UV-B light

$E = (6.626 \times 10^{-34}\ J \cdot s)(2.998 \times 10^8\ m/s)/(3.00 \times 10^{-7}\ m)$
$= 6.62 \times 10^{-19}$ J/photon

The UV-B light has 2.33 times higher energy per photon than red light.

6.2 What Makes the Colors in Fireworks?

1. Yellow light is from the 589 and 590 nm emissions.

2. Primary emission for Sr is red. This has a longer wavelength than yellow light.

3. $4\ Mg(s) + KClO_4(s) \rightarrow KCl(s) + 4\ MgO(s)$

6.3 Chemistry of the Sun

1. $\nu = c/\lambda = (2.998 \times 10^8\ m/s)/(5.876 \times 10^{-7}\ m) = 5.102 \times 10^{14}\ s^{-1}$

2. $\lambda = c/\nu = (2.998 \times 10^8\ m/s)/(5.688 \times 10^{14}\ s^{-1}) = 5.271 \times 10^{-7}$ m (= 527.1 nm)

3. For $\lambda = 589.00$ nm,

$$E = (6.6261 \times 10^{-34}\ \text{J} \cdot \text{s})(2.9979 \times 10^{8}\ \text{m/s})/(5.8900 \times 10^{-7}\ \text{m})$$
$$= 3.3726 \times 10^{-19}\ \text{J}$$

For $\lambda = 589.59$ nm,

$$E = (6.6261 \times 10^{-34}\ \text{J} \cdot \text{s})(2.9979 \times 10^{8}\ \text{m/s})/(5.8959 \times 10^{-7}\ \text{m})$$
$$= 3.3692 \times 10^{-19}\ \text{J}$$
$$\Delta E = 3.4 \times 10^{-22}\ \text{J}$$

4. Per photon: $E = hc/\lambda$

$$= (6.626 \times 10^{-34}\ \text{J} \cdot \text{s})(2.998 \times 10^{8}\ \text{m/s})/(4.341 \times 10^{-7}\ \text{m})$$
$$= 4.5761 \times 10^{-19}\ \text{J}$$

Per mole: $E = (4.5761 \times 10^{-19}\ \text{J/photon})(6.022 \times 10^{23}\ \text{photons/mol})(1\ \text{kJ}/1000\ \text{J})$
$= 275.6$ kJ/mol photons

5. Line F corresponds to a wavelength of 486 nm. Based on Figure 6.10, this line arises from the electron in hydrogen moving from $n = 4$ to $n = 2$.

Study Questions

6.1 (a) Microwaves
(b) Red light
(c) Infrared

6.3 (a) Green light has a higher frequency than amber light
(b) $5.04 \times 10^{14}\ \text{s}^{-1}$

6.5 Frequency = $6.0 \times 10^{14}\ \text{s}^{-1}$; energy per photon = 4.0×10^{-19} J; energy per mol of photons = 2.4×10^{5} J

6.7 Frequency = $7.5676 \times 10^{14}\ s^{-1}$; energy per photon = 5.0144×10^{-19} J; 301.97 kJ/mol of photons

6.9 In order of increasing energy: FM station (d) < microwaves (c) < yellow light (a) < x-rays (b)

6.11 Light with a wavelength as long as 6.0×10^{2} nm would be sufficient. This is in the visible region.

6.13 (a) The light of shortest wavelength has a wavelength of 253.652 nm.
(b) Frequency = $1.18190 \times 10^{15}\ \text{s}^{-1}$. Energy per photon = 7.83139×10^{-19} J/photon.
(c) The lines at 404 nm (violet) and 436 nm (blue) are in the visible region of the spectrum.

6.15 The color is violet. $n_{\text{initial}} = 6$ and $n_{\text{final}} = 2$

6.17 (a) 10 lines possible
(b) Highest frequency (highest energy), $n = 5$ to $n = 1$
(c) Longest wavelength (lowest energy), $n = 5$ to $n = 4$

6.19 (a) $n = 3$ to $n = 2$
(b) $n = 4$ to $n = 1$. The energy levels are progressively closer at higher levels, so the energy difference from $n = 4$ to $n = 1$ is greater than from $n = 5$ to $n = 2$.

6.21 Wavelength = 102.6 nm and frequency = $2.923 \times 10^{15}\ \text{s}^{-1}$. Light with these properties is in the ultraviolet region.

6.23 Wavelength = 0.29 nm

6.25 The wavelength is 4.8×10^{-25} nm. (Calculated from $\lambda = h/m \cdot v$, where m is the ball's mass in kg and v is the velocity.) To have a wavelength of 5.6×10^{-3} nm, the ball would have to travel at 2.6×10^{-21} m/s.

6.27 (a) $n = 4$, $\ell = 0, 1, 2, 3$
(b) When $\ell = 2$, $m_\ell = -2, -1, 0, 1, 2$
(c) For a 4*s* orbital, $n = 4$, $\ell = 0$, and $m_\ell = 0$
(d) For a 4*f* orbital, $n = 4$, $\ell = 3$, and $m_\ell = -3, -2, -1, 0, 1, 2, 3$

6.29 Set 1: $n = 4$, $\ell = 1$, and $m_\ell = -1$
Set 2: $n = 4$, $\ell = 1$, and $m_\ell = 0$
Set 3: $n = 4$, $\ell = 1$, and $m_\ell = +1$

6.31 Four subshells. (The number of subshells in a shell is always equal to n.)

6.33 (a) ℓ must have a value no greater than $n - 1$.
(b) When $\ell = 0$, m_ℓ can only equal 0.
(c) When $\ell = 0$, m_ℓ can only equal 0.

6.35 (a) None. The quantum number set is not possible. When $\ell = 0$, m_ℓ can only equal 0.
(b) 3 orbitals
(c) 11 orbitals
(d) 1 orbital

6.37 (a) $m_s = 0$ is not possible. m_s may only have values of $\pm 1/2$.

One possible set of quantum numbers: $n = 4$, $\ell = 2$, $m_\ell = 0$, $m_s = +1/2$

(b) m_ℓ cannot equal -3 in this case. If $\ell = 1$, m_ℓ can only be -1, 0, or 1.

One possible set of quantum numbers: $n = 3$, $\ell = 1$, $m_\ell = -1$, $m_s = -1/2$

(c) $\ell = 3$ is not possible in this case. The maximum value of ℓ is $n - 1$.

One possible set of quantum numbers: $n = 3$, $\ell = 2$, $m_\ell = -1$, $m_s = +1/2$

6.39 2*d* and 3*f* orbitals cannot exist. The $n = 2$ shell consists only of *s* and *p* subshells. The $n = 3$ shell consists only of *s*, *p*, and *d* subshells.

6.41 (a) For 2*p*: $n = 2$, $\ell = 1$, and $m_\ell = -1$, 0, or $+1$
(b) For 3*d*: $n = 3$, $\ell = 2$, and $m_\ell = -2, -1, 0, +1$, or $+2$
(c) For 4*f*: $n = 4$, $\ell = 3$, and $m_\ell = -3, -2, -1, 0, +1, +2$, or $+3$

6.43 (d) 4*d*

6.45 (a) 2*s* has 0 nodal surfaces that pass through the nucleus ($\ell = 0$).
(b) 5*d* has 2 nodal surfaces that pass through the nucleus ($\ell = 2$).
(c) 5*f* has three nodal surfaces that pass through the nucleus ($\ell = 3$).

6.47 (a) Correct
(b) Incorrect. The intensity of a light beam is independent of frequency and is related to the number of photons of light with a certain energy.
(c) Correct

6.49 Considering only angular nodes (nodal surfaces that pass through the nucleus):

s orbital	0 nodal surfaces through the nucleus
p orbitals	1 nodal surface or plane passing through the nucleus
d orbitals	2 nodal surfaces or planes passing through the nucleus
f orbitals	3 nodal surfaces or planes passing through the nucleus

6.51

ℓ Value	Orbital Type
3	*f*
0	*s*
1	*p*
2	*d*

6.53 Considering only angular nodes (nodal surfaces that pass through the nucleus):

Orbital Type	Number of Orbitals in a Given Subshell	Number of Nodal Surfaces
s	1	0
p	3	1
d	5	2
f	7	3

6.55 (a) Green light
(b) Red light has a wavelength of 680 nm, and green light has a wavelength of 500 nm.
(c) Green light has a higher frequency than red light.

6.57 (a) Wavelength = 0.35 m
(b) Energy = 0.34 J/mol
(c) Violet light (with λ = 420 nm) has an energy of 280 kJ/mol of photons.
(d) Violet light has an energy (per mol of photons) that is 840,000 times greater than a mole of photons from a cell phone.

6.59 The ionization energy for He^+ is 5248 kJ/mol. This is four times the ionization energy for the H atom.

6.61 $1s < 2s = 2p < 3s = 3p = 3d < 4s$

In the H atom orbitals in the same shell (e.g., 2*s* and 2*p*) have the same energy.

6.63 Frequency = 2.836×10^{20} s^{-1} and wavelength = 1.057×10^{-12} m

6.65 260 s or 4.3 min

6.67 (a) Size and energy
(b) ℓ
(c) More
(d) 7 (when $\ell = 3$ these are *f* orbitals)
(e) One orbital
(f) (Left to right) *d*, *s*, and *p*
(g) ℓ = 0, 1, 2, 3, 4
(h) 16 orbitals (1 *s* orbital, 3 *p* orbitals, 5 *d* orbitals, and 7 *f* orbitals) ($= n^2$)

6.69 Energy = 4.576×10^{-19} J
Frequency = 6.906×10^{14} s^{-1}
Wavelength = 434.1 nm

6.71 The pickle glows because it was made by soaking a cucumber in brine, a concentrated solution of NaCl. The sodium atoms in the pickle are excited by the electric current and release energy as yellow light as they return to the ground state. Excited sodium atoms are the source of the yellow light you see in fireworks and in certain kinds of street lighting.

6.73 (a) λ = 0.0005 cm = 5 μm
(b) The left side is the higher energy side, and the right side is the lower energy side.
(c) The interaction with O—H requires more energy.

6.75 (c) Electrons are moving from a given energy level to one of lower energy.

6.77 An experiment can be done that shows that the electron can behave as a particle, and another experiment can be done to show that it has wave properties. (However, no single experiment shows both properties of the electron.) The modern view of atomic structure is based on the wave properties of the electron.

6.79 (a) and (b)

6.81 Radiation with a wavelength of 93.8 nm is sufficient to raise the electron to the $n = 6$ quantum level (see Figure 6.10). There should be 15 emission lines involving transitions from $n = 6$ to lower energy levels. (There are five lines for transitions from $n = 6$ to lower levels, four lines for $n = 5$ to lower levels, three for $n = 4$ to lower levels, two lines for $n = 3$ to lower levels, and one line for $n = 2$ to $n = 1$.) Wavelengths for many of the lines are given in Figure 6.10. For example, there will be an emission involving an electron moving from $n = 6$ to $n = 2$ with a wavelength of 410.2 nm.

6.83 (a) Group 7B (IUPAC Group 7); Period 5
(b) $n = 5$, $\ell = 0$, $m_\ell = 0$, $m_s = +1/2$
(c) $\lambda = 8.79 \times 10^{-12}$ m; $\nu = 3.41 \times 10^{19}$ s^{-1}
(d) (i) $HTcO_4(aq) + NaOH(aq) \rightarrow H_2O(\ell) + NaTcO_4(aq)$
(ii) 8.5×10^{-3} g $NaTcO_4$ produced; 1.8×10^{-3} g NaOH needed
(e) 0.28 mg $NaTcO_4$; 0.00015 M

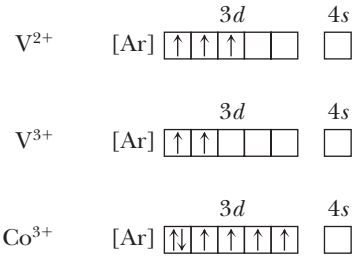
Chapter 7

Check Your Understanding



7.1 (a) chlorine (Cl)
(b) $1s^2 2s^2 2p^6 3s^2 3p^3$

7.2 Calcium has two valence electrons in the 4*s* subshell. Quantum numbers for these two electrons are $n = 4$, $\ell = 0$, $m_\ell = 0$, and $m_s = \pm 1/2$

7.3 Obtain the answers from Table 7.3.

7.4

All three ions are paramagnetic with three, two, and four unpaired electrons, respectively.

7.5 (a) Increasing atomic radius: C < B < Al
(b) Increasing ionization energy: Al < B < C
(c) Carbon is predicted to have the more negative electron attachment enthalpy.

Applying Chemical Principles

7.1 The Not-So-Rare Earths

1. (a) Sm^{3+}: $[Xe]4f^5$
(b) $4\ Sm(s) + 3\ O_2(g) \rightarrow 2\ Sm_2O_3(s)$

2. Y has a $[Kr]4d^1 5s^2$ configuration, while La has a $[Xe]5d^1 6s^2$ configuration and Lu has a $[Xe]4f^{14} 5d^1 6s^2$ configuration. Based on electronic structure, both La and Lu are appropriately located under yttrium. All three elements have electronic structures that finish with a filled outermost *s*-orbital and one electron in the outermost *d*-subshell.

3. (a) [Xe]

(b) The most common oxidation state is +3, corresponding to the loss of the two 6*s* and one 5*d* electrons. The electron configuration of Gd^{3+} is $[Xe]4f^7$.

4. (a) The electron configuration of the outermost shell of La and Lu is $6s^2$, but lutetium has an additional 14 electrons in the 4*f* orbitals. These electrons are poorly shielding so that the outermost electrons feel a large portion of the charge from the additional 14 protons in the nucleus, leading to a smaller radius.

(b) The elements in the 5*d* block have similar but larger radii than the atoms directly above them in the 4*d* block. Lanthanum might be considered a more appropriate fit below yttrium on the periodic table.

5. $\nu = c/\lambda = (2.998 \times 10^8\ m/s)/(6.12 \times 10^{-7}\ m)$
$= 4.899 \times 10^{14}\ s^{-1} = 4.90 \times 10^{14}\ s^{-1}$

$E = h\nu = (6.626 \times 10^{-34}\ J\ s/photon)(4.899 \times 10^{14}\ s^{-1})$
$= 3.25 \times 10^{-19}\ J/photon$

6. Molar mass of $Nd_2Fe_{14}B = 1081.13\ g/mol$

% Nd = [(2)(144.24 g/mol)/1081.13 g/mol] × 100%
= 26.683%

7.2 Metals in Biochemistry and Medicine

1. Fe: $[Ar]3d^6 4s^2$; Fe^{2+}: $[Ar]3d^6$; Fe^{3+}: $[Ar]3d^5$

2. Both iron ions are paramagnetic.

3. The slightly larger size of Cu compared to Fe is related to greater electron–electron repulsions.

4. Fe^{2+} is larger than Fe^{3+} and will fit less well into the structure. As a result, some distortion of the ring structure from planarity occurs.

Study Questions

7.1 Phosphorus: $1s^2 2s^2 2p^6 3s^2 3p^3$

The element is in the third period in Group 5A. Therefore, it has five electrons in the third shell.
Chlorine: $1s^2 2s^2 2p^6 3s^2 3p^5$

The element is in the third period and in Group 7A. Therefore, it has seven electrons in the third shell.

7.3 (a) Chromium: $1s^2 2s^2 2p^6 3s^2 3p^6 3d^5 4s^1$
(b) Iron: $1s^2 2s^2 2p^6 3s^2 3p^6 3d^6 4s^2$

7.5 (a) Arsenic: $1s^2 2s^2 2p^6 3s^2 3p^6 3d^{10} 4s^2 4p^3$; $[Ar]3d^{10} 4s^2 4p^3$
(b) Krypton: $1s^2 2s^2 2p^6 3s^2 3p^6 3d^{10} 4s^2 4p^6$;
$[Ar]3d^{10} 4s^2 4p^6 = [Kr]$

7.7 (a) Tantalum: This is the third element in the transition series in the sixth period. Therefore, it has a core equivalent to Xe plus two 6*s* electrons, 14 4*f* electrons, and three electrons in 5*d*: $[Xe]4f^{14} 5d^3 6s^2$
(b) Platinum: This is the eighth element in the transition series in the sixth period. Therefore, it is predicted to have a core equivalent to Xe plus two 6*s* electrons, 14 4*f* electrons, and eight electrons in 5*d*: $[Xe]4f^{14} 5d^8 6s^2$. In reality, its actual configuration (Table 7.3) is $[Xe]4f^{14} 5d^9 6s^1$.

7.9 Americium: $[Rn]5f^7 7s^2$ (see Table 7.3)

7.11 (a) 2
(b) 1
(c) None (because ℓ cannot equal n)

7.27 Increasing size: C < B < Al < Na < K

7.29 (a) Cl^-
(b) Al
(c) In

7.31 (c) Li < Si < C < Ne

7.33 (a) Largest radius, Na
(b) Most negative electron attachment enthalpy: O
(c) Ionization energy: Na < Mg < P < O

7.35 (a) Increasing ionization energy: S < O < F. S is less than O because the IE decreases down a group. F is greater than O because IE generally increases across a period.
(b) Largest IE: O. IE decreases down a group.
(c) Most negative electron attachment enthalpy: Cl. Electron attachment enthalpy generally becomes more negative across the periodic table and on ascending a group.
(d) Largest size: O^{2-}. Negative ions are larger than their corresponding neutral atoms. F^- is thus larger than F. O^{2-} and F^- are isoelectronic, but the O^{2-} ion has only eight protons in its nucleus to attract the 10 electrons, whereas the F^- has nine protons, making the O^{2-} ion larger.

7.37 (a) Li (b) K (c) Sc

7.39 Identify orbitals that contain electrons: In H and He only the 1*s* orbital is occupied; in Li electrons are present in the 1*s* and 2*s* orbitals. The intensities of peaks in the Li PES are 1 (for the 2*s* electron) and 2 (for the 1*s* electrons).

7.41 (a) Cr configuration: $[Ar]3d^5 4s^1$
Cr^{3+} configuration: $[Ar]3d^3$
(b) Both Cr^{2+} and Cr^{3+} are paramagnetic
(c) The radii are similar (radius for Al^{3+} = 57 nm), which is the reason that Cr^{3+} ions are sometimes found in solid Al_2O_3 in place of Al^{3+}.

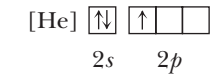
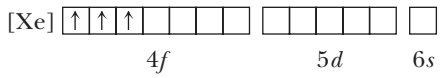
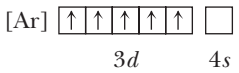
7.47 (a) Valid. Possible elements are Li and Be.
(b) Not valid. The maximum value of ℓ is $(n - 1)$.
(c) Valid. Possible elements are B through Ne.
(d) Valid. Possible elements are Y through Cd.



7.49 (a) Neodymium, Nd: [Xe]$4f^4 6s^2$ (Table 7.3)



Iron, Fe: [Ar]$3d^6 4s^2$



Boron, B: [He]$2s^2 2p^1$

(b) All three elements have unpaired electrons and so should be paramagnetic.
(c) Neodymium(III) ion, Nd^{3+}: [Xe]$4f^3$

Iron(III) ion, Fe^{3+}: [Ar]$3d^5$

Both neodymium(III) and iron(III) have unpaired electrons and are paramagnetic.

7.51 K < Ca < Si < P

7.53 (a) Metal
(b) B
(c) A
(d) A
(e) A_2B or Rb_2Se

7.55 In^{4+}: Indium has three outer shell electrons and so is unlikely to form a 4^+ ion.

Fe^{6+}: Although iron has eight electrons in its 3*d* and 4*s* orbitals, ions with a 6^+ charge are highly unlikely. The ionization energy is too large.

Sn^{5+}: Tin has four outer shell electrons and so is unlikely to form a 5^+ ion.

7.57 (a) Se
(b) Br^-
(c) Na
(d) N
(e) N^{3-}

7.59 (a) Na
(b) C
(c) Na < Al < B < C

7.61 (a) Cobalt
(b) Paramagnetic
(c) Four unpaired electrons

7.63 (a) metal
(b) B
(c) A
(d) B
(e) A
(f) AB_2 or SrI_2

7.65 (a) 0.421 g
(b) Paramagnetic; two unpaired electrons
(c) 99.8 mg; the nickel powder is paramagnetic and will stick to a magnet.

7.67 Li has three electrons ($1s^2 2s^1$) and Li^+ has only two electrons ($1s^2$). The ion is smaller than the atom because there are only two electrons to be held by three protons in the ion. Also, an electron in a larger orbital has been removed. Fluorine atoms have nine electrons and nine protons ($1s^2 2s^2 2p^5$). The anion, F^-, has one additional electron, which means that 10 electrons must be held by only nine protons, and so the ion is larger than the atom.

7.69 (a) The electron removed from Al is in the 3*p* orbital, which has a less negative energy than the 3*s* orbital from which the electron is removed in Mg. See the plot of orbital energies in *A Closer Look: Orbital Energies, Z*, and Electron Configurations,* page 322.
(b) The electron removed from S is one of a pair. Electron-electron repulsion lowers the energy required to remove the electron. (The 3*p* electrons of P are not paired.)

7.71 The most stable configuration is (d) (parallel spins in different orbitals, according to Hund's rule.) Configuration (b) is less stable than (c) due to repulsion of the two electrons in the same orbital. Configuration (a) is not an acceptable possibility; two electrons cannot have the same set of quantum numbers.

7.73 K ($1s^2 2s^2 2p^6 3s^2 3p^6 4s^1$) → K^+($1s^2 2s^2 2p^6 3s^2 3p^6$)

K^+($1s^2 2s^2 2p^6 3s^2 3p^6$) → K^{2+}($1s^2 2s^2 2p^6 3s^2 3p^5$)

The first ionization is for the removal of an electron from the valence shell of electrons. The second electron, however, is removed from the 3*p* subshell. This subshell is significantly lower in energy than the 4*s* subshell, and considerably more energy is required to remove this second electron.

7.75 (a) In going from one element to the next across the period, the effective nuclear charge increases slightly and the attraction between the nucleus and the electrons increases.
(b) The size of fourth period transition elements, for example, is a reflection of the size of the 4*s* orbital. As *d* electrons are added across the series, protons are added to the nucleus. Adding protons should lead to a decreased atom size, but the effect of the protons is balanced by repulsions of the 3*d* electrons and 4*s* electrons, and the atom size is changed little.

7.77 Among the arguments for a compound composed of Mg^{2+} and O^{2-} are the following:

(a) Chemical experience suggests that all Group 2A elements form 2^+ cations, and that oxygen is typically the O^{2-} ion in its compounds.

(b) Other alkaline earth elements form oxides such as BeO, CaO, and BaO.

A possible experiment is to measure the melting point of the compound. An ionic compound such as NaF (with ions having 1^+ and 1^- charges) melts at 990 °C, whereas a compound analogous to MgO, CaO, melts at a much higher temperature (2580 °C).

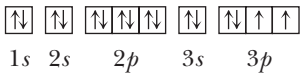
7.79 (a) The effective nuclear charge increases, causing the valence orbital energies to become more negative on moving across the period.

(b) As the valence orbital energies become more negative, it is increasingly difficult to remove an electron from the atom, and the *IE* increases. Toward the end of the period, the orbital energies have become so negative that removing an electron requires significant energy. Instead, the effective nuclear charge has reached the point that the atom forms a negative ion, in line with the more negative electron attachment enthalpy for elements on the right side of the periodic table.

(c) The valence orbital energies are in the order:

Li (−520.0 kJ) < Be (−899.3 kJ) >
B (−800.8 kJ) < C (−1029 kJ)

This means it is more difficult to remove an electron from Be than from either Li or B. The energy is more negative for C than for B, so it is more difficult to remove an electron from C than from B.



7.81 The size declines across this series of elements while their mass increases. Thus, the mass per volume, the density, increases.

7.83 (a) Element 113: $[Rn]5f^{14}6d^{10}7s^27p^1$
Element 115: $[Rn]5f^{14}6d^{10}7s^27p^3$

(b) Element 113 is in Group 3A (with elements such as boron and aluminum), and element 115 is in Group 5A (with elements such as nitrogen and phosphorus).

(c) Americium (Z = 95) + argon (Z = 18) = element 113

7.85 (a) Sulfur electron configuration

(b) One possible set of quantum numbers for a 3*p* electron is:
n = 3, ℓ = 1, m_ℓ = 1, and m_s = +1/2

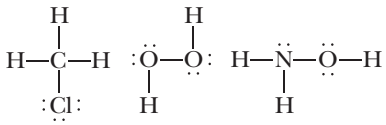
(c) S has the smallest ionization energy and O has the smallest radius.

(d) S is smaller than the S^{2-} ion.

(e) 584 g SCl_2

(f) 10.0 g of SCl_2 is the limiting reactant, and 11.6 g of $SOCl_2$ can be produced.

(g) $\Delta_f H°[SCl_2(g)]$ = −17.6 kJ/mol

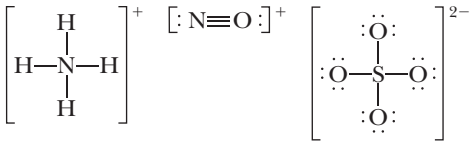


7.87 (a) Z^* for F is 5.20; Z^* for Ne is 5.85. The effective nuclear charge increases from O to F to Ne. As the effective nuclear charge increases, the atomic radius decreases, and the first ionization energy increases.

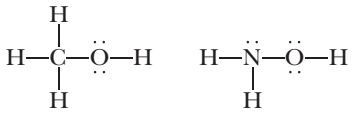
(b) Z^* for a 3*d* electron in Mn is 5.6; for a 4*s* electron it is only 3.6. The effective nuclear charge experienced by a 4*s* electron is much smaller than that experienced by a 3*d* electron. A 4*s* electron in Mn is thus more easily removed.

Chapter 8

Check Your Understanding

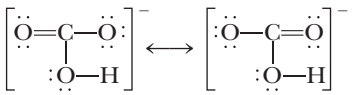


8.1



8.2

8.3



8.4

8.5 (a) CN^- : formal charge on C is −1; formal charge on N is 0.

(b) SO_3^{2-}: formal charge on S is +1; formal charge on each O is −1.

8.6 Resonance structures for the HCO_3^- ion:

(a) No. Three resonance structures are needed in the description of CO_3^{2-}; only two are needed to describe HCO_3^-.

(b) In each resonance structure: carbon's formal charge is 0; the oxygen of the —OH group and the double-bonded oxygen have a formal charge of zero; the singly bonded oxygen has a formal charge of −1. The average formal charge on the latter two oxygen atoms is $-1/2$. In the carbonate ion, each of the three oxygen atoms has an average formal charge of $-2/3$.

(c) H^+ would be expected to add to one of the oxygens with a negative formal charge; that is, one of the oxygens with formal charge of $-1/2$ in this structure.

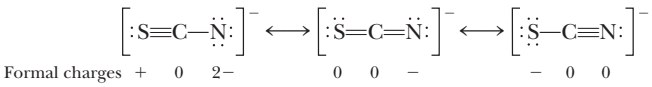
8.7  ClF_2^+, 2 bond pairs and 2 lone pairs.

 ClF_2^-, 2 bond pairs and 3 lone pairs.

8.8 Tetrahedral geometry around carbon. The Cl—C—Cl bond angle will be close to 109.5°.

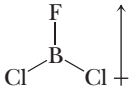


8.9 For each species, the electron-pair geometry and the molecular shape are the same. BF_3: trigonal-planar; BF_4^-: tetrahedral. Adding F^- to BF_3 adds an electron pair to the central atom and changes the shape.

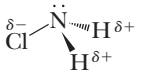
8.10 The electron-pair geometry around I is trigonal-bipyramidal. The molecular geometry of the ion is linear.

8.11 (a) The H atom is the positive pole in each case. H—F ($\Delta\chi = 1.8$) is more polar than H—I ($\Delta\chi = 0.5$).
(b) The B atom is the positive pole in each case. B—F ($\Delta\chi = 2.0$) is more polar than B—C ($\Delta\chi = 0.5$).
(c) C—Si ($\Delta\chi = 0.6$) is more polar than C—S ($\Delta\chi = 0.1$). In C—Si, C is the negative pole, and Si is the positive pole. In C—S, S is the negative pole, and C the positive pole.

8.12 16 valence electrons

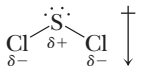


Formal charge considerations favor the middle structure because it has less formal charge than the left structure and, unlike the right structure, it has the negative formal charge on the most electronegative atom in the ion.

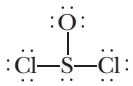


Bond polarity: For the C—N bond, $\Delta\chi = 0.5$, so this bond is polar and should have a partially positive C and a partially negative N. For the C—S bond, $\Delta\chi = 0.1$, so this bond should be only slightly polar with a partially positive C and a partially negative S.

Comparison of formal charge and bond polarity: The bonding in SCN^- will be closest to the middle resonance structure with a smaller contribution of the resonance structure on the right. From this we conclude that both N and S will have a negative formal charge, with N having the more negative value. The polarities of the C—N and C—S bonds match this description, with N and S being the negative end of each polar bond.



8.13 $BFCl_2$, polar, negative side is the F atom because F is the most electronegative atom in the molecule.



NH_2Cl, polar, negative side is the Cl atom.

SCl_2, polar, Cl atoms are on the negative side.

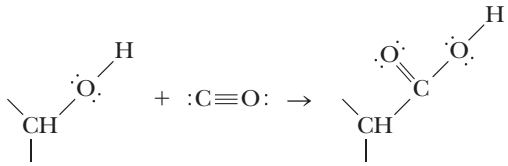
8.14 (a)

Formal charges: S = +1, O = −1, Cl = 0

(b) Geometry: trigonal-pyramidal. The molecule is polar. The positive charge is on sulfur, the negative charge on oxygen.

8.15 $CH_4(g) + 2\ O_2(g) \rightarrow CO_2(g) + 2\ H_2O(g)$

Break 4 C—H bonds and 2 O=O bonds:
(4 mol)(413 kJ/mol) + (2 mol)(498 kJ/mol) = 2648 kJ



Make 2 C=O bonds and 4 H—O bonds:
(2 mol)(803 kJ/mol) + (4 mol)(463 kJ/mol) = 3458 kJ

$\Delta_r H° = 2648\ kJ - 3458\ kJ = -810.\ kJ/mol\text{-}rxn$
(value calculated using enthalpies of formation = −802 kJ/mol-rxn)

Applying Chemical Principles

8.1 Ibuprofen, A Study in Green Chemistry

1. The Lewis structures for the key portions of the molecules where the reaction takes place are the following:

Bonds broken: 1 C—O and 1 C≡O

(1 mol C—O/1 mol-rxn)(358 kJ/mol C—O) +
(1 mol C≡O/1 mol-rxn)(1046 kJ/mol C≡O) =
1404 kJ/mol-rxn

Bonds formed: 1 C—C, 1 C=O, and 1 C—O

(1 mol C—C/1 mol-rxn)(346 kJ/mol C—C) +
(1 mol C=O/1 mol-rxn)(745 kJ/mol C=O) +
(1 mol C—O/1 mol-rxn)(358 kJ/mol C—O) =
1449 kJ/mol-rxn

$\Delta_r H° \approx 1404\ kJ/mol\text{-}rxn - 1449\ kJ/mol\text{-}rxn = -45\ kJ/mol\text{-}rxn$

The reaction is thus predicted to be exothermic.

2. All of the atoms in ibuprofen have a formal charge of zero.

3. The most polar bond in the molecule is the O—H bond.

4. The molecule is not symmetrical and so is polar.

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

5. The shortest bond in the molecule is the O—H bond.

6. The C═O bond has the highest bond order. The C═C bonds in the ring have an order of 1.5.

7. Yes, there are 120° bond angles present: the bond angles around the C atoms in the ring and those around the C atom in the $—CO_2H$ group are all 120°. There are no 180° angles in this molecule.

8. There is one acid group in ibuprofen ($—CO_2H$), therefore 1 mol of ibuprofen will react with 1 mol of NaOH.

   200. mg ibuprofen (1 g/1000 mg)(1 mol ibuprofen/206.3 g ibuprofen)(1 mol NaOH/1 mol ibuprofen)(1 L/0.0259 mol NaOH)(1000 mL/1 L) = 37.4 mL

   Therefore 37.4 mL of the NaOH solution would be required.

8.2 van Arkel Triangles and Bonding

1. (a) CuZn is metallic.
   (b) GaAs and BP are semiconductors. As and B are metalloids; Ga and P are not. In both compounds, only one element is a metalloid.
   (c) Mg_3N_2 and $SrBr_2$ are ionic. Both are composed of a metal combined with a nonmetal.
   (d) Covalent bonding
   (e) SBr_2 and C_3N_4 are covalent. Both elements in the compounds are nonmetallic.
2. The electronegativity difference between Be(1.6) and Cl(3.2) is 1.6. The average electronegativity of the two is 2.4. On the figure locate the point for this compound, which is on the border between ionic (red) and covalent (yellow) compounds.

8.3 Linus Pauling and the Origin of the Concept of Electronegatvity

1. Using average bond dissociation enthalpies:

$$\chi_{Cl} - \chi_H = 0.102[\Delta_{diss}H(HCl) - (\Delta_{diss}H(HH) + \Delta_{diss}H(ClCl))/2]^{1/2}$$
$$= 0.102[432\ kJ/mol - (436\ kJ/mol + 242\ kJ/mol)/2]^{1/2}$$
$$= 0.98$$

   According to Figure 8.11, $\chi_{Cl} - \chi_H = 1.0$

2. $\chi_N - \chi_I = 0.102[\Delta_{diss}H(NI) - (\Delta_{diss}H(NN) + \Delta_{diss}H(II))/2]^{1/2}$

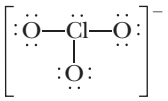
   $3.0 - 2.7 = 0.102[x - (163\ kJ/mol + 151\ kJ/mol)/2]^{1/2}$

   $x = 200\ kJ/mol$

3. $\chi_S = 1.97 \times 10^{-3}(IE - \Delta_{EA}H) + 0.19$
   $= 1.97 \times 10^{-3}(1000\ kJ/mol - -200.41\ kJ/mol) + 0.19$
   $= 2.55$

   This matches the value of 2.6 in Figure 8.11 well.

Study Questions



8.1. (a) Group 6A, six valence electrons
(b) Group 3A, three valence electrons
(c) Group 1A, one valence electron
(d) Group 2A, two valence electrons
(e) Group 7A, seven valence electrons
(f) Group 6A, six valence electrons

8.3 Group 4A, four bonds
Group 5A, three bonds (for a neutral compound)
Group 6A, two bonds (for a neutral compound)
Group 7A, one (for a neutral compound)

8.5 (a) NF_3, 26 valence electrons

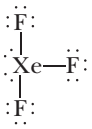
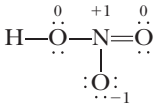
8.11 (a) BrF_3, 28 valence electrons



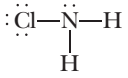
(b) I_3^-, 22 valence electrons

(c) XeO_2F_2, 34 valence electrons

(d) XeF_3^+, 28 valence electrons



8.13 (a) N = 0; H = 0
(b) P = +1; O = −1
(c) B = −1; H = 0
(d) All are zero.



8.15 (a) N = +1; O = 0
(b) The central N is 0. The singly bonded O atom is −1, and the doubly bonded O atom is 0.

(c) N and F are both 0.
(d) The central N atom is +1, one of the O atoms is −1, and the other two O atoms and the H atom are all 0.

8.17 (a) Electron-pair geometry around N is tetrahedral. Molecular geometry is trigonal-pyramidal.

(b) Electron-pair geometry around O is tetrahedral. Molecular geometry is bent.

(c) Electron-pair geometry around C is linear. Molecular geometry is linear.

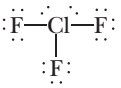
(d) Electron-pair geometry around O is tetrahedral. The molecular geometry is bent.

8.19 (a) Electron-pair geometry around C is linear. Molecular geometry is linear.

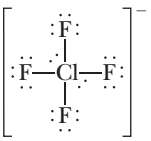
(b) Electron-pair geometry around N is trigonal-planar. Molecular geometry is bent.

(c) Electron-pair geometry around O is trigonal-planar. Molecular geometry is bent.

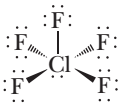
(d) Electron-pair geometry around Cl atom is tetrahedral. Molecular geometry is bent.



All have two atoms attached to the central atom. As the bond and lone pairs vary, the electron-pair geometries vary from linear to tetrahedral, and the molecular geometries vary from linear to bent.



8.21 (a) Electron-pair geometry around Cl is trigonal-bipyramidal. Molecular geometry is linear.



(b) Electron-pair geometry around Cl is trigonal-bipyramidal. Molecular geometry is T-shaped.

(c) Electron-pair geometry around Cl is octahedral. Molecular geometry is square-planar.

(d) Electron-pair geometry around Cl is octahedral. Molecular geometry is a square-pyramidal.

8.23 (a) Ideal O—S—O angle = 120°
(b) 120°
(c) 120°
(d) H—C—H = 109° and C—C—N angle = 180°

8.25 1 = 120°; 2 = 109°; 3 = 120°; 4 = 109°; 5 = 109°

The chain cannot be linear because the first two carbon atoms in the chain have bond angles of 109° and the final one has a bond angle of 120°. These bond angles do not lead to a linear chain.

8.27 (a) $\overset{\longrightarrow}{\underset{+\delta\ -\delta}{C—O}}$ $\overset{\longrightarrow}{\underset{+\delta\ -\delta}{C—N}}$

CO is more polar

(b) $\overset{\longrightarrow}{\underset{+\delta\ -\delta}{P—Cl}}$ $\overset{\longrightarrow}{\underset{+\delta\ -\delta}{P—Br}}$

PCl is more polar

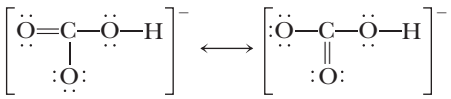
(c) $\overset{\longrightarrow}{\underset{+\delta\ -\delta}{B—O}}$ $\overset{\longrightarrow}{\underset{+\delta\ -\delta}{B—S}}$

BO is more polar

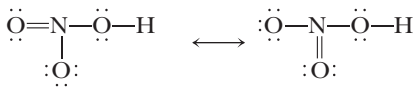
(d) $\overset{\longrightarrow}{\underset{+\delta\ -\delta}{B—F}}$ $\overset{\longrightarrow}{\underset{+\delta\ -\delta}{B—I}}$

BF is more polar

8.29 (a) CH and CO bonds are polar.
(b) The CO bond is most polar, and O is the most negative atom.



8.31 (a) OH^-: The formal charge on O is −1 and on H it is 0.
(b) BH_4^-: Even though the formal charge on B is −1 and on H is 0, H is slightly more electronegative than B. The four H atoms are therefore more likely to bear the −1 charge of the ion. The BH bonds are polar with the H atom the negative end.
(c) The CH and CO bonds are all polar (but the C—C bond is not). The negative charge in the CO bonds lies on the O atoms.



8.33 Structure C is most reasonable. The charges are as small as possible, and the negative charge resides on the more electronegative atom.

$$\overset{-2\ +1\ +1}{:\!\ddot{N}—N\equiv O:} \longleftrightarrow \overset{-1\ +1\ 0}{:\!\ddot{N}=N=\ddot{O}} \longleftrightarrow \overset{0\ +1\ -1}{:N\equiv N—\ddot{O}:}$$

A B C

8.35 Lewis structures:

(a) These species are isoelectronic.
(b) Each has two major resonance structures.
(c) In HCO_3^-, the H, C, and O attached to the H all have a formal charge of 0. Each of the other oxygen atoms has a formal charge of −1/2.

In HNO_3, the same formal charges are present as in HCO_3^- except that the central N has a formal charge of +1.

(d) HNO_3 is much more acidic than HCO_3^-. This is due, in part, to simple electrostatics. It is much easier to remove a positively charged species (H^+) from a neutral species (HNO_3) than from a negatively charged one (HCO_3^-).

8.37 (a) $\left[\overset{-1\ 0\ 0}{:\!\ddot{O}—N=\ddot{O}}\right]^- \longleftrightarrow \left[\overset{0\ 0\ -1}{\ddot{O}=N—\ddot{O}:}\right]^-$

(b) If an H^+ ion were to attack NO_2^-, it would attach to an O atom because the O atoms bear the negative charge in this ion.

(c) $H—\ddot{O}—N=O: \longleftrightarrow :\!\ddot{O}—N=O—H$

The structure on the left is strongly favored because all of the atoms have zero formal charge, whereas the structure on the right has a −1 formal charge on one oxygen (*left*) and a +1 formal charge on the other (*right*).

8.39 (i) The most polar bonds are in H_2O (because O and H have the largest difference in electronegativity).
(ii) Not polar: CO_2 and CCl_4
(iii) The F atom is more negatively charged.

8.41 (a) $BeCl_2$, nonpolar linear molecule
(b) HBF_2, polar trigonal-planar molecule with F atoms on the negative end of the dipole and the H atom on the positive end.
(c) CH_3Cl, polar tetrahedral molecule. The Cl atom is on the negative end of the dipole and the three H atoms are on the positive side of the molecule.
(d) SO_3, a nonpolar trigonal-planar molecule

8.43 (a) Two C—H bonds, bond order is 1; 1 C═O bond, bond order is 2.
(b) Three S—O single bonds, bond order is 1.
(c) Two nitrogen–oxygen double bonds, bond order is 2.
(d) One N═O double bond, bond order is 2; one N—Cl bond, bond order is 1.

8.45 (a) B—Cl
(b) C—O
(c) P—O
(d) C═O

8.47 NO bond orders: 2 in NO_2^+, 1.5 in NO_2^-; 1.33 in NO_3^-. The NO bond is longest in NO_3^- and shortest in NO_2^+.

8.49 The CO bond in carbon monoxide is a triple bond, so it is both shorter and stronger than the CO double bond in H_2CO.

8.51 Using bond dissociation enthalpy data, $\Delta_r H° \approx -44$ kJ/mol-rxn. Using $\Delta_f H°$ data, $\Delta_r H° = -45.9$ kJ/mol-rxn.

8.53 $\Delta_r H = -126$ kJ

8.55 O—F bond dissociation energy = 192 kJ/mol

8.57

Element	Number of Valence Electrons
Li	1
Ti	4
Zn	2
Si	4
Cl	7

8.59 SeF_4, BrF_4^-, XeF_4

8.61

Bond order = 3/2

8.63 To estimate the enthalpy change, we need bond dissociation enthalpies for the following bonds: O═O, H—H, and H—O.

ΔH to break bonds ≈ 498 kJ (for O═O) + 2 × 436 kJ (for H—H) = 1370 kJ

ΔH evolved when bonds are made ≈ 4 × 463 kJ (for O—H) = 1852 kJ

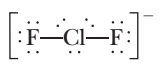
$\Delta_r H \approx -482$ kJ

8.65 All the species in the series have 16 valence electrons and all are linear.

(a)

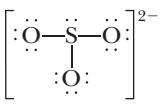
(b)

(c)



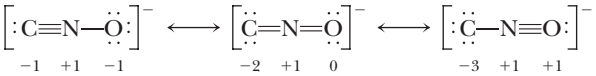
8.67 The N—O bonds in NO_2^- have a bond order of 1.5, whereas in NO_2^+ the bond order is 2. The shorter bonds (110 pm) are the NO bonds with the higher bond order (in NO_2^+), whereas the longer bonds (124 pm) in NO_2^- have a lower bond order.

8.69 The F—Cl—F bond angle in ClF_2^+, which has a tetrahedral electron-pair geometry, is approximately 109°.



The ClF_2^- ion has a trigonal-bipyramidal electron-pair geometry with F atoms in the axial positions and the lone pairs in the equatorial positions. Therefore, the F—C—F angle is 180°.

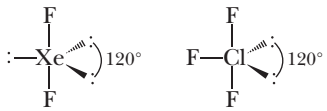
The anion ClF_2^- has the greater bond angle.



8.71 An H^+ ion will attach to an O atom of SO_3^{2-} and not to the S atom. The O atoms each have a formal charge of −1, whereas the S atom formal charge is +1.

8.73 (a) Calculation from bond dissociation enthalpies: $\Delta_r H° = -1070$ kJ/mol-rxn; $\Delta H° = -535$ kJ/mol CH_3OH

(b) Calculation from thermochemical data: $\Delta_r H° = -1352.3$ kJ/mol-rxn; $\Delta H° = -676$ kJ/mol CH_3OH



8.75 (a)

(b) The first resonance structure is the most reasonable because oxygen, the most electronegative atom, has a negative formal charge, and the unfavorable negative charge on the least electronegative atom, carbon, is smallest.

(c) This species is so unstable because carbon, the least electronegative element in the ion, has a negative formal charge. In addition, all three resonance structures have an unfavorable charge distribution.

8.77

(a) XeF_2 has three lone pairs around the Xe atom. The electron-pair geometry is trigonal-bipyramidal. Because lone pairs require more space than bond pairs, it is better to place the lone pairs in the equator of the bipyramid where the angles between them are 120°.

(b) Like XeF_2, ClF_3 has a trigonal-bipyramidal electron-pair geometry, but with only two lone pairs around the Cl. These are again placed in the equatorial plane where the angle between them is 120°.

8.79 (a) Angle 1 = 109°; angle 2 = 120°; angle 3 = 109°; angle 4 = 109°; and angle 5 = 109°

(b) The O—H bond is the most polar bond.

8.81 $\Delta_r H = +146 \text{ kJ} = 2\ (\Delta H_{C-N}) + \Delta H_{C=O} - [\Delta H_{N-N} + \Delta H_{C\equiv O}]$

8.83 (a) Two C—H bonds and one O═O are broken and two O—C bonds and two H—O bonds are made in the reaction. $\Delta_r H = -318$ kJ/mol-rxn. The reaction is exothermic.

(b) Both hydroxyacetone and acetone are polar.

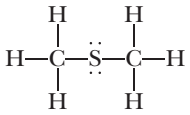
(c) The O—H hydrogen atoms are the most positive in dihydroxyacetone.

8.85 (a) The C═C bond is stronger than the C—C bond.

(b) The C—C single bond is longer than the C═C double bond.

(c) Ethylene is nonpolar, whereas acrolein is polar.

(d) The reaction is exothermic ($\Delta_r H = -45$ kJ/mol-rxn).



8.87 $\Delta_r H = -211$ kJ/mol-rxn

8.89 Methanol is a polar solvent. Methanol contains two bonds of significant polarity, the C—O bond and the O—H bond. The C—O—H atoms are in a bent configuration, leading to a polar molecule. Toluene contains only carbon and hydrogen atoms, which have similar electronegativites and which are arranged in tetrahedral or trigonal planar geometries, leading to a molecule that is largely nonpolar.

8.91 (a)

The bond angles are all approximately 109°.

(b) The sulfur atom should have a slight partial negative charge, and the carbons should have slight partial positive charges. The molecule has a bent shape and is polar.

(c) 1.6×10^{18} molecules

8.93 (a) C═O (Based on the difference in electronegativities, the C═O bond is slightly more polar than the N—H bond.)

(b) Predicted = 120° (Actual = 124°)

(c) Predicted = 120° (Actual = 113°)

(d) Approximately 109.5° (slightly less, similar to the H—N—H bond angles in ammonia)

8.95 (a) $P_4 + 6\ Cl_2 \rightarrow 4\ PCl_3$

(b) $\Delta_r H = -1206.9$ kJ/mol-rxn

(c) Bonds broken: 6 mol P—P, 6 mol Cl—Cl
Bonds formed: 12 mol P—Cl
$\Delta H_{P—Cl} = 322$ kJ/mol; the value in Table 8.8 is 326 kJ/mol

8.97 (a) Odd electron molecules: BrO (13 electrons)

(b) $Br_2(g) \rightarrow 2\ Br(g)$ $\Delta_r H = +193$ kJ
$2\ Br(g) + O_2(g) \rightarrow 2\ BrO(g)$ $\Delta_r H = +96$ kJ
$BrO(g) + H_2O(g) \rightarrow HOBr(g) + OH(g)$
$\Delta_r H = 0$ kJ

(c) $\Delta_f H$ [HOBr(g)] = −101 kJ/mol

(d) The reactions in part (b) are endothermic (or thermal-neutral for the third reaction), and the enthalpy of formation in part (c) is exothermic.

Chapter 9

Check Your Understanding

9.1 The carbon and nitrogen atoms in CH_3NH_2 are sp^3 hybridized. The C—H bonds arise from overlap of carbon sp^3 orbitals and hydrogen 1*s* orbitals. The bond between C and N is formed by overlap of sp^3 orbitals from these atoms. Overlap of nitrogen sp^3 and hydrogen 1*s* orbitals gives the two N—H bonds, and there is a lone pair in the remaining sp^3 orbital on nitrogen.

9.2 (a) sp^3

(b) (from left to right) sp^2, sp^2, sp^3

(c) sp^2

9.3 The two CH_3 carbon atoms are sp^3 hybridized, and the center carbon atom is sp^2 hybridized. For each of the carbon atoms in the methyl groups, the sp^3 orbitals overlap with hydrogen 1*s* orbitals to form the three C—H bonds, and the fourth sp^3 orbital overlaps with an sp^2 orbital on the central carbon atom, forming a carbon–carbon sigma bond. Overlap of an sp^2 orbital on the central carbon and an oxygen sp^2 orbital gives the sigma bond between these elements. The π bond between carbon and oxygen arises by overlap of a *p* orbital from each element.

9.4 H_2^+: $(\sigma_{1s})^1$ The ion has a bond order of $^1/_2$ and is expected to exist. A bond order of $^1/_2$ is predicted for He_2^+ and H_2^-, both of which are predicted to have electron configurations $(\sigma_{1s})^2(\sigma^*_{1s})^1$.

9.5 Li_2^- is predicted to have an electron configuration $(\sigma_{1s})^2(\sigma^*_{1s})^2(\sigma_{2s})^2(\sigma^*_{2s})^1$ and a bond order of $^1/_2$, the positive value implying that the ion might exist.

9.6 O_2^+: [core electrons] $(\sigma_{2s})^2(\sigma^*_{2s})^2(\sigma_{2p})^2(\pi_{2p})^4(\pi^*_{2p})^1$. The bond order is 2.5. The ion is paramagnetic with one unpaired electron.

Applying Chemical Principles

9.1 Probing Molecules with Photoelectron Spectroscopy

1. Metal

2. $E = h\nu = hc/\lambda = (6.626 \times 10^{-34}\ J \cdot s)(2.998 \times 10^8\ m/s)/(58.4 \times 10^{-9}\ m)$
$= 3.401 \times 10^{-18}$ J/photon

$(3.401 \times 10^{-18}$ J/photon$)(6.022 \times 10^{23}$ photons/mol$)$
$= 2.05 \times 10^6$ J/mol $= 2.05 \times 10^3$ kJ/mol

3. σ_{2p}

4. $E = h\nu = 3.401 \times 10^{-18}$ J from problem 2.

$IE = h\nu - KE = 3.401 \times 10^{-18}\ J - 4.23 \times 10^{-19}\ J$
$= 2.978 \times 10^{-18}$ J/electron

$(2.978 \times 10^{-18}$ J/electron$)(6.022 \times 10^{23}$ electrons/mol$)(1$ kJ/1000 J$)$
$= 1.79 \times 10^3$ kJ/mol

$(2.978 \times 10^{-18}\ J)(1\ eV/1.60218 \times 10^{-19}\ J) = 18.6$ eV

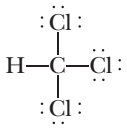
5. The 15.6 eV and 16.7 eV ejected electrons came from bonding orbitals. Removing an electron from a bonding orbital weakens the bond and thus results in a longer bond length. The 18.6 eV ejected electron comes from an antibonding orbital.

9.2 Green Chemistry, Safe Dyes, and Molecular Orbitals

1. C_8H_4BrNO

2. The energy per photon is inversely proportional to wavelength. The light absorbed by butter yellow has a smaller wavelength than that absorbed by nitrated butter yellow; therefore, butter yellow absorbs higher energy light than does nitrated butter yellow.

3. Tyrian purple: 9



Nitrated butter yellow: 8

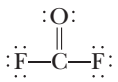
Study Questions

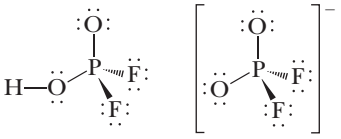
9.1 The electron-pair and molecular geometry of $CHCl_3$ are both tetrahedral. Each C—Cl bond is formed by the overlap of an sp^3 hybrid orbital on the C atom with a 3*p* orbital on a Cl atom to form a sigma bond. A C—H sigma bond is formed by the overlap of an sp^3 hybrid orbital on the C atom with an H atom 1*s* orbital.



9.3

Both the N and the O are sp^3 hybridized. One of the sp^3 orbitals on the N overlaps with one of the sp^3 hybrid orbitals on the O.

9.5

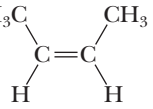


The electron-pair and molecular geometries are both trigonal-planar. The carbon atom is sp^2 hybridized. The σ bond between the C and O is formed by the overlap of an sp^2 hybrid orbital on C with an sp^2 hybrid orbital on O. The π bond is formed by the overlap of a 2*p* orbital on C with a 2*p* orbital on O.

9.7

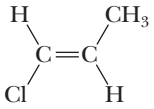
	Electron-Pair Geometry	Molecular Geometry	Hybrid Orbital Set
(a)	Trigonal-planar	Trigonal-planar	sp^2
(b)	Linear	Linear	sp
(c)	Tetrahedral	Tetrahedral	sp^3
(d)	Trigonal-planar	Trigonal-planar	sp^2

9.9 (a) C, sp^3; O, sp^3
(b) CH_3, sp^3; middle C, sp^2; CH_2, sp^2
(c) CH_2, sp^3; CO_2H, sp^2; N, sp^3



9.11 There are 32 valence electrons in both HPO_2F_2 and its anion. Both have a tetrahedral molecular geometry, so the P atom in both is sp^3 hybridized.

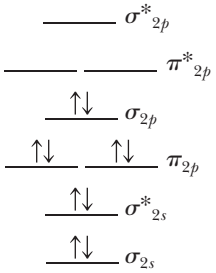
9.13 The C atom is sp^2 hybridized. Two of the sp^2 hybrid orbitals are used to form C—Cl σ bonds, and the third is used to form the C—O σ bond. The *p* orbital not used in the C atom hybrid orbitals is used to form the CO pi bond.



9.15 The electron-pair geometry around S is tetrahedral, and the molecular geometry is trigonal-pyramidal. The S atom is sp^3 hybridized.

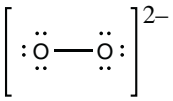
9.17 (a)

cis isomer



(b)

trans isomer



9.19 H_2^+ ion: $(\sigma_{1s})^1$. Bond order is 0.5. The bond in H_2^+ is weaker than in H_2 (bond order = 1).

9.21 MO diagram for C_2^{2-} ion

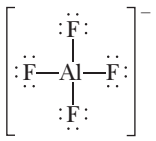
(a) There are one net σ bond and two net π bonds.
(b) 3
(c) VB and MO descriptions give the same result.
(d) The bond order increases from 2 to 3 on going from C_2 to C_2^{2-}.
(e) No, it is diamagnetic.

9.23 O_2: (core electrons)$(\sigma_{2s})^2(\sigma^*_{2s})^2(\sigma_{2p})^2(\pi_{2p})^4(\pi^*_{2p})^2$
O_2^{2-}: (core electrons)$(\sigma_{2s})^2(\sigma^*_{2s})^2(\sigma_{2p})^2(\pi_{2p})^4(\pi^*_{2p})^4$

(a) O_2 is paramagnetic; O_2^{2-} is diamagnetic; O_2 has one net σ bond and one net π bond, and O_2^{2-} has one net σ bond; O_2 bond order = 2; O_2^{2-} bond order = 1; the bond length in O_2 is shorter than that in O_2^{2-}.
(b) Both valence bond and MO theories predict one σ bond and one π bond in O_2 and one σ bond in O_2^{2-}. Both theories predict bond orders of 2 for O_2 and 1 for O_2^{2-}. Notice, however, that valence bond theory does not predict the paramagnetic behavior of O_2.

9.25 Shortest, N_2; longest, Li_2

9.27 (a) ClO has 13 valence electrons



$$[\text{core}](\sigma_s)^2(\sigma^*_s)^2(\pi_p)^4(\sigma_p)^2(\pi^*_p)^3$$

(b) π^*_p
(c) Paramagnetic
(d) There are net 1 σ bond and 0.5 π bonds; bond order is 1.5.

9.29

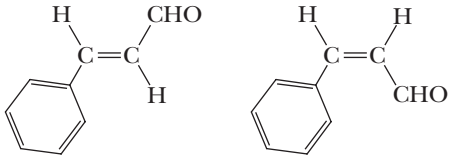
The electron pair and molecular geometries are both tetrahedral. The Al atom is sp^3 hybridized, so the Al—F bonds are formed by overlap of an Al sp^3 orbital with a p orbital on each F atom. The formal charge on each of the fluorines is 0, and that on the Al is −1. This is not a reasonable charge distribution because the less electronegative atom, aluminum, has the negative charge.

9.31

The electron-pair geometry is trigonal-planar. The molecular geometry is bent (or angular). The O—N—O angle will be about 120°, the average N—O bond order is 3/2, and the N atom is sp^2 hybridized.

9.33 The resonance structures of N_2O, with formal charges, are shown here.

A B C

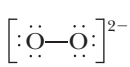


The central N atom is *sp* hybridized in all structures. The two *sp* hybrid orbitals on the central N atom are used to form N—N and N—O σ bonds. The two *p* orbitals not used in the N atom hybridization are used to form the required π bonds.

9.35 (a) All three have the formula C_2H_4O. (These are isomers because they have the same formula. However, they have different structures.)
(b) *Ethylene oxide:* Both C atoms are sp^3 hybridized.
Acetaldehyde: The CH_3 carbon atom has sp^3 hybridization, and the other C atom is sp^2 hybridized.
Vinyl alcohol: Both C atoms are sp^2 hybridized.
(c) *Ethylene oxide:* 109°
Acetaldehyde: 109°
Vinyl alcohol: 120°
(d) All are polar.
(e) Acetaldehyde has the strongest CO bond, and vinyl alcohol has the strongest C—C bond.

9.37 (a) CH_3 carbon atom: sp^3
C═N carbon atom: sp^2
N atom: sp^2
(b) C—N—O bond angle = 120°

9.39 (a) C(1) = sp^2; O(2) = sp^3; N(3) = sp^3; C(4) = sp^3; P(5) = sp^3
(b) Angle A = 120°; angle B = 109°; angle C = 109°; angle D = 109°
(c) The P—O and O—H bonds are most polar ($\Delta\chi$ = 1.3).



9.41 (a) C═O bond is most polar.
(b) 18 σ bonds and five π bonds
(c)

trans isomer *cis* isomer

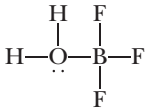
(d) All C atoms are sp^2 hybridized.
(e) All bond angles are 120°.

9.43 (a) The peroxide ion has a bond order of 1.

(b) [Core electrons]$(\sigma_{2s})^2(\sigma^*_{2s})^2(\sigma_{2p})^2(\pi_{2p})^4(\pi^*_{2p})^4$
This configuration also leads to a bond order of 1.
(c) Both theories lead to a diamagnetic ion with a bond order of 1.

9.45 Paramagnetic diatomic molecules: B_2 and O_2

Bond order of 1: Li_2, B_2, F_2; bond order of 2: C_2 and O_2; highest bond order: N_2



9.47 CN has nine valence electrons.

[core electrons]$(\sigma_{2s})^2(\sigma^*_{2s})^2(\pi_{2p})^4(\sigma_{2p})^1$

(a) HOMO, σ_{2p}
(b, c) Bond order = 2.5 (0.5 σ bond and 2 π bonds)
(d) Paramagnetic

9.49 (a) All C atoms are sp^3 hybridized.
(b) About 109°
(c) Polar
(d) The six-membered ring cannot be planar, owing to the tetrahedral C atoms of the ring. The bond angles are all 109°.

9.51 (a) The geometry about the boron atom is trigonal-planar in BF_3 but tetrahedral in $H_3N—BF_3$.
(b) Boron is sp^2 hybridized in BF_3 but sp^3 hybridized in $H_3N—BF_3$.
(c) The ammonia molecule is polar with the N atom partially negative. While the BF_3 molecule is nonpolar overall, each of the B—F bonds is polarized such that the B has a partial positive charge. The partially negative N in NH_3 is attracted to the partially positive B in BF_3.
(d) One of the lone pairs on the oxygen of H_2O can form a coordinate covalent bond with the B in BF_3. The resulting compound would be (the lone pairs on the F's not shown):

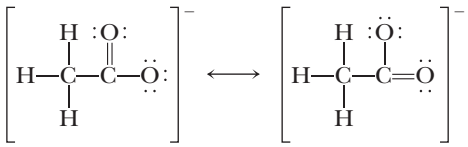
9.53 (a) NH_2^-: electron-pair geometry = tetrahedral, molecular geometry = bent, hybridization of N = sp^3

SO_3: electron-pair geometry = molecular geometry = trigonal-planar, hybridization of S = sp^2

(b)



The bond angles around the N and the S are all approximately 109°.

(c) The N does not undergo any change in its hybridization; the S changes from sp^2 to sp^3.

(d) The SO_3 is the acceptor of an electron pair in this reaction. The electrostatic potential map confirms this to be reasonable because the sulfur has a partial positive charge.

9.55

Hybridization of C in $—CO_2^-$ is sp^2

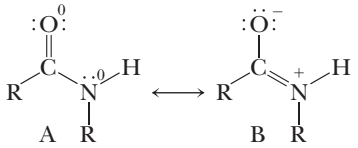
C—C bond: overlap of sp^2 hybrid orbital on the carbon of $—CO_2^-$ with sp^3 hybrid orbital on the other C.

C—O σ bond of C=O double bond: overlap of sp^2 hybrid orbital on C with sp^2 hybrid orbital on O

C—O π bond of C=O double bond: overlap of p orbital on C with p orbital on O

C—O single bond: The Lewis structure by itself would make it appear this bond is formed by the overlap of an sp^2 hybrid orbital on C with an sp^3 hybrid orbital on O. In the resonance hybrid, however, this oxygen would also have sp^2 hybridization.

9.57



MO theory pictures one net σ bond for each S—O linkage plus a contribution from π bonding. The π bonding in this molecule will be similar to that in O_3 discussed in the text. There will be two electrons in a π bonding MO and two electrons in a π nonbonding MO. This gives an overall bond order of 1 for the π bonding in the entire molecule and therefore a net π bond order of 0.5 for each S—O linkage. The total bond order for each S—O linkage is therefore 1.5 (1 from σ bonding, 0.5 from π bonding).

9.59 A C atom may form, at most, four hybrid orbitals (sp^3). The minimum number is two, for example, the sp hybrid orbitals used by carbon in CO. Carbon has only four valence orbitals, so it cannot form more than four hybrid orbitals.

9.61 (a) C, sp^2; N (predicted based on Lewis structure), sp^3

(b) The amide or peptide link has two resonance structures (shown here with formal charges on the O and N atoms). Structure B is less favorable, owing to the separation of charge.

(c) The fact that the amide link is planar indicates that structure B has some importance and that the N of the peptide linkage is sp^2 hybridized.

The principal sites of positive charge are the nitrogen in the amide linkage and the hydrogen of the —O—H group. The principal regions of negative charge are oxygen atoms and the nitrogen of the free $—NH_2$ group.

9.63 MO theory is better to use when explaining or understanding the effect of adding energy to molecules. A molecule can absorb energy and an electron can thus be promoted to a higher level. Using MO theory, one can see how this can occur. Additionally, MO theory is a better model to use to predict whether a molecule is paramagnetic.

9.65 Lowest energy = orbital C < orbital B < orbital A = highest energy

9.67 B surrounded by three electron pairs: electron-pair geometry = molecular geometry = trigonal planar; hybridization = sp^2; formal charge = 0

B surrounded by four electron pairs; electron-pair geometry = molecular geometry = tetrahedral; hybridization = sp^3; formal charge = −1

9.69 HF has a bond order of 1. HF_2^- has a bond order of 1 for the entire three-center-four-electron bond and thus a 0.5 bond order per H—F linkage. It should therefore be easier to break the bond in HF_2^-, leading to a smaller bond enthalpy for HF_2^- than for HF.

9.71 (a) empirical formula = Br_2O

The O should have sp^3 hybrid orbitals.

(b) 13 valence electrons; $(\sigma_s)^2(\sigma^*_s)^2(\pi_p)^4(\sigma_p)^2(\pi^*_p)^3$

HOMO = π^*_p

9.73 (a) Bonds broken: two N—H bonds (one N—H bond for each N in urea); two C—O bonds in malonic acid (at each end of the molecule). Bonds made: two N—C bond in barbituric acid; two O—H bonds, one in each molecule of H_2O (the other product of this reaction). Estimated enthalpy change calculated from average bond energies: 38 kJ evolved, exothermic.

(b) $H_2NCONH_2 + HO_2CCH_2CO_2H \rightarrow C_4H_4N_2O_3 + 2\ H_2O$

(c) 109.5° angles in bonds to C in the CH_2 group; all other angles will be close to 120°
(d) The C and N atoms in the ring are sp^2 hybridized except for the C atom of the CH_2 group where the C atom is sp^3 hybridized.
(e) C═O group, as the difference in electronegativity is greatest between C and O.
(f) yes, it is polar.

Chapter 10

Check Your Understanding

10.1 0.29 atm(760 mm Hg/1 atm) = 220 mm Hg
0.29 atm(1.01325 bar/1 atm) = 0.29 bar
0.29 bar(10^5 Pa/1 bar)(1 kPa/10^3 Pa) = 29 kPa

10.2 $V_2 = P_1V_1/P_2 =$
(745 mm Hg)(65.0 L)/[0.70(745 mm Hg)] = 93 L

10.3 V_1 = 45 L and T_1 = 298 K; V_2 = ? and T_2 = 263 K
$V_2 = V_1(T_2/T_1)$ = (45 L)(263 K/298 K) = 40. L

10.4 $V_2 = V_1(P_1/P_2)(T_2/T_1) =$
(22 L)(150 atm/0.9934 atm)(295 K/304 K) = 3200 L
At 5.0 L per balloon, there is sufficient He to fill 640 balloons.

10.5 44.8 L of O_2(g) is required; 44.8 L of H_2O(g) and 22.4 L of CO_2(g) are produced.

10.6 $PV = nRT$
(750/760 atm)(V) =
(1300 mol)(0.08206 L · atm/mol · K)(296 K)
$V = 3.2 \times 10^4$ L

10.7 According to Equation 10.5, density is inversely proportional to T (K).
d (at 55° C) = (1.18 g/L)(298 K/328 K) = 1.07 g/L

10.8 $PV = (m/M)RT$; $M = mRT/PV$
M = (0.105 g)(0.08206 L · atm/mol · K)(296.2 K)/
[(561/760) atm (0.125 L)] = 27.7 g/mol

10.9 2 Na(s) + 2 $H_2O(\ell) \rightarrow$ 2 NaOH(aq) + H_2(g)
Amount H_2 = (15.0 g Na)(1 mol Na/22.99 g Na)
(1 mol H_2/2 mol Na) = 0.3262 mol
Volume of H_2 = $V = nRT/P$ = (0.3262 mol)
(0.08206 L atm/mol K)(298.2 K)/1.10 atm = 7.26 L

10.10 $P_{halothane}$ (5.00 L) =
(0.0760 mol)(0.08206 L · atm/mol · K) (298.2 K)
$P_{halothane}$ = 0.3719 atm (or 282.7 mm Hg)
= 0.372 atm (or 283 mm Hg)
P_{oxygen} (5.00 L) =
(0.734 mol)(0.08206 L · atm/mol · K)(298.2 K)
P_{oxygen} = 3.592 atm (or 2730 mm Hg)
= 3.59 atm (or 2730 mm Hg)
$P_{total} = P_{halothane} + P_{oxygen} =$
282.7 mm Hg + 2730 mm Hg = 3010 mm Hg

10.11 For He: Use Equation 10.9, with M = 4.00×10^{-3} kg/mol, T = 298 K, and R = 8.314 J/mol · K to calculate the rms speed of 1360 m/s. A similar calculation for N_2, with $M = 28.01 \times 10^{-3}$ kg/mol, gives an rms speed of 515 m/s.

10.12 The molar mass of CH_4 is 16.0 g/mol.

$$\frac{\text{Rate for } CH_4}{\text{Rate for unknown}} = \frac{n \text{ molecules}/1.50 \text{ min}}{n \text{ molecules}/4.73 \text{ min}} = \sqrt{\frac{M_{unknown}}{16.0}}$$

$M_{unknown}$ = 159 g/mol

Applying Chemical Principles

10.1 The Atmosphere and Altitude Sickness

1. Data points for the graph: (0 m, 760 mm Hg), (3000 m, 532 mm Hg), (5000 m, 380 mm Hg), (8848 m, 220 mm Hg). As the altitude increases, the pressure decreases. Although the relationship at lower altitudes is close to linear, at the highest altitude there is a significant deviation from linearity. More data points from higher altitudes are needed, but this appears to be suggesting an asymptotic relationship. (Refer to the Internet for further information on atmospheric pressure *vs.* altitude to confirm this non-linear relationship.)
2. Atmospheric pressure = 90 mm Hg/0.21 = 429 mm Hg
Plotting the best-fit line for the first three points using Microsoft Excel gives a line with the equation: $y = -0.076x + 760$. Substituting y = 429 mm Hg into this equation gives a value of about 4400 m for x (elevation). There are not enough data to give a truly accurate and precise answer.

10.2 The Goodyear Blimp

1. d = PM/(RT) = (1.00 atm)(4.003 g/mol)/
[0.082057 L · atm/mol · K)(298.2 K)]
= 0.164 g/L

2. M = (28.01 g/mol)(0.7808) + (32.00 g/mol)(0.2095) +
(39.95 g/mol)(0.00934) + (44.01 g/mol)(0.000393)
= 28.96 g/mol

This compares well to the value reported in the footnote of Table 10.1 of 28.960 g/mol.

d = PM/(RT) = (1.00 atm)(28.960 g/mol)/
[0.082057 L · atm/mol · K)(298.2 K)]
= 1.184 g/L = 1.18 g/L

3. The volume of the blimp is the difference between the volume of its envelope (5740 m^3) and the volume of the ballonets (340 m^3). The volume of the blimp is thus 5400 m^3.

From Question 2, we know that the density of dry air is 1.184 g/L = 1.184 kg/m^3. To have neutral buoyancy, the blimp must have a mass of $m = V \times d$ = (5400 m^3) (1.184 kg/m^3) = 6391 kg

Mass of passengers + ballast = 6391 kg − 5820 kg
= 570 kg

10.3 The Chemistry of Airbags

1. (a) The decomposition of NaN_3 produces 3 mol N_2 from 2 mol NaN_3. From the reaction that captures the sodium by-product, there will be an additional 1 mol N_2 produced from 10 mol Na (or 0.2 mol of N_2 per 2 mol Na, which corresponds to 2 mol NaN_3). Adding these amounts of N_2 from the two reactions shows that 3.2 mol of N_2 will be produced per 2 mol of NaN_3.
First calculate the amount of N_2 needed using $PV = nRT$, and then complete the stoichiometry problem.
$n = (3.0\text{ atm})(75\text{ L})/[(0.08206\text{ L} \cdot \text{atm/mol} \cdot \text{K})(298.2\text{ K})] = 9.19\text{ mol } N_2$
$9.19\text{ mol } N_2(2\text{ mol } NaN_3/3.2\text{ mol } N_2)(65.01\text{ g } NaN_3/1\text{ mol } NaN_3) = 374\text{ g } NaN_3 = 370\text{ g } NaN_3$
(b) $374\text{ g } NaN_3(1\text{ mol } NaN_3/65.01\text{ g } NaN_3)(2\text{ mol Na}/2\text{ mol } NaN_3)(2\text{ mol } KNO_3/10\text{ mol Na})(101.1\text{ g } KNO_3/1\text{ mol } KNO_3) = 116\text{ g } KNO_3$

2. (a) 9.19 mol of gases are needed (see Question 1), and 3 mol (1 mol N_2O and 2 mol H_2O) of gas are produced per mol of NH_4NO_3.
$(9.19\text{ mol gases})(1\text{ mol } NH_4NO_3/3\text{ mol gases})(80.04\text{ g } NH_4NO_3/1\text{ mol } NH_4NO_3) = 250\text{ g } NH_4NO_3$
(b) 1.0 atm of $N_2O(g)$ and 2.0 atm of $H_2O(g)$

Study Questions

10.1 (a) 0.58 atm
(b) 0.59 bar
(c) 59 kPa

10.3 (a) 0.754 bar
(b) 650 kPa
(c) 934 kPa

10.5 2.70×10^2 mm Hg

10.7 3.7 L

10.9 250 mm Hg

10.11 3.2×10^2 mm Hg

10.13 9.72 atm

10.15 (a) 75 mL O_2
(b) 150 mL NO_2

10.17 0.919 atm

10.19 $V = 2.9$ L

10.21 1.9×10^6 g He

10.23 3.7×10^{-4} g/L

10.25 34.0 g/mol

10.27 57.5 g/mol

10.29 Molar mass = 74.9 g/mol; (d) B_6H_{10}

10.31 0.096 atm; 73 mm Hg

10.33 170 g NaN_3

10.35 1.7 atm O_2

10.37 4.1 atm H_2; 1.6 atm Ar; total pressure = 5.7 atm

10.39 (a) 0.30 mol halothane/1 mol O_2
(b) 3.0×10^2 g halothane

10.41 (a) CO_2 has the higher kinetic energy.
(b) The root mean square speed of the H_2 molecules is greater than the root mean square speed of the CO_2 molecules.
(c) The number of CO_2 molecules is greater than the number of H_2 molecules $[n(CO_2) = 1.8n(H_2)]$.
(d) The mass of CO_2 is greater than the mass of H_2.

10.43 Average speed of CO_2 molecules = 3.65×10^4 cm/s

10.45 Average speed increases (and molar mass decreases) in the order $CH_2F_2 < Ar < N_2 < CH_4$.

10.47 (a) F_2 (38 g/mol) effuses faster than CO_2 (44 g/mol).
(b) N_2 (28 g/mol) effuses faster than O_2 (32 g/mol).
(c) C_2H_4 (28.1 g/mol) effuses faster than C_2H_6 (30.1 g/mol).
(d) $CFCl_3$ (137 g/mol) effuses faster than $C_2Cl_2F_4$ (171 g/mol).

10.49 36 g/mol

10.51 (c) 10 atm, 0 °C (high pressure and low temperature)

10.53 P from the van der Waals equation = 26.0 atm
P from the ideal gas law = 30.6 atm

10.55 (a) As an ideal gas, $P = 162$ atm. Using the van der Waals equation, $P = 111.10$ atm.
(b) $a(n/V)^2$

10.57

	atm	mm Hg	kPa	bar
Standard atmosphere	1	760	101.325	1.013
N_2 partial pressure	0.780	593	79.1	0.791
H_2 pressure	131	9.98×10^4	1.33×10^4	133
Air	0.333	253	33.7	0.337

10.59 $T = 290.$ K or 17 °C

10.61 $2\ C_4H_9SH(g) + 15\ O_2(g) \rightarrow 8\ CO_2(g) + 10\ H_2O(g) + 2\ SO_2(g)$
Total pressure = 37.3 mm Hg. Partial pressures: CO_2 = 14.9 mm Hg, H_2O = 18.6 mm Hg, and SO_2 = 3.73 mm Hg.

10.63 4 mol

10.65 $V = 44.8$ L O_2

10.67 Ni is the limiting reactant; 1.31 g $Ni(CO)_4$

10.69 (a, b) Sample 4 (He) has the largest number of molecules and sample 3 (H_2 at 27 °C and 760 mm Hg) has the fewest number of molecules.
(c) Sample 2 (Ar)

10.71 8.54 g $Fe(CO)_5$

10.73 S_2F_{10}

10.75 (a) 28.7 g/mol ≃ 29 g/mol
(b) X of O_2 = 0.17 and X of N_2 = 0.83

10.77 Molar mass = 86.4 g/mol. The gas is probably ClO_2F.

10.79 Calculate molar mass (44 g/mol). Gas is probably CO_2.

10.81 (d) is not correct. The rate of effusion is really inversely proportional to the square root of a gas's molar mass.

10.83 1.3×10^2 g/mol

10.85 $n(He) = 0.0128$ mol

10.87 Weight percent $KClO_3 = 69.1\%$

10.89 (a) $NO_2 < O_2 < NO$
(b) $P(O_2) = 75$ mm Hg
(c) $P(NO_2) = 150$ mm Hg

10.91 $P(NH_3) = 69$ mm Hg and $P(F_2) = 51$ mm Hg
Pressure after reaction = 17 mm Hg

10.93 (a) At 20 °C, there is 7.8×10^{-3} g H_2O/L.
(b) At 0 °C, there is 4.6×10^{-3} g H_2O/L. The mass of water is greater at 20 °C and 45% relative humidity.

10.95 The mixture contains 0.22 g CO_2 and 0.77 g CO.
$P(CO_2) = 0.22$ atm; $P(O_2) = 0.12$ atm;
$P(CO) = 1.22$ atm

10.97 The formula of the iron compound is $Fe(CO)_5$.

10.99 (a) $P(B_2H_6) = 0.0160$ atm
(b) $P(H_2) = 0.0320$ atm, so $P_{total} = 0.0480$ atm

10.101 Amount of $Na_2CO_3 = 0.00424$ mol
Amount of $NaHCO_3 = 0.00951$ mol
Amount of CO_2 produced = 0.0138 mol
Volume of CO_2 produced = 0.343 L

10.103 Decomposition of 1 mol of $Cu(NO_3)_2$ should give 2 mol NO_2 and $^1/_2$ mol of O_2. Total actual amount $= 4.72 \times 10^{-3}$ mol of gas.
Average molar mass = 41.3 g/mol
Mole fractions: $X(NO_2) = 0.666$ and $X(O_2) = 0.334$
Amount of each gas: 3.13×10^{-3} mol NO_2 and 1.57×10^{-3} mol O_2. The ratio of these amounts is 1.99 mol NO_2/mol O_2. This is different from the 4 mol NO_2/mol O_2 ratio expected from the reaction. If some NO_2 molecules combine to form N_2O_4, the apparent mole fraction of NO_2 would be smaller than expected (= 0.8). As this is the case, it is apparent that some N_2O_4 has been formed (as is observed in the experiment).

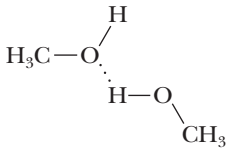
10.105 (a) $M = 138$ g/mol; the unknown compound is P_2F_4.
(b) $M = 1.4 \times 10^2$ g/mol; this is consistent with the result obtained in part (a).

10.107 (a) 10.0 g of O_2 represents more molecules than 10.0 g of CO_2. Therefore, O_2 has the greater partial pressure.
(b) The average speed of the O_2 molecules is greater than the average speed of the CO_2 molecules.
(c) The gases are at the same temperature and so have the same average kinetic energy.

10.109 (a) $P(C_2H_2) > P(CO)$
(b) There are more molecules in the C_2H_2 container than in the CO container.

10.111 (a) Not a gas. A gas would expand to an infinite volume.
(b) Not a gas. A density of 8.2 g/mL is typical of a solid.
(c) Insufficient information
(d) Gas

10.113 (a) There are more molecules of H_2 than atoms of He.
(b) The mass of He is greater than the mass of H_2.



10.115 The speed of gas molecules is related to the square root of the absolute temperature, so a doubling of the temperature will lead to an increase of about $(2)^{1/2}$ or 1.4.

Chapter 11

Check Your Understanding

11.1 Because F^- is the smaller ion, water molecules can approach more closely and interact more strongly. Thus, F^- should have the more negative enthalpy of hydration.

11.2

Hydrogen bonding in methanol entails the attraction of the hydrogen atom bearing a partial positive charge (δ^+) on one molecule to the oxygen atom bearing a partial negative charge (δ^-) on a second molecule. The strong attractive force of hydrogen bonding will cause the boiling point and the enthalpy of vaporization of methanol to be quite high.

11.3 Water is a polar solvent, while hexane and CCl_4 are nonpolar. London dispersion forces are the primary forces of attraction between all pairs of dissimilar solvents. For mixtures of water with the other solvents, dipole–induced dipole forces will also be important.

11.4 (a) O_2: induced dipole–induced dipole forces only.
(b) CH_3OH: strong hydrogen bonding (dipole–dipole forces) as well as induced dipole–induced dipole forces.
(c) Forces between water molecules: strong hydrogen bonding and induced dipole–induced dipole forces. Between N_2 and H_2O: dipole-induced dipole forces and induced dipole–induced dipole forces.

11.5 $(1.00 \times 10^3$ g)(1 mol/32.04 g)(35.2 kJ/mol) $= 1.10 \times 10^3$ kJ

11.6 (a) At 40 °C, the vapor pressure of ethanol is about 120 mm Hg.
(b) The equilibrium vapor pressure of ethanol at 60 °C is about 320 mm Hg. At 60 °C and 600 mm Hg, ethanol is a liquid. If vapor is present, it will condense to a liquid.

Applying Chemical Principles

11.1 Chromatography

1. (a) The 1,5-pentanediol is most attracted to the mobile phase. The primary attractive force is hydrogen bonding. Dipole–dipole forces and dispersion forces are also present.
(b) The ethyl propyl ether is most attracted to the stationary phase by dispersion forces but there are also some dipole–induced dipole interactions.
(c) The molecules will elute in the following order (first to last): 1,5-pentanediol, 1-pentanol, and propyl ethyl ether.

2. Order of elution from first to last: pentane, hexane, octane. The forces of attraction between the hydrocarbons and the stationary phase increase in this order.

11.2 A Pet Food Catastrophe

1. % N in melamine = 84/126 × 100 = 67%

% N in cyanuric acid = 42/129 × 100 = 33%

Both of these compounds have a greater percentage of nitrogen than the average protein.

2. 454 g sample (0.14 g melamine/1,000,000 g sample) = 6.4×10^{-5} g melamine = 0.064 mg melamine = 64 μg melamine

Study Questions

11.1 (a) Dipole–dipole interactions (and hydrogen bonds)
(b) Induced dipole–induced dipole forces
(c) Dipole–dipole interactions (and hydrogen bonds)

11.3 (a) Induced dipole–induced dipole forces
(b) Induced dipole–induced dipole forces
(c) Dipole–dipole forces
(d) Dipole–dipole forces (and hydrogen bonding)

11.5 (a), (b), and (c). The boiling points of these liquids are: Ne, (−246 °C), CO (−192 °C), CH_4 (−162 °C), and CCl_4 (77 °C).

11.7 (c) HF; (d) acetic acid; (f) CH_3OH

11.9 (a) LiCl. The Li^+ ion is smaller than Cs^+ (Figure 7.11), which makes the ion–ion forces of attraction stronger in LiCl.
(b) $Mg(NO_3)_2$. The Mg^{2+} ion is smaller than the Na^+ ion (Figure 7.11), and the magnesium ion has a 2+ charge (as opposed to 1+ for sodium). Both of these effects lead to stronger ion–ion forces of attraction in magnesium nitrate.
(c) $NiCl_2$. The nickel(II) ion has a larger charge than Rb^+ and is considerably smaller. Both effects mean that there are stronger ion–ion forces of attraction in nickel(II) chloride.

11.11 q = +90.1 kJ

11.13 (a) Water vapor pressure is about 150 mm Hg at 60 °C. (Appendix G gives a value of 149.4 mm Hg at 60 °C.)
(b) 600 mm Hg at about 93 °C
(c) At 70 °C, ethanol has a vapor pressure of about 520 mm Hg, whereas that of water is about 225 mm Hg.

11.15 At 30 °C, the vapor pressure of ether is about 590 mm Hg. (This pressure requires 0.23 g of ether in the vapor phase at the given conditions, so there is sufficient ether in the flask.) At 0 °C, the vapor pressure is about 160 mm Hg, so some ether condenses when the temperature declines.

11.17 (a) O_2 (−183 °C) (bp of N_2 = −196 °C)
(b) SO_2 (−10 °C) (CO_2 sublimes at −78 °C)
(c) HF (+19.7 °C) (HI, −35.6 °C)
(d) GeH_4 (−90.0 °C) (SiH_4, −111.8 °C)

11.19 (a) CS_2, about 620 mm Hg; CH_3NO_2, about 80 mm Hg
(b) CS_2, induced dipole–induced dipole forces; CH_3NO_2, dipole–dipole forces
(c) CS_2, about 46 °C; CH_3NO_2, about 100 °C
(d) About 39 °C
(e) About 95 °C

11.21 (a) 80.1 °C
(b) At about 48 °C, the liquid has a vapor pressure of 250 mm Hg. The vapor pressure is 650 mm Hg at 75 °C.
(c) 33.5 kJ/mol (from slope of plot)

11.23 No, CO cannot be liquefied at room temperature because the critical temperature is lower than room temperature.

11.25 The layer of molecules on the surface of a liquid is harder to break through than the bulk liquid. The energy needed to break through this skin is the surface tension. An application of surface tension is that it is possible to float a paperclip on the surface of water, but if the paperclip breaks through the surface, it will sink. Surface tension results from intermolecular forces because molecules in the interior of a liquid interact through intermolecular forces with molecules all around them, but molecules on the surface have intermolecular forces only with molecules at or below the surface layer and thus feel a net inward force of attraction.

11.27 This phenomenon results from capillary action. The water is attracted to —OH groups in the paper. As a result of these adhesive forces, some water molecules begin to move up the paper. Other water molecules remain in contact with these water molecules by means of cohesive forces. A stream of water molecules thus moves up the paper.

11.29 (a) Induced dipole-induced dipole
(b) Induced dipole-induced dipole, dipole-dipole
(c) Induced dipole-induced dipole, dipole-dipole, hydrogen bonding.

11.31 Li^+ ions are smaller than Cs^+ ions (78 pm and 165 pm, respectively; see Figure 7.11). Thus, there will be a stronger attractive force between Li^+ ions and water molecules than between Cs^+ ions and water molecules.

11.33 (a) 350 mm Hg
(b) Ethanol (lower vapor pressure at every temperature)
(c) 84 °C
(d) CS_2, 46 °C; C_2H_5OH, 78 °C; C_7H_{16}, 99 °C
(e) CS_2, gas; C_2H_5OH, gas; C_7H_{16}, liquid

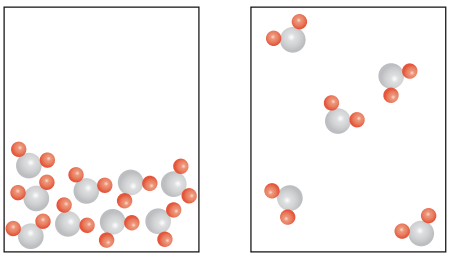
11.35 Molar enthalpy of vaporization increases with increasing intermolecular forces: C_2H_6 (14.69 kJ/mol; induced dipole) < HCl (16.15 kJ/mol; dipole) < CH_3OH (35.21 kJ/mol, hydrogen bonds). (The molar enthalpies of vaporization here are given at the boiling point of the liquid.)

11.37 5.49×10^{19} atoms/m^3

11.39 (a) 70.3 °C

(b)

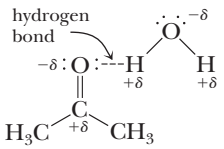
Using the equation for the straight line in the plot



$\ln P = -3885\ (1/T) + 17.949$

we calculate that T = 311.6 K (39.5 °C) when P = 250 mm Hg. When P = 650 mm Hg, T = 338.7 K (65.5 °C).

(c) Calculated $\Delta_{vap}H$ = 32.3 kJ/mol



11.41 (a) When the can is inverted in cold water, the water vapor pressure in the can, which was approximately 760 mm Hg, drops rapidly—say, to 9 mm Hg at 10 °C. This creates a partial vacuum in the can, and the can is crushed because of the difference in pressure inside the can and the pressure of the atmosphere pressing down on the outside of the can.

(b)

Before heating | After heating

11.43 Acetone and water can interact by hydrogen bonding.

11.45 Ethylene glycol's viscosity will be greater than ethanol's, owing to the greater hydrogen-bonding capacity of ethylene glycol.

11.47 (a) Water has two OH bonds and two lone pairs, whereas the O atom of ethanol has only one OH bond (and two lone pairs). More extensive hydrogen bonding is likely for water.

(b) Water and ethanol interact extensively through hydrogen bonding, so the volume is expected to be slightly smaller than the sum of the two volumes.

11.49 Two pieces of evidence for $H_2O(\ell)$ having considerable intermolecular attractive forces:

(a) Based on the boiling points of the Group 6A hydrides (Figure 11.4), the boiling point of water should be approximately −80 °C. The actual boiling point of 100 °C reflects the significant hydrogen bonding that occurs.

(b) Liquid water has a specific heat capacity that is higher than almost any other liquid. This reflects the fact that a relatively larger amount of energy is necessary to overcome intermolecular forces and raise the temperature of the liquid.

11.51 (a) HI, hydrogen iodide

(b) The large iodine atom in HI leads to a significant polarizability for the molecule and thus to a large dispersion force.

(c) The dipole moment of HCl (1.07 D, Table 8.6) is larger than for HI (0.38 D).

(d) HI. See part (b).

11.53 A gas can be liquefied at or below its critical temperature. The critical temperature for CF_4 (−45.7 °C) is below room temperature (25 °C), so it cannot be liquefied at room temperature.

11.55 Hydrogen bonding is most likely at the O—H group at the "right" end of the molecule, and at the C═O and N—H groups in the amide group (—NH—CO—).

11.57 Boiling point, enthalpy of vaporization, volatility, surface tension

11.59 The more branching in the hydrocarbons, the lower the boiling point. This implies weaker induced dipole–induced dipole forces. Greater branching results in a more compact shape with less surface area available for contact and therefore smaller induced dipole–induced dipole forces.

11.61 $F_2 < Cl_2 < Br_2 < I_2$

He < Ne < Ar < Kr < Xe

Molar mass and boiling point correlate with these orders.

11.63 The boiling point of the water in the pressure cooker is 121 °C.

11.65 Using the equation of the line from Question 11.64, P = 9.8 atm.

11.67 (a) There will be water in the tube in equilibrium with its vapor, but almost all of the water will be present as liquid water.

(b) 760. mm Hg

(c) 10.4 cm^3

(d) 0.0233 g H_2O

Chapter 12

Check Your Understanding

12.1 (a) The strategy to solve this problem is given in Example 12.1.

Step 1. Mass of the unit cell
= (197.0 g/mol)(1 mol/6.022 × 10^{23} atom)
(4 atoms/unit cell)
= 1.3085 × 10^{-21} g/unit cell

Step 2. Volume of unit cell
= (1.3085 × 10^{-21} g/unit cell)(1 cm^3/19.32 g)
= 6.7730 × 10^{-23} cm^3/unit cell

Step 3. Length of side of unit cell
= [6.7730 × 10^{-23} cm^3/unit cell]$^{1/3}$
= 4.0762 × 10^{-8} cm

Step 4. Calculate the radius from the edge dimension.

Diagonal distance = 4.0762 × 10^{-8} cm ($2^{½}$) = 4 (r_{Au})

r_{Au} = 1.441 × 10^{-8} cm (= 144.1 pm)

(b) To verify a body-centered cubic structure, calculate the mass contained in the unit cell. If the structure is bcc, then the mass will be the mass of 2 Fe atoms. (Other possibilities: fcc − mass of 4 Fe; primitive cubic − mass of 1 Fe atom.) This calculation uses the four steps from the previous exercise in reverse order.

Step 1. Use radius of Fe to calculate cell dimensions. In a body-centered cube, atoms touch across the diagonal of the cube.

Diagonal distance = side dimension ($\sqrt{3}$) = 4 r_{Fe}

Side dimension of cube =
4 (1.26 × 10^{-8} cm)/($\sqrt{3}$) = 2.910 × 10^{-8} cm

Step 2. Calculate unit cell volume

Unit cell volume = (2.910 × 10^{-8} cm)^3 =
2.464 × 10^{-23} cm^3

Step 3. Combine unit cell volume and density to find the mass of the unit cell.

Mass of unit cell = (2.464 × 10^{-23} cm^3) ×
(7.8740 g/cm^3) = 1.94 × 10^{-22} g

Step 4. Calculate the mass of 2 Fe atoms, and compare this to the answer from step 3.

Mass of 2 Fe atoms =
55.85 g/mol (1 mol/6.022 × 10^{23} atoms)(2 atoms)
= 1.85 × 10^{-22} g.

This is a fairly good match, and clearly much better than the two other possibilities, primitive and fcc.

12.2 M_2X. In a face-centered cubic unit cell, there are four anions and eight tetrahedral holes in which to place metal ions. All of the tetrahedral holes are inside the unit cell, so the ratio of atoms in the unit cell is 2:1.

12.3 We need to calculate the mass and volume of the unit cell from the information given. The density of KCl will then be mass/volume. Select units so the density is calculated as g/cm^3.

Step 1. Mass: The unit cell contains 4 K^+ ions and 4 Cl^- ions.

Unit cell mass = (39.10 g/mol)(1 mol/6.022 × 10^{23} K^+ ions)(4 K^+ ions) + (35.45 g/mol)(1 mol/6.022 × 10^{23} Cl^- ions)(4 Cl^- ions) = 2.5971 × 10^{-22} g + 2.3547 × 10^{-22} g = 4.9518 × 10^{-22} g

Step 2. Volume: Assuming K^+ and Cl^- ions touch along one edge of the cube, the side dimension = 2 r_{K^+} + 2 r_{Cl^-}. The volume of the cube is the cube of this value. (Convert the ionic radius from pm to cm.)

V = [2(1.33 × 10^{-8} cm) + 2(1.81 × 10^{-8} cm)]^3 = 2.477 × 10^{-22} cm^3

Step 3. Density = mass/volume =
4.9518 ×10^{-22} g/2.477 × 10^{-22} cm^3) = 2.00 g/cm^3

Applying Chemical Principles

12.1 Lithium and "Green Cars"

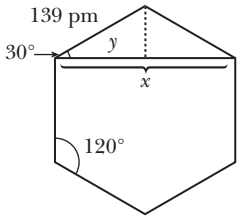
1. 73,000,000 metric tons Li_2CO_3 (13.88 metric tons Li/73.89 metric tons Li_2CO_3) = 1.4 × 10^7 metric tons Li (= 14 million metric tons Li)

2. The unit cell for lithium metal is body-centered cubic. (There are atoms at each of the corners of a cube and one atom embedded in the middle of the cube.)

3. 351 pm (1 m/10^{12} pm)(100 cm/1 m) = 3.51 × 10^{-8} cm

V of unit cell = (3.51 × 10^{-8} cm)^3 = 4.324 × 10^{-23} cm^3

Mass of unit cell = 6.941 g Li/mol
(1 mol/6.022 × 10^{23} atoms)(2 atoms/unit cell) =
2.3052 × 10^{-23} g/unit cell



Density = mass/volume =
2.3052 × 10^{-23} g/4.324 × 10^{-23} cm^3 = 0.533 g/cm^3

4. One method is to carry out the following gas-forming reaction:

$$Li_2CO_3(aq) + 2\ HCl(aq) \rightarrow 2\ LiCl(aq) + H_2O(\ell) + CO_2(g)$$

12.2 Nanotubes and Graphene—The Hottest New Network Solids

1. We want to know the distance *x* in the diagram of the hexagon. You know the interior angles in a hexagon are all 120°. To find *x*, we can find the distance *y* in the figure and then double it ($x = 2y$). The angle bounded by the side of the hexagon and *y* is 30°, and, from geometry, cos 30° = *y*/(hexagon side) so *y* = (cos 30°) (139 pm) = (0.866)(139 pm) = 120.4 pm. Finally, *x* = 240.8 pm = 241 pm.

2. 1.0 μm (1 m/10^6 μm)(10^{12} pm/1 m)(1 C_6-ring/240.8 pm) = 4.2×10^3 C_6-rings

3. The thickness would be approximately 150 pm. This corresponds to the diameter of a carbon atom, found by multiplying the radius of a carbon atom (given in Figure 7.5) by 2 and rounding off to two significant figures.

12.3 Tin Disease

1. β-Tin has four atoms in the unit cell. α-Tin has eight atoms in the unit cell.

2. Volume of unit cell = $(5.83 \times 10^{-8}$ cm)$(5.83 \times 10^{-8}$ cm)$(3.18 \times 10^{-8}$ cm) = 1.081×10^{-22} cm^3

   Mass of unit cell = (118.7 g Sn/1 mol Sn)(1 mol/6.022×10^{23} atoms)(4 atoms/unit cell) = 7.8844×10^{-22} g

   Density = 7.8844×10^{-22} g/1.081×10^{-22} cm^3 = 7.29 g/cm^3

3. There are eight atoms per unit cell (8 corner atoms $\times$ 1/8 + 6 face atoms $\times$ 1/2 + 4 body atoms $\times$ 1 = 8).

   Mass of unit cell = (118.7 g Sn/1 mol Sn)(1 mol/6.022×10^{23} atoms)(8 atoms/unit cell) = 1.5769×10^{-21} g

   Volume = mass/density = 1.5769×10^{-21} g/5.769 g/cm^3 = 2.7334×10^{-22} cm^3

   Length of one side = $(2.7334 \times 10^{-22}$ cm$^3)^{1/3}$ = 6.490×10^{-8} cm = 649.0 pm

4. Tetragonal: The unit cell of β-tin contains 4 atoms. The volume of the unit cell (from question 2) is 1.081×10^{-22} cm^3 = 1.081×10^8 pm^3. The volume of space occupied by four atoms is $V = 4(4/3)(\pi r^3) = 4[(4/3)\pi(141 \text{ pm})^3] = 4.697 \times 10^7$ pm^3. The percent of space occupied is (4.697×10^7 pm^3/1.081×10^8 pm^3) $\times$ 100% = 43.5%

   Cubic: The unit cell of gray tin contains 8 atoms. The volume of the unit cell (from question 3) is 2.7334×10^{-22} cm^3 = 2.7334×10^8 pm^3. The volume of space occupied by eight atoms is $V = 8(4/3)(\pi r^3) = 8[(4/3)\pi(141 \text{ pm})^3] = 9.394 \times 10^7$ pm^3. The percent of space occupied is (9.394×10^7 pm^3/2.7334×10^8 pm^3) $\times$ 100% = 34.4%.

Study Questions

12.1 Two possible unit cells are illustrated here. The simplest formula is AB_8.

12.3 (a) Body-centered cubic

(b) Mass of unit cell = (39.10 g K/1 mol K)(1 mol/6.022×10^{23} atoms)(2 atoms/unit cell) = 1.2986×10^{-22} g

Volume of unit cell = $(5.33 \times 10^{-8}$ cm$)^3$ = 1.514×10^{-22} cm^3

Density = 1.2986×10^{-22} g/1.514×10^{-22} cm^3 = 0.858 g/cm^3

12.5 Ca^{2+} ions at eight corners = 1 net Ca^{2+} ion

O^{2-} ions in six faces = 3 net O^{2-} ions

Ti^{4+} ion in center of unit cell = 1 net Ti^{4+} ion

Formula = $CaTiO_3$

12.7 (a) There are eight O^{2-} ions at the corners and one in the center for a net of two O^{2-} ions per unit cell. There are four Cu ions in the interior in tetrahedral holes. The ratio of ions is Cu_2O.
(b) The oxidation number of copper must be +1.

12.9 Calcium atom radius = 197 pm

12.11 There are three ways the edge dimensions can be calculated:
(a) Calculate mass of unit cell (= 1.103×10^{-21} g/uc)

Calculate volume of unit cell from mass (= 3.53×10^{-22} cm^3/uc)

Calculate edge length from volume (= 707 pm)
(b) Assume I^- ions touch along the cell diagonal (Check Your Understanding 12.1) and use I^- radius to find the edge length. Radius I^- = 220 pm

Edge = $4(220 \text{ pm})/2^{1/2}$ = 622 pm
(c) Assume the I^- and K^+ ions touch along the cell edge (page 537)

Edge = 2 $\times$ I^- radius + 2 $\times$ K^+ radius = 706 pm

Methods (a) and (c) agree. It is apparent that the sizes of the ions are such that the I^- ions cannot touch along the cell diagonal.

12.13 Increasing lattice energy: RbI < LiI < LiF < CaO

12.15 As the ion–ion distance decreases, the force of attraction between ions increases. This should make the lattice more stable, and more energy should be required to melt the compound.

12.17 $\Delta_f H° = -607$ kJ/mol

12.19 The 1000 2*s* orbitals will combine to form 1000 molecular orbitals. In the lowest energy state, 500 of these will be populated by pairs of electrons, and 500 will be empty.

12.21 In metals, thermal energy causes some electrons to occupy higher-energy orbitals in the band of molecular orbitals. For each electron promoted, two singly occupied levels result: a negative electron above the Fermi level and a positive hole below the Fermi level. Electrical conductivity results because in the presence of an electric field, these negative electrons will move toward the positive side of the field and the positive holes will move toward the negative side.

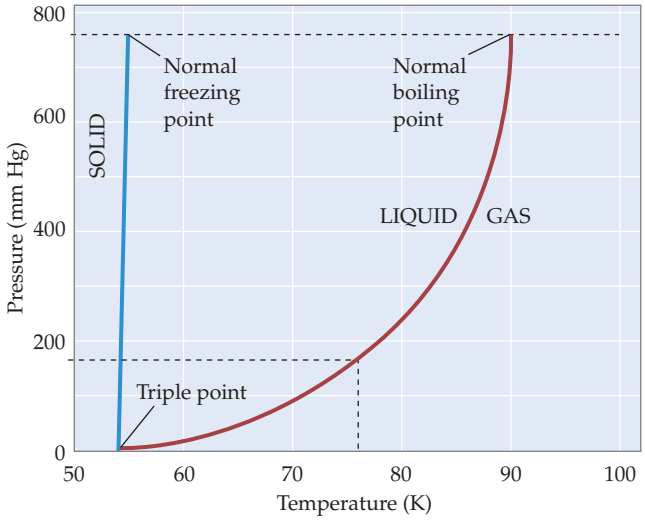
12.23 In carbon the band gap is too large for electrons to move up in energy from the valence band to the conduction band, whereas in silicon the band gap is small enough to permit this.

12.25 An intrinsic semiconductor (such as Si or Ge) is one that naturally can have electrons move across the band gap, whereas an extrinsic semiconductor (such as Ge with added As) requires the addition of dopants in order for it to conduct.

12.27 (c) Buckyballs (made up of C_{60} molecules)

12.29 (a) Eight C atoms per unit cell. There are eight corners (= 1 net C atom), six faces (= 3 net C atoms), and four internal C atoms.
(b) Face-centered cubic (fcc) with C atoms in the tetrahedral holes

12.31 Type of solid: particles, forces of attraction
(a) Metallic: metal atoms, electrostatic forces between metal ions and a sea of electrons
(b) Ionic: ions, ion–ion interactions
(c) Molecular: molecules, covalent bonds within the molecules and intermolecular forces between the molecules
(d) Network: extended network of covalently bonded atoms, covalent bonds
(e) Amorphous: covalently bonded networks with no long-range regularity, covalent bonds
(f) Alloy: two or more metal atoms, electrostatic forces between metal ions and a sea of electrons



12.33 Substance: type of solid, particles, forces, property
(a) Gallium arsenide: network, covalently bonded atoms, covalent bonds, semiconductor
(b) Polystyrene: amorphous, covalent bonds within the polymer molecules and dispersion forces between the polymer molecules, thermal insulator
(c) Silicon carbide: network, covalently bonded atoms, covalent bonds, very hard material
(d) Perovskite: ionic, Ca^{2+} and TiO_3^{2-} ions, ion–ion interactions, high melting point

12.35 q (for fusion) = −1.97 kJ; q (for melting) = +1.97 kJ

12.37 (a) The density of liquid CO_2 is less than that of solid CO_2.
(b) CO_2 is a gas at 5 atm and 0 °C.
(c) Critical temperature = 31 °C, so CO_2 cannot be liquefied at 45 °C.

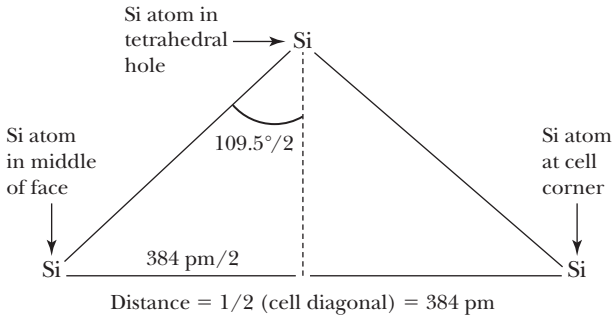
12.39 q (to heat the liquid) = 9.42×10^2 kJ
q (to vaporize NH_3) = 1.64×10^4 kJ
q (to heat the vapor) = 8.79×10^2 kJ
$q_{total} = 1.8 \times 10^4$ kJ

12.41 O_2 phase diagram. (i) Note the slight positive slope of the solid–liquid equilibrium line. It indicates that the density of solid O_2 is greater than that of liquid O_2. (ii) Using the diagram here, the vapor pressure of O_2 at 77 K is between 150 and 200 mm Hg.

12.43 Radius of silver = 145 pm

12.45 1.356×10^{-8} cm (literature value is 1.357×10^{-8} cm)

12.47 Mass of 1 CaF_2 unit calculated from crystal data = 1.29633×10^{-22} g. Divide molar mass of CaF_2 (78.077 g/mol) by mass of 1 CaF_2 to obtain Avogadro's number. Calculated value = 6.0230×10^{23} CaF_2/mol.



12.49 Diagram A leads to a surface coverage of 78.5%. Diagram B leads to 90.7% coverage.

12.51 (a) The lattice can be described as an fcc lattice of Si atoms.
(b) Si atoms are located in one half of the tetrahedral holes.
(c) There are eight Si atoms in the unit cell.
(d) Mass of unit cell = 3.7311×10^{-22} g
Volume of unit cell = 1.6019×10^{-22} cm^3
Density = 2.329 g/cm^3 (which is the same as the literature value)

(e) In the Si unit cell we cannot assume the atoms touch along the edge or along the face diagonal. Instead, we know that the Si atoms in the tetrahedral holes are bonded to the Si atoms at the corner.

Distance = 1/2 (cell diagonal) = 384 pm

Distance across cell face diagonal = 768.1 pm

Sin (109.5°/2) = 0.8166 = (384.0 pm/2)/(Si-Si distance)

Distance from Si in tetrahedral hole to face or corner Si = 235.1 pm

Si radius = 118 pm

Figure 7.5 gives Si radius as 117 pm

12.53 (a) Mg^{2+} ions are in $^1/_8$ of the eight possible tetrahedral holes, and Al^{3+} ions are in $^1/_2$ of the four available octahedral holes.
(b) Fe^{2+} ions are in $^1/_8$ of the eight possible tetrahedral holes, and Cr^{3+} ions are in $^1/_2$ of the four available octahedral holes.

12.55 8.5×10^2 nm

12.57 Germanium has a smaller band gap, so it has a higher conductivity.

12.59 Because boron is electron deficient in comparison to carbon, this is a p-type semiconductor.

12.61 Lead(II) sulfide has the same structure as sodium chloride, not the same structure as ZnS. There are four Pb^{2+} ions and four S^{2-} ions per unit cell, a 1:1 ratio that matches the compound formula.

12.63 4 formula units/unit cell; mass of unit cell = 7.905×10^{-22} g

Dimension of one side of unit cell = $2r(K^+) + 2r(Br^-) = 6.58 \times 10^{-8}$ cm; so volume of the unit cell = $side^3 = 2.849 \times 10^{-22}$ cm^3

Density = 7.905×10^{-22} g/2.849×10^{-22} cm^3 = 2.77 g/cm^3

12.65 (a) $BBr_3(g) + PBr_3(g) + 3\ H_2(g) \rightarrow BP(s) + 6\ HBr(g)$
(b) If B atoms are in an fcc lattice, then the P atoms must be in $^1/_2$ of the tetrahedral holes. (In this way it resembles Si in Question 12.51.)
(c) Unit cell volume = 1.092×10^{-22} cm^3
Unit cell mass = 2.775×10^{-22} g
Density = 2.54 g/cm^3
(d) The solution to this problem is identical to Question 12.51. In the BP lattice, the cell face diagonal is 676.0 pm. Therefore, the calculated BP distance is 207 pm.

12.67 Assuming the spheres are packed in an identical way, the water levels are the same. A face-centered cubic lattice, for example, uses 74% of the available space, regardless of the sphere size.

12.69 Step 1. There are four atoms within a ccp unit cell. Calculate the volume of these four atoms (V of a sphere = $(4/3)\pi r^3$).

Step 2. Calculate the total volume of the unit cell ($V_{cell} = side^3$).

Step 3. Percent occupancy = $(V_{atoms}/V_{cell})100\%$

12.71 (a) Two triple points. One with diamond, graphite and liquid C; the second with liquid C, graphite, and carbon vapor.
(b) No
(c) Diamond
(d) Graphite is the stable form of carbon at room temperature and 1 atmosphere of pressure.

Chapter 13

Check Your Understanding

13.1 (a) 10.0 g sucrose = 0.02921 mol; 250. g H_2O = 13.88 mol

$X_{sucrose}$ = (0.02921 mol)/(0.02921 mol + 13.88 mol) = 0.00210

$c_{sucrose}$ = (0.02921 mol sucrose)/(0.250 kg solvent) = 0.117 *m*

Weight % sucrose = (10.0 g sucrose/260.0 g soln)(100%) = 3.85%

(b) 1.08×10^4 ppm = 1.08×10^4 mg Na^+ per 1000 g soln = (1.08×10^4 mg Na^+/1000 g soln)(1050 g soln/1 L) = 1.134×10^4 mg Na^+/L = 11.34 g Na^+/L

(11.34 g Na^+/L)(58.44 g NaCl/22.99 g Na^+) = 28.8 g NaCl/L

13.2 $\Delta_{soln}H° = \Delta_fH°[NaOH(aq)] - \Delta_fH°[NaOH(s)]$
$= -469.2$ kJ/mol $- (-425.9$ kJ/mol)
$= -43.3$ kJ/mol

13.3 Solubility of $CO_2 = k_HP_g = 0.034$ mol/kg · bar $\times$ 0.33 bar = 1.1×10^{-2} mol/kg

13.4 The solution contains sucrose [(10.0 g)(1 mol/342.3 g) = 0.02921 mol] in water [(225 g)(1 mol/18.02 g) = 12.49 mol].

X_{water} = (12.49 mol H_2O)/(12.49 mol + 0.02921 mol) = 0.9977

$P_{water} = X_{water}P°_{water}$ = 0.9977(149.4 mm Hg) = 149 mm Hg

13.5 $c_{glycol} = \Delta T_{bp}/K_{bp}$ = 1.0 °C/(0.512 °C/*m*) = 1.95 *m* = 1.95 mol/kg

$mass_{glycol}$ = (1.95 mol/kg)(0.125 kg)(62.07 g/mol) = 15 g

13.6 c_{glycol} = (525 g)(1 mol/62.07 g)/(3.00 kg) = 2.819 *m*

$\Delta T_{fp} = K_{fp} \times m = (-1.86\ °C/m)(2.819\ m)$
$= -5.24\ °C$

You will be protected only to about −5 °C and not to −25 °C.

13.7 *c* (mol/L) = (0.033 g bradykinin)(1 mol bradykinin/1060 g bradykinin)/0.0500 L = 6.23×10^{-4} M

$\Pi = cRT = (6.23 \times 10^{-4}\ mol/L)$
$(0.082057\ L \cdot atm/mol \cdot K)(293\ K) = 0.015\ atm$

13.8 $\Delta T_{fp} = 5.265\ °C - 5.50\ °C = -0.235\ °C$

$\Delta T_{fp} = K_{fp} \times m_{solute}$

$m_{solute} = -0.235\ °C/-5.12\ °C/m = 0.0459$ mol/kg

m_{solute} = (0.0459 mol solute/kg benzene)
(0.02346 kg benzene) = 0.00108 mol solute

M = 0.448 g/0.00108 mol = 416 g/mol

M(compound)/M(empirical formula) =
416 g/mol/104.1 g/mol = 4.0

Molecular formula = $(C_2H_5)_8Al_4F_4$

13.9 *c* (mol/L) = Π/RT = [(1.86 mm Hg)(1 atm/760 mm Hg)]/[(0.08206 L · atm/mol · K)(298 K)] = 1.001×10^{-4} M

$(1.001 \times 10^{-4}\ mol/L)(0.100\ L) = 1.001 \times 10^{-5}$ mol

Molar mass = 1.40 g/1.001×10^{-5} mol =
1.40×10^{5} g/mol

(Assuming the polymer is composed of CH_2 units, the polymer is about 10,000 units long.)

13.10 c_{NaCl} = (25.0 g NaCl)(1 mol/58.44 g)/(0.525 kg)
= 0.8148 *m*

$\Delta T_{fp} = K_{fp} \times m \times i = (-1.86\ °C/m)(0.8148\ m)(1.85)$
$= -2.80\ °C$

Applying Chemical Principles

13.1 Distillation

1. X(hexane) = 0.59

2. Four plates

3. Mass hexane = 0.20 mol C_6H_{14}(86.18 g C_6H_{14}/1 mol C_6H_{14}) = 17.2 g C_6H_{14}

Mass heptane = 0.80 mol C_7H_{16}(100.20 g C_7H_{16}/1 mol C_7H_{16}) = 80.2 g C_7H_{16}

Mass percent hexane = 17.2 g C_6H_{14}/(17.2 g C_6H_{14} + 80.2 g C_7H_{16}) × 100% = 18% hexane

4. $\ln(P_2/P_1) = -(\Delta_{vap}H/R)(1/T_2 - 1/T_1)$

$\ln(361.5\ mm\ Hg/760\ mm\ Hg) = -(\Delta_{vap}H/$
$0.0083145\ kJ/\ mol \cdot K)(1/348.2\ K - 1/371.6\ K)$

$\Delta_{vap}H$ = 34.2 kJ/mol

13.2 Henry's Law and Exploding Lakes

1. $PV = nRT$

4.0 atm(0.025 L) = n(0.08206 L · atm/mol · K)(298 K);
$n = 4.1 \times 10^{-3}$ mol

2. $P_1V_1 = P_2V_2$

4.0 atm(0.025 L) = 3.7×10^{-4} atm (V_2); V_2 = 270 L

The gas expanded by a factor of 11,000 (= 270 L/0.025 L).

3. Solubility of $CO_2 = k_HP_g$ = 0.034 mol/kg · bar
(3.7 × 10^{-4} bar) = 1.26×10^{-5} mol/kg
= 1.3×10^{-5} mol/kg

4. Before opening: Solubility of CO_2 before opening = k_HP_g = 0.034 mol/kg · bar (4.0 bar) = 0.136 mol/kg

Assume the density of the solution is 1.0 g/cm³, therefore 1.0 L corresponds to 1.0 kg. The amount of CO_2 dissolved is 0.136 mol.

After opening: Solubility of $CO_2 = 1.26 \times 10^{-5}$ mol/kg as calculated in part 3 above. The amount of CO_2 in 1.0 kg is 1.26×10^{-5} mol.

Mass of CO_2 released = (0.136 mol CO_2 − 1.26×10^{-5} mol CO_2)(44.01 g CO_2/1 mol CO_2) = 6.0 g CO_2

13.3 Narcosis and the Bends

1. Density of water in SI units = 1.00 g/cm³(1 kg/1000 g)(100 cm/1 m)³ = 1.00×10^3 kg/m³

Pressure of water in pascals = density × acceleration due to gravity × depth = 1.00×10^3 kg/m³(9.81 m/s²)(10.0 m) = 9.81×10^4 Pa

Pressure of water in atm = 9.81×10^4 Pa(1 atm/101325 Pa) = 0.9682 atm

Total pressure = 1.000 atm + 0.9682 atm = 1.9682 atm = 1.968 atm

Partial pressure of $N_2 = X_{N_2}(P_{total})$ = 0.7808(1.9682 atm) = 1.537 atm

Partial pressure of $O_2 = X_{O_2}(P_{total})$ = 0.2095(1.9682 atm) = 0.4123 atm

2. Partial pressure of $O_2 = X_{O_2}(P_{total})$ = 0.2095(3.0 atm) = 0.629 atm

Solubility of $O_2 = k_HP_g$ = $(1.3 \times 10^{-3}$ mol/kg · bar)(0.629 atm)(1 bar/0.98692 atm) = 8.28×10^{-4} mol/kg = 8.3×10^{-4} mol/kg

Assume the density of water is 1.00 g/cm³, so 1.0 L corresponds to 1.0 kg of water.

1.0 kg(8.28×10^{-4} mol O_2/kg)(32.00 g O_2/mol O_2) = 0.026 g O_2

3. Partial pressure of $N_2 = X_{N_2}(P_{total})$ = 0.7808(1.0 atm) = 0.781 atm

Solubility of $N_2 = k_HP_g$ = $(6.0 \times 10^{-4}$ mol/kg · bar)(0.781 atm)(1 bar/0.98692 atm) = 4.75×10^{-4} mol/kg

Partial pressure of $O_2 = X_{O_2}(P_{total})$ = 0.209(1.0 atm) = 0.209 atm

Solubility of $O_2 = k_HP_g$ = $(1.3 \times 10^{-3}$ mol/kg · bar)(0.209 atm)(1 bar/0.98692 atm) = 2.75×10^{-4} mol/kg

In 1.0 L (= 1.0 kg) of H_2O, there are 4.75×10^{-4} mol N_2 and 2.75×10^{-4} mol O_2 that will be expelled.

$X_{O_2} = 2.75 \times 10^{-4}$ mol/(2.75×10^{-4} mol + 4.75×10^{-4} mol) = 0.37

Study Questions

13.1 Concentration (m) = 0.0434 m
Mole fraction of acid = 0.000781
Weight percent of acid = 0.509%

13.3

Compound	Molality	Weight Percent	Mole Fraction
NaI	0.15	2.2	2.7×10^{-3}
C_2H_5OH	1.1	5.0	0.020
$C_{12}H_{22}O_{11}$	0.15	4.9	2.7×10^{-3}

13.5 2.65 g Na_2CO_3; $X(Na_2CO_3) = 3.59 \times 10^{-3}$

13.7 220 g glycerol; 5.7 m

13.9 (a) 16.2 m; (b) 37.1%

13.11 Molality = 2.6×10^{-5} m (assuming that 1 kg of seawater is equivalent to 1 kg of solvent)

13.13 (b) and (c)

13.15 $\Delta_{soln}H°$ for LiCl = −36.9 kJ/mol. This is an exothermic enthalpy of solution, as compared with the very slightly endothermic value for NaCl.

13.17 Raise the temperature of the solution, and add some NaCl. Above 40 °C the solubility increases with temperature.

13.19 2×10^{-3} g O_2

13.21 1100 mm Hg or 1.5 bar

13.23 (a) $S = 2.0 \times 10^{-3}$ mol/kg
(b) Raising the pressure to 1.7 atm will result in an increased concentration of dissolved O_2; lowering the pressure to 1.0 atm will lead to a lower concentration of dissolved O_2.

13.25 35.0 mm Hg

13.27 $X(H_2O)$ = 0.8692; 16.71 mol glycol; 1040 g glycol

13.29 Calculated boiling point = 84.2 °C

13.31 ΔT_{bp} = 0.8082 °C; solution boiling point = 62.51 °C

13.33 (a) Molality = 8.60 m; (b) 28.4%

13.35 Molality = 0.1948 m; ΔT_{fp} = fp = −0.362 °C

13.37 (a) ΔT_{fp} = −0.3482 °C; fp = −0.348 °C
(b) ΔT_{bp} = +0.09588 °C; bp = 100.0959 °C
(c) Π = 4.58 atm
The osmotic pressure is large and can be measured with a small experimental error.

13.39 Molar mass = 6.0×10^3 g/mol

13.41 Molar mass = 360 g/mol; $C_{20}H_{16}Fe_2$

13.43 Molar mass = 150 g/mol

13.45 Molar mass = 170 g/mol

13.47 Freezing point = −24.6 °C

13.49 0.08 m $CaCl_2$ < 0.1 m NaCl < 0.04 m Na_2SO_4 < 0.1 sugar

13.51 (a) $BaCl_2(aq) + Na_2SO_4(aq) \rightarrow BaSO_4(s) + 2\ NaCl(aq)$
(b) Initially, the $BaSO_4$ particles form a colloidal suspension.
(c) Over time, the particles of $BaSO_4$(s) grow and precipitate.

13.53 Molar mass = 110 g/mol

13.55 (a) Increase in vapor pressure of water
0.20 m Na_2SO_4 < 0.50 m sugar < 0.20 m KBr < 0.35 m ethylene glycol
(b) Increase in boiling point
0.35 m ethylene glycol < 0.20 m KBr < 0.50 m sugar < 0.20 m Na_2SO_4

13.57 (a) 0.4564 mol DMG and 11.40 mol ethanol; X(DMG) = 0.0385
(b) 0.869 m
(c) VP ethanol over the solution at 78.4 °C = 730.7 mm Hg
(d) bp = 79.5 °C

13.59 For ammonia: 23 m; $X(NH_3)$ = 0.29; 28%

13.61 0.592 g Na_2SO_4

13.63 (a) 0.20 m KBr; (b) 0.10 m Na_2CO_3

13.65 Freezing point = −11 °C

13.67 4.0×10^2 g/mol

13.69 4.7×10^{-4} mol/kg

13.71 (a) Molar mass = 4.9×10^4 g/mol
(b) $\Delta T_{fp} = -3.8 \times 10^{-4}$ °C
It would not be easy to determine the molar mass of starch by measuring the freezing point depression because the freezing point depression is so small.

13.73 $\Delta_{soln}H°$ [Li_2SO_4] = −28.0 kJ/mol
$\Delta_{soln}H°$ [LiCl] = −36.9 kJ/mol
$\Delta_{soln}H°$ [K_2SO_4] = +23.7 kJ/mol
$\Delta_{soln}H°$ [KCl] = +17.2 kJ/mol
Both lithium compounds have exothermic enthalpies of solution, whereas both potassium compounds have endothermic values. Consistent with this is the fact that lithium salts (LiCl) are often more water-soluble than potassium salts (KCl) (see Figure 13.11).

13.75 X(benzene in solution) = 0.667 and X(toluene in solution) = 0.333

$$P_{total} = P_{toluene} + P_{benzene} = 7.33 \text{ mm Hg} + 50.0 \text{ mm Hg} = 57.3 \text{ mm Hg} = 57 \text{ mm Hg}$$

$$X(\text{toluene in vapor}) = \frac{7.33 \text{ mm Hg}}{57.3 \text{ mm Hg}} = 0.13$$

$$X(\text{benzene in vapor}) = \frac{50.0 \text{ mm Hg}}{57.3 \text{ mm Hg}} = 0.87$$

13.77 $i = 1.7$. That is, there is 1.7 mol of ions in solution per mole of compound.

13.79 (a) Calculate the number of moles of ions in 10^6 g H_2O: 550.0 mol Cl^-; 469.8 mol Na^+; 53.08 mol Mg^{2+}; 9.421 mol SO_4^{2-}; 10.28 mol Ca^{2+}; 9.719 mol K^+; 0.839 mol Br^-. Total moles of ions = 1103.1 per 10^6 g water. This gives ΔT_{fp} of -2.05 °C.

(b) $\Pi = 27.0$ atm. This means that a minimum pressure of 27 atm would have to be used in a reverse osmosis device.

13.81 (a) $i = 2.06$

(b) There are approximately two particles in solution, so $H_3O^+ + HSO_4^-$ best represents H_2SO_4 in aqueous solution.

13.83 Mass of N_2O = 0.53 g; concentration = 1.1×10^3 ppm

13.85 The best method would be to shine a laser through the liquid and look for the Tyndall effect. Some other properties of colloids that could be utilized are that the dispersed material in a colloid will either not crystallize or crystallize only with difficulty and will either not diffuse across a membrane or do so much more slowly than a true solute.

13.87 The calculated molality at the freezing point of benzene is 0.47 *m*, whereas it is 0.99 *m* at the boiling point. A higher molality at the higher temperature indicates more molecules are dissolved. Therefore, assuming benzoic acid forms dimers like acetic acid (page 499), dimer formation is more prevalent at the lower temperature. In this process two molecules become one entity, lowering the number of separate species in solution and lowering the molality.

13.89 Molar mass in benzene = 1.20×10^2 g/mol; molar mass in water = 62.4 g/mol. The actual molar mass of acetic acid is 60.1 g/mol. In benzene, the molecules of acetic acid form "dimers." That is, two molecules form a single unit through hydrogen bonding (page 499).

13.91 The empirical formula, calculated from the percent composition data, is $C_7H_6N_2$. The calculated molar mass of the compound is 118 g/mol, which agrees with the molar mass calculated from the vapor pressure data.

13.93 The strength of the interactions is related to the size of the ion. Thus, Be^{2+} is most strongly hydrated, and Ca^{2+} is least strongly hydrated.

13.95 Colligative properties depend on the number of ions or molecules in solution. Each mole of $CaCl_2$ provides 1.5 times as many ions as each mole of NaCl.

13.97 Benzene is a nonpolar solvent. Thus, ionic substances such as $NaNO_3$ and NH_4Cl will certainly not dissolve. However, naphthalene is also nonpolar and resembles benzene in its structure; it should dissolve very well. (A chemical handbook gives a solubility of 33 g naphthalene per 100 g benzene.) Diethyl ether is weakly polar but is miscible to some extent with benzene.

Water is a polar solvent. The ionic compounds, $NaNO_3$ and NH_4Cl, are both soluble in water ($NaNO_3$ solubility (at 25 °C) = 91 g per 100 g water; NH_4Cl solubility (at 25 °C) = 40 g per 100 g water). The slightly polar compound diethyl ether is soluble to a small extent in water (about 6 g per 100 g water at 25 °C). Nonpolar naphthalene is not soluble in water (solubility at 25 °C = 0.003 g per 100 g water).

13.99 The C—C and C—H bonds in hydrocarbons are nonpolar or weakly polar and tend to make such dispersions hydrophobic (water-hating). The C—O and O—H bonds in starch present opportunities for hydrogen bonding with water. Hence, starch is expected to be more hydrophilic.

13.101 [NaCl] = 1.0 M and [KNO_3] = 0.88 M. The KNO_3 solution has a higher solvent concentration, so solvent will flow from the KNO_3 solution to the NaCl solution.

13.103 (a) $X(C_2H_5OH) = 0.051$; $X(H_2O) = 0.949$

(b) $P(C_2H_5OH)$ over mixture = 38 mm Hg; $P°(H_2O)$ calculated by linear interpolation using the vapor pressures at 78 °C and 79 °C = 334.2 mm Hg; $P(H_2O)$ over mixture = 317 mm Hg

(c) $X(C_2H_5OH) = 0.11$; $X(H_2O) = 0.89$

(d) The mole fraction of ethanol increased from 0.051 to 0.11, a factor of 2.2 times.

Weight percent of C_2H_5OH = 24%

13.105 The molality of the 5.00% NaCl solution is 0.9006 *m*. Assuming no dissociation, this leads to ΔT_{fp}(calculated) = -1.675 °C and $i = 1.82$. The molality of the 5.00% Na_2SO_4 solution is 0.3705 *m*, ΔT_{fp}(calculated) = -0.6892 °C, and $i = 1.97$. These values are consistent with the trends seen in Table 13.4. As the concentration of the ionic solute increases, the value of *i* continues to decrease for both solutes, and rate of decrease is falling for both solutes. In the case of NaCl, this value is leveling off quite a bit. In the case of Na_2SO_4, it is continuing to decrease by significant amounts. Interestingly, the value of *i* for Na_2SO_4 has now fallen below 2 and is getting closer to that for NaCl.

13.107 This does not lend credence to this story. The reported lowest temperature for a NaCl solution corresponds to a temperature of 2.372 °F. The temperature of 0 °F is still below this.

Chapter 14

Check Your Understanding

14.1 For the first 2 hours:

$-\Delta[\text{sucrose}]/\Delta t = -[(0.033 - 0.050)\text{ mol/L}]/(2.0\text{ h}) = 0.0085\text{ mol/L} \cdot \text{h}$

For the last 2 hours:

$-\Delta[\text{sucrose}]/\Delta t = -[(0.010 - 0.015)\text{ mol/L}]/(2.0\text{ h}) = 0.003\text{ mol/L} \cdot \text{h}$

14.2 $-\frac{1}{2}(\Delta[\text{NOCl}]/\Delta t) = \frac{1}{2}(\Delta[\text{NO}]/\Delta t) = \Delta[\text{Cl}_2]/\Delta t$

14.3 Compare experiments 1 and 2: Doubling $[O_2]$ causes the rate to double, so the rate is first order in $[O_2]$. Compare experiments 2 and 4: Doubling [NO] causes the rate to increase by a factor of 4, so the rate is second order in [NO]. Thus, the rate law is

$\text{Rate} = -(\Delta[\text{NO}]/\Delta t) = k[\text{NO}]^2[\text{O}_2]$

Using the data in experiment 1 to determine k:

$0.028\text{ mol/L} \cdot \text{s} = k[0.020\text{ mol/L}]^2[0.010\text{ mol/L}]$

$k = 7.0 \times 10^3\text{ L}^2/\text{mol}^2 \cdot \text{s}$

14.4 $\text{Rate} = k[\text{Pt(NH}_3)_2\text{Cl}_2] = (0.27\text{ h}^{-1})(0.020\text{ mol/L}) = 0.0054\text{ mol/L} \cdot \text{h}$

14.5 $\ln([\text{sucrose}]/[\text{sucrose}]_o) = -kt$

$\ln([\text{sucrose}]/[0.010]) = -(0.21\text{ h}^{-1})(5.0\text{ h})$

$[\text{sucrose}] = 0.0035\text{ mol/L}$

14.6 (a) The fraction remaining is $[\text{CH}_3\text{N}_2\text{CH}_3]/[\text{CH}_3\text{N}_2\text{CH}_3]_o$.

$\ln([\text{CH}_3\text{N}_2\text{CH}_3]/[\text{CH}_3\text{N}_2\text{CH}_3]_o) = -(3.6 \times 10^{-4}\text{ s}^{-1})(150\text{ s})$

$[\text{CH}_3\text{N}_2\text{CH}_3]/[\text{CH}_3\text{N}_2\text{CH}_3]_o = 0.95$

(b) After the reaction is 99% complete

$[\text{CH}_3\text{N}_2\text{CH}_3]/[\text{CH}_3\text{N}_2\text{CH}_3]_o = 0.010$

$\ln(0.010) = -(3.6 \times 10^{-4}\text{ s}^{-1})(t)$

$t = 1.3 \times 10^4\text{ s (210 min)}$

14.7 $1/[\text{HI}] - 1/[\text{HI}]_o = kt$

$1/[\text{HI}] - 1/[0.010\text{ M}] = (30.\text{ L/mol} \cdot \text{min})(12\text{ min})$

$[\text{HI}] = 0.0022\text{ M}$

14.8 $(0.060\text{ M}/0.24\text{ M}) = 0.25$; thus $\frac{1}{4}$ of the original material remains and two half-lives have transpired. $t_{1/2} = 141\text{ min}$.

$k = \ln 2/t_{1/2} = (\ln 2)/141\text{ min} = 4.916 \times 10^{-3}\text{ min}^{-1} = 4.92 \times 10^{-3}\text{ min}^{-1}$

$\text{Initial rate} = k[\text{H}_2\text{O}_2]_0 = 4.916 \times 10^{-3}\text{ min}^{-1}(0.24\text{ mol/L}) = 1.2 \times 10^{-3}\text{ mol/L} \cdot \text{min}$

14.9 (a) For ^{241}Am, $t_{1/2} = 0.693/k = 0.693/(0.0016\text{ y}^{-1}) = 430\text{ y}$

For ^{125}I, $t_{1/2} = 0.693/(0.011\text{ d}^{-1}) = 63\text{ d}$

(b) ^{125}I decays much faster.

(c) $\ln[(n)/(1.6 \times 10^{15}\text{ atoms})] = -(0.011\text{ d}^{-1})(2.0\text{ d})$

$n/1.6 \times 10^{15}\text{ atoms} = 0.9782$;

$n = 1.57 \times 10^{15}\text{ atoms}$

Since the answer should have two significant figures, we should round this off to 1.6×10^{15} atoms. The approximately 2% that has decayed is not discernable within the limits of accuracy of the data presented.

14.10 An Arrhenius plot was constructed by plotting $\ln k$ on the y-axis and $1/T$ on the x-axis. Using Microsoft Excel, the equation of the best-fit line is $y = -22336x + 27.304$.

$E_a = -R \cdot (\text{slope}) = -(0.0083145\text{ kJ/mol} \cdot \text{K})(-22336\text{ K}) = 1.9 \times 10^2\text{ kJ/mol}$

14.11 $\ln(k_2/k_1) = (-E_a/R)(1/T_2 - 1/T_1)$

$\ln[(1.00 \times 10^4)/(4.5 \times 10^3)] = -(E_a/8.3145 \times 10^{-3}\text{ kJ/mol} \cdot \text{K})(1/283\text{ K} - 1/274\text{ K})$

$E_a = 57\text{ kJ/mol}$

14.12 All three steps are bimolecular.

For step 3: $\text{Rate} = k[\text{N}_2\text{O}][\text{H}_2]$.

There are two intermediates, $N_2O_2(g)$ and $N_2O(g)$.

When the three equations are added, N_2O_2 (a product in the first step and a reactant in the second step) and N_2O (a product in the second step and a reactant in the third step) cancel, leaving the net equation:

$2\text{ NO(g)} + 2\text{ H}_2\text{(g)} \rightarrow \text{N}_2\text{(g)} + 2\text{ H}_2\text{O(g)}$.

14.13 (a) $2\text{ NH}_3\text{(aq)} + \text{OCl}^-\text{(aq)} \rightarrow \text{N}_2\text{H}_4\text{(aq)} + \text{Cl}^-\text{(aq)} + \text{H}_2\text{O}(\ell)$

(b) The second step is the rate-determining step.

(c) $\text{Rate} = k[\text{NH}_2\text{Cl}][\text{NH}_3]$

(d) NH_2Cl, $N_2H_5^+$, and OH^- are intermediates.

14.14 Overall reaction: $2\text{ NO}_2\text{Cl(g)} \rightarrow 2\text{ NO}_2\text{(g)} + \text{Cl}_2\text{(g)}$

$\text{Rate} = k'[\text{NO}_2\text{Cl}]^2/[\text{NO}_2]$ (where $k' = k_1k_2/k_{-1}$)

Increasing $[NO_2]$ causes the reaction rate to decrease.

Applying Chemical Principles

14.1 Enzymes—Nature's Catalysts

1. To decompose an equivalent amount of H_2O_2 catalytically would take 1.0×10^{-7} years; this is equivalent to 3.2 seconds.
2. $(100.\text{ mL})(2\text{ mg/mL})(1\text{ g}/1000\text{ mg})(1\text{ mol}/29{,}000\text{ g}) = 6.9 \times 10^{-6}\text{ mol enzyme} = 7 \times 10^{-6}\text{ mol enzyme}$

$(6.9 \times 10^{-6}\text{ mol enzyme})(1 \times 10^6\text{ mol CO}_2/\text{mol enzyme} \cdot \text{s})(44\text{ g CO}_2/\text{mol CO}_2) = 3 \times 10^2\text{ g CO}_2/\text{s}$

14.2 Kinetics and Mechanisms: A 70-Year-Old Mystery Solved

1. (a) $E = hc/\lambda$

$= (6.626 \times 10^{-34}\text{ J} \cdot \text{s})(2.998 \times 10^8\text{ m/s})/(5.78 \times 10^{-7}\text{ m})$

$= 3.437 \times 10^{-19}\text{ J/photon}$

Energy per mole of photons $= (3.437 \times 10^{-19}\text{ J/photon})(6.022 \times 10^{23}\text{ photons/mol photons})(1\text{ kJ}/1000\text{ J}) = 207\text{ kJ/mol photons}$

(b) $(151\text{ kJ/mol photons})(1000\text{ J}/1\text{ kJ})(1\text{ mol photons}/6.022 \times 10^{23}\text{ photons}) = 2.507 \times 10^{-19}\text{ J/photon}$

$\lambda = hc/E$

$= (6.626 \times 10^{-34}\text{ J} \cdot \text{s})(2.998 \times 10^8\text{ m/s})/(2.507 \times 10^{-19}\text{ J})$

$= 7.922 \times 10^{-7}\text{ m}(10^9\text{ nm}/1\text{ m}) = 792\text{ nm}$

2. For the fast equilibrium, the rate of the forward reaction equals the rate of the reverse reaction, thus $k_1[I_2] = k_{-1}[I]^2$ where k_1 and k_{-1} are the forward and reverse rate constants, respectively. The rate limiting step determines the rate law, Rate $= k_2[H_2][I]^2$. Substituting for $[I]^2$ gives Rate $= (k_1k_2/k_{-1})[H_2][I_2] = k[H_2][I_2]$.

3. The probability of three particles colliding simultaneously with the correct geometry for a successful reaction is low.

4. A graph of $\ln(k)$ versus $1/T$, where T is in kelvins, yields a straight line with a slope of -2.235×10^4 K. So, -2.235×10^4 K $= -E_a/R$ where $R = 8.3145 \times 10^{-3}$ kJ/K · mol. $E_a =$ 186 kJ/mol.

Study Questions

14.1 (a) $-\frac{1}{2}\frac{\Delta[O_3]}{\Delta t} = \frac{1}{3}\frac{\Delta[O_2]}{\Delta t}$

(b) $-\frac{1}{2}\frac{\Delta[HOF]}{\Delta t} = \frac{1}{2}\frac{\Delta[HF]}{\Delta t} = \frac{\Delta[O_2]}{\Delta t}$

14.3 $\frac{1}{3}\frac{\Delta[O_2]}{\Delta t} = -\frac{1}{2}\frac{\Delta[O_3]}{\Delta t}$ or $\frac{\Delta[O_3]}{\Delta t} = -\frac{2}{3}\frac{\Delta[O_2]}{\Delta t}$

so $\Delta[O_3]/\Delta t = -1.0 \times 10^{-3}$ mol/L · s.

14.5 (a) The graph of [B] (product concentration) versus time shows [B] increasing from zero. The line is curved, indicating the rate changes with time; thus the rate depends on concentration. Rates for the four 10–s intervals are as follows: 0–10 s, 0.0326 mol/L · s; from 10–20 s, 0.0246 mol/L · s; 20–30 s, 0.0178 mol/L · s; 30–40 s, 0.0140 mol/L · s.

(b) $-\frac{\Delta[A]}{\Delta t} = \frac{1}{2}\frac{\Delta[B]}{\Delta t}$ throughout the reaction

In the interval 10–20 s, $\frac{\Delta[A]}{\Delta t} = -0.0123 \frac{\text{mol}}{\text{L} \cdot \text{s}}$

14.7 The reaction is second order in A, first order in B, and third order overall.

14.9 (a) Rate $= k[NO_2][O_3]$
(b) If $[NO_2]$ is tripled, the rate triples.
(c) If $[O_3]$ is halved, the rate is halved.

14.11 (a) The reaction is second order in [NO] and first order in $[O_2]$.
(b) Rate $= \frac{-\Delta[NO]}{\Delta t} = k[NO]^2[O_2]$
(c) $k = 25$ L^2/mol^2 · s
(d) Rate $= 2.8 \times 10^{-5}$ mol/L · s
(e) When $-\Delta[NO]/\Delta t = 1.0 \times 10^{-4}$ mol/L · s, $\Delta[O_2]/\Delta t = 5.0 \times 10^{-5}$ mol/L · s and $\Delta[NO_2]/\Delta t = 1.0 \times 10^{-4}$ mol/L · s.

14.13 (a) Rate $= -\Delta[NO]/\Delta t = k[NO]^2[O_2]$
(b) 50. L^2/mol^2 · h
(c) Rate $= 8.4 \times 10^{-9}$ mol/L · h

14.15 $k = 3.73 \times 10^{-3}$ min^{-1}

14.17 5.0×10^2 min

14.19 (a) 153 min
(b) 1790 min

14.21 140 s

14.23 6.3 s

14.25 (a) $t_{1/2} = 1.0 \times 10^4$ s (b) 34,000 s

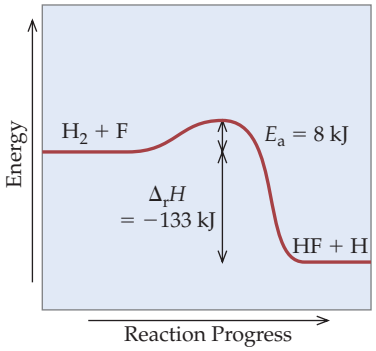
14.27 1.0×10^3 min

14.29 Fraction of ^{64}Cu remaining = 0.030

14.31 The straight line obtained in a graph of $\ln[N_2O]$ versus time indicates a first-order reaction.

$k = (-\text{slope}) = 0.0128$ min^{-1}

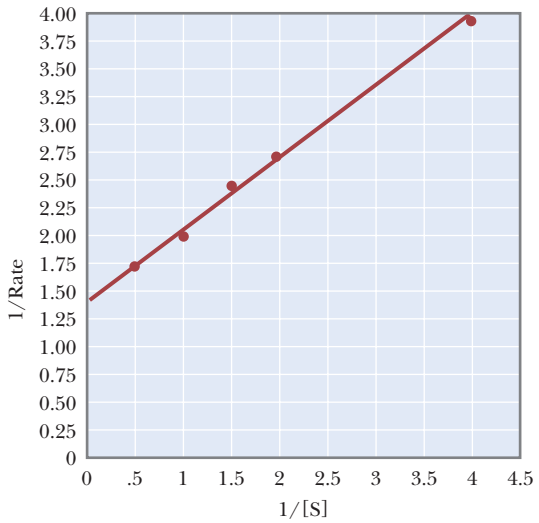
The rate when $[N_2O] = 0.035$ mol/L is 4.5×10^{-4} mol/L · min.



14.33 The graph of $1/[NO_2]$ versus time gives a straight line, indicating the reaction is second order with respect to $[NO_2]$ (see Table 14.1 on page 626). The slope of the line is k, so $k = 1.1$ L/mol · s.

14.35 $-\Delta[C_2F_4]/\Delta t = k[C_2F_4]^2 = (0.04$ L/mol · s$)[C_2F_4]^2$

14.37 Activation energy = 102 kJ/mol



14.39 $k = 0.3$ s^{-1}

14.41

14.43 The lock-and-key model assumes a rigid structure for the enzyme in which the key (the substrate) fits precisely in the active site (the lock). The induced-fit model suggests that there is flexibility in the enzyme that allows the enzyme active site to change to fit the substrate. The induced-fit model is currently favored.

14.45

From the graph, we obtain a value of 1/Rate = 1.47 when 1/[S] = 0. From this, $\text{Rate}_{max} = 0.68$ mmol/min.

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

14.47 **(a)** Rate = $k[NO_3][NO]$
(b) Rate = $k[Cl][H_2]$
(c) Rate = $k[(CH_3)_3CBr]$

14.49 (a) The second step; (b) Rate = $k[O_3][O]$

14.51 (a) NO_2 is a reactant in the first step and a product in the second step. CO is a reactant in the second step. NO_3 is an intermediate, and CO_2 is a product. NO is a product.
(b) Reaction coordinate diagram

14.53 Doubling the concentration of A will increase the rate by a factor of 4 because the concentration of A appears in the rate law as $[A]^2$. Halving the concentration of B will halve the rate The net result is that the rate of the reaction will double.

14.55 After measuring pH as a function of time, one could then calculate pOH and then $[OH^-]$. Finally, a plot of $1/[OH^-]$ versus time would give a straight line with a slope equal to k.

14.57 72 s represents two half-lives, so $t_{1/2}$ = 36 s.

14.59 (a) A plot of $1/[C_2F_4]$ versus time indicates the reaction is second order with respect to $[C_2F_4]$. The rate law is Rate = $k[C_2F_4]^2$.
(b) The rate constant (= slope of the line) is about 0.045 L/mol · s. (The graph does not allow a very accurate calculation.)
(c) Using k = 0.045 L/mol · s, the concentration after 600 s is 0.03 M (to one significant figure).
(d) Time = 2000 s [using k from part (b)].

14.61 (a) A plot of $1/[NH_4NCO]$ versus time is linear, so the reaction is second order with respect to NH_4NCO.
(b) Slope = k = 0.0109 L/mol · min.
(c) $t_{1/2}$ = 200. min
(d) $[NH_4NCO]$ = 0.0997 mol/L

14.63 Mechanism 2

14.65 k = 0.0176 h^{-1} and $t_{1/2}$ = 39.3 h

14.67 (a) After 125 min, 0.250 g remains. After 145, 0.144 g remains.
(b) Time = 43.9 min
(c) Fraction remaining = 0.016

14.69 Plotting 1/concentration versus the time gives a reasonably good linear correlation. The reaction is second order.

14.71 The rate equation for the slow step is Rate = $k[O_3][O]$. The equilibrium constant, K, for step 1 is $K = [O_2][O]/[O_3]$. Solving this for [O], we have $[O] = K[O_3]/[O_2]$. Substituting the expression for [O] into the rate equation we find

Rate = $k[O_3]\{K[O_3]/[O_2]\} = kK[O_3]^2/[O_2]$

14.73 The slope of the ln k versus $1/T$ plot is −6370. From slope = $-E_a/R$, we derive E_a = 53.0 kJ/mol.

14.75 Step 2 is the rate-determining step, and N_2O_2 is an intermediate.

Rate = $-\frac{1}{2}\,\Delta[NO]/\Delta t = k[NO]^2[O_2]$

14.77 (a) k = 3.41 L/mol · min
(b) The rate constant (k') for the rewritten equation is $\frac{1}{2}$ the value of the rate constant, k, for the original equation. The rate equation for the original equation is $-\Delta[NO_2]/\Delta t = k[NO_2]$. For the rewritten equation the rate equation is $-(\frac{1}{2})\Delta[NO_2]/\Delta t = k'[NO_2]$ or $-\Delta[NO_2]/\Delta t = 2k'[NO_2]$. Therefore, $k = 2k'$ or $k' = (\frac{1}{2})k$.

14.79 Estimated time at 90 °C = 4.76 min

14.81 After 30 min (one half-life), P_{HOF} = 50.0 mm Hg and P_{total} = 125.0 mm Hg. After 45 min, P_{HOF} = 35.4 mm Hg and P_{total} = 132 mm Hg.

14.83 (a) Reaction is first order in NO_2NH_2 and −1 for H_3O^+. In a buffered solution, $[H_3O]^+$ is constant, so the reaction has an apparent order of 1.
(b, c) Mechanism 3

In step 1, $K = k_4/k_4' = [NO_2NH^-][H_3O^+]/[NO_2NH_2]$

Rearrange this and substitute into the rate law for the slow step.

Rate = $k_5[NO_2NH^-] = k_5K[NO_2NH_2]/[H_3O^+]$

This is the same as the experimental rate law, where the overall rate constant $k = k_5K$.
(d) Addition of OH^- ions will shift the equilibrium in step 1 (by reacting with H_3O^+) to produce a larger concentration of NO_2NH^-, the reactant in the rate-determining step, thus the reaction rate will increase.

14.85 (a) Average rate for t = 0 to t = 15 is about 4.7×10^{-5} M/s. For t = 100 s to 125 s, the average rate is about 1.6×10^{-5} M/s. The rate slows because the rate of the reaction is dependent on the concentration of reactant and this concentration is declining with time.
(b) A plot of ln (concentration) versus time is a straight line with an equation of $y = -0.010x - 5.30$. This indicates the reaction is a first-order reaction; Rate = k[phenolphthalein]. The slope, which is equal to $-k$, is −0.010, so k = 0.010 s^{-1}.
(c) From the data the half-life is 69.3 s, and the same value comes from the relation $t_{1/2} = \ln 2/k$.

14.87 A plot of 1/Rate versus 1/[S] gives the equation

1/Rate = 94 (1/[S]) + 7.6×10^4

so $\text{Rate}_{max} = 1/(7.6 \times 10^4) = 1.3 \times 10^{-5}$ M min^{-1}.

14.89 (a) The reaction is first order in $[ClO^-]$ (experiments 1 and 3), first order in $[I^-]$ (experiments 2 and 3), and −1 order in $[OH^-]$ (experiments 3 and 4). Therefore, Rate = $k[ClO^-][I^-]/[OH^-]$

(b) Step 2 is the rate determining step. For this step, rate = $k[I^-][HOCl]$. From the first step, $K_{eq} = [HOCl][OH^-]/[ClO^-]$, so $[HOCl] = K_{eq}[ClO^-]/[OH^-]$; substituting for [HOCl] in the rate equation for the second step gives the observed rate law.

14.91 The finely divided rhodium metal will have a significantly greater surface area than the small block of metal. This leads to a large increase in the number of reaction sites and vastly increases the reaction rate.

14.93 (a) False. The reaction may occur in a single step but this does not have to be true.
(b) True
(c) False. Raising the temperature increases the value of k.
(d) False. Temperature has no effect on the value of E_a.
(e) False. If the concentrations of both reactants are doubled, the rate will increase by a factor of 4.
(f) True

14.95 (a) True
(b) True
(c) False. As a reaction proceeds, the reactant concentration decreases and the rate decreases.
(d) False. It is possible to have a one-step mechanism for a third-order reaction if the slow, rate-determining step is termolecular.

14.97 (a) Decrease
(b) Increase
(c) No change
(d) No change
(e) No change
(f) No change

14.99 (a) There are three mechanistic steps.
(b) The overall reaction is exothermic.

14.101 (b) The atoms are lined up so that the new N—O bond can form and the O—O bond can break concurrently.

Chapter 15

Check Your Understanding

15.1 (a) $K = [CO]^2/[CO_2]$
(b) $K = [Cu^{2+}][NH_3]^4/[Cu(NH_3)_4^{2+}]$
(c) $K = [H_3O^+][CH_3CO_2^-]/[CH_3CO_2H]$

15.2 (a) $Q = 0.00218/0.00097 = 2.2$. The system is not at equilibrium; $Q < K$. To reach equilibrium, [isobutane] will increase and [butane] will decrease.
(b) $Q = 0.00260/0.00075 = 3.5$. The system is not at equilibrium; $Q > K$. To reach equilibrium, [butane] will increase and [isobutane] will decrease.

15.3 (a)

Equation	$C_6H_{10}I_2$	⇌	C_6H_{10}	+	I_2
Initial (M)	0.050		0		0
Change (M)	−0.035		+0.035		+0.035
Equilibrium (M)	0.015		0.035		0.035

(b) $K = (0.035)(0.035)/(0.015) = 0.082$

15.4

Equation	H_2	+	I_2	⇌	2 HI
Initial (M)	6.00×10^{-3}		6.00×10^{-3}		0
Change (M)	$-x$		$-x$		$+2x$
Equilibrium (M)	$0.00600 - x$		$0.00600 - x$		$+2x$

$$K_c = 33 = \frac{(2x)^2}{(0.00600 - x)^2}$$

$x = 0.00445$ M, so $[H_2] = [I_2] = 0.0015$ M and $[HI] = 0.0089$ M.

15.5

Equation	$PCl_5(g)$	⇌	$PCl_3(g)$	+	$Cl_2(g)$
Initial (M)	0.1000		0		0
Change (M)	$-x$		$+x$		$+x$
Equilibrium (M)	$0.1000 - x$		x		x

$K_c = [PCl_3][Cl_2]/[PCl_5]$

$33.3 = x^2/0.1000 - x$

We cannot use the simplifying assumption in this case (K is > 1 and $100 \cdot K > 0.1000$), so we must solve using the quadratic formula.

$x^2 + 33.3x - 3.33 = 0$

Using the quadratic formula, $x = 0.09970$ (the other root, $x = -33.40$, is not possible because it leads to negative concentrations).

$[PCl_3] = [Cl_2] = 0.09970$ M $= 0.0997$ M

$[PCl_5] = 0.1000$ M $- 0.09970$ M $= 0.0003$ M

15.6 (a) $K' = K^2 = (2.5 \times 10^{-29})^2 = 6.25 \times 10^{-58} = 6.3 \times 10^{-58}$
(b) $K'' = 1/K^2 = 1/(6.25 \times 10^{-58}) = 1.6 \times 10^{57}$

15.7

Equation	Butane	⇌	Isobutane
Initial (M)	0.020		0.050
After adding more isobutane (M)			
	0.020		0.050 + 0.0200
Change (M)	$+x$		$-x$
Equilibrium (M)	$0.020 + x$		$0.070 - x$

$K = 2.50 = (0.070 - x)/(0.020 + x)$

Solving for x gives $x = 0.00571$ M. Therefore, [isobutane] = 0.070 − 0.00571 = 0.064 M and [butane] = 0.020 + 0.00571 = 0.026 M.

Applying Chemical Principles

15.1 Applying Equilibrium Concepts—The Haber-Bosch Ammonia Process

1. (a) Oxidize part of the NH_3 to HNO_3, then react NH_3 and HNO_3 (an acid–base reaction) to form NH_4NO_3.

$$4\ NH_3 + 7\ O_2 \rightarrow 4\ NO_2 + 6\ H_2O$$

$$4\ NO_2 + 2\ H_2O \rightarrow 2\ HNO_3 + 2\ HNO_2$$

$$2\ HNO_3 + 2\ NH_3 \rightarrow 2\ NH_4NO_3$$

$$6\ NH_3 + 7\ O_2 \rightarrow 4\ H_2O + 2\ HNO_2 + 2\ NH_4NO_3$$

(b) $\Delta_r H° = (1\ \text{mol}\ (NH_2)_2CO/\text{mol-rxn})[\Delta_f H°\{(NH_2)_2CO\}] + (1\ \text{mol}\ H_2O/\text{mol-rxn})[\Delta_f H°(H_2O)] - (2\ \text{mol}\ NH_3/\text{mol-rxn})[\Delta_f H°(NH_3)] - (1\ \text{mol}\ CO_2/\text{mol-rxn})[\Delta_f H°(CO_2)]$

$\Delta_r H° = (1\ \text{mol}\ (NH_2)_2CO/\text{mol-rxn})(-333.1\ \text{kJ/mol}) + (1\ \text{mol}\ H_2O/\text{mol-rxn})(-241.8\ \text{kJ/mol}) - (2\ \text{mol}\ NH_3/\text{mol-rxn})(-45.90\ \text{kJ/mol}) - (1\ \text{mol}\ CO_2/\text{mol-rxn})(-393.5\ \text{kJ/mol})$

$\Delta_r H° = -89.6\ \text{kJ/mol-rxn}.$

The reaction as written is exothermic, so the equilibrium will be more favorable for product formation at a low temperature. The reaction converts three moles of gaseous reactants to one mole of gaseous products; thus, high pressure will be more favorable to product formation.

2. (a) For $CH_4(g) + H_2O(g) \rightarrow CO(g) + 3\ H_2(g)$

$\Delta_r H° = (1\ \text{mol CO/mol-rxn})[\Delta_f H°(CO)] - (1\ \text{mol}\ CH_4/\text{mol-rxn})[\Delta_f H°(CH_4)] - (1\ \text{mol}\ H_2O/\text{mol-rxn})[\Delta_f H°(H_2O)]$

$\Delta_r H° = (1\ \text{mol CO/mol-rxn})(-110.5\ \text{kJ/mol}) - (1\ \text{mol}\ CH_4/\text{mol-rxn})(-74.87\ \text{kJ/mol}) - (1\ \text{mol}\ H_2O/\text{mol-rxn})(-241.8\ \text{kJ/mol}) = 206.2\ \text{kJ/mol-rxn (endothermic)}$

For $CO(g) + H_2O(g) \rightarrow CO_2(g) + H_2(g)$

$\Delta_r H° = (1\ \text{mol}\ CO_2/\text{mol-rxn})[\Delta_f H°(CO_2)] - (1\ \text{mol CO/mol-rxn})[\Delta_f H°(CO)] - (1\ \text{mol}\ H_2O/\text{mol-rxn})[\Delta_f H°(H_2O)]$

$\Delta_r H° = (1\ \text{mol}\ CO_2/\text{mol-rxn})(-393.5\ \text{kJ/mol}) - (1\ \text{mol CO/mol-rxn})(-110.5\ \text{kJ/mol}) - (1\ \text{mol}\ H_2O/\text{mol-rxn})(-241.8\ \text{kJ/mol}) = -41.2\ \text{kJ/mol-rxn (exothermic)}$

(b) (15 billion kg = 1.5×10^{13} g)

Add the two equations:

$CH_4(g) + 2\ H_2O(g) \rightarrow CO_2(g) + 4\ H_2(g)$

CH_4 required = $(1.5 \times 10^{13}\ \text{g}\ NH_3)(1\ \text{mol}\ NH_3/17.03\ \text{g}\ NH_3)(3\ \text{mol}\ H_2/2\ \text{mol}\ NH_3)(1\ \text{mol}\ CH_4/4\ \text{mol}\ H_2)(16.04\ \text{g}\ CH_4/1\ \text{mol}\ CH_4) = 5.3 \times 10^{12}\ \text{g}\ CH_4$

CO_2 formed = $(1.5 \times 10^{13}\ \text{g}\ NH_3)(1\ \text{mol}\ NH_3/17.03\ \text{g}\ NH_3)(3\ \text{mol}\ H_2/2\ \text{mol}\ NH_3)(1\ \text{mol}\ CO_2/4\ \text{mol}\ H_2)(44.01\ \text{g}\ CO_2/1\ \text{mol}\ CO_2) = 1.5 \times 10^{13}\ \text{g}\ CO_2$

15.2 Trivalent Carbon

1. (a) Concentration (molality) = $-0.542\ °C/-5.12\ °C/m = 0.1059$ mol dimer/kg benzene

Amount dimer = (0.1059 mol dimer/kg benzene)(0.0100 kg benzene) = 1.059×10^{-3} mol dimer

Molar mass of dimer = $0.503\ \text{g}/1.059 \times 10^{-3}\ \text{mol} = 475\ \text{g/mol}$

(b) Each molecule of the dimer that decomposes produces two monomer particles, increasing the total number of moles of particles in solution. When the mass of the dimer is divided by the moles of particles, the calculated molar mass is too low.

2. $K_c = 4.1 \times 10^{-4} = (2x)^2/(0.015 - x)$
Solving the quadratic equation gives $x = 0.00119$ M. The concentration of the monomer = 2(0.00119 M) = 0.0024 M. The concentration of the dimer = 0.015 M − 0.00119 M = 0.014 M.

3. $[\text{Dimer}]_0 = ((0.64\ \text{g})(1\ \text{mol}/486.655\ \text{g}))/0.0250\ \text{L} = 0.0526\ \text{M}$

$K_c = 4.1 \times 10^{-4} = (2x)^2/(0.0526 - x)$
Solving the quadratic equation gives $x = 0.00227$ M.
[Monomer] = 2(0.00227 M) = 0.0045 M
[Dimer] = 0.0526 M − 0.00227 M = 0.050 M

4. The monomer, the product of the reaction, is yellow in color. Heating produces more of the monomer so the reaction is endothermic.

5. (b) Triphenylmethyl radical

Study Questions

15.1 (a) $K_c = \dfrac{[H_2O]^2[O_2]}{[H_2O_2]^2}$

(b) $K_c = \dfrac{[CO_2]}{[CO][O_2]^{1/2}}$

(c) $K_c = \dfrac{[CO]^2}{[CO_2]}$

(d) $K_c = \dfrac{[CO_2]}{[CO]}$

15.3 $Q = (2.0 \times 10^{-8})^2/(0.020) = 2.0 \times 10^{-14}$
$Q < K_c$, so the reaction proceeds to the right.

15.5 $Q = 1.0 \times 10^3$, so $Q > K_c$ and the reaction is not at equilibrium. It proceeds to the left to convert products to reactants.

15.7 $K_c = 1.2$

15.9 (a) $K_c = 0.025$
(b) $K_c = 0.025$
(c) The amount of solid does not affect the equilibrium.

15.11 (a) $[COCl_2] = 0.00308$ M; $[CO] = 0.0071$ M
(b) $K_c = 140$

15.13 [isobutane] = 0.024 M; [butane] = 0.010 M

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

15.15 $[I_2] = 6.14 \times 10^{-3}$ M; $[I] = 4.79 \times 10^{-3}$ M

15.17 $[COBr_2] = 0.0026$ M; $[CO] = [Br_2] = 0.0224$ M
89.6% of the $COBr_2$ has decomposed.

15.19 (b) $K_2 = K_1^2$

15.21 (e) $K_2 = 1/(K_1)^2$

15.23 $K_c = 13.7$

15.25 (a) $K_c = K_p/(RT)^{\Delta n} = 0.16/[(0.08206)(298)] = 6.5 \times 10^{-3}$
(b) $\Delta n = 0$, therefore $K_c = K_p = 1.05$

15.27 (a) Equilibrium shifts to the right
(b) Equilibrium shifts to the left
(c) Equilibrium shifts to the right
(d) Equilibrium shifts to the left

15.29 Equilibrium concentrations are the same under both circumstances: [butane] = 1.1 M and [isobutane] = 2.9 M.

15.31 $K_c = 3.9 \times 10^{-4}$

15.33 For decomposition of $COCl_2$, $K_p = 1/(K_p$ for $COCl_2$ formation$) = 1/(6.5 \times 10^{11}) = 1.5 \times 10^{-12}$

15.35 $K_c = 3.9$

15.37 Q is less than K_c, so the system shifts to form more isobutane.

At equilibrium, [butane] = 0.86 M and [isobutane] = 2.14 M.

15.39 To obtain the second equation, the first equation has been reversed and multiplied by 2.
(c) $K_2 = 1/K_1^2$

15.41 (a) No change
(b) Shifts left
(c) No change
(d) Shifts right
(e) Shifts right

15.43 (a) The equilibrium will shift to the left on adding more Cl_2.
(b) K_c is calculated (from the quantities of reactants and products at equilibrium) to be 0.004709. After Cl_2 is added, the concentrations are: $[PCl_5] = 0.00198$ M, $[PCl_3] = 0.00231$ M, and $[Cl_2] = 0.00404$ M.

15.45 $K_p = 0.215$

15.47 (a) Fraction dissociated = 0.15
(b) Fraction dissociated = 0.189. If the pressure decreases, the equilibrium shifts to the right, increasing the fraction of N_2O_4 dissociated.

15.49 $[NH_3] = 0.67$ M; $[N_2] = 0.57$ M; $[H_2] = 1.7$ M; $P_{total} = 180$ atm

15.51 (a) $[NH_3] = [H_2S] = 0.013$ M
(b) $[NH_3] = 0.027$ M and $[H_2S] = 0.0067$ M

15.53 $P(NO_2) = 0.066$ atm and $P(N_2O_4) = 0.066$ atm; P(total) = 0.16 atm

15.55 (a) $K_p = K_c = 56$. Because 2 mol of reactant gases gives 2 mol of product gases, Δn does not change and $K_p = K_c$ (page 676).
(b) Total pressure before reaction is 0.52 atm. After reaction the total pressure is the same because the amount of gas present has not changed.
(c) After reaction, at equilibrium, $P(H_2) = P(I_2) = 0.052$ atm and $P(HI) = 0.42$ atm.

15.57 $P(CO) = 0.0010$ atm

15.59 3.9×10^{17} O atoms

15.61 Glycerin concentration should be 1.7 M

15.63 (a) $K_p = 0.20$
(b) When initial $[N_2O_4] = 1.00$ atm, the equilibrium pressures are $[N_2O_4] = 0.80$ atm and $[NO_2] = 0.40$ atm. When initial $[N_2O_4] = 0.10$ atm, the equilibrium pressures are $[N_2O_4] = 0.050$ atm and $[NO_2] = 0.10$ atm. The percent dissociation is now 50.%. This is in accord with Le Chatelier's principle: If the initial pressure of the reactant is smaller, the equilibrium shifts to the right, increasing the fraction of the reactant dissociated. [This might be clearer if you imagine beginning with the equilibrium system in the case when the initial pressure of N_2O_4 was 1.00 atm and then increasing the volume tenfold (obtaining the same equilibrium system as starting with 0.10 atm N_2O_4). Le Chatelier's principle predicts a shift in the direction that has a greater number of gas molecules.

15.65 (a) The flask containing $(H_3N)B(CH_3)_3$ will have the largest partial pressure of $B(CH_3)_3$.
(b) $P[B(CH_3)_3] = P(NH_3) = 0.23$ and $P[(H_3N)B(CH_3)_3] = 0.012$ atm

$P_{total} = 0.48$ atm

Percent dissociation = 95%

15.67 (a) As more KSCN is added, Le Chatelier's principle predicts more of the red complex ion $[Fe(H_2O)_5(SCN)]^+$ will form.
(b) Adding Ag^+ ions leads to a precipitate of AgSCN, thus removing SCN^- ions from solution. The equilibrium shifts left, dropping the concentration of the red complex ion.

15.69 (a) False. The magnitude of K is always dependent on temperature.
(b) True
(c) False. The equilibrium constant for a reaction is the reciprocal of the value of K for its reverse.
(d) True
(e) False. $\Delta n = 1$, so $K_p = K_c(RT)$

15.71 (a) Product-favored, $K >> 1$
(b) Reactant-favored, $K << 1$
(c) Product-favored, $K >> 1$

15.73 Begin with an equilibrium system containing $^{14}N_2$, H_2, and $^{14}NH_3$. Introduce some $^{15}N_2$ and allow the system to equilibrate. The presence of $^{15}NH_3$ indicates that the forward reaction has occurred. In addition, the presence of $^{15}N^{14}N$ indicates that the reverse reaction has occurred. Further evidence of the reverse reaction occurring could be obtained by carrying out another trial in which $^{15}NH_3$ is added to the initial equilibrium mixture. The presence of $^{15}N^{14}N$ or $^{15}N_2$ indicates that the reverse reaction is occurring. (A similar set of experiments could be run using ^2H instead of ^{15}N.)

15.75 $K_p = 3.2 \times 10^{-7}$

Chapter 16

Check Your Understanding

16.1 $[H_3O^+] = 4.0 \times 10^{-3}$ M; $[OH^-] = K_w/[H_3O^+] = 2.5 \times 10^{-12}$ M

16.2 (a) pH = 7
(b) pH < 7 (NH_4^+ is an acid)
(c) pH < 7 $[Al(H_2O)_6]^{3+}$ is an acid
(d) pH > 7 (HPO_4^{2-} is a stronger base than it is an acid)

16.3 (a) NH_4^+ is a stronger acid than HCO_3^-. CO_3^{2-}, the conjugate base of HCO_3^-, is a stronger base than NH_3, the conjugate base of NH_4^+.
(b) Reactant-favored; the reactants are the weaker acid and base.
(c) Reactant-favored; the reactants are the weaker acid and base, so reaction lies to the left.

16.4 From the pH, we can calculate $[H_3O^+] = 1.91 \times 10^{-3}$ M. Also, [butanoate$^-$] = $[H_3O^+] = 1.91 \times 10^{-3}$ M. Use these values along with [butanoic acid] to calculate K_a.

$K_a = [1.91 \times 10^{-3}]\,[1.91 \times 10^{-3}]/(0.055 - 1.91 \times 10^{-3}) = 6.8 \times 10^{-5}$

16.5 $K_a = 1.8 \times 10^{-5} = [x][x]/(0.10 - x)$

$x = 1.34 \times 10^{-3}$ M

$[H_3O^+] = [CH_3CO_2^-] = 1.3 \times 10^{-3}$ M; $[CH_3CO_2H] = 0.099$ M; pH = 2.87

16.6 $HF(aq) + H_2O(\ell) \rightleftharpoons H_3O^+(aq) + F^-(aq)$

$K_a = 7.2 \times 10^{-4} = [x][x]/(0.00150 - x)$

The x in the denominator cannot be dropped. This equation must be solved with the quadratic formula or by successive approximations. Because this problem follows the section dealing with the method of successive approximations, that method will be used here.

$7.2 \times 10^{-4} = x^2/(0.00150)$; $x = 1.04 \times 10^{-3}$

$7.2 \times 10^{-4} = x^2/(0.00150 - 1.04 \times 10^{-3})$; $x = 5.76 \times 10^{-4}$

$7.2 \times 10^{-4} = x^2/(0.00150 - 5.76 \times 10^{-4})$; $x = 8.16 \times 10^{-4}$

$7.2 \times 10^{-4} = x^2/(0.00150 - 8.16 \times 10^{-4})$; $x = 7.02 \times 10^{-4}$

$7.2 \times 10^{-4} = x^2/(0.00150 - 7.02 \times 10^{-4})$; $x = 7.58 \times 10^{-4}$

$7.2 \times 10^{-4} = x^2/(0.00150 - 7.58 \times 10^{-4})$; $x = 7.31 \times 10^{-4}$

$7.2 \times 10^{-4} = x^2/(0.00150 - 7.31 \times 10^{-4})$; $x = 7.44 \times 10^{-4}$

$7.2 \times 10^{-4} = x^2/(0.00150 - 7.44 \times 10^{-4})$; $x = 7.38 \times 10^{-4}$

$7.2 \times 10^{-4} = x^2/(0.00150 - 7.38 \times 10^{-4})$; $x = 7.41 \times 10^{-4}$

$7.2 \times 10^{-4} = x^2/(0.00150 - 7.41 \times 10^{-4})$; $x = 7.39 \times 10^{-4}$

$7.2 \times 10^{-4} = x^2/(0.00150 - 7.39 \times 10^{-4})$; $x = 7.40 \times 10^{-4}$

$7.2 \times 10^{-4} = x^2/(0.00150 - 7.40 \times 10^{-4})$; $x = 7.40 \times 10^{-4}$

The result has converged to three digits.

$[H_3O^+] = [F^-] = 7.40 \times 10^{-4}$ M $= 7.4 \times 10^{-4}$ M

$[HF] = 0.00150$ M $- 7.40\ 10^{-4}$ M $= 7.6 \times 10^{-4}$ M

pH = 3.13

16.7 $OCl^-(aq) + H_2O(\ell) \rightleftharpoons HOCl(aq) + OH^-(aq)$

$K_b = 2.9 \times 10^{-7} = [x][x]/(0.015 - x)$

$x = 6.60 \times 10^{-5}$ M

$[OH^-] = [HOCl] = 6.6 \times 10^{-5}$ M

pOH = 4.181; pH = 9.82

16.8 Equivalent amounts of acid and base react to form water, $CH_3CO_2^-$ and Na^+. Acetate ion hydrolyzes to a small extent, giving CH_3CO_2H and OH^-. We need to determine $[CH_3CO_2^-]$ and then solve a weak base equilibrium problem to determine $[OH^-]$.

Amount $CH_3CO_2^-$ = moles base = 0.12 mol/L $\times$ 0.015 L $= 1.80 \times 10^{-3}$ mol

Total volume = 0.030 L, so $[CH_3CO_2^-] = (1.80 \times 10^{-3}$ mol$)/0.030$ L $= 0.0600$ M $= 0.060$ M

$CH_3CO_2^-(aq) + H_2O(\ell) \rightleftharpoons CH_3CO_2H(aq) + OH^-(aq)$

$K_b = 5.6 \times 10^{-10} = [x][x]/(0.0600 - x)$

$x = 5.80 \times 10^{-6}$ M

$[OH^-] = [CH_3CO_2H] = 5.8 \times 10^{-6}$ M

pOH = 5.237; pH = 8.76

16.9 $H_2C_2O_4(aq) + H_2O(\ell) \rightleftharpoons H_3O^+(aq) + HC_2O_4^-(aq)$

$K_{a1} = 5.9 \times 10^{-2} = [x][x]/(0.10 - x)$

The x in the denominator cannot be dropped. This equation must be solved with the quadratic formula or by successive approximations.

$x = 5.28 \times 10^{-2}$ M

$[H_3O^+] = [HC_2O_4^-] = 5.3 \times 10^{-2}$ M

pH = 1.28

$K_{a2} = [H_3O^+][C_2O_4^{2-}]/[HC_2O_4^-]$; because $[H_3O^+] = [HC_2O_4^-]$,

$[C_2O_4^{2-}] = K_{a2} = 6.4 \times 10^{-5}$ M

Applying Chemical Principles

16.1 Would You Like Some Belladonna Juice in Your Drink?

1. (100. mg $C_{17}H_{23}NO_3$)(1 g/1000 mg)(1 mol $C_{17}H_{23}NO_3$/289.4 g $C_{17}H_{23}NO_3$) = 3.46×10^{-4} mol $C_{17}H_{23}NO_3$

2. The proton will attach to the N.

3. The pK_a of protonated atropine (4.35) is less than that of the ammonium (pK_a = 9.26), methylammonium (pK_a = 10.70), and anilinium (pK_a = 4.60) ions.

16.2 The Leveling Effect, Nonaqueous Solvents, and Superacids

1. $HClO_4$ ($K = 5 \times 10^{-6}$) > H_2SO_4 ($K = 2 \times 10^{-7}$) > HCl ($K = 2 \times 10^{-9}$)

2. (a) $2\ CH_3CO_2H \rightleftharpoons CH_3CO_2H_2^+ + CH_3CO_2^-$

   (b) Let $x = [CH_3CO_2H_2^+] = [CH_3CO_2^-]$

   $x^2 = 3.2 \times 10^{-15}$

   $x = [CH_3CO_2H_2^+] = [CH_3CO_2^-] = 5.7 \times 10^{-8}$ M

3. $NH_2^-(aq) + H_2O(\ell) \rightleftharpoons NH_3(aq) + OH^-(aq)$
   The reaction is product-favored at equilibrium.

4. $HClO_4$ in glacial acetic acid is a weak conductor of electricity as it only partially ionizes.

5. (a) $2\ NH_3 \rightleftharpoons NH_4^+ + NH_2^-$
   (b) The strongest acid is NH_4^+; the strongest base is NH_2^-.
   (c) HCl is a stronger acid than NH_4^+, so HCl will be completely ionized. The solution will be a strong conductor.
   (d) $O^{2-} + NH_3 \rightleftharpoons OH^- + NH_2^-$
   The reaction is product-favored at equilibrium.

Study Questions

16.1 (a) CN^-, cyanide ion
(b) SO_4^{2-}, sulfate ion
(c) F^-, fluoride ion

16.3 (a) $H_3O^+(aq) + NO_3^-(aq)$; $H_3O^+(aq)$ is the conjugate acid of H_2O, and $NO_3^-(aq)$ is the conjugate base of HNO_3.
(b) $H_3O^+(aq) + SO_4^{2-}(aq)$; $H_3O^+(aq)$ is the conjugate acid of H_2O, and $SO_4^{2-}(aq)$ is the conjugate base of HSO_4^-.
(c) $H_2O + HF$; H_2O is the conjugate base of H_3O^+, and HF is the conjugate acid of F^-.

16.5 Brønsted acid: $HC_2O_4^-(aq) + H_2O(\ell) \rightleftharpoons H_3O^+(aq) + C_2O_4^{2-}(aq)$
Brønsted base: $HC_2O_4^-(aq) + H_2O(\ell) \rightleftharpoons H_2C_2O_4(aq) + OH^-(aq)$

16.7

	Acid (A)	Base (B)	Conjugate Base of A	Conjugate Acid of B
(a)	HCO_2H	H_2O	HCO_2^-	H_3O^+
(b)	H_2S	NH_3	HS^-	NH_4^+
(c)	HSO_4^-	OH^-	SO_4^{2-}	H_2O

16.9 $[H_3O^+] = 1.8 \times 10^{-4}$ M; acidic

16.11 HCl is a strong acid, so $[H_3O^+]$ = concentration of the acid. $[H_3O^+] = 0.0075$ M and $[OH^-] = 1.3 \times 10^{-12}$ M. pH = 2.12.

16.13 $Ba(OH)_2$ is a strong base, so $[OH^-] = 2 \times$ concentration of the base.
$[OH^-] = 3.0 \times 10^{-3}$ M; pOH = 2.523; and pH = 11.48

16.15 $K_a = [H_3O^+][NH_3]/[NH_4^+]$

16.17 (a) The strongest acid is HCO_2H (largest K_a) and the weakest acid is C_6H_5OH (smallest K_a).
(b) The strongest acid (HCO_2H) has the weakest conjugate base.
(c) The weakest acid (C_6H_5OH) has the strongest conjugate base.

16.19 (c) HOCl, the weakest acid in this list (Table 16.2), has the strongest conjugate base.

16.21 (a) HCO_3^-. Decide based on the base strength (Table 16.2). The strongest base of the three listed examples has the weakest conjugate acid.

16.23 $CO_3^{2-}(aq) + H_2O(\ell) \rightleftharpoons HCO_3^-(aq) + OH^-(aq)$

16.25 Highest pH, (a) Na_2S; lowest pH, (f) $AlCl_3$ (which gives the weak acid $[Al(H_2O)_6]^{3+}$ in solution)

16.27 $pK_a = 4.19$

16.29 $K_a = 3.0 \times 10^{-10}$; in Table 16.2, this acid falls between hexaaquairon(II) ion and the hydrogen carbonate ion.

16.31 (b) 2-Chlorobenzoic acid is the stronger acid; it has the smaller pK_a value.

16.33 $K_b = 7.1 \times 10^{-12}$

16.35 $K_b = 6.3 \times 10^{-5}$

16.37 $CH_3CO_2H(aq) + HCO_3^-(aq) \rightleftharpoons CH_3CO_2^-(aq) + H_2CO_3(aq)$
Equilibrium lies predominantly to the right because CH_3CO_2H is a stronger acid than H_2CO_3.

16.39 (a) Left; NH_3 and HBr are the stronger base and acid, respectively.
(b) Left; PO_4^{3-} and CH_3CO_2H are the stronger base and acid, respectively.
(c) Right; $[Fe(H_2O)_6]^{3+}$ and HCO_3^- are the stronger acid and base, respectively.

16.41 (a) $OH^-(aq) + HPO_4^{2-}(aq) \rightleftharpoons H_2O(\ell) + PO_4^{3-}(aq)$
(b) OH^- is a stronger base than PO_4^{3-}, so the equilibrium will lie to the right.

16.43 (a) $CH_3CO_2H(aq) + HPO_4^{2-}(aq) \rightleftharpoons CH_3CO_2^-(aq) + H_2PO_4^-(aq)$
(b) CH_3CO_2H is a stronger acid than $H_2PO_4^-$, so the equilibrium will lie to the right.

16.45 (a) 2.1×10^{-3} M; (b) $K_a = 3.5 \times 10^{-4}$

16.47 $K_b = 6.6 \times 10^{-9}$

16.49 (a) $[H_3O^+] = 1.6 \times 10^{-4}$ M
(b) Moderately weak; $K_a = 1.1 \times 10^{-5}$

16.51 $[CH_3CO_2^-] = [H_3O^+] = 1.9 \times 10^{-3}$ M and $[CH_3CO_2H] = 0.20$ M

16.53 $[H_3O^+] = [CN^-] = 3.2 \times 10^{-6}$ M; [HCN] = 0.025 M; pH = 5.50

16.55 $[NH_4^+] = [OH^-] = 1.6 \times 10^{-3}$ M; $[NH_3]$ = 0.15 M; pH = 11.22

16.57 $[OH^-] = 0.010$ M; pH = 12.01; pOH = 1.99

16.59 pH = 3.25

16.61 $[H_3O^+] = 1.1 \times 10^{-5}$ M; pH = 4.98

16.63 $[HCN] = [OH^-] = 3.3 \times 10^{-3}$ M; $[H_3O^+] = 3.0 \times 10^{-12}$ M; $[Na^+] = 0.441$ M

16.65 $[H_3O^+] = 1.5 \times 10^{-9}$ M; pH = 8.81

16.67 (a) The reaction produces acetate ion, the conjugate base of acetic acid. The solution is weakly basic. pH is greater than 7.
(b) The reaction produces NH_4^+, the conjugate acid of NH_3. The solution is weakly acidic. pH is less than 7.
(c) The reaction mixes equal molar amounts of strong base and strong acid. The solution will be neutral. pH will be 7.

16.69 $H_2C_2O_4(aq) + H_2O(\ell) \rightleftharpoons HC_2O_4^-(aq) + H_3O^+(aq)$
$HC_2O_4^-(aq) + H_2O(\ell) \rightleftharpoons C_2O_4^{2-}(aq) + H_3O^+(aq)$

16.71 $H_2C_2O_4(aq) + H_2O(\ell) \rightleftharpoons HC_2O_4^-(aq) + H_3O^+(aq)$
$K_{a1} = 5.2 \times 10^{-2}$
$HC_2O_4^-(aq) + H_2O(\ell) \rightleftharpoons H_2C_2O_4(aq) + OH^-(aq)$
$K_{b2} = 1.9 \times 10^{-13}$
Sum: $2\ H_2O(\ell) \rightleftharpoons H_3O^+(aq) + OH^-(aq)$
$K_w = K_{a1} \times K_{b2} = 1.0 \times 10^{-14}$

16.73 (a) pH = 1.17; (b) $[SO_3^{2-}] = 6.2 \times 10^{-8}$ M

16.75 (a) $[OH^-] = [N_2H_5^+] = 9.2 \times 10^{-5}$ M; $[N_2H_6^{2+}] = 8.9 \times 10^{-16}$ M
(b) pH = 9.96

16.77 HOCN should be a stronger acid than HCN because the H atom in HOCN is attached to the more electronegative O atom. The electron attachment enthalpy of OCN is thus more negative than that of CN, which stabilizes the conjugate base that forms and makes the ionization of HOCN more product-favored.

16.79 The S atom is surrounded by three highly electronegative O atoms. These help stabilize the conjugate base that needs to form so that the negative charge is more readily accepted.

16.81 (a) Lewis base
(b) Lewis acid
(c) Lewis base (owing to lone pair of electrons on the N atom)

16.83 CO is a Lewis base in its reactions with transition metal atoms. It donates a lone pair of electrons on the C atom.

16.85 pH = 2.671

16.87 Both $Ba(OH)_2$ and $Sr(OH)_2$ dissolve completely in water to provide M^{2+} and OH^- ions. 2.50 g $Sr(OH)_2$ in 1.00 L of water gives $[Sr^{2+}] = 0.021$ M and $[OH^-] = 0.041$ M. This concentration of OH^- is reflected in a pH of 12.61.

16.89 $H_2S(aq) + CH_3CO_2^-(aq) \rightleftharpoons CH_3CO_2H(aq) + HS^-(aq)$
The equilibrium lies to the left and favors the reactants.

16.91 $[X^-] = [H_3O^+] = 3.0 \times 10^{-3}$ M; [HX] = 0.007 M; pH = 2.52

16.93 $K_a = 1.37 \times 10^{-5}$; $pK_a = 4.86$

16.95 pH = 5.84

16.97 (a) Ethylamine is a stronger base than ethanolamine.
(b) For ethylamine, the pH of the solution is 11.82.

16.99 pH = 7.66

16.101 Acidic: $NaHSO_4$, NH_4Br, $FeCl_3$
Neutral: $KClO_4$, $NaNO_3$, LiBr
Basic: Na_2CO_3, $(NH_4)_2S$, Na_2HPO_4
Highest pH: $(NH_4)_2S$, lowest pH: $NaHSO_4$

16.103 $K_{net} = K_{a1} \times K_{a2} = 3.8 \times 10^{-6}$

16.105 For the reaction $HCO_2H(aq) + OH^-(aq) \rightarrow H_2O(\ell) + HCO_2^-(aq)$,
$K_{net} = K_a$ (for HCO_2H) $\times [1/K_w] = 1.8 \times 10^{10}$

16.107 To double the percent ionization, you must dilute 100 mL of solution to 400 mL.

16.109 $H_2O > H_2C_2O_4 > HC_2O_4^- = H_3O^+ > C_2O_4^{2-} > OH^-$

16.111 Measure the pH of 0.1 M solutions of the three bases. The solution containing the strongest base will have the highest pH. The solution having the weakest base will have the lowest pH.

16.113 The possible cation–anion combinations are NaCl (neutral), NaOH (basic), NH_4Cl (acidic), NH_4OH (basic), HCl (acidic), and H_2O (neutral).
A = H^+ solution; B = NH_4^+ solution; C = Na^+ solution; Y = Cl^- solution; Z = OH^- solution

16.115 $K_a = 3.0 \times 10^{-5}$

16.117 (a) Aniline is both a Brønsted and a Lewis base. As a proton acceptor it gives $C_6H_5NH_3^+$. The N atom can also donate an electron pair to give a Lewis acid–base adduct, $F_3B \leftarrow NH_2C_6H_5$.
(b) pH = 7.97

16.119 Water can both accept a proton (a Brønsted base) and donate a lone pair (a Lewis base). Water can also donate a proton (Brønsted acid), but it cannot accept a pair of electrons (and act as a Lewis acid).

Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

16.121 (a) HOCl is the strongest acid (smallest pK_a and largest K_a), and HOI is the weakest acid.

(b) Cl is more electronegative than Br or I, so the OCl^- anion is more stable than the other two oxoanions.

16.123 (a) $HClO_4 + H_2SO_4 \rightleftharpoons ClO_4^- + H_3SO_4^+$

(b) The O atoms on sulfuric acid have lone pairs of electrons that can be used to bind to an H^+ ion.

16.125 (a) 

(b) $I^-(aq)$ [Lewis base] + $I_2(aq)$ [Lewis acid] $\rightarrow$ $I_3^-(aq)$

16.127 (a) For the weak acid HA, the concentrations at equilibrium are $[HA] = C_0 - \alpha C_0$, $[H_3O^+] = [A^-] = \alpha C_0$. Putting these into the usual expression for K_a we have $K_a = \alpha^2 C_0/(1-\alpha)$.

(b) For 0.10 M NH_4^+, $\alpha = 7.5 \times 10^{-5}$ (reflecting the fact that NH_4^+ is a much weaker acid than acetic acid).

16.129 (a) Add the three equations.

$$NH_4^+(aq) + H_2O(\ell) \rightleftharpoons NH_3(aq) + H_3O^+(aq) \quad K_1 = K_a$$

$$CN^-(aq) + H_2O(\ell) \rightleftharpoons HCN(aq) + OH^-(aq) \quad K_2 = K_b$$

$$H_3O^+(aq) + OH^-(aq) \rightleftharpoons 2\ H_2O(\ell) \quad K_3 = 1/K_w$$

$$NH_4^+(aq) + CN^-(aq) \rightleftharpoons NH_3(aq) + HCN(aq) \quad K_{net} = K_1K_2K_3 = K_aK_b/K_w$$

(b) The salts NH_4CN, $NH_4CH_3CO_2$, and NH_4F have K_{net} values of 1.4, 3.1×10^{-5}, and 7.8×10^{-7}, respectively. Only in the case of NH_4CN is the base (the cyanide ion) strong enough to remove a proton from the ammonium ion and produce a significant concentration of products.

(c) NH_4CN: basic, K_b of $CN^- > K_a$ of NH_4^+

$NH_4CH_3CO_2$: neutral, K_b of $CH_3CO_2^- = K_a$ of NH_4^+

NH_4F: acidic, K_b of $F^- < K_a$ of NH_4^+

Chapter 17

Check Your Understanding

17.1 pH of 0.30 M HCO_2H:

$K_a = [H_3O^+][HCO_2^-]/[HCO_2H]$

$1.8 \times 10^{-4} = [x][x]/[0.30 - x]$

$x = 7.35 \times 10^{-3}$ M; pH = 2.13

pH of 0.30 M formic acid + 0.10 M $NaHCO_2$

$K_a = [H_3O^+][HCO_2^-]/[HCO_2H]$

$1.8 \times 10^{-4} = [x][0.10 + x]/(0.30 - x)$

$x = 5.40 \times 10^{-4}$ M; pH = 3.27

17.2

Equation	$HCO_2H + H_2O$	$\rightleftharpoons$	H_3O^+	+	HCO_2^-
Initial (M)	0.50		0		0.70
Change (M)	$-x$		$+x$		$+x$
Equilibrium (M)	$0.50 - x$		x		$0.70 + x$

$K_a = 1.8 \times 10^{-4} = (x)(0.70 + x)/(0.50 - x)$

The value of x will be insignificant compared to 0.50 M and 0.70 M.

$1.8 \times 10^{-4} = (x)(0.70)/(0.50)$

$x = [H_3O^+] = 1.29 \times 10^{-4}$ M

$pH = -\log[H_3O^+] = 3.89$

17.3 (15.0 g $NaHCO_3$)(1 mol/84.01 g) = 0.1786 mol $NaHCO_3$, and (18.0 g Na_2CO_3)(1 mol/106.0 g) = 0.1698 mol Na_2CO_3

$pH = pK_a + \log\{[base]/[acid]\}$

$pH = -\log(4.8 \times 10^{-11}) + \log\{[0.1698]/[0.1786]\}$

$pH = 10.319 - 0.022 = 10.30$

17.4 $pH = pK_a + \log\{[base]/[acid]\}$

$5.00 = -\log(1.8 \times 10^{-5}) + \log\{[base]/[acid]\}$

$5.00 = 4.745 + \log\{[base]/[acid]\}$

$[base]/[acid] = 1.8$

To prepare this buffer solution, the ratio [base]/[acid] must equal 1.8. For example, you can dissolve 1.8 mol (148 g) of $NaCH_3CO_2$ and 1.0 mol (60.05 g) of CH_3CO_2H in some amount of water.

17.5 Initial pH (before adding acid):

$pH = pK_a + \log\{[base]/[acid]\}$
$= -\log(1.8 \times 10^{-4}) + \log\{[0.70]/[0.50]\}$
$= 3.745 + 0.146 = 3.89$

After adding acid, the added HCl will react with the weak base (formate ion) and form more formic acid. The net effect is to change the ratio of [base]/[acid] in the buffer solution.

Initial amount $HCO_2H = 0.50$ mol/L $\times$ 0.500 L = 0.250 mol

Initial amount $HCO_2^- = 0.70$ mol/L $\times$ 0.50 L = 0.350 mol

Amount HCl added = 1.0 mol/L $\times$ 0.010 L = 0.0100 mol

Amount HCO_2H after HCl addition = 0.250 mol + 0.0100 mol = 0.260 mol

Amount HCO_2^- after HCl addition = 0.350 mol $-$ 0.0100 mol = 0.340 mol

$pH = pK_a + \log\{[base]/[acid]\}$

$pH = -\log(1.8 \times 10^{-4}) + \log\{[0.340]/[0.260]\}$

$pH = 3.745 + 0.117 = 3.86$

17.6 35.0 mL base will partially neutralize the acid.

Initial amount CH_3CO_2H = (0.100 mol/L)(0.1000 L) = 0.01000 mol

Amount NaOH added = (0.100 mol/L)(0.0350 L) = 0.003500 mol

Amount CH_3CO_2H after reaction = 0.01000 − 0.003500 = 0.00650 mol

Amount $CH_3CO_2^-$ after reaction = 0.003500 mol

$[CH_3CO_2H]$ after reaction = 0.00650 mol/0.1350 L = 0.0481 M

$[CH_3CO_2^-]$ after reaction = 0.00350 mol/0.1350 L = 0.02593 M

$K_a = [H_3O^+][CH_3CO_2^-]/[CH_3CO_2H]$

$1.8 \times 10^{-5} = [x][0.02593 + x]/[0.0481 - x]$

$x = [H_3O^+] = 3.34 \times 10^{-5}$ M; pH = 4.48

17.7 75.0 mL acid will partially neutralize the base.

Initial amount NH_3 = (0.100 mol/L)(0.1000 L) = 0.01000 mol

Amount HCl added = (0.100 mol/L)(0.0750 L) = 0.007500 mol

Amount NH_3 after reaction = 0.01000 − 0.007500 = 0.00250 mol

Amount NH_4^+ after reaction = 0.007500 mol

Solve using the Henderson–Hasselbalch equation; use K_a for the weak acid NH_4^+:

pH = pK_a + log {[base]/[acid]}

pH = −log (5.6×10^{-10}) + log {[0.00250]/[0.007500]}

pH = 9.252 − 0.477 = 8.77

17.8 $BaF_2(s) \rightleftharpoons Ba^{2+}(aq) + 2\ F^-(aq)$

$[F^-] = 2[Ba^{2+}] = 2(3.6 \times 10^{-3}\ M) = 7.2 \times 10^{-3}$ M

$K_{sp} = [Ba^{2+}][F^-]^2 = (3.6 \times 10^{-3})(7.2 \times 10^{-3})^2 = 1.9 \times 10^{-7}$

17.9 $AgCN(s) \rightleftharpoons Ag^+(aq) + CN^-(aq)$

$K_{sp} = [Ag^+][CN^-]$

Let x = solubility of AgCN in mol/L

$6.0 \times 10^{-17} = x^2$

$x = 7.75 \times 10^{-9}$ mol/L $= 7.7 \times 10^{-9}$ mol/L

$(7.75 \times 10^{-9}$ mol AgCN/L)(133.9 g AgCN/1 mol AgCN) $= 1.0 \times 10^{-6}$ g/L

17.10 $Ca(OH)_2(s) \rightleftharpoons Ca^{2+}(aq) + 2\ OH^-(aq)$

$K_{sp} = [Ca^{2+}][OH^-]^2$; $K_{sp} = 5.5 \times 10^{-5}$

$5.5 \times 10^{-5} = [x][2x]^2$ (where x = solubility in mol/L)

$x = 2.40 \times 10^{-2}$ mol/L $= 2.4 \times 10^{-2}$ mol/L

Solubility in g/L = $(2.40 \times 10^{-2}$ mol/L)(74.1 g/mol) = 1.8 g/L

17.11 (a) In pure water:

$K_{sp} = [Ba^{2+}][SO_4^{2-}]$; $1.1 \times 10^{-10} = [x][x]$;

$x = 1.0 \times 10^{-5}$ mol/L

(b) In 0.010 M $Ba(NO_3)_2$, which furnishes 0.010 M Ba^{2+} in solution:

$K_{sp} = [Ba^{2+}][SO_4^{2-}]$

$1.1 \times 10^{-10} = [0.010 + x][x]$

$x = 1.1 \times 10^{-8}$ mol/L

17.12 When $[Pb^{2+}] = 1.1 \times 10^{-3}$ M, $[I^-] = 2.2 \times 10^{-3}$ M.

$Q = [Pb^{2+}][I^-]^2 = [1.1 \times 10^{-3}][2.2 \times 10^{-3}]^2 = 5.3 \times 10^{-9}$

This value is less than K_{sp}, which means that the system has not yet reached equilibrium and more PbI_2 will dissolve.

17.13 $K_{sp} = [Pb^{2+}][I^-]^2$. Let x be the concentration of I^- required at equilibrium.

$9.8 \times 10^{-9} = [0.050][x]^2$

$x = [I^-] = 4.4 \times 10^{-4}$ mol/L. A concentration greater than this value will result in precipitation of PbI_2.

Let x be the concentration of Pb^{2+} in solution, in equilibrium with 0.0015 M I^-.

$9.8 \times 10^{-9} = [x][1.5 \times 10^{-3}]^2$

$x = [Pb^{2+}] = 4.4 \times 10^{-3}$ M

17.14 First, determine the concentrations of Ag^+ and Cl^-; then calculate Q, and see whether it is greater than or less than K_{sp}. Concentrations are calculated using the final volume, 105.0 mL, in the equation $C_{dil} \times V_{dil} = C_{conc} \times V_{conc}$.

$[Ag^+](0.1050\ L) = (0.0010\ mol/L)(0.1000\ L)$

$[Ag^+] = 9.52 \times 10^{-4}$ M

$[Cl^-](0.1050\ L) = (0.025\ M)(0.0050\ L)$

$[Cl^-] = 1.19 \times 10^{-3}$ M

$Q = [Ag^+][Cl^-] = [9.52 \times 10^{-4}][1.19 \times 10^{-3}] = 1.1 \times 10^{-6}$

Because $Q > K_{sp}$, precipitation occurs.

17.15

Equation	$[Ag(NH_3)_2]^+ \rightleftharpoons$	Ag^+ +	$2\ NH_3$
Initial (M)	0.0050	0	1.00 − 2(0.0050)
Change	$-x$	$+x$	$+2x$
Equilibrium (M)	0.0050 − x	x	0.99 + $2x$

$K = 1/K_f = 1/1.1 \times 10^7 = [x][0.99]^2/0.0050$

$x = [Ag^+] = 4.6 \times 10^{-10}$ mol/L

17.16 $Cu(OH)_2(s) \rightleftharpoons Cu^{2+}(aq) + 2\ OH^-(aq)$

$K_{sp} = [Cu^{2+}][OH^-]^2$

$Cu^{2+}(aq) + 4\ NH_3(aq) \rightleftharpoons [Cu(NH_3)_4]^{2+}(aq)$

$K_f = [Cu(NH_3)_4^{2+}]/[Cu^{2+}][NH_3]^4$

Net: $Cu(OH)_2(s) + 4\ NH_3(aq) \rightleftharpoons [Cu(NH_3)_4^{2+}](aq) + 2\ OH^-(aq)$

$K_{net} = K_{sp} \times K_f = (2.2 \times 10^{-20})(2.1 \times 10^{13}) = 4.6 \times 10^{-7}$

Applying Chemical Principles

17.1 Everything That Glitters . . .

1. (0.10 g NaCN)(100 g solution/0.035 g NaCN)
(1 mL solution/1 g solution) = 2.9×10^2 mL

2. (1.0×10^3 kg ore)(1000 g/1 kg)(0.012 g Au/100 g ore)
(1 mol Au/196.97 g Au)(8 mol NaCN/4 mol Au)
(1 L/0.0071 mol NaCN) = 1.7×10^2 L

3. $Au^+(aq) + 2\ CN^-(aq) \rightleftharpoons [Au(CN)_2]^-(aq)$

$K_f = [[Au(CN)_2]^-]/([Au^+][CN^-]^2)$
$2.0 \times 10^{38} = 1.1 \times 10^{-4}/(x(0.0071)^2)$

$x = [Au^+] = 1.1 \times 10^{-38}$ M. Yes, the conclusion is reasonable; less than one free Au^+ ion is present per liter of solution.

4. (a) $K_1 = 1/K_{sp} = 1/(6.0 \times 10^{-17}) = 1.67 \times 10^{16} = 1.7 \times 10^{16}$

(b) $K_3 = K_1K_2$
$1.3 \times 10^{21} = (1.67 \times 10^{16})(K_2)$
$K_2 = 7.80 \times 10^4 = 7.8 \times 10^4$

(c) Because $K_2 >> 1$, assume that the reaction to form the complex goes to completion and then calculate the ammount of dissociation of the complex.

Equation	$[Ag(CN)_2]^-$	$\rightleftharpoons$	AgCN	+	CN^-
Initial (M)	0.0071				0
Change	$-x$				$+x$
Equilibrium (M)	$0.0071 - x$				x

$1/K_2 = [CN^-]/[[Ag(CN)_2]^-]$
$1/(7.80 \times 10^4) = x/(0.0071 - x)$
$x = 9.10 \times 10^{-8}$ M
$[CN^-] = 9.1 \times 10^{-8}$ M; $[[Ag(CN)_2]^-] = 0.0071$ M

5. $2\ NaAu(CN)_2(aq) + Zn(s) \rightarrow 2\ Au(s) + Na_2Zn(CN)_4(aq)$

17.2 Take a Deep Breath

1. $pH = pK_a + \log[HPO_4^{2-}]/[H_2PO_4^-]$
$7.40 = 7.20 + \log[HPO_4^{2-}]/[H_2PO_4^-]$
$[HPO_4^{2-}]/[H_2PO_4^-] = 1.58 = 1.6$

2. Assign $x = [HPO_4^{2-}]$, then $[H_2PO_4^-] = (0.020 - x)$
$1.58 = x/(0.020 - x)$; $x = 0.0123$
$[HPO_4^{2-}] = x = 0.012$ mol/L
$[H_2PO_4^-] = 0.020 - x = 0.008$ mol/L

Study Questions

17.1 (a) Decrease pH; (b) increase pH; (c) no change in pH

17.3 pH = 9.25

17.5 pH = 4.38

17.7 pH = 9.12; pH of buffer is lower than the pH of the original solution of NH_3 (pH = 11.17).

17.9 4.7 g

17.11 pH = 4.92

17.13 $[CH_3CO_2H]/[CH_3CO_2^-] = 0.56$

17.15 (a) pH = 3.59; (b) $[HCO_2H]/[HCO_2^-] = 0.45$

17.17 (b) $NH_3 + NH_4Cl$

17.19 The buffer must have a ratio of 0.51 mol NaH_2PO_4 to 1 mol Na_2HPO_4. For example, dissolve 0.51 mol NaH_2PO_4 (61 g) and 1.0 mol Na_2HPO_4 (140 g) in some amount of water.

17.21 46 mL of 1.0 M NaOH

17.23 (a) pH = 4.95; (b) pH = 5.05

17.25 (a) pH = 9.55; (b) pH = 9.50

17.27 (a) Original pH = 5.62
(b) $[Na^+] = 0.0323$ M, $[OH^-] = 1.5 \times 10^{-3}$ M, $[H_3O^+] = 6.5 \times 10^{-12}$ M, and $[C_6H_5O^-] = 0.0308$ M
(c) pH = 11.19

17.29 (a) Original NH_3 concentration = 0.0154 M
(b) At the equivalence point $[H_3O^+] = 1.9 \times 10^{-6}$ M, $[OH^-] = 5.3 \times 10^{-9}$ M, $[NH_4^+] = 6.25 \times 10^{-3}$ M.
(c) pH at equivalence point = 5.73

17.31 The titration curve begins at pH = 13.00 and drops slowly as HCl is added. Just before the equivalence point (when 30.0 mL of acid has been added), the curve falls steeply. The pH at the equivalence point is exactly 7. Just after the equivalence point, the curve flattens again and begins to approach the final pH of just over 1.0. The total volume at the equivalence point is 60.0 mL.

17.33 (a) Starting pH = 11.12
(b) pH at equivalence point = 5.28
(c) pH at midpoint (half-neutralization point) = 9.25
(d) Methyl red, bromcresol green
(e)

Acid (mL)	Added pH
5.00	9.85
15.0	9.08
20.0	8.65
22.0	8.39
30.0	2.04

17.35 See Figure 17.11 on page 782.
(a) Thymol blue or bromphenol blue
(b) Phenolphthalein
(c) Methyl red; thymol blue

17.37 (a) Silver chloride, AgCl; lead(II) chloride, $PbCl_2$
(b) Zinc carbonate, $ZnCO_3$; zinc sulfide, ZnS
(c) Iron(II) carbonate, $FeCO_3$; iron(II) oxalate, FeC_2O_4

17.39 (a) and (b) are soluble, (c) and (d) are insoluble.

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

17.41 (a) $AgCN(s) \rightarrow Ag^+(aq) + CN^-(aq)$, $K_{sp} = [Ag^+][CN^-]$
(b) $NiCO_3(s) \rightarrow Ni^{2+}(aq) + CO_3^{2-}(aq)$, $K_{sp} = [Ni^{2+}][CO_3^{2-}]$
(c) $AuBr_3(s) \rightarrow Au^{3+}(aq) + 3\ Br^-(aq)$, $K_{sp} = [Au^{3+}][Br^-]^3$

17.43 $K_{sp} = (1.9 \times 10^{-3})^2 = 3.6 \times 10^{-6}$

17.45 $K_{sp} = 4.37 \times 10^{-9}$

17.47 $K_{sp} = 1.4 \times 10^{-15}$

17.49 (a) 9.2×10^{-9} M; (b) 2.2×10^{-6} g/L

17.51 (a) 2.4×10^{-4} M; (b) 0.018 g/L

17.53 Only 2.1×10^{-4} g dissolves.

17.55 (a) $PbCl_2$; (b) FeS; (c) $Fe(OH)_2$

17.57 Solubility in pure water = 1.0×10^{-6} mol/L; solubility in 0.010 M SCN^- = 1.0×10^{-10} mol/L

17.59 (a) Solubility in pure water = 2.2×10^{-6} mg/mL
(b) Solubility in 0.020 M $AgNO_3$ = 1.0×10^{-12} mg/mL

17.61 $[Fe^{2+}] = 4.9 \times 10^{-3}$ M

17.63 (a) PbS
(b) Ag_2CO_3
(c) $Al(OH)_3$

17.65 $Q < K_{sp}$, so no precipitate forms.

17.67 $Q > K_{sp}$; $Zn(OH)_2$ will precipitate.

17.69 $[OH^-]$ must exceed 1.0×10^{-5} M.

17.71 Using K_{sp} for $Zn(OH)_2$ and K_f for $[Zn(OH)_4]^{2-}$, K_{net} for

$$Zn(OH)_2(s) + 2\ OH^-(aq) \rightleftharpoons [Zn(OH)_4]^{2-}(aq)$$

is 1×10^1. This indicates that the reaction is definitely product-favored.

17.73 K_{net} for $AgCl(s) + 2\ NH_3(aq) \rightleftharpoons [Ag(NH_3)_2]^+(aq) + Cl^-(aq)$is 1.98×10^{-3}. When all the AgCl dissolves, $[Ag(NH_3)_2^+] = [Cl^-] = 0.050$ M. To achieve these concentrations, $[NH_3]$ must be 1.124 M. Therefore, the amount of NH_3 added must be 2×0.050 mol/L (to react with the AgCl) plus 1.124 mol/L (to achieve the proper equilibrium concentration). The total is 1.22 mol/L NH_3.

17.75 (a) Solubility in pure water = 1.3×10^{-5} mol/L or 0.0019 g/L.
(b) K_{net} for $AgCl(s) + 2\ NH_3(aq) \rightleftharpoons [Ag(NH_3)_2]^+(aq) + Cl^-(aq)$ is 1.98×10^{-3}. When using 1.0 M NH_3, the concentrations of species in solution are $[Ag(NH_3)_2]^+ = [Cl^-] = 0.0409$ M = 0.041 M and so $[NH_3] = 1.0 - 2(0.0409)$ M or about 0.9 M. The amount of AgCl dissolved is 0.041 mol/L or 5.9 g/L.

17.77 (a) $NaBr(aq) + AgNO_3(aq) \rightarrow NaNO_3(aq) + AgBr(s)$
(b) $2\ KCl(aq) + Pb(NO_3)_2(aq) \rightarrow 2\ KNO_3(aq) + PbCl_2(s)$

17.79 $Q > K_{sp}$, so $BaSO_4$ precipitates.

17.81 $[H_3O^+] = 1.9 \times 10^{-10}$ M; pH = 9.73

17.83 $BaCO_3 < Ag_2CO_3 < Na_2CO_3$

17.85 Original pH = 8.62; dilution will not affect the pH.

17.87 (a) 0.100 M acetic acid has a pH of 2.87. Adding sodium acetate slowly raises the pH.
(b) Adding $NaNO_3$ to 0.100 M HNO_3 has no effect on the pH.
In part (a), adding the conjugate base of a weak acid creates a buffer solution. In part (b), HNO_3 is a strong acid, but its conjugate base (NO_3^-) is so weak that the base has no effect on the complete ionization of the acid.

17.89 (a) pH = 4.13
(b) 0.6 g of $C_6H_5CO_2H$
(c) 8.2 mL of 2.0 M HCl should be added

17.91 $K = 2.1 \times 10^6$; the equilibrium lies to the right; yes, AgI forms

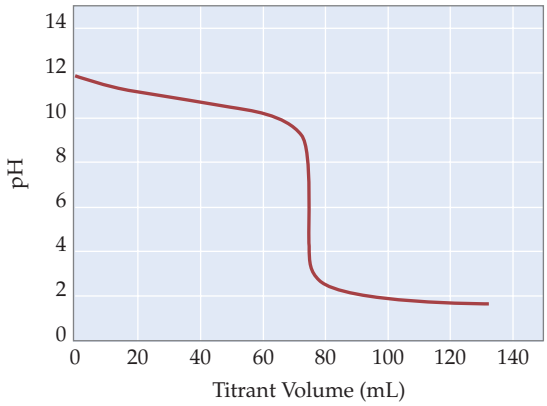
17.93 (a) 0.030 L (30. mL)
(b) 0.48 g CaC_2O_4

17.95 (a) $[F^-] = 1.3 \times 10^{-3}$ M
(b) $[Ca^{2+}] = 2.9 \times 10^{-5}$ M

17.97 (a) $PbSO_4$ will precipitate first.
(b) $[Pb^{2+}] = 5.1 \times 10^{-6}$ M

17.99 When $[CO_3^{2-}] = 0.050$ M, $[Ca^{2+}] = 6.8 \times 10^{-8}$ M. This means only 6.8×10^{-4} % of the ions remain, or that essentially all of the calcium ions have been removed.

17.101 (a) Add H_2SO_4, precipitating $BaSO_4$ and leaving $Na^+(aq)$ in solution.
(b) Add HCl or another source of chloride ion. $PbCl_2$ will precipitate, but $NiCl_2$ is water-soluble.



17.103 (a) $BaSO_4$ will precipitate first.
(b) $[Ba^{2+}] = 1.8 \times 10^{-7}$ M

17.105 (a) pH = 2.81
(b) pH at equivalence point = 8.72
(c) pH at the midpoint = pK_a = 4.62
(d) Phenolphthalein
(e) After 10.0 mL, pH = 4.39.
After 20.0 mL, pH = 5.07.
After 30.0 mL, pH = 11.84.
(f) A plot of pH versus volume of NaOH added would begin at a pH of 2.81, rise slightly to the midpoint at pH = 4.62, and then begin to rise more steeply as the equivalence point is approached (when the volume of NaOH added is 27.0 mL). The pH rises vertically through the equivalence point, and then begins to level off above a pH of about 11.0.

17.107 The K_b value for ethylamine (4.27×10^{-4}) is found in Appendix I.
(a) pH = 11.89
(b) Midpoint pH = 10.63
(c) pH = 10.15
(d) pH = 5.93 at the equivalence point
(e) pH = 2.13
(f) Titration curve

(g) Alizarin or bromcresol purple (see Figure 17.11)

17.109 110 mL NaOH

17.111 Add dilute HCl, say 1 M HCl, to a solution of the salts. Both AgCl and $PbCl_2$ will precipitate, but Cu^{2+} ions will stay in solution (as $CuCl_2$ is water-soluble). Decant off the copper-containing solution to leave a precipitate of white AgCl and $PbCl_2$. Lead(II) chloride ($K_{sp} = 1.7 \times 10^{-5}$) is much more soluble than AgCl ($K_{sp} = 1.8 \times 10^{-10}$). Warming the precipitates in water will dissolve the $PbCl_2$ and leave the AgCl as a white solid.

17.113 $Cu(OH)_2$ will dissolve in a nonoxidizing acid such as HCl, whereas CuS will not.

17.115 When Ag_3PO_4 dissolves slightly, it produces a small concentration of the phosphate ion, PO_4^{3-}. This ion is a strong base and hydrolyzes to HPO_4^{2-}. As this reaction removes the PO_4^{3-} ion from equilibrium with Ag_3PO_4, the equilibrium shifts to the right, producing more PO_4^{3-} and Ag^+ ions. Thus, Ag_3PO_4 dissolves to a greater extent than might be calculated from a K_{sp} value (unless the K_{sp} value was actually determined experimentally).

17.117 (a) Base is added to increase the pH. The added base reacts with acetic acid to form more acetate ions in the mixture. Thus, the fraction of acid declines and the fraction of conjugate base rises (i.e., the ratio $[CH_3CO_2H]/[CH_3CO_2^-]$ decreases) as the pH rises.
(b) At pH = 4, acid predominates (85% acid and 15% acetate ions). At pH = 6, acetate ions predominate (95% acetate ions and 5% acid).
(c) At the point the lines cross, $[CH_3CO_2H] = [CH_3CO_2^-]$. At this point pH = pK_a, so pK_a for acetic acid is 4.74.

17.119 (a) C—C—C angle, 120°; O—C═O, 120°; C—O—H, 109°; C—C—H, 120°
(b) Both the ring C atoms and the C in CO_2H are sp^2 hybridized.
(c) $K_a = 1 \times 10^{-3}$
(d) 10%
(e) pH at half-way point = pK_a = 3.0; pH at equivalence point = 7.3

Chapter 18

Check Your Understanding

18.1 (a) O_3; larger molecules generally have higher entropies than smaller molecules.
(b) $SnCl_4(g)$; gases have higher entropies than liquids.

18.2 (a) $\Delta_r S° = \Sigma nS°(\text{products}) - \Sigma nS°(\text{reactants})$

$\Delta_r S° = (1 \text{ mol/mol-rxn})\, S°[NH_4Cl(aq)]) - (1 \text{ mol/mol-rxn})\, S°[NH_4Cl(s)]$

$\Delta_r S° = (1 \text{ mol/mol-rxn})(169.9 \text{ J/mol} \cdot \text{K}) - (1 \text{ mol/mol-rxn})(94.85 \text{ J/mol} \cdot \text{K})$

$= 75.1 \text{ J/K} \cdot \text{mol-rxn}$

A gain in entropy for the formation of a mixture (solution) is expected.

(b) $\Delta_r S° = (2 \text{ mol } CO_2/\text{mol-rxn})\, S°(CO_2) + (3 \text{ mol } H_2O/\text{mol-rxn})\, S°(H_2O) - [(1 \text{ mol } C_2H_5OH/\text{mol-rxn})\, S°(C_2H_5OH) + (3 \text{ mol } O_2/\text{mol-rxn})\, S°(O_2)]$

$\Delta_r S° = (2 \text{ mol/mol-rxn})(213.74 \text{ J/mol} \cdot \text{K}) + (3 \text{ mol/mol-rxn})(188.84 \text{ J/mol} \cdot \text{K}) - [(1 \text{ mol/mol-rxn})(282.70 \text{ J/mol} \cdot \text{K}) + (3 \text{ mol/mol-rxn})(205.07 \text{ J/mol} \cdot \text{K})]$

$\Delta_r S° = 96.09 \text{ J/K} \cdot \text{mol-rxn}$

An increase in entropy is expected because there is an increase in the number of moles of gases.

18.3 $\Delta S°(\text{system}) = \Delta_r S° = \Sigma nS°(\text{products}) - \Sigma nS°(\text{reactants})$

$\Delta_r S° = (2 \text{ mol HCl/mol-rxn})\, S°[HCl(g)] - \{(1 \text{ mol } H_2/\text{mol-rxn})\, S°[H_{2(g)}] + (1 \text{ mol } Cl_2/\text{mol-rxn})\, S°[Cl_{2(g)}]\}$

$= (2 \text{ mol HCl/mol-rxn})(186.2 \text{ J/K} \cdot \text{mol HCl}) - \{(1 \text{ mol } H_2/\text{mol-rxn})(130.7 \text{ J/K} \cdot \text{mol } H_2) + (1 \text{ mol } Cl_2/\text{mol-rxn})\, (223.08 \text{ J/K} \cdot \text{mol } Cl_2(g)\}$

$= 18.62 \text{ J/K} \cdot \text{mol-rxn} = 18.6 \text{ J/K} \cdot \text{mol-rxn}$

$\Delta_r H° = \Sigma n\Delta_f H°(\text{products}) - \Sigma n\Delta_f H°(\text{reactants})$

$\Delta_r H° = (2 \text{ mol HCl/mol-rxn})\, \Delta_f H°[HCl(g)] - \{(1 \text{ mol } H_2/\text{mol-rxn})\, \Delta_f H°[H_{2(g)}] + (1 \text{ mol } Cl_2/\text{mol-rxn})\, \Delta_f H°[Cl_{2(g)}]\}$

$= (2 \text{ mol HCl/mol-rxn})(-92.31 \text{ kJ/mol HCl}) - \{(1 \text{ mol } H_2/\text{mol-rxn})(0 \text{ kJ/mol } H_2) + (1 \text{ mol } Cl_2/\text{mol-rxn})\, (0 \text{ kJ/mol } Cl_2(g)\}$

$= -184.62 \text{ kJ/mol-rxn}$

Both $\Delta_r H°$ (< 0) and $\Delta_r S°$ (> 0) are favorable, so this reaction is predicted to be spontaneous under standard conditions.

$\Delta S°(\text{surroundings}) = -\Delta_r H°/T = -(-184.62 \text{ kJ/mol-rxn})/298.15 \text{ K} = 0.619219 \text{ kJ/K} \cdot \text{mol-rxn} = 619.219 \text{ J/K} \cdot \text{mol-rxn}$

$\Delta S°(\text{universe}) = \Delta S°(\text{system}) + \Delta S°(\text{surroundings}) = 18.62 \text{ J/K} \cdot \text{mol-rxn} + 619.219 \text{ J/K} \cdot \text{mol-rxn} = 637.8 \text{ J/K} \cdot \text{mol-rxn}$

$\Delta S°(\text{universe}) > 0$, so the reaction is spontaneous under standard conditions.

18.4 For the reaction $N_2(g) + 3\ H_2(g) \rightarrow 2\ NH_3(g)$:

$\Delta_r H° = (2 \text{ mol/mol-rxn})\ \Delta_f H°$ for $NH_3(g) = (2 \text{ mol/mol-rxn})(-45.90 \text{ kJ/mol}) = -91.80 \text{ kJ/mol-rxn}$

$\Delta_r S° = (2 \text{ mol/mol-rxn})\ S°(NH_3) - [(1 \text{ mol/mol-rxn})\ S°(N_2) + (3 \text{ mol/mol-rxn})\ S°(H_2)]$

$\Delta_r S° = (2 \text{ mol/mol-rxn})(192.77 \text{ J/ mol} \cdot \text{K}) - [(1 \text{ mol/mol-rxn})(191.56 \text{ J/mol} \cdot \text{K}) + (3 \text{ mol/mol-rxn})(130.7 \text{ J/mol} \cdot \text{K})]$

$\Delta_r S° = -198.12 \text{ J/K} \cdot \text{mol-rxn} = -198.1 \text{ J/K} \cdot \text{mol-rxn}\ (= -0.1981 \text{ kJ/K} \cdot \text{mol-rxn})$

$\Delta_r G° = \Delta_r H° - T\Delta_r S° = -91.80 \text{ kJ/mol-rxn} - (298 \text{ K})(-0.19812 \text{ kJ/K} \cdot \text{mol-rxn})$

$\Delta_r G° = -32.8 \text{ kJ/mol-rxn}$

18.5 $SO_2(g) + {}^1/_2\ O_2(g) \rightarrow SO_3(g)$

$\Delta_r G° = \Sigma n\Delta_f G°(\text{products}) - \Sigma n\Delta_f G°(\text{reactants})$

$\Delta_r G° = (1 \text{ mol/mol-rxn})\Delta_f G°[SO_3(g)] - \{(1 \text{ mol/mol-rxn})\Delta_f G°[SO_2(g)] + (0.5 \text{ mol/mol-rxn})\Delta_f G°[O_2(g)]\}$

$\Delta_r G° = -371.04 \text{ kJ/mol-rxn} - (-300.13 \text{ kJ/mol-rxn} + 0 \text{ kJ/mol-rxn}) = -70.91 \text{ kJ/mol-rxn}$

18.6 $HgO(s) \rightarrow Hg(\ell) + {}^1/_2\ O_2(g)$; determine the temperature at which $\Delta_r G° = \Delta_r H° - T\Delta_r S° = 0$. T is the unknown in this problem.

$\Delta_r H° = [-\Delta_f H°$ for $HgO(s)] = 90.83 \text{ kJ/mol-rxn}$

$\Delta_r S° = S°[Hg(\ell)] + {}^1/_2\ S°[O_{2(g)}] - S°[HgO(s)]$

$\Delta_r S° = (1 \text{ mol/mol-rxn})(76.02 \text{ J/mol} \cdot \text{K}) + [(0.5 \text{ mol/mol-rxn})(205.07 \text{ J/mol} \cdot \text{K}) - (1 \text{ mol/mol-rxn})(70.29 \text{ J/mol} \cdot \text{K})] = 108.27 \text{ J/K} \cdot \text{mol-rxn}$

$\Delta_r H° - T(\Delta_r S°) = 0 = 90{,}830 \text{ J/mol-rxn} - T(108.27 \text{ J/K} \cdot \text{mol-rxn})$

$T = 839 \text{ K}\ (566\ °\text{C})$

18.7 $C(s) + CO_2(g) \rightleftharpoons 2\ CO(g)$

$\Delta_r G° = \Sigma\ n\Delta_f G°(\text{products}) - \Sigma\ n\Delta_f G°(\text{reactants})$

$\Delta_r G° = 2\ \Delta_f G°(CO) - \Delta_f G°(CO_2)$

$\Delta_r G° = (2 \text{ mol/mol-rxn})(-137.17 \text{ kJ/mol}) - (1 \text{ mol/mol-rxn})(-394.36 \text{ kJ/mol})$

$\Delta_r G° = 120.02 \text{ kJ/mol-rxn}$

$\Delta_r G° = -RT \ln K$

$120{,}020 \text{ J/mol-rxn} = -(8.3145 \text{ J/mol-rxn} \cdot \text{K})(298.15 \text{ K})(\ln K)$

$K = 9.41 \times 10^{-22}$

18.8 $\Delta_r G° = \Sigma n\Delta_f G°(\text{products}) - \Sigma n\Delta_f G°(\text{reactants})$

$\Delta_r G° = (2 \text{ mol/mol-rxn})\Delta_f G°[H_2(g)] + (1 \text{ mol/mol-rxn})\Delta_f G°[O_2(g)] - (2 \text{ mol/mol-rxn})\Delta_f G°[H_2O(\ell)]$

$\Delta_r G° = (2 \text{ mol/mol-rxn})(0 \text{ kJ/mol}) + (1 \text{ mol/mol-rxn})(0 \text{ kJ/mol}) - (2 \text{ mol/mol-rxn})(-237.15 \text{ kJ/mol})$

$\Delta_r G° = 474.30 \text{ kJ/mol-rxn}$

$K_p = e^{-\Delta_r G°/(RT)} = e^{-(474.30 \text{ kJ/mol-rxn})/[(0.0083145 \text{ kJ/ K} \cdot \text{ mol-rxn})(298.2 \text{ K})]} = 8 \times 10^{-84}$

18.9 (a) $\Delta_r G° = 2\ \Delta_f G°(NO) = 2 \text{ mol/mol-rxn} \times 86.58 \text{ kJ/mol} = 173.16 \text{ kJ/mol-rxn} = 173.2 \text{ kJ/mol-rxn}$

The reaction is reactant-favored at equilibrium.

(b) $\Delta_r G = \Delta_r G° + RT \ln Q = 173.16 \text{ kJ/mol-rxn} + (0.0083145 \text{ kJ/K} \cdot \text{mol-rxn})(298.15 \text{ K})\ \ln[P(NO)]^2/[P(N_2)][P(O_2)]$

$\Delta_r G = 173.16 \text{ kJ/mol-rxn} - 11.42 \text{ kJ/mol-rxn} = 161.7 \text{ kJ/mol-rxn}$. The reaction is not spontaneous.

Applying Chemical Principles

18.1 Thermodynamics and Living Things

1. Creatine phosphate + $H_2O \rightarrow$ creatine + HP_i $\quad \Delta_r G° = -43.3 \text{ kJ/mol}$

Adenosine + $HP_i \rightarrow$ adenosine monophosphate + H_2O $\quad \Delta_r G° = +9.2 \text{ kJ/mol}$

Net reaction (sum of the two reactions):

Creatine phosphate + adenosine $\rightarrow$ creatine + adenosine monophosphate

For this, $\Delta_r G° = -43.3 \text{ kJ/mol} + 9.2 \text{ kJ/mol} = -34.1 \text{ kJ/mol}$. The negative value indicates that the transfer of phosphate from creatine phosphate to adenosine is product-favored.

2. $\Delta_r G°' = \Delta_r G° + RT \ln[C][H_3O^+]/[A][B] = \Delta_r G° + (8.31 \times 10^{-3} \text{ kJ/mol} \cdot \text{K})(298 \text{ K})\ \ln[1][1 \times 10^{-7}]/[1][1]$

$\Delta_r G°' = \Delta_r G° - 39.9 \text{ kJ/mol}$

18.2 Are Diamonds Forever?

1. C(diamond) → C(graphite)

(a) $\Delta_r G° = \Sigma n\Delta_f G°(\text{products}) - \Sigma n\Delta_f G°(\text{reactants})$

$\Delta_r G° = (1\ \text{mol/mol-rxn})\Delta_f G°[\text{C(graphite)}] - (1\ \text{mol/mol-rxn})\Delta_f G°[\text{C(diamond]}$

$\Delta_r G° = (1\ \text{mol/mol-rxn})(0\ \text{kJ/mol}) - (1\ \text{mol/mol-rxn})(2.900\ \text{kJ/mol})$

$\Delta_r G° = -2.900\ \text{kJ/mol-rxn}$

$K_p = e^{-\Delta_r G°/(RT)}$

$= e^{-(-2.900\ \text{kJ/mol-rxn})/[(0.0083145\ \text{kJ/ K · mol-rxn})(298.2\ \text{K})]}$

$= 3.22$

(b) $\Delta_r H° = \Sigma n\Delta_f H°(\text{products}) - \Sigma n\Delta_f H°(\text{reactants})$

$\Delta_r H° = (1\ \text{mol/mol-rxn})\Delta_f H°[\text{C(graphite)}] - (1\ \text{mol/mol-rxn})\Delta_f H°[\text{C(diamond]}$

$\Delta_r H° = (1\ \text{mol/mol-rxn})(0\ \text{kJ/mol}) - (1\ \text{mol/mol-rxn})(1.8\ \text{kJ/mol})$

$\Delta_r H° = -1.8\ \text{kJ/mol-rxn}$

$\Delta_r S° = \Sigma nS°(\text{products}) - \Sigma nS°(\text{reactants})$

$\Delta_r S° = (1\ \text{mol/mol-rxn})S°[\text{C(graphite)}] - (1\ \text{mol/mol-rxn})S°[\text{C(diamond]}$

$\Delta_r S° = (1\ \text{mol/mol-rxn})(5.6\ \text{kJ/mol · K}) - (1\ \text{mol/mol-rxn})(2.4\ \text{kJ/mol · K})$

$\Delta_r S° = 3.2\ \text{kJ/mol-rxn · K} = 0.0032\ \text{kJ/ mol · K}$

$\Delta_r G° = \Delta_r H° - T\Delta_r S° = -1.8\ \text{kJ/mol-rxn} - (1000\ \text{K})(0.0032\ \text{kJ/K · mol-rxn})$

$\Delta_r G° = -5.0\ \text{kJ/mol-rxn}$

$K_p = e^{-\Delta_r G°/(RT)}$

$= e^{-(-5.0\ \text{kJ/mol-rxn})/[(0.0083145\ \text{kJ/ K · mol-rxn})(1000\ \text{K})]}$

$= 1.8$

Though still favoring graphite, the equilibrium has shifted more toward diamond.

(c) Greater pressures favor the formation of diamond, which is more dense than graphite.

(d) The rate of reaction is negligibly slow at room temperature.

2. $C_{60}(s) \rightarrow 60\ C(\text{diamond})$

(a) $\Delta_r H° = \Sigma n\Delta_f H°(\text{products}) - \Sigma n\Delta_f H°(\text{reactants})$

$\Delta_r H° = (60\ \text{mol/mol-rxn})\Delta_f H°[\text{C(diamond)}] - (1\ \text{mol/mol-rxn})\Delta_f H°[C_{60}(s)]$

$\Delta_r H° = (60\ \text{mol/mol-rxn})(1.8\ \text{kJ/mol}) - (1\ \text{mol/mol-rxn})(2320\ \text{kJ/mol})$

$\Delta_r H° = -2212\ \text{kJ/mol-rxn} = -2210\ \text{kJ/mol-rxn}$

(b) $\Delta_r S° \approx 0\ \text{kJ/mol-rxn · K}$

$\Delta_r G° = \Delta_r H° - T\Delta_r S° = -2212\ \text{kJ/mol-rxn} - (298.2\ \text{K})(0\ \text{kJ/K · mol-rxn})$

$\Delta_r G° = -2210\ \text{kJ/mol-rxn}$

Thus, the formation of diamond from C_{60} is product-favored.

Study Questions

18.1 (a) Endothermic
(b) Yes
(c) Yes
(d) Yes

18.3 All four processes are spontaneous.

18.5 (a) Decrease in the entropy of the system.
(b) Decrease in the entropy of the system.
(c) Increase in the entropy of the system.
(d) Increase in the entropy of the system.

18.7 (c) is reversible; (a), (b), and (d) are not reversible

18.9 To calculate $\Delta S°$(universe), you need $S°$ and $\Delta_f H°$ for $H_2O(g)$ and $H_2O(\ell)$.

18.11 $q_{rev} = (-333\ \text{J/g})(18.015\ \text{g/mol})(0.50\ \text{mol}) = -3.00 \times 10^3\ \text{J}$

$\Delta S° = q_{rev}/T = -3.00 \times 10^3\ \text{J}/373\ \text{K} = 8.0\ \text{J/K}$

18.13 $\Delta S = k\ln(W_{final} - W_{initial})$

$= (1.381 \times 10^{-23}\ \text{J/K})\ln(30 - 5)$

$= 4.45 \times 10^{-23}\ \text{J/K}$

18.15 The specific heat capacity for $H_2O(s)$ and the enthalpy of fusion for water are needed.

18.17 (a) $CO_2(g)$ at 0 °C
(b) Liquid water at 50 °C
(c) Ruby
(d) One mole of N_2 at 1 bar

18.19 (a) $\Delta_r S° = +12.7\ \text{J/K · mol-rxn}$. Entropy increases.
(b) $\Delta_r S° = -102.56\ \text{J/K · mol-rxn}$. Significant decrease in entropy.
(c) $\Delta_r S° = +93.3\ \text{J/K · mol-rxn}$. Entropy increases.
(d) $\Delta_r S° = -129.7\ \text{J/K · mol-rxn}$. The solution has a smaller entropy (with H^+ forming H_3O^+ and hydrogen bonding occurring) than HCl in the gaseous state.

18.21 (a) $\Delta_r S° = +9.3\ \text{J/K · mol-rxn}$
(b) $\Delta_r S° = -294.0\ \text{J/K · mol-rxn}$

18.23 (a) $\Delta_r S° = -507.3\ \text{J/K · mol-rxn}$; entropy declines as a gaseous reactant is incorporated in a solid compound.
(b) $\Delta_r S° = +313.25\ \text{J/K · mol-rxn}$; entropy increases as five molecules (three of them in the gas phase) form six molecules of products (all gases).

18.25 $\Delta S°(\text{system}) = -134.2\ \text{J/K · mol-rxn}$; $\Delta H°(\text{system}) = -662.75\ \text{kJ/mol-rxn}$; $\Delta S°(\text{surroundings}) = +2222.9\ \text{J/K · mol-rxn}$; $\Delta S°(\text{universe}) = +2088.8\ \text{J/K · mol-rxn}$. The reaction is spontaneous under standard conditions.

18.27 $\Delta S°(\text{system}) = +163.3\ \text{J/K · mol-rxn}$; $\Delta H°(\text{system}) = +285.83\ \text{kJ/mol-rxn}$; $\Delta S°(\text{surroundings}) = -958.68\ \text{J/K · mol-rxn}$; $\Delta S°(\text{universe}) = -795.4\ \text{J/K · mol-rxn}$

The reaction is not spontaneous under standard conditions because the overall entropy change in the universe is negative. The reaction is disfavored by energy dispersal.

18.29 (a) Type 2. The reaction is enthalpy-favored but entropy-disfavored. It is more favorable at low temperatures.
(b) Type 4. This endothermic reaction is not favored by the enthalpy change nor is it favored by the entropy change. It is not spontaneous under standard conditions at any temperature.

18.31 (a) $\Delta_r H° = -438\ \text{kJ/mol-rxn}$; $\Delta_r S° = -201.7\ \text{J/K · mol-rxn}$; $\Delta_r G° = -378\ \text{kJ/mol-rxn}$. The reaction is product-favored at equilibrium and is enthalpy-driven.

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

(b) $\Delta_r H° = -86.61$ kJ/mol-rxn; $\Delta_r S° = -79.4$ J/K · mol-rxn; $\Delta_r G° = -62.9$ kJ/mol-rxn. The reaction is product-favored at equilibrium. The enthalpy change favors the reaction.

18.33 (a) $\Delta_r H° = +116.7$ kJ/mol-rxn; $\Delta_r S° = +168.0$ J/K · mol-rxn; $\Delta_f G° = +66.6$ kJ/mol
(b) $\Delta_r H° = -425.93$ kJ/mol-rxn; $\Delta_r S° = -154.6$ J/K · mol-rxn; $\Delta_f G° = -379.82$ kJ/mol
(c) $\Delta_r H° = +17.51$ kJ/mol-rxn; $\Delta_r S° = +77.95$ J/K · mol-rxn; $\Delta_f G° = -5.73$ kJ/mol

The reactions in (b) and (c) are predicted to be product-favored under standard conditions.

18.35 (a) $\Delta_r G° = -817.54$ kJ/mol-rxn; product-favored
(b) $\Delta_r G° = +256.6$ kJ/mol-rxn; reactant-favored
(c) $\Delta_r G° = -1101.14$ kJ/mol-rxn; product-favored

18.37 $\Delta_f G°[BaCO_3(s)] = -1134.4$ kJ/mol

18.39 (a) $\Delta_r H° = +66.2$ kJ/mol-rxn; $\Delta_r S° = -121.62$ J/K · mol-rxn; $\Delta_r G° = +102.5$ kJ/mol-rxn

Both the enthalpy and the entropy changes are unfavorable. There is no temperature at which the reaction will be product-favored at equilibrium. This is a case like that in the right panel in Figure 18.11 and is a Type 4 reaction (Table 18.1). As the temperature increases, the reaction becomes even more reactant-favored (the value of $\Delta_r G°$ becomes more positive).

(b) $\Delta_r H° = -221.05$ kJ/mol-rxn; $\Delta_r S° = +179.1$ J/K · mol-rxn; $\Delta_r G° = -274.45$ kJ/mol-rxn

The reaction is favored by both enthalpy and entropy and is product-favored at all temperatures. This is a case like that in the left panel in Figure 18.11 and is a Type 1 reaction. As the temperature increases, the reaction becomes even more product-favored (the value of $\Delta_r G°$ becomes more negative).

(c) $\Delta_r H° = -179.0$ kJ/mol-rxn; $\Delta_r S° = -160.2$ J/K · mol-rxn; $\Delta_r G° = -131.23$ kJ/mol-rxn

The reaction is favored by the enthalpy change but disfavored by the entropy change. The reaction becomes less product-favored as the temperature increases; it is a case like the blue line in the middle panel of Figure 18.11.

(d) $\Delta_r H° = +822.2$ kJ/mol-rxn; $\Delta_r S° = +181.28$ J/K · mol-rxn; $\Delta_r G° = +768.19$ kJ/mol-rxn

The reaction is not favored by the enthalpy change but favored by the entropy change. The reaction becomes more product-favored as the temperature increases; it is a case like the red line in the middle panel of Figure 18.11.

18.41 (a) $\Delta_r S° = +174.75$ J/K · mol-rxn; $\Delta_r H° = +116.94$ kJ/mol-rxn $\Delta_r G° = +64.84$ kJ/mol-rxn.

(b) The reaction is not product-favored under standard conditions at 298.15 K.

(c) As the temperature increases, $\Delta_r S°$ becomes more important, so $\Delta_r G°$ can become negative at a sufficiently high temperature and the reaction is product-favored.

18.43 $\Delta_r G° = -RT\ln K$
$= -(8.3145 \text{ J/K} \cdot \text{mol})(298 \text{ K})\ln(1.8 \times 10^{-5})$
$= 2.71 \times 10^4$ J/mol $= 27.1$ kJ/mol

The reaction is reactant-favored at equilibrium.

18.45 $K_p = 6.8 \times 10^{-16}$. Note that K_p is very small and that $\Delta_r G°$ is positive. Both indicate a process that is reactant-favored at equilibrium.

18.47 $\Delta_r G° = -100.24$ kJ/mol-rxn and $K_p = 3.6 \times 10^{17}$. Both the free energy change and K indicate a process that is product-favored at equilibrium.

18.49 (a) $\Delta_r G° = -32.74$ kJ/mol-rxn. The reaction is product-favored at equilibrium.
(b) $\Delta_r G = -21.33$ kJ/mol-rxn. The reaction is spontaneous in the forward direction.

18.51 (a) HBr(g)
(b) NH_4Cl(aq)
(c) C_2H_4(g)
(d) NaCl(g)

18.53 $\Delta_r G° = -98.9$ kJ/mol-rxn. The reaction is product-favored at equilibrium. It is enthalpy-driven.

18.55 $\Delta_r H° = -1428.66$ kJ/mol-rxn; $\Delta_r S° = +47.1$ J/K · mol-rxn; $\Delta S°$(universe) $= +4840$ J/K · mol-rxn. Combustion reactions are spontaneous, and this is confirmed by the sign of $\Delta S°$(universe).

18.57 (a) The reaction occurs spontaneously and is product-favored. Therefore, $\Delta S°$(universe) is positive and $\Delta_r G°$ is negative. The reaction is likely to be exothermic, so $\Delta_r H°$ is negative, and $\Delta S°$(surroundings) is positive. $\Delta S°$(system) is expected to be negative because two moles of gas form one mole of solid. The calculated values are as follows:

$\Delta S°$(system) $= -284.1$ J/K · mol-rxn

$\Delta_r H° = -176.34$ kJ/mol-rxn

$\Delta S°$(surroundings) $= +591.45$ J/K · mol-rxn

$\Delta S°$(universe) $= +307.4$ J/K · mol-rxn

$\Delta_r G° = -91.64$ kJ/mol-rxn

(b) $K_p = 1.1 \times 10^{16}$

18.59 $K_p = 1.3 \times 10^{29}$ at 298 K ($\Delta_r G° = -166.1$ kJ/mol-rxn). The reaction is already extremely product-favored at 298 K. A higher temperature would make the reaction less product-favored because $\Delta_r S°$ has a negative value (-242.3 J/K · mol-rxn).

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

18.61 At the boiling point, $\Delta_r G° = 0 = \Delta_r H° - T\Delta_r S°$.

Here $\Delta_r S° = \Delta_r H°/T = 112$ J/K · mol-rxn at 351.15 K.

18.63 $\Delta_r S°$ is +137.2 J/K · mol-rxn. A positive entropy change means that raising the temperature will increase the product favorability of the reaction (because $-T\Delta S°$ will become more negative).

18.65 The reaction is exothermic, so $\Delta_r H°$ should be negative. Also, a gas and an aqueous solution are formed, so $\Delta_r S°$ should be positive. The calculated values are $\Delta_r H° = -183.32$ kJ/mol-rxn (with a negative sign as expected) and $\Delta_r S° = -7.7$ J/K · mol-rxn

The entropy change is slightly negative, not positive as predicted. The reason for this is the negative entropy change upon dissolving NaOH. Apparently the OH^- ions in water hydrogen-bond with water molecules, an effect that also leads to a small, negative entropy change.

18.67 $\Delta_r H° = +126.03$ kJ/mol-rxn; $\Delta_r S° = +78.2$ J/K · mol-rxn; and $\Delta_r G° = +103$ kJ/mol-rxn. The reaction is not product-favored at equilibrium.

18.69 $\Delta_r G°$ from K value = 4.87 kJ/mol-rxn

$\Delta_r G°$ from free energies of formation = 4.73 kJ/mol-rxn

18.71 $\Delta_r G° = -2.27$ kJ/mol-rxn

18.73 (a) $\Delta_r G° = +141.82$ kJ/mol-rxn, so the reaction is not product-favored at equilibrium.

(b) $\Delta_r H° = +197.86$ kJ/mol-rxn; $\Delta_r S° = +187.95$ J/K · mol-rxn

$T = \Delta_r H°/\Delta_r S° = 1052.7$ K or 779.6 °C

(c) $\Delta_r G°$ at 1500 °C (1773 K) = −135.4 kJ/mol-rxn

K_p at 1500 °C = 1×10^4

18.75 $\Delta_r S° = -459.0$ J/K · mol-rxn; $\Delta_r H° = -793$ kJ/mol-rxn; $\Delta_r G° = -657$ kJ/mol-rxn

The reaction is product-favored at equilibrium. It is enthalpy-driven.

18.77 (a) $\Delta_r G°$ at 80.0 °C = +0.14 kJ/mol-rxn

$\Delta_r G°$ at 110.0 °C = −0.12 kJ/mol-rxn

Rhombic sulfur is more stable than monoclinic sulfur at 80 °C, but the reverse is true at 110 °C.

(b) $T = 370$ K or about 96 °C. This is the temperature at which the two forms are at equilibrium under standard conditions.

18.79 $\Delta_r G°$ at 298 K = 22.64 kJ/mol; reaction is not product-favored at equilibrium. It does become product-favored above 469 K (196 °C).

18.81 $\Delta_f G°[HI(g)] = -10.9$ kJ/mol

18.83 (a) $\Delta_r G° = +194.8$ kJ/mol-rxn and $K = 6.7 \times 10^{-11}$

(b) The reaction is reactant-favored at equilibrium at 727 °C.

(c) Keep the pressure of CO as low as possible (by removing it during the course of the reaction).

18.85 $K_p = P_{Hg(g)}$ at any temperature

$K_p = 1$ at 620.3 K or 347.2 °C when $P_{Hg(g)} = 1.000$ bar

T when $P_{Hg(g)} = (1/760)$ bar is 398.3 K or 125.2 °C.

18.87 (a) True

(b) False. Whether an exothermic system is spontaneous also depends on the entropy change for the system.

(c) False. Reactions with $+\Delta_r H°$ and $+\Delta_r S°$ are product-favored at higher temperatures.

(d) True

18.89 Dissolving a solid such as NaCl in water is a product-favored process. Thus, $\Delta G° < 0$. If $\Delta H° = 0$, then the only way the free energy change can be negative is if $\Delta S°$ is positive. Generally the entropy change is the important factor in forming a solution.

18.91 $2\ C_2H_6(g) + 7\ O_2(g) \rightarrow 4\ CO_2(g) + 6\ H_2O(g)$

(a) Not only is this an exothermic combustion reaction, but there is also an increase in the number of molecules of gases from reactants to products. Therefore, we would predict a positive value for $\Delta S°$ for both the system and the surroundings and thus for the universe as well.

(b) The exothermic reaction has $\Delta_r H° < 0$. Combined with a positive $\Delta S°$(system), the value of $\Delta_r G°$ is negative.

(c) The value of K_p is likely to be much greater than 1. Further, because $\Delta S°$(system) is positive, the value of K_p will be even larger at a higher temperature. (See the left panel of Figure 18.11.)

18.93 Reaction 1: $\Delta_r S°_1 = -80.7$ J/K · mol-rxn

Reaction 2: $\Delta_r S°_2 = -161.60$ J/K · mol-rxn

Reaction 3: $\Delta_r S°_3 = -242.3$ J/K · mol-rxn

$\Delta_r S°_1 + \Delta_r S°_2 = \Delta_r S°_3$; entropy is a state function.

18.95 (a) $\Delta_r H° = -352.88$ kJ/mol-rxn and $\Delta_r S° = +21.31$ J/K · mol-rxn. Therefore, at 298 K, $\Delta_r G° = -359.23$ kJ/mol-rxn.

(b) 4.8 g of Mg is required.

18.97 (a) $N_2H_4(\ell) + O_2(g) \rightarrow 2\ H_2O(\ell) + N_2(g)$

O_2 is the oxidizing agent and N_2H_4 is the reducing agent.

(b) $\Delta_r H° = -622.29$ kJ/mol-rxn and $\Delta_r S° = +4.87$ J/K · mol-rxn. Therefore, at 298 K, $\Delta_r G° = -623.74$ kJ/mol-rxn.

(c) 0.0027 K

(d) 7.5 mol O_2

(e) 4.8×10^3 g solution

(f) 7.5 mol $N_2(g)$ occupies 170 L at 273 K and 1.0 atm of pressure.

18.99 Iodine dissolves readily, so the process is product-favored and $\Delta G°$ must be less than zero. Because $\Delta H° = 0$, the process is entropy-driven.

18.101 $CH_3OH(g) \rightarrow C(s, \text{graphite}) + 2\ H_2(g) + 1/2\ O_2(g)$

(a) The reaction becomes more product-favored at equilibrium as temperature increases.

(b) There is no temperature between 400 K and 1000 K at which the decomposition is product-favored at equilibrium.

18.103 (a) For the electrolysis of water: $\Delta_r G° = 474.3$ kJ. For the formation from methane: $\Delta_r G° = 142.2$ kJ.

(b) For the electrolysis of water: $\Delta_r G° = 237.2$ kJ/mol H_2
For the formation from methane: $\Delta_r G° = 47.4$ kJ/mol H_2

(c) The free energy change for the formation of H_2 from methane is clearly less than that to obtain H_2 from water electrolysis.

18.105 (a, b)

Temperature (K)	$\Delta_r G°$ (kJ/mol)	K
298.0 K	−32.74	5.5×10^5
800.0 K	+72.9	2×10^{-5}
1300. K	+184.0	4.0×10^{-8}

(c) The largest mole fraction of NH_3 in an equilibrium mixture will be at 298 K.

18.107 (a) False
(b) True
(c) False
(d) False

Chapter 19

Check Your Understanding

19.1 Oxidation (Fe^{2+}, the reducing agent, is oxidized):

$Fe^{2+}(aq) \rightarrow Fe^{3+}(aq) + e^-$

Reduction (MnO_4^-, the oxidizing agent, is reduced)

$MnO_4^-(aq) + 8\ H^+(aq) + 5\ e^- \rightarrow Mn^{2+}(aq) + 4\ H_2O(\ell)$

Overall reaction:

$MnO_4^-(aq) + 8\ H^+(aq) + 5\ Fe^{2+}(aq) \rightarrow Mn^{2+}(aq) + 5\ Fe^{3+}(aq) + 4\ H_2O(\ell)$

19.2 (a) Oxidation half-reaction:

$Al(s) + 3\ OH^-(aq) \rightarrow Al(OH)_3(s) + 3\ e^-$

Reduction half-reaction:

$S(s) + H_2O(\ell) + 2\ e^- \rightarrow HS^-(aq) + OH^-(aq)$

Overall reaction:

$2\ Al(s) + 3\ S(s) + 3\ H_2O(\ell) + 3\ OH^-(aq) \rightarrow 2\ Al(OH)_3(s) + 3\ HS^-(aq)$

(b) Aluminum is the reducing agent and is oxidized; sulfur is the oxidizing agent and is reduced.

19.3 Construct two half-cells, the first with a silver electrode and a solution containing $Ag^+(aq)$, and the second with a nickel electrode and a solution containing $Ni^{2+}(aq)$. Connect the two half-cells with a salt bridge. When the electrodes are connected through an external circuit, electrons will flow from the anode (the nickel electrode) to the cathode (the silver electrode). The overall cell reaction is $Ni(s) + 2\ Ag^+(aq) \rightarrow Ni^{2+}(aq) + 2\ Ag(s)$. To maintain electrical neutrality in the two half-cells, negative ions will flow from the $Ag|Ag^+$ half-cell to the $Ni|Ni^{2+}$ half-cell, and positive ions will flow in the opposite direction.

19.4 $Zn(s)|Zn^{2+}(aq)\|SO_4^{2-}|PbSO_4(s)|Pb(s)$

19.5 (a) Using Appendix M, the order determined for these metals from least strong reducing agent to strongest reducing agent is Hg < Pb < Sn. (The farther down the table, the stronger the metal is as a reducing agent.)

(b) F_2, Cl_2, and Br_2 all can oxidize mercury to mercury(II); Hg is located "southeast" of them on the table. I_2 cannot oxidize mercury to mercury(II); mercury is located "northeast" rather than "southeast" of it.

19.6 Overall reaction: $2\ Al(s) + 3\ Fe^{2+}(aq) \rightarrow 2\ Al^{3+}(aq) + 3\ Fe(s)$

$(E°_{cell} = 1.22\ V,\ n = 6)$

$E_{cell} = E°_{cell} - (0.0257/n)\ \ln\{[Al^{3+}]^2/[Fe^{2+}]^3\}$
$= 1.22 - (0.0257/6)\ \ln\{[0.025]^2/[0.50]^3\}$
$= 1.22\ V - (-0.0227)\ V = 1.24\ V$

19.7 Overall reaction: $2\ Ag^+(aq) + H_2(g) \rightarrow 2\ Ag(s) + 2\ H^+(aq)$

$(E°_{cell} = 0.7994\ V,\ n = 2)$

$E_{cell} = E°_{cell} - (0.0257/n)\ \ln\{[H^+]^2/([Ag^+]^2\ P_{H2})\}$

$0.902\ V = 0.7994 - (0.0257/2)\ \ln\{x^2/([1.0]^2(1.0)\}$

$x = [H^+] = 0.0185\ M = 0.018\ M$

$pH = -\log(0.0185) = 1.73$

19.8 $\Delta_r G° = -nFE°$
$= -(2\ \text{mol}\ e^-)(96{,}500\ \text{C/mol}\ e^-)(-0.76\ V)(1\ J/1\ C \cdot V)$
$= 150{,}000\ J = 150\ kJ$

The negative value of $E°$ and the positive value of $\Delta_r G°$ both indicate a reactant-favored reaction at equilibrium.

19.9 $E°_{cell} = E°_{cathode} - E°_{anode} = 0.799\ V - 0.855\ V = -0.056\ V;\ n = 2$

$nE°/0.0257 = \ln K$

$2(-0.056)/0.0257 = \ln K$

$K = 0.013$

19.10 Cathode: $2\ H_2O(\ell) + 2\ e^- \rightarrow 2\ OH^-(aq) + H_2(g)$

$E°_{cathode} = -0.83$ V

Anode: $4\ OH^-(aq) \rightarrow O_2(g) + 2\ H_2O(\ell) + 4\ e^-$

$E°_{anode} = 0.40$ V

Overall: $2\ H_2O(\ell) \rightarrow 2\ H_2(g) + O_2(g)$

$E°_{cell} = E°_{cathode} - E°_{anode} = -0.83\ V - 0.40\ V = -1.23\ V$

The minimum voltage needed under standard conditions to cause this reaction to occur is 1.23 V.

19.11 (1) O_2 is formed at the anode, by the reaction

$$2\ H_2O(\ell) \rightarrow 4\ H^+(aq) + O_2(g) + 4\ e^-.$$

$(0.445\ A)(45\ min)(60\ s/min)(1\ C/1\ A \cdot s)$
$(1\ mol\ e^-/96{,}500\ C)(1\ mol\ O_2/4\ mol\ e^-)$
$(32\ g\ O_2/1\ mol\ O_2) = 0.10\ g\ O_2$

(2) The cathode reaction (electrolysis of molten NaCl) is

$$Na^+(melt) + e^- \rightarrow Na(\ell).$$

$(25 \times 10^3\ A)(60\ min)(60\ s/min)(1\ C/1\ A \cdot s)$
$(1\ mol\ e^-/96{,}500\ C)(1\ mol\ Na/mol\ e^-)(23\ g\ Na/1\ mol\ Na) = 21{,}000\ g\ Na = 21\ kg$

Applying Chemical Principles

19.1 Electric Batteries versus Gasoline

1. (a) $\Delta_rG° = -nFE°$
$= -(1\ mol\ e^-)(96{,}485\ C/mol\ e^-)(3.6\ V)$
$= -3.47 \times 10^5\ C \cdot V$
$\Delta_rG° = (-3.47 \times 10^5\ C \cdot V)(1\ J/1\ C \cdot V)$
$(1\ kJ/1000\ J) = -347\ kJ = -350\ kJ$

(b) $(1000\ g)(1\ mol\ Li/6.94\ g\ Li)(-347\ kJ/mol) = -5.00 \times 10^4\ kJ = -5.0 \times 10^4\ kJ$

2. $(15\ gallons)(4\ qt/1\ gallon)(1\ L/1.057\ qt)(0.70\ kg/L)(46\ MJ/kg)(1000\ kJ/1\ MJ) = 1.83 \times 10^6\ kJ = 1.8 \times 10^6\ kJ$

3. $(1.83 \times 10^6\ kJ)/(5.00 \times 10^4\ kJ/kg\ Li) = 37\ kg\ Li$

19.2 Sacrifice!

1. An insulator will prevent the flow of electrons from the zinc to copper, preventing zinc from keeping the copper reduced.

2. (a) tin, (c) iron, (d) nickel, and (e) chromium

3. (e) chromium

4. (a) Oxidation half-reaction: $Cu(s) \rightarrow Cu^{2+}(aq) + 2\ e^-$

Reduction half-reaction:
$1/2\ O_2(g) + H_2O(\ell) + 2\ e^- \rightarrow 2\ OH^-(aq)$

(b) Equation 1:
$Cu(s) \rightarrow Cu^{2+}(aq) + 2\ e^-$
$E° = -0.337$ V; $\Delta_rG° = -nFE° = -(2\ mol\ e^-)(96{,}485\ C/mol\ e^-)(-0.337\ V)(1\ J/1\ C \cdot V) = 6.503 \times 10^4\ J$

Equation 2:
$1/2\ O_2(g) + H_2O(\ell) + 2\ e^- \rightarrow 2\ OH^-(aq)$
$E° = 0.40$ V; $\Delta_rG° = -nFE° = -(2\ mol\ e^-)(96{,}485\ C/mol\ e^-)(0.40\ V)(1\ J/1\ C \cdot V) = -7.72 \times 10^4\ J$

Equation 3:
$Cu^{2+}(aq) + 2\ OH^-(aq) \rightarrow Cu(OH)_2(s)$
$K = 1/K_{sp} = 1/(2.2 \times 10^{-20}) = 4.55 \times 10^{19}$;
$\Delta_rG° = -RT\ln K = -(8.3145\ J/K \cdot mol)(298\ K)\ln(4.55 \times 10^{19}) = -1.121 \times 10^5\ J$

Total $\Delta_rG° = 6.503 \times 10^4$ J/mol-rxn $+ 7.72 \times 10^4$ J/mol-rxn $+ -1.121 \times 10^5$ J/mol-rxn $= -1.243 \times 10^5$ J/mol-rxn

$K = e^{-\Delta_rG°/(RT)}$
$= e^{-(-1.243 \times 105\ J/mol\text{-}rxn)/[(8.3145\ J/\ K\ \cdot\ mol\text{-}rxn)(298\ K)]}$
$= 6.1 \times 10^{21}$

5. (a) $Cu(OH)_2(s) + 2\ e^- \rightarrow Cu(s) + 2\ OH^-(aq)$
(b) $Zn(s) + 2\ OH^-(aq) \rightarrow Zn(OH)_2(s) + 2\ e^-$
(c) $Cu(OH)_2(s) + Zn(s) \rightarrow Cu(s) + Zn(OH)_2(s)$
(d) $E = -0.36\ V - (-1.245\ V) = 0.89\ V$

Study Questions

19.1 (a) $Cr(s) \rightarrow Cr^{3+}(aq) + 3\ e^-$

Cr is a reducing agent; this is an oxidation reaction.

(b) $AsH_3(g) \rightarrow As(s) + 3\ H^+(aq) + 3\ e^-$

AsH_3 is a reducing agent; this is an oxidation reaction.

(c) $VO_3^-(aq) + 6\ H^+(aq) + 3\ e^- \rightarrow V^{2+}(aq) + 3\ H_2O(\ell)$

$VO_3^-(aq)$ is an oxidizing agent; this is a reduction reaction.

(d) $2\ Ag(s) + 2\ OH^-(aq) \rightarrow Ag_2O(s) + H_2O(\ell) + 2e^-$

Silver is a reducing agent; this is an oxidation reaction.

19.3 (a) $Ag(s) \rightarrow Ag^+(aq) + e^-$
$e^- + NO_3^-(aq) + 2\ H^+(aq) \rightarrow NO_2(g) + H_2O(\ell)$
$Ag(s) + NO_3^-(aq) + 2\ H^+(aq) \rightarrow Ag^+(aq) + NO_2(g) + H_2O(\ell)$

(b) $2[MnO_4^-(aq) + 8\ H^+(aq) + 5\ e^- \rightarrow Mn^{2+}(aq) + 4\ H_2O(\ell)]$
$5[HSO_3^-(aq) + H_2O(\ell) \rightarrow SO_4^{2-}(aq) + 3\ H^+(aq) + 2\ e^-]$
$2\ MnO_4^-(aq) + H^+(aq) + 5\ HSO_3^-(aq) \rightarrow 2\ Mn^{2+}(aq) + 3\ H_2O(\ell) + 5\ SO_4^{2-}(aq)$

(c) $4[Zn(s) \rightarrow Zn^{2+}(aq) + 2\ e^-]$
$2\ NO_3^-(aq) + 10\ H^+(aq) + 8\ e^- \rightarrow N_2O(g) + 5\ H_2O(\ell)$
$4\ Zn(s) + 2\ NO_3^-(aq) + 10\ H^+(aq) \rightarrow 4\ Zn^{2+}(aq) + N_2O(g) + 5\ H_2O(\ell)$

(d) $Cr(s) \rightarrow Cr^{3+}(aq) + 3\ e^-$
$3\ e^- + NO_3^-(aq) + 4\ H^+(aq) \rightarrow NO(g) + 2\ H_2O(\ell)$
$Cr(s) + NO_3^-(aq) + 4\ H^+(aq) \rightarrow Cr^{3+}(aq) + NO(g) + 2\ H_2O(\ell)$

19.5 (a) $2[Al(s) + 4\ OH^-(aq) \rightarrow Al(OH)_4^-(aq) + 3\ e^-]$

$3[2\ H_2O(\ell) + 2\ e^- \rightarrow H_2(g) + 2\ OH^-(aq)]$

$2\ Al(s) + 2\ OH^-(aq) + 6\ H_2O(\ell) \rightarrow 2\ Al(OH)_4^-(aq) + 3\ H_2(g)$

(b) $2[CrO_4^{2-}(aq) + 4\ H_2O(\ell) + 3\ e^- \rightarrow Cr(OH)_3(s) + 5\ OH^-(aq)]$

$3[SO_3^{2-}(aq) + 2\ OH^-(aq) \rightarrow SO_4^{2-}(aq) + H_2O(\ell) + 2\ e^-]$

$2\ CrO_4^{2-}(aq) + 3\ SO_3^{2-}(aq) + 5\ H_2O(\ell) \rightarrow 2\ Cr(OH)_3(s) + 3\ SO_4^{2-}(aq) + 4\ OH^-(aq)$

(c) $Zn(s) + 4\ OH^-(aq) \rightarrow [Zn(OH)_4]^{2-}(aq) + 2\ e^-$

$Cu(OH)_2(s) + 2\ e^- \rightarrow Cu(s) + 2\ OH^-(aq)$

$Zn(s) + 2\ OH^-(aq) + Cu(OH)_2(s) \rightarrow [Zn(OH)_4]^{2-}(aq) + Cu(s)$

(d) $3[HS^-(aq) + OH^-(aq) \rightarrow S(s) + H_2O(\ell) + 2\ e^-]$

$ClO_3^-(aq) + 3\ H_2O(\ell) + 6\ e^- \rightarrow Cl^-(aq) + 6\ OH^-(aq)$

$3\ HS^-(aq) + ClO_3^-(aq) \rightarrow 3\ S(s) + Cl^-(aq) + 3\ OH^-(aq)$

19.7 Electrons flow from the Cr electrode to the Fe electrode. Negative ions move via the salt bridge from the $Fe|Fe^{2+}$ half-cell to the $Cr|Cr^{3+}$ half-cell (and positive ions move in the opposite direction).

Anode (oxidation): $Cr(s) \rightarrow Cr^{3+}(aq) + 3\ e^-$

Cathode (reduction): $Fe^{2+}(aq) + 2\ e^- \rightarrow Fe(s)$

19.9 (a) Oxidation: $Fe(s) \rightarrow Fe^{2+}(aq) + 2\ e^-$

Reduction: $O_2(g) + 4\ H^+(aq) + 4\ e^- \rightarrow 2\ H_2O(\ell)$

Overall: $2\ Fe(s) + O_2(g) + 4\ H^+(aq) \rightarrow 2\ Fe^{2+}(aq) + 2\ H_2O(\ell)$

(b) Anode, oxidation: $Fe(s) \rightarrow Fe^{2+}(aq) + 2\ e^-$

Cathode, reduction: $O_2(g) + 4\ H^+(aq) + 4\ e^- \rightarrow 2\ H_2O(\ell)$

(c) Electrons flow from the negative anode (Fe) to the positive cathode (site of the O_2 half-reaction). Negative ions move through the salt bridge from the cathode compartment in which the O_2 reduction occurs to the anode compartment in which Fe oxidation occurs (and positive ions move in the opposite direction).

19.11 (a) Reduction of Fe^{3+} ions by copper.

Reduction: $Fe^{3+}(aq) + e^- \rightarrow Fe^{2+}(aq)$

Oxidation: $Cu(s) \rightarrow Cu^{2+}(aq) + 2\ e^-$

Overall: $2\ Fe^{3+}(aq) + Cu(s) \rightarrow 2\ Fe^{2+}(aq) + Cu^{2+}(aq)$

(b) Reduction of Fe^{3+} ions by lead

Reduction: $Fe^{3+}(aq) + e^- \rightarrow Fe^{2+}(aq)$

Oxidation: $Pb(s) + SO_4^{2-}(aq) \rightarrow PbSO_4(s) + 2\ e^-$

Overall: $Pb(s) + SO_4^{2-}(aq) + 2\ Fe^{3+}(aq) \rightarrow PbSO_4(s) + 2\ Fe^{2+}(aq)$

19.13 $Cu(s)|Cu^{2+}(aq)\|Cl^-(aq)|Cl_2(g)|Pt$

19.15 (a) All are primary batteries, not rechargeable.
(b) Dry cells and alkaline batteries have Zn anodes and are primary batteries. Ni-Cd batteries have a cadmium anode and are rechargeable.
(c) Dry cells have an acidic environment, whereas the environment is alkaline for alkaline and Ni-Cd cells.

19.17 (a) $E°_{cell} = -1.298$ V; not product-favored
(b) $E°_{cell} = -0.51$ V; not product-favored
(c) $E°_{cell} = -1.023$ V; not product-favored
(d) $E°_{cell} = +0.028$ V; product-favored

19.19 (a) $Sn^{2+}(aq) + 2\ Ag(s) \rightarrow Sn(s) + 2\ Ag^+(aq)$

$E°_{cell} = -0.94$ V; not product-favored

(b) $3\ Sn^{4+}(aq) + 2\ Al(s) \rightarrow 3\ Sn^{2+}(aq) + 2\ Al^{3+}(aq)$

$E°_{cell} = +1.81$ V; product-favored

(c) $2\ ClO_3^-(aq) + 10\ Ce^{3+}(aq) + 12\ H^+(aq) \rightarrow Cl_2(aq) + 10\ Ce^{4+}(aq) + 6\ H_2O(\ell)$

$E°_{cell} = -0.14$ V; not product-favored

(d) $3\ Cu(s) + 2\ NO_3^-(aq) + 8\ H^+(aq) \rightarrow 3\ Cu^{2+}(aq) + 2\ NO(g) + 4\ H_2O(\ell)$

$E°_{cell} = +0.62$ V; product-favored

19.21 (a) Al
(b) Zn and Al
(c) $Fe^{2+}(aq) + Sn(s) \rightarrow Fe(s) + Sn^{2+}(aq)$; reactant-favored at equilibrium
(d) $Zn^{2+}(aq) + Sn(s) \rightarrow Zn(s) + Sn^{2+}(aq)$; reactant-favored at equilibrium

19.23 Best reducing agent, (e) Cr(s) (Use Appendix M.)

19.25 (d) Ag^+

19.27 See Example 19.5
(a) F_2, most readily reduced
(b) F_2 and Cl_2

19.29 $E°_{cell} = +0.3923$ V. When $[Zn(OH)_4^{2-}] = [OH^-] = 0.025$ M and $P(H_2) = 1.0$ bar, $E_{cell} = 0.345$ V.

19.31 $E°_{cell} = +1.563$ V and $E_{cell} = +1.58$ V

19.33 $E°_{cell} = +1.563$ V. When $E_{cell} = 1.48$ V, $n = 2$, and $[Zn^{2+}] = 1.0$ M, the concentration of $Ag^+ = 0.040$ M.

19.35 (a) $\Delta_rG° = -29.0$ kJ; $K = 1 \times 10^5$
(b) $\Delta_rG° = +89$ kJ; $K = 3 \times 10^{-16}$

19.37 $E°_{cell}$ for $AgBr(s) \rightarrow Ag^+(aq) + Br^-(aq)$ is -0.7281 V. $K_{sp} = 4.9 \times 10^{-13}$

19.39 $K_{formation} = 2 \times 10^{25}$

19.41 See Figure 19.20. Electrons from the battery or other source enter the cathode where they are transferred to Na^+ ions, reducing the ions to Na metal. Chloride ions move toward the positively charged anode where an electron is transferred from each Cl^- ion, and Cl_2 gas is formed.

19.43 O_2 from the oxidation of water is more likely than F_2. See Example 19.10.

19.45 See Example 19.10.
(a) Cathode: $2\ H_2O(\ell) + 2\ e^- \rightarrow H_2(g) + 2\ OH^-(aq)$
(b) Anode: $2\ Br^-(aq) \rightarrow Br_2(\ell) + 2\ e^-$

19.47 Mass of Ni = 0.0334 g

19.49 Time = 2300 s or 38 min

19.51 Time = 250 h

19.53 (b) Only Mg, among the four choices.

19.55 $E°_{cell} = E°_{cathode} - E°_{anode} = 0.40\ V - (-0.44\ V) = 0.84\ V$. A positive $E°_{cell}$ indicates that the reaction is product-favored at equilibrium. Decreasing the pH decreases $[OH^-]$. Because OH^- is one of the products of the net reaction, decreasing its concentration will result in more product favorability.

19.57 (a) $UO_2{}^+(aq) + 4\ H^+(aq) + e^- \rightarrow U^{4+}(aq) + 2\ H_2O(\ell)$
(b) $ClO_3{}^-(aq) + 6\ H^+(aq) + 6\ e^- \rightarrow Cl^-(aq) + 3\ H_2O(\ell)$
(c) $N_2H_4(aq) + 4\ OH^-(aq) \rightarrow N_2(g) + 4\ H_2O(\ell) + 4\ e^-$
(d) $ClO^-(aq) + H_2O(\ell) + 2\ e^- \rightarrow Cl^-(aq) + 2\ OH^-(aq)$

19.59 (a, c) The electrode at the right is a magnesium anode. (Magnesium metal supplies electrons and is oxidized to Mg^{2+} ions.) Electrons pass through the wire to the silver cathode, where Ag^+ ions are reduced to silver metal. Nitrate ions move via the salt bridge from the $AgNO_3$ solution to the $Mg(NO_3)_2$ solution (and Na^+ ions move in the opposite direction). A salt bridge is needed to maintain electrical neutrality in each half-cell and to complete the electrical circuit.
(b) Anode: $Mg(s) \rightarrow Mg^{2+}(aq) + 2\ e^-$
Cathode: $Ag^+(aq) + e^- \rightarrow Ag(s)$
Net reaction: $Mg(s) + 2\ Ag^+(aq) \rightarrow Mg^{2+}(aq) + 2\ Ag(s)$

19.61 (a) For 1.7 V:
Use chromium as the anode to reduce $Ag^+(aq)$ to Ag(s) at the cathode. The cell potential is +1.71 V.
(b) For 0.5 V:
(i) Use copper as the anode to reduce silver ions to silver metal at the cathode. The cell potential is +0.46 V.
(ii) Use silver as the anode to reduce chlorine to chloride ions. The cell potential would be +0.56 V. (In practice, this setup is not likely to work well because the product would be insoluble silver chloride.)

19.63 (a) $Zn^{2+}(aq)$
(b) $Au^+(aq)$
(c) Zn(s)
(d) Au(s)
(e) Yes, Sn(s) will reduce Cu^{2+}.
(f) No, Ag(s) can only reduce $Au^+(aq)$.
(g) Cu^{2+}, Ag^+ and Au^+
(h) $Ag^+(aq)$ can oxidize Cu, Sn, Co, and Zn.

19.65 (a) The cathode is the site of reduction, so the half-reaction must be $2\ H^+(aq) + 2\ e^- \rightarrow H_2(g)$. This is the case with the following half-reactions: $Cr^{3+}(aq) \rightarrow Cr(s)$, $Fe^{2+}(aq) \rightarrow Fe(s)$, and $Mg^{2+}(aq) \rightarrow Mg(s)$.
(b) Choosing from the half-cells in part (a), the reaction of Mg(s) and $H^+(aq)$ would produce the most positive potential (2.37 V), and the reaction of H_2 with Cu^{2+} would produce the least positive potential (+0.337 V).

19.67 8.1×10^5 g Al

19.69 (a) $E°_{anode} = -0.268$ V
(b) $K_{sp} = 2 \times 10^{-5}$

19.71 $\Delta_r G° = -409$ kJ

19.73 6700 kWh; 820 kg Na; 1300 kg Cl_2

19.75 Ru^{2+}, $Ru(NO_3)_2$

19.77 9.5×10^6 g Cl_2 per day

19.79 Anode: $2\ H_2O(\ell) \rightarrow O_2(g) + 4\ H^+(aq) + 4\ e^-$
Cathode: $Cu^{2+}(aq) + 2\ e^- \rightarrow Cu(s)$

19.81 The rate of the reaction with H_2O is more rapid than the rate of the reaction with $NO_3{}^-$.
Products formed at anode: $O_2(g)$ and $H^+(aq)$
Anode half-reaction: $2\ H_2O(\ell) \rightarrow O_2(g) + 4\ H^+(aq) + 4\ e^-$

19.83 Under standard conditions, the spontaneous reaction is $Hg^{2+}(aq) + 2\ Fe^{2+}(aq) \rightarrow Hg(\ell) + 2\ Fe^{3+}(aq)$ with $E° = 0.084$ V.
Under the conditions present, $E = -0.244$ V. The reaction is not spontaneous in the same direction as under standard conditions but in the opposite direction: $Hg(\ell) + 2\ Fe^{3+}(aq) \rightarrow Hg^{2+}(aq) + 2\ Fe^{2+}(aq)$. Under these conditions, the anode for the spontaneous reaction is the $Hg(\ell)|Hg^{2+}(aq, 0.020\ M)$ electrode and the measured voltage will be 0.244 V.

19.85 $E° = 0.771$ V. When $[H^+] = 1.0 \times 10^{-7}$ M, $E = 1.185$ V. The reaction is more favorable at a lower $[H^+]$ (higher pH). The reaction is thus less favorable at lower pH.

19.87 (a) See Figure 19.5
In this case, both electrodes are made of silver metal. On one side, the solution contains 1.0×10^{-5} M Ag^+ and on the other the solution contains 1.0 M Ag^+. The cathode is the electrode on the side that has the 1.0 M Ag^+ solution [half-reaction: $Ag^+(aq) + e^- \rightarrow Ag(s)$], and the anode is the electrode on the side that has the 1.0×10^{-5} M Ag^+ solution [half-reaction: $Ag(s) \rightarrow Ag^+(aq) + e^-$]. Connecting the two electrodes is a wire. Electrons flow through the wire from the anode to the cathode. A salt bridge also connects the two compartments.
(b) $E = 0.30$ V

19.89 (a) $K = 3.4 \times 10^{-10}$; reactant-favored at equilibrium
(b) $K = 3.0$; product-favored at equilibrium

19.91 (a) $\Delta_r G° = -3.6 \times 10^2$ kJ/mol-rxn
(b) $\Delta_r G° = -79$ kJ/mol-rxn

19.93 (a) $2[Ag^+(aq) + e^- \rightarrow Ag(s)]$

$$C_6H_5CHO(aq) + H_2O(\ell) \rightarrow C_6H_5CO_2H(aq) + 2\ H^+(aq) + 2\ e^-$$

$$2\ Ag^+(aq) + C_6H_5CHO(aq) + H_2O(\ell) \rightarrow C_6H_5CO_2H(aq) + 2\ H^+(aq) + 2\ Ag(s)$$

(b) $3[CH_3CH_2OH(aq) + H_2O(\ell) \rightarrow CH_3CO_2H(aq) + 4\ H^+(aq) + 4\ e^-]$

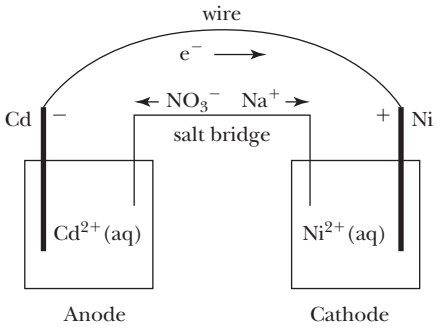
$$2[Cr_2O_7^{2-}(aq) + 14\ H^+(aq) + 6\ e^- \rightarrow 2\ Cr^{3+}(aq) + 7\ H_2O(\ell)]$$

$$3\ CH_3CH_2OH(aq) + 2\ Cr_2O_7^{2-}(aq) + 16\ H^+(aq) \rightarrow 3\ CH_3CO_2H(aq) + 4\ Cr^{3+}(aq) + 11\ H_2O(\ell)$$

19.95 (a) 0.974 kJ/g
(b) 0.60 kJ/g
(c) The silver-zinc battery produces more energy per gram of reactants.

19.97 (a) $2\ NO_3^-(aq) + 3\ Mn^{2+}(aq) + 2\ H_2O(\ell) \rightarrow 2\ NO(g) + 3\ MnO_2(s) + 4\ H^+(aq)$

$3\ MnO_2(s) + 4\ H^+(aq) + 2\ NH_4^+(aq) \rightarrow N_2(g) + 3\ Mn^{2+}(aq) + 6\ H_2O(\ell)$



(b) $E°$ for reduction of NO_3^- with Mn^{2+} is -0.27 V.
$E°$ for oxidation of NH_4^+ with MnO_2 is $+1.50$ V.

19.99 (a) $Fe^{2+}(aq) + 2\ e^- \rightarrow Fe(s)$
$2[Fe^{2+}(aq) \rightarrow Fe^{3+}(aq) + e^-]$
$3\ Fe^{2+}(aq) \rightarrow Fe(s) + 2\ Fe^{3+}(aq)$
(b) $E°_{cell} = -1.21$ V; not product-favored
(c) $K = 1 \times 10^{-41}$

19.101 (a) +4 in CoO_2 and +3 in $LiCoO_2$
(b) Cathode reaction:
$CoO_2(s) + Li^+(Solv) + e^- \rightarrow LiCoO_2(s)$
Anode reaction: $Li(on\ carbon) \rightarrow Li^+(solv) + e^-$
(c) No, because Li, an alkali metal, would react directly with water (giving H_2 and LiOH)

19.103 No, both Na and K would react vigorously and rapidly with seawater.

19.105 (a)

(b) Anode: $Cd(s) \rightarrow Cd^{2+}(aq) + 2\ e^-$
Cathode: $Ni^{2+}(aq) + 2\ e^- \rightarrow Ni(s)$
Net: $Cd(s) + Ni^{2+}(aq) \rightarrow Cd^{2+}(aq) + Ni(s)$
(c) The anode is negative and the cathode is positive.
(d) $E°_{cell} = E°_{cathode} - E°_{anode} = (-0.25\ V) - (-0.40\ V) = +0.15$ V
(e) Electrons flow from anode (Cd) to cathode (Ni).
(f) Positive ions move from the anode compartment to the cathode compartment. Anions move in the opposite direction.
(g) $K = 1 \times 10^5$
(h) $E_{cell} = 0.21$ V; yes, the net reaction is still the same.
(i) 480 h

19.107 0.054 g Au

19.109 I^- is the strongest reducing agent of the three halide ions. Iodide ion reduces Cu^{2+} to Cu^+, forming insoluble CuI(s).

$$2\ Cu^{2+}(aq) + 4\ I^-(aq) \rightarrow 2\ CuI(s) + I_2(aq)$$

19.111 (a) 92 g HF required; 230 g CF_3SO_2F and 9.3 g H_2 isolated
(b) H_2 is produced at the cathode.
(c) 48 kWh

19.113 290 h

19.115 (a) 3.6 mol glucose and 22 mol O_2
(b) 86 mol electrons
(c) 96 amps
(d) 96 watts

Chapter 20

Applying Chemical Principles

20.1 Chlorination of Water Supplies

1. (a) One chlorine atom is oxidized (oxidation number increases from 0 to +1), and one chlorine atom is reduced (oxidation number decreases from 0 to −1).
   (b) Reduction, cathode:
   $Cl_2 + 2\ e^- \rightarrow 2\ Cl^-$
   Oxidation, anode:
   $Cl_2 + 2\ H_2O \rightarrow 2\ HClO + 2\ H^+ + 2e^-$
   $E°_{cell} = E°_{cathode} - E°_{anode} = 1.36\ V - 1.63\ V = -0.27$ V
   (c) In the overall reaction, H^+ appears on the right side of the equation. Increasing pH (decreasing $[H^+]$ and making the solution more basic) shifts the equilibrium to the right, making the reaction more favorable. Decreasing pH (making the solution more acidic) will have the opposite effect.
2. $\ln K = nE°/0.0257 = 2(-0.27)/0.0257 = -21.0$; $K = 7 \times 10^{-10}$
3. $K_b = K_w/K_a = 2.86 \times 10^{-7} = x^2/(0.010 - x)$
$x = 5.35 \times 10^{-7}$ M
$[HClO] = [OH^-] = 5.3 \times 10^{-5}$; pH = 9.73
4. $H_2O_2(aq) + ClO^-(aq) \rightarrow Cl^-(aq) + H_2O(\ell) + O_2(g)$
5. The reaction of chlorine bleach (which contains hypochlorite ion, ClO^-) and ammonia in basic solution produces toxic vapors of chloramine, $NH_2Cl(g)$.

20.2 Hard Water

1. For Mg^{2+}: (50. mg)(1 mmol Mg^{2+}/24.31 mg) (1 mmol CaO/mmol Mg^{2+})(56.08 mg CaO/ 1 mmol CaO) = 115 mg CaO

For Ca^{2+}: (150 mg)(1 mmol Ca^{2+}/40.08 mg) (1 mmol CaO/mmol Ca^{2+})(56.08 mg CaO/ 1 mmol CaO) = 210 mg CaO

Total CaO = 115 mg + 210 mg = 330 mg (two significant figures)

We get 2 mol $CaCO_3$ per mole Ca^{2+} and 1 mol each of $CaCO_3$ and $MgCO_3$ per mole Mg^{2+}

$CaCO_3$ from Ca^{2+} reaction: (0.15 g Ca^{2+}) (1 mol/40.08 g Ca^{2+})(2 mol $CaCO_3$/1 mol Ca^{2+}) (100.1 g $CaCO_3$/1 mol $CaCO_3$) = 0.749 g

$CaCO_3$ from Mg^{2+} reaction: (0.050 g Mg^{2+}) (1 mol/24.31 g Mg^{2+})(1 mol $CaCO_3$/1 mol Mg^{2+}) (100.1 g $CaCO_3$/1 mol $CaCO_3$) = 0.206 g

$MgCO_3$ from Mg^{2+} reaction: (0.050 g Mg^{2+}) (1 mol/24.31 g Mg^{2+})(1 mol $MgCO_3$/1 mol Mg^{2+}) (84.31 g $MgCO_3$/1 mol $MgCO_3$) = 0.173 g

Total mass of solids = 0.749 g + 0.206 g + 0.173 g = 1.13 g

2. $CaCO_3(s) + 2\ CH_3CO_2H(aq) \rightarrow Ca(CH_3CO_2)_2(aq) + H_2O(\ell) + CO_2(g)$

This is a gas-forming reaction.

Study Questions

20.1 (b) CH_4

20.3 For gases, ppm refers to numbers of particles, and hence to mole fractions. Gas pressure exerted is directly proportional to mole fraction. Thus, 40,000 ppm water vapor would exert a pressure of 40,000/1,000,000 of one atmosphere, or 30.4 mm Hg (0.0400 × 760 mm Hg). This would be the case at a little over 29 °C, at 100% humidity.

20.5 (a) 
Electron-pair geometry around N is trigonal planar and around O (between H and N) is tetrahedral.
(b) 5.95×10^{-7} m (or 595 nm)

20.7 (d) $Al_2(SO_4)_3$

20.9 $[HCO_3^-]/[CO_3^-] = 170$

20.11 The amount of NaCl is limited by the amount of sodium present. From a 1.0-L sample of seawater, a maximum of 0.460 mol NaCl could be obtained. The mass of this amount of NaCl is 26.9 g [(0.460 mol/L) (1.00 L)(58.43 g NaCl/1 mol NaCl) = 26.9 g].

20.13 $Ca(OH)_2(s) + Mg^{2+}(aq) \rightarrow Mg(OH)_2(s) + Ca^{2+}(aq)$
$Mg(OH)_2(s) + 2\ H_3O^+(aq) \rightarrow Mg^{2+}(aq) + 4\ H_2O(\ell)$
$MgCl_2(\ell) \rightarrow Mg(s) + Cl_2(g)$

20.15 $NH_4^+(aq) + NO_2^-(aq) \rightarrow N_2(g) + 2\ H_2O(\ell)$
$2\ NH_4^+(aq) + 3\ O_2(g) \rightarrow 2\ NO_2^-(aq) + 2\ H_2O(\ell) + 4\ H^+(aq)$

20.17 (b) hydroelectric power

20.19 From methane: $H_2O(g) + CH_4(g) \rightarrow 3\ H_2(g) + CO(g)$
37.7 g of H_2 produced
From petroleum: $H_2O(g) + CH_2(\ell) \rightarrow 2\ H_2(g) + CO\ (g)$
28.7 g H_2 produced
From coal: $H_2O(g) + C(s) \rightarrow H_2(g) + CO(g)$
16.8 g H_2 produced

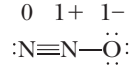
20.21 70. lb(453.6 g/lb)(33 kJ/g) = 1.0×10^6 kJ

20.23 Assume burning oil produces 43 kJ/g (the value for crude petroleum in Table 20.4)
7.0 gal(3.785 L/gal)(1000 cm^3/L)(0.8 g/cm^3)(43 kJ/g) = 0.9×10^6 kJ. Uncertainty in the numbers is one significant figure. This value is close to the value for the energy obtained by burning from 70 kg of coal (calculated in Question 20.21).

20.25 $\Delta_r H°$ for the reaction $CH_3OH(\ell) + 1.5\ O_2(g) \rightarrow CO_2(g) + 2\ H_2O(\ell)$ is −726.8 kJ/mol-rxn.
Energy per liter = -17.85×10^3 kJ/L.
Finally, use the kW-h to kJ conversion factor to obtain the answer.
(17.85×10^3 kJ/L)(1 kW-h/3600 kJ) = 4.96 kW-h/L.

20.27 (a) Area of parking lot = 1.625×10^4 m^2
(2.6×10^7 J/m^2)(1.625×10^4 m^2) = 4.2×10^{11} J
(b) 1.3×10^7 g C

20.29 Energy per gallon of gas = 1.339×10^5 kJ/gal
Energy to travel 1 mile = 2430 kJ



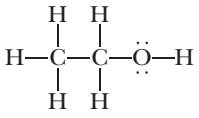
20.31 (a) The cage is a dodecahedron, so it has 20 vertices, each of which is the O atom of a water molecule (the red spheres in the model are O atoms).
(b) 30 hydrogen bonds. (This estimate is made by assuming there is an H bond on each of the edges.)
(c) A dodecahedron has 12 faces.

20.33 (c) Hydrogen is explosive

20.35 (a) $C_{13}H_{27}CO_2CH_3(\ell) + 43/2\ O_2(g) \rightarrow 15\ CO_2(g) + 15\ H_2O(g)$
(b) $\Delta_r H° = -8759.1$ kJ/mol-rxn
(c) Hexadecane ($\Delta H° = -9951.2$ kJ/mol) provides more energy per mole of fuel than methyl myristate ($\Delta H° = -8759.1$ kJ/mol).
Hexadecane ($\Delta H° = -3.4 \times 10^4$ kJ/L) also provides more energy per liter of fuel than methyl myristate ($\Delta H° = -3.1 \times 10^4$ kJ/L).

20.37 (d) O_2

20.39 (a) The most significant resonance structure is the following with formal charges as shown. The molecular geometry is linear.



(b) If the connectivity were N—O—N, the central oxygen would have a formal charge of 2+, a highly unfavorable situation.
(c) (1.00 L)(800 nmol/L)(1 mol/10^9 nmol) (44.01 g/mol) = 4×10^{-5} g

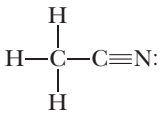
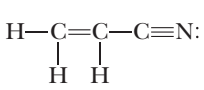
20.41 (a)



Ethanol

Both carbon atoms are tetrahedral; oxygen atom is bent.



Ethylamine

Both carbon atoms are tetrahedral. Nitrogen atom is pyramidal.

Acetonitrile

CH_3 carbon atom is tetrahedral. Carbon atom of CN group is linear.

Acrylonitrile

CH_2 and CH carbon atoms are trigonal planar. Carbon atom of CN group is linear.

(b) $CH_3CH_2OH + NH_3 \rightarrow CH_3CH_2NH_2 + H_2O$
$CH_3CH_2NH_2 + O_2 \rightarrow CH_3CN + 2\ H_2O$

(c) Reactants (CH_3CH_2OH, NH_3, and O_2) have 2 C, 9 H, 1 N, and 3 O; molar mass = 95. Product (CH_3CN) has 2 C, 3 H, and 1 N; molar mass = 41. Atom economy = (41/95) × 100% = 43%

20.43 Using a C—Cl bond energy of 339 kJ/mol, the wavelength of the required radiation is 3.53×10^{-7} m or 353 nm. This is in the ultraviolet region.

20.45 $NH_4^+(aq) + 2\ H_2O(\ell) \rightarrow NO_2^-(aq) + 8\ H^+(aq) + 6\ e^-$
$NO_2^-(aq) + H_2O(\ell) \rightarrow NO_3^-(aq) + 2\ H^+(aq) + 2\ e^-$

20.47 (a) Isooctane:

$C_8H_{18}(\ell) + 25/2\ O_2(g) \rightarrow 8\ CO_2(g) + 9\ H_2O(\ell)$

$\Delta_r H° = -5461.2$ kJ/mol-rxn
(or −47,809 kJ/kg C_8H_{18})

Ethanol:

$C_2H_5OH(\ell) + 3\ O_2(g) \rightarrow 2\ CO_2(g) + 3\ H_2O(\ell)$

$\Delta_r H° = -1367.5$ kJ/mol-rxn
(or −29,684 kJ/kg C_2H_5OH)

Isooctane releases more energy per kilogram.

(b) Isooctane = 70.0 mol CO_2 and ethanol = 43.4 mol CO_2. Ethanol produces less CO_2 per kilogram.

(c) On the basis of this simplistic comparison, there is not a clear winner. Isooctane releases more energy per kilogram but also releases more CO_2 per kilogram.

20.49 (a) Only 92% of the ice is submerged, and the water displaced by ice (the volume of ice under the surface of water) is 23 cm^3 ($0.92 \times 25\ cm^3 = 23\ cm^3$). Thus, the liquid level in the graduated cylinder will be 123 mL.

(b) Melting 25 cm^3 of ice will produce 23 mL of liquid water [25 cm^3 ice (0.92 g H_2O/cm^3 ice) (1.0 cm^3 liquid H_2O/g H_2O) = 23 cm^3 liquid H_2O]. The water level will be 123 mL (the same as in (a); that is, the water level won't rise as the ice melts).

20.51 Nonrenewable resources are not replenished when used. Renewable resources are, for the foreseeable future, not depleted when used. Nonrenewable: coal, natural gas; renewable: solar, geothermal energy, wind power.

20.53 Troposphere: ozone is toxic and a health hazard, particularly with regard to respiratory problems. Stratosphere: The presence of O_3 is beneficial. Ozone shields the planet from harmful ultraviolet radiation.

20.55 Mercury: from coal burning power plants

Lead: paint residues (before 1970), soil (from the use of tetraethyllead in gasoline), water supplies (from use of lead in pipes and plumbing)

Arsenic: some ground water sources, residual from some common chemicals (use in wood treatment, for example)

20.57 (a) Fracking: Positive; greatly increased supply and decreased cost of this energy resource. Negative: contamination of water supplies, excessive water use, release of CH_4 into the atmosphere.

(b) Ethanol in gasoline: Positive: this is a renewable resource. Negative: serious questions about energy balance (energy required to produce ethanol versus energy generated with its use). Diverts foodstuff from human consumption.

(c) Cars powered by electricity and natural gas: Positive: energy efficiency, zero or low air pollution. Negative: high relative costs even with government subsidies, lack of energy distribution network (electrical distribution stations, natural gas).

20.59 The main pollutant is SO_2, arising from the burning of coal. Some SO_3 in the atmosphere arises from oxidation of SO_2, and this combines with water to give H_2SO_4, a primary component of acid rain. Removing SO_2 is best done at the source, by extracting it from the flue gases of coal burning plants. This can be done by passing the gases from coal oxidation through a scrubber containing a $CaCO_3$ slurry.

Chapter 21

Check Your Understanding

21.1 (a) $2\ Na(s) + Br_2(\ell) \rightarrow 2\ NaBr(s)$
(b) $Ca(s) + Se(s) \rightarrow CaSe(s)$
(c) $2\ Pb(s) + O_2(g) \rightarrow 2\ PbO(s)$

Lead(II) oxide, a red compound commonly called *litharge,* is the most widely used inorganic lead compound. Maroon-colored lead(IV) oxide is the product of lead oxidation in lead-acid storage batteries. Other oxides such as Pb_3O_4 also exist.

(d) $2\ Al(s) + 3\ Cl_2(g) \rightarrow 2\ AlCl_3(s)$

21.2 (a) H_2Te
(b) Na_3AsO_4
(c) $SeCl_6$
(d) $HBrO_4$

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

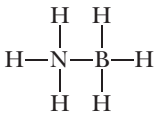
21.3 (a) NH_4^+ (ammonium ion)
(b) O_2^{2-} (peroxide ion)
(c) N_2H_4 (hydrazine)
(d) NF_3 (nitrogen trifluoride)

21.4 In Na_2Cl, chlorine would have the unlikely charge of 2− (to balance the two positive charges of the two Na^+ ions).
The formula $CaCH_3CO_2$ would require either the calcium ion to have the formula Ca^+ or the acetate ion to have the formula $CH_3CO_2^{2-}$. In all of its compounds, calcium occurs as the Ca^{2+} ion. The acetate ion, formed from acetic acid by loss of H^+, has a 1− charge.
In Mg_2O, the magnesium ions would need to have the incorrect charge of 1+ to balance charge of the O^{2-} ion or else the oxygen would need to have the incorrect charge of 4− to balance the charge of the two Mg^{2+} ions. Neither of these possibilities is acceptable.

Applying Chemical Principles

21.1 Lead in the Environment

1. 50. ppb is 50. g in 1×10^9 g of blood.
Assume the density of blood is 1.0 g/mL.
In 1.0×10^3 mL (i.e., 1.0 L) of blood, there will be $50. \times 10^{-6}$ g of Pb. From this:



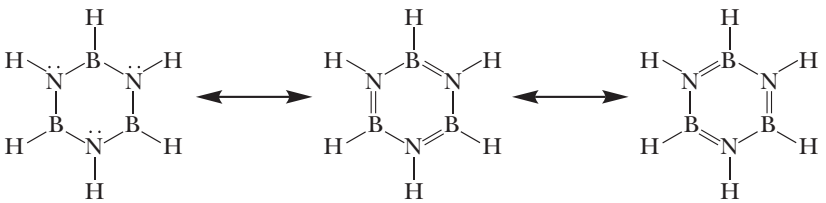
$(50. \times 10^{-6}\text{ g})\ (1\text{ mol Pb}/207.2\text{ g Pb})$
$(6.022 \times 10^{23}\text{ atoms Pb/mol Pb}) = 1.5 \times 10^{17}\text{ atoms Pb}$

2. (750 mL wine)(1.0 g wine/mL wine)
(2000 g Pb/1,000,000 g wine) = 1.5 g Pb

3. (0.15 g paint)(12 g Pb/100 g paint)
(1 mol Pb/207.2 g Pb)/4.7 L = 1.8×10^{-5} M

21.2 Hydrogen Storage

1.



Formal charges: N, 1+; B, 1−; H, 0.

2. Percent H = (6.047 g/30.865 g) × 100% = 19.59%
Mass H in 1 kg = $(1.00 \times 10^3\text{ g})(0.1959)$ = 196 g

3. $(1.00\text{ L})(1000\text{ cm}^3/1\text{ L})(0.780\text{ g/cm}^3) = 780.\text{ g}$
Mass hydrogen in 780. g of ammonia borane =
(780. g)(0.1959) = 152.8 g; therefore the hydrogen density = 152.8 g/L = 153 g/L

4. (140 g/152.8 g) × 100% = 92%

5.

The compound is isoelectronic with benzene.

Study Questions

21.1 (d) Ca_2O_3

21.3 (b) +3

21.5 $4\text{ Li(s)} + O_2\text{(g)} \rightarrow 2\text{ Li}_2\text{O(s)}$
$\text{Li}_2\text{O(s)} + \text{H}_2\text{O}(\ell) \rightarrow 2\text{ LiOH(aq)}$
$2\text{ Ca(s)} + O_2\text{(g)} \rightarrow 2\text{ CaO(s)}$
$\text{CaO(s)} + \text{H}_2\text{O}(\ell) \rightarrow \text{Ca(OH)}_2\text{(s)}$

21.7 These are the elements of Group 3A: boron, B; aluminum, Al; gallium, Ga; indium, In; and thallium, Tl.

21.9 $2\text{ Na(s)} + \text{Cl}_2\text{(g)} \rightarrow 2\text{ NaCl(s)}$
The reaction is exothermic and the product is ionic (see Figure 1.2).

21.11 The product, NaCl, is a colorless solid and is soluble in water. Other alkali metal chlorides have similar properties.

21.13 Calcium will not exist in the Earth's crust because the metal reacts with water.

21.15 Increasing basicity: $CO_2 < SiO_2 < SnO_2$

21.17 (a) $2\text{ Na(s)} + \text{Br}_2(\ell) \rightarrow 2\text{ NaBr(s)}$
(b) $2\text{ Mg(s)} + O_2\text{(g)} \rightarrow 2\text{ MgO(s)}$
(c) $2\text{ Al(s)} + 3\text{ F}_2\text{(g)} \rightarrow 2\text{ AlF}_3\text{(s)}$
(d) $\text{C(s)} + O_2\text{(g)} \rightarrow \text{CO}_2\text{(g)}$

21.19 (a) Neon

21.21 $2\text{ H}_2\text{(g)} + O_2\text{(g)} \rightarrow 2\text{ H}_2\text{O(g)}$
$\text{H}_2\text{(g)} + \text{Cl}_2\text{(g)} \rightarrow 2\text{ HCl(g)}$
$3\text{ H}_2\text{(g)} + \text{N}_2\text{(g)} \rightarrow 2\text{ NH}_3\text{(g)}$

21.23 $\text{CH}_4\text{(g)} + \text{H}_2\text{O(g)} \rightarrow \text{CO(g)} + 3\text{ H}_2\text{(g)}$
$\Delta_r H° = +206.2$ kJ/mol-rxn; $\Delta_r S° = +214.7$ J/K · mol-rxn; $\Delta_r G° = +142.2$ kJ/mol-rxn (at 298 K).

21.25 Step 1: $2\text{ SO}_2\text{(g)} + 4\text{ H}_2\text{O}(\ell) + 2\text{ I}_2\text{(s)} \rightarrow 2\text{ H}_2\text{SO}_4(\ell) + 4\text{ HI(g)}$
Step 2: $2\text{ H}_2\text{SO}_4(\ell) \rightarrow 2\text{ H}_2\text{O}(\ell) + 2\text{ SO}_2\text{(g)} + O_2\text{(g)}$
Step 3: $4\text{ HI(g)} \rightarrow 2\text{ H}_2\text{(g)} + 2\text{ I}_2\text{(g)}$
Net: $2\text{ H}_2\text{O}(\ell) \rightarrow 2\text{ H}_2\text{(g)} + O_2\text{(g)}$

21.27 (b) Has a high melting point (> 400 °C)

21.29 $2\ Na(s) + F_2(g) \rightarrow 2\ NaF(s)$

$2\ Na(s) + Cl_2(g) \rightarrow 2\ NaCl(s)$

$2\ Na(s) + Br_2(\ell) \rightarrow 2\ NaBr(s)$

$2\ Na(s) + I_2(s) \rightarrow 2\ NaI(s)$

The alkali metal halides are white, crystalline solids. They have high melting and boiling points, and they are soluble in water.

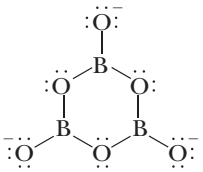
21.31 (a) $2\ NaCl(aq) + 2\ H_2O(\ell) \rightarrow Cl_2(g) + H_2(g) + 2\ NaOH(aq)$

(b) If this were the only process used to produce chlorine, the mass of Cl_2 reported for industrial production would be 0.88 times the mass of NaOH produced (2 mol NaCl, 117 g, would yield 2 mol NaOH, 80 g, and 1 mol Cl_2, 70 g). The amounts quoted indicate a Cl_2 to NaOH mass ratio of 0.96. Chlorine is presumably also prepared by other routes than this one.

21.33 (c) Gypsum, $CaSO_4 \cdot 2\ H_2O$

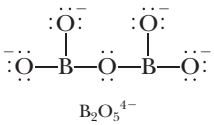
21.35 $2\ Mg(s) + O_2(g) \rightarrow 2\ MgO(s)$

$3\ Mg(s) + N_2(g) \rightarrow Mg_3N_2(s)$



21.37 $CaCO_3$ is used in agriculture to neutralize acidic soil, to prepare CaO for use in mortar, and in steel production.

$CaCO_3(s) + H_2O(\ell) + CO_2(g) \rightarrow Ca^{2+}(aq) + 2\ HCO_3^-(aq)$



21.39 1.4×10^6 g SO_2

21.41 (c) Third

21.43

$B_3O_6^{3-}$

$B_2O_5^{4-}$

21.45 (a) $2\ B_5H_9(g) + 12\ O_2(g) \rightarrow 5\ B_2O_3(s) + 9\ H_2O(g)$

(b) Enthalpy of combustion of B_5H_9 = −4341.2 kJ/mol. This is more than double the enthalpy of combustion of B_2H_6.

(c) Enthalpy of combustion of $C_2H_6(g)$ [to give $CO_2(g)$ and $H_2O(g)$] = −1428.7 kJ/mol. C_2H_6 produces 47.5 kJ/g, whereas diborane produces much more (73.7 kJ/g).

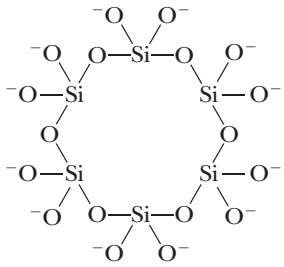
21.47 $2\ Al(s) + 6\ HCl(aq) \rightarrow 2\ Al^{3+}(aq) + 6\ Cl^-(aq) + 3\ H_2(g)$

$2\ Al(s) + 3\ Cl_2(g) \rightarrow 2\ AlCl_3(s)$

$4\ Al(s) + 3\ O_2(g) \rightarrow 2\ Al_2O_3(s)$

21.49 $2\ Al(s) + 2\ OH^-(aq) + 6\ H_2O(\ell) \rightarrow 2\ Al(OH)_4^-(aq) + 3\ H_2(g)$

Volume of H_2 obtained from 13.2 g Al = 18.4 L



21.51 $Al_2O_3(s) + 3\ H_2SO_4(aq) \rightarrow Al_2(SO_4)_3(s) + 3\ H_2O(\ell)$

Mass of H_2SO_4 required = 860. g and mass of Al_2O_3 required = 298 g.

21.53 (c) SiO_2

21.55 Pyroxenes have as their basic structural unit an extended chain of linked SiO_4 tetrahedra. The ratio of Si to O is 1 : 3.

21.57 This structure has a six-member ring of Si atoms with O atom bridges. Each Si also has two O atoms attached. The basic unit is SiO_3^{2-}, and the overall charge is −12 in $[(SiO_3)_6]^{-12}$. (Electron lone pairs are omitted in the following structure.)

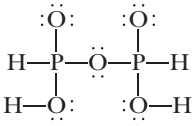
21.59 (c) Between 2 and 3

21.61 Consider the general decomposition reaction:

$$N_xO_y \rightarrow {}^x/_2\ N_2 + {}^y/_2\ O_2$$

For all N_xO_y molecules $\Delta_rG° = -\Delta_fG°$. These data show that the decomposition reaction is spontaneous for all of the nitrogen oxides. All are unstable with respect to decomposition to the elements.

Compound	$-\Delta_fG°$ (kJ/mol)
NO(g)	−86.58
NO_2	−51.23
N_2O	−104.20
N_2O_4	−97.73



21.63 $\Delta_rH° = -114.4$ kJ/mol-rxn; exothermic $\Delta_rG° = -70.7$ kJ/mol-rxn, product-favored at equilibrium

21.65 (a) $N_2H_4(aq) + O_2(g) \rightarrow N_2(g) + 2\ H_2O(\ell)$

(b) 1.32×10^3 g

21.67 (a) Oxidation number = +3

(b) Diphosphorous acid ($H_4P_2O_5$) should be a diprotic acid (losing the two H atoms attached to O atoms).

21.69 (c) +3

21.71 (a) 3.5×10^3 kg SO_2

(b) 4.1×10^3 kg $Ca(OH)_2$

21.73

disulfide ion

21.75 (b) Cl_2

21.77 $E°_{cell} = E°_{cathode} - E°_{anode} = +1.44\ V - (+1.51\ V) = -0.07\ V$

The reaction is not product-favored under standard conditions.

21.79 $Cl_2(aq) + 2\ Br^-(aq) \rightarrow 2\ Cl^-(aq) + Br_2(\ell)$

Cl_2 is the oxidizing agent, Br^- is the reducing agent; $E°_{cell} = 0.28\ V$.

21.81 The reaction consumes 4.32×10^8 C to produce 8.51×10^4 g F_2.

21.83 (c) XeF_3^+

21.85 Xe-F bond dissociation energy = 132 kJ/mol

21.87 0.015 g/L of argon; 2.6×10^3 L for 1.0 mol of argon.

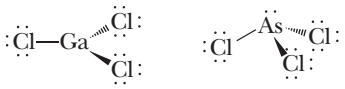
21.89

Element	Appearance	State
Na, Mg, Al	Silvery metal	Solids
Si	Black, shiny metalloid	Solid
P	White, red, and black allotropes; nonmetal	Solid
S	Yellow nonmetal	Solid
Cl	Pale green nonmetal	Gas
Ar	Colorless nonmetal	Gas

21.91 (a) $2\ K(s) + Cl_2(g) \rightarrow 2\ KCl(s)$

$Ca(s) + Cl_2(g) \rightarrow CaCl_2(s)$

$2\ Ga(s) + 3\ Cl_2(g) \rightarrow 2\ GaCl_3(s)$



$Ge(s) + 2\ Cl_2(g) \rightarrow GeCl_4(\ell)$

$2\ As(s) + 3\ Cl_2(g) \rightarrow 2\ AsCl_3(\ell)$

($AsCl_5$ has been prepared but is not stable.)

(b) KCl and $CaCl_2$ are ionic; the other products are covalent.

(c) The electron-pair and molecular geometries of $GaCl_3$ are both trigonal-planar; the electron-pair geometry of $AsCl_3$ is tetrahedral, and its molecular geometry is trigonal-pyramidal.

21.93 (a) $2\ KClO_3(s) \rightarrow 2\ KCl(s) + 3\ O_2(g)$

(b) $2\ H_2S(g) + 3\ O_2(g) \rightarrow 2\ H_2O(g) + 2\ SO_2(g)$

(c) $2\ Na(s) + O_2(g) \rightarrow Na_2O_2(s)$

(d) $P_4(s) + 3\ KOH(aq) + 3\ H_2O(\ell) \rightarrow PH_3(g) + 3\ KH_2PO_2(aq)$

(e) $NH_4NO_3(s) \rightarrow N_2O(g) + 2\ H_2O(g)$

(f) $2\ In(s) + 3\ Br_2(\ell) \rightarrow 2\ InBr_3(s)$

(g) $SnCl_4(\ell) + 2\ H_2O(\ell) \rightarrow SnO_2(s) + 4\ HCl(aq)$

21.95 1.4×10^5 metric tons

21.97 Mg: $\Delta_rG° = +64.9$ kJ/mol-rxn

Ca: $\Delta_rG° = +131.40$ kJ/mol-rxn

Ba: $\Delta_rG° = +219.4$ kJ/mol-rxn

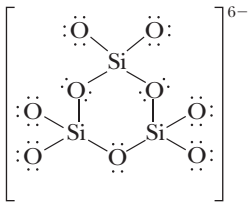
Relative tendency to decompose: $MgCO_3 > CaCO_3 > BaCO_3$

21.99 (a) $\Delta_fG°$ should be more negative than $(-95.1\ kJ) \times n$.

(b) Ba, Pb, Ti

21.101 O—F bond energy = 190 kJ/mol

21.103 (a) N_2O_4 is the oxidizing agent (N is reduced from +4 to 0 in N_2), and $H_2NN(CH_3)_2$ is the reducing agent.



(b) 1.3×10^4 kg N_2O_4 is required. Product masses: 5.7×10^3 kg N_2; 4.9×10^3 kg H_2O; 6.0×10^3 kg CO_2.

21.105 $\Delta_rH° = -257.78$ kJ/mol-rxn. This reaction is entropy-disfavored, however, with $\Delta_rS° = -963\ J/K \cdot$ mol-rxn because of the decrease in the number of moles of gases. Combining these values gives $\Delta_rG° = +29.19$ kJ/mol-rxn, indicating that under standard conditions at 298 K the reaction is not spontaneous. (The reaction has a favorable $\Delta_rG°$ at temperatures less than 268 K, indicating that further research on this system might be worthwhile. Note that at that temperature water is a solid.)

21.107 A = B_2H_6; B = B_4H_{10}; C = B_5H_{11}; D = B_5H_9; E = $B_{10}H_{14}$

21.109 $x = 1.5$

21.111

The ring is not expected to be planar because a tetrahedral electron-pair geometry is predicted for each atom in the ring.

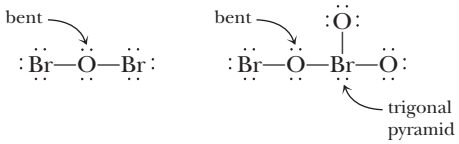
21.113 $\Delta_rG° = -834.28$ kJ/mol-rxn, therefore the reaction is product-favored at equilibrium at 298 K. $\Delta_rS° = -149.9\ J/K \cdot$ mol-rxn at 298 K. Because this is negative, the reaction will be less product-favored at high temperatures.

21.115 (a) $2\ CH_3Cl(g) + Si(s) \rightarrow (CH_3)_2SiCl_2(\ell)$

(b) 0.823 atm

(c) 12.2 g

21.117 $5\ N_2H_5^+(aq) + 4\ IO_3^-(aq) \rightarrow 5\ N_2(g) + 2\ I_2(aq) + H^+(aq) + 12\ H_2O(\ell)$



$E°_{net} = 1.43\ V$

21.119 (a) Br_2O_3

(b) The structure of Br_2O is reasonably well known. Several possible structures for Br_2O_3 can be imagined, but experiment confirms the structure below.

21.121 (a) The NO bond with a length of 114.2 pm is a double bond. The other two NO bonds (with a length of 121 pm) have a bond order of 1.5 (as there are two resonance structures involving these bonds).

(b) $K = 1.90$; $\Delta_r S° = 141$ J/K · mol-rxn

(c) $\Delta_f H° = 82.9$ kJ/mol

21.123 Generally, a sodium fire can be extinguished by smothering it with sand. The worst choice is to use water (which reacts violently with sodium to give H_2 gas and NaOH).

21.125 Nitrogen is a relatively unreactive gas, so it will not participate in any reaction typical of hydrogen or oxygen. The most obvious property of H_2 is that it burns, so attempting to burn a small sample of the gas would immediately confirm or deny the presence of H_2. If O_2 is present, it can be detected by allowing it to react as an oxidizing agent. There are many reactions known with low-valent metals, especially transition metal ions in solution, that can be detected by color changes.

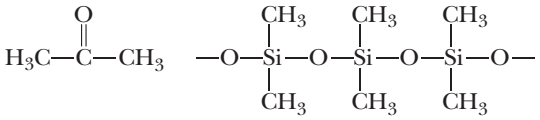
21.127 The reducing ability of the Group 3A metals declines considerably on descending the group, with the largest drop occurring on going from Al to Ga. The reducing ability of gallium and indium are similar, but another large change is observed on going to thallium. In fact, thallium is most stable in the +1 oxidation state. This same tendency for elements to be more stable with lower oxidation numbers is seen in Groups 4A (Ge and Pb) and 5A (Bi).

21.129 (a) $CH_4(g) + 2\ H_2O(\ell) \rightarrow CO_2(g) + 4\ H_2(g)$

$SiH_4(g) + 2\ H_2O(\ell) \rightarrow SiO_2(s) + 4\ H_2(g)$

(b) Reaction of CH_4:

$\Delta_r G° = \Delta_f G°(CO_2) - \Delta_f G°(CH_4) - 2\ \Delta_f G°(H_2O) = +130.7$ kJ



Reaction of SiH_4:

$\Delta_r G° = \Delta_f G°(SiO_2) - \Delta_f G°(SiH_4) - 2\ \Delta_f G°(H_2O) = -439.51$ kJ

The reaction of silane with water is product-favored at equilibrium. This is an important difference between methane and silane.

(c) Electronegativities: C = 2.5, Si = 1.9, H = 2.2. Polarities are in opposite directions: in CH_4, $C^{\delta-}H^{\delta+}$ (H is positive); in SiH_4, $Si^{\delta+}H^{\delta-}$ (H is negative).

(d) Si prefers to form four single bonds, rather than form a double bond to O, similar to what is seen in acetone. We predict that a molecular species Si_2H_4, analogous to ethene, will not exist; a compound of this formula will be a polymer $—(SiH_2SiH_2)_x—$

Acetone $\qquad$ $[(CH_3)_2SiO]_n$ polymer

21.131 (a) $HXeO_4^-$ (Xe oxidation number = +6) is both oxidized (to XeO_6^{4-}, Xe oxidation number = +8) and reduced (to Xe). In addition, O is oxidized to O_2.

(b) One Xe atom in $HXeO_4^-$ loses 2 electrons to give the Xe atom in XeO_6^{4-}. A second Xe atom in $HXeO_4^-$ gains 6 electrons to give Xe. Thus, 2 $HXeO_4^-$ ions require a net of 4 electrons. These electrons can be supplied by the oxidation of 2 O^{2-} ions to give O_2.

Chapter 22

Check Your Understanding

22.1 (a) $Co(NH_3)_3Cl_3$

(b) $Fe(H_2NCH_2CH_2NH_2)_2Br_2 = Fe(en)_2Br_2$

22.2 (a) (i) $K_3[Co(NO_2)_6]$: a complex of cobalt(III) with a coordination number of 6

(ii) $Mn(NH_3)_4Cl_2$: a complex of manganese(II) with a coordination number of 6

(b) $NH_4[Co(EDTA)]$: a complex of cobalt(III) with a coordination number of 6

22.3 (a) hexaaquanickel(II) sulfate

(b) dicyanobis(ethylenediamine)chromium(III) chloride

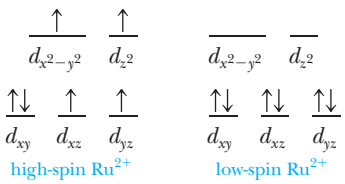
(c) potassium amminetrichloroplatinate(II)

(d) potassium dichlorocuprate(I)

22.4 (a) Geometric isomers are possible (with the NH_3 ligands in *cis* and *trans* positions).

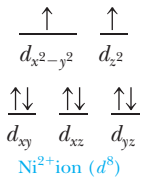
(b) Only a single structure is possible.

(c) Only a single structure is possible.



(d) This compound is chiral; there are two optical isomers.

(e) Only a single structure is possible.



(f) Two structural isomers are possible based on coordination of the NO_2^- ligand through oxygen or nitrogen.

Copyright 2019 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. 22.5 (a) $[Ru(H_2O)_6]^{2+}$: an octahedral complex of ruthenium(II) (d^6). A low-spin complex has no unpaired electrons and is diamagnetic. A high-spin complex has four unpaired electrons and is paramagnetic.

(b) $[Ni(NH_3)_6]^{2+}$: an octahedral complex of nickel(II) (d^8). Only one electron configuration is possible; it has two unpaired electrons and is paramagnetic.

22.6 1. A wavelength of 500 nm corresponds to green light being absorbed. The complex ion will appear magenta.

2. The complex appears yellow because blue light is being absorbed. The high energy of blue light indicates that Δ_o is large and the complex is therefore low spin.

Applying Chemical Principles

22.1 Life-Saving Copper

1. Cu: $[Ar]3d^{10}4s^1$, 1 unpaired electron
Cu^+: $[Ar]3d^{10}$, 0 unpaired electrons
Cu^{2+}: $[Ar]3d^9$, 1 unpaired electron

2. There are four atoms per face-centered cubic unit cell.

Unit cell mass = (63.5 g/1 mol)(1 mol/6.022 × 10^{23} atoms)(4 atoms/unit cell) = 4.218 × 10^{-22} g/unit cell

Unit cell volume = mass/density = (4.218 × 10^{-22} g)/(8.960 g/cm^3) = 4.707 × 10^{-23} cm^3/unit cell

Length of cell edge = (4.707 × 10^{-23} cm^3)$^{1/3}$ = 3.611 × 10^{-8} cm = 361.1 pm

Diagonal of unit cell = $(2)^{1/2}$(361.1 pm) = 510.6 pm

Radius = diagonal/4 = 510.6 pm/4 = 128 pm

3. 5.0 × 10^{-15} mol Cu^{2+} [= (5.0 × 10^{-15} mol Cu^{2+}) (63.5 g Cu^{2+}/1 mol Cu^{2+}) = 3.18 × 10^{-13} g Cu^{2+}]

22.2 *Cisplatin:* Accidental Discovery of a Chemotherapy Agent

1. $k = 0.693/t_{1/2} = 0.277\ hr^{-1}$

ln (fraction remain) = −(0.277 hr^{-1})(24 hr) = −6.65

fraction remain = $e^{-6.65}$ = 0.0013

Mass remaining = 0.01 mg

2. *Cis*-diamminedichloroplatinum(II)

3. The *d*-orbitals split into four groups, in order of increasing energy: $d_{xz} = d_{yz} < d_{z^2} < d_{xy} < d_{x^2-y^2}$. The four pairs of electrons occupy the four lowest energy orbitals.

22.3 The Rare Earths

1. Nd: $[Xe]4f^46s^2$; Eu: $[Xe]4f^76s^2$

2. Ce^{3+}: $[Xe]4f^1$
Nd^{3+}: $[Xe]4f^3$

3. $Fe^{2+}(aq) + [Ce(NO_3)_6]^{2-}(aq) \rightarrow Fe^{3+}(aq) + Ce^{3+}(aq) + 6\ NO_3^-(aq)$

C = [0.181 g Fe(1 mol Fe/55.85 g Fe) (1 mol $[Ce(NO_3)_6]^{2-}$/mol Fe)]/0.03133 L = 0.103 M

4. $2\ CeO_2(s) + CO(g) \rightarrow Ce_2O_3(s) + CO_2(g)$
$2\ Ce_2O_3(s) + O_2(g) \rightarrow 4\ CeO_2(s)$

Study Questions

22.1 Curium (Cm) and californium (Cf)

22.3 Rhodium (Rh) and ruthenium (Ru)

22.5 Chemical property: (a)
Physical property: (b), (c), (d), (e)

22.7 (a) Os
(b) Hg
(c) Tc
(d) Fe, Co, Mo

22.9 (a) Cr^{3+}: $[Ar]3d^3$, paramagnetic
(b) V^{2+}: $[Ar]3d^3$, paramagnetic
(c) Ni^{2+}: $[Ar]3d^8$, paramagnetic
(d) Cu^+: $[Ar]3d^{10}$, diamagnetic

22.11 (a) Fe^{3+}: $[Ar]3d^5$, isoelectronic with Mn^{2+}
(b) Zn^{2+}: $[Ar]3d^{10}$, isoelectronic with Cu^+
(c) Fe^{2+}: $[Ar]3d^6$, isoelectronic with Co^{3+}
(d) Cr^{3+}: $[Ar]3d^3$, isoelectronic with V^{2+}

22.13 (b) Atomic radii similar to 5th period transition elements.

22.15 (b) Iron oxide

22.17 C and CO

22.19 Monodentate: CH_3NH_2, CH_3CN, N_3^-, Br^-
Bidentate: en, phen (see Figure 22.12)

22.21 (a) $H_2NCH_2CH_2NH_2$
(b) $C_2O_4^{2-}$
(c) ammonia
(d) thiocyanate ion

22.23 (a) Mn^{2+}; (b) Co^{3+}; (c) Co^{3+}; (d) Cr^{2+}

22.25 $[Ni(en)(NH_3)_3(H_2O)]^{2+}$

22.27 (a) $Ni(en)_2Cl_2$ (en = $H_2NCH_2CH_2NH_2$)
(b) $K_2[PtCl_4]$
(c) $K[Cu(CN)_2]$
(d) $[Fe(NH_3)_4(H_2O)_2]^{2+}$

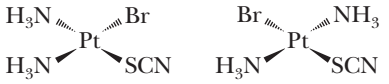
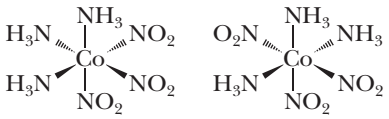
(c) Potassium diaquabis(oxalato)chromate(III)
(d) $(NH_4)_2[PtCl_4]$



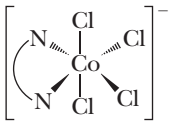
22.33 *Cis* and *trans* geometric isomers. The *cis* isomer is chiral giving rise to two optical isomer.

22.35 **(a)**



cis *trans*

(b)

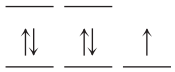


cis *trans*

(c)

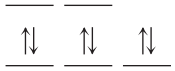
fac *mer*

(d)



Only one structure possible. (N—N is the bidentate ethylenediamine ligand.)

22.37 (a) Fe^{2+} is a chiral center.
(b) Co^{3+} is not a chiral center.
(c) Co^{3+} is not a chiral center.
(d) Pt^{2+} is not a chiral center. Square-planar complexes are never chiral.



22.39 In ligand field theory, the bonds between ligands and the metal are described as ionic, attraction being between the positively charged metal ion and a negatively charged anion or polar molecule.

22.41 The lower energy group is made up of the d_{xy}, d_{yz}, and d_{xz} orbitals.

22.43 (a) $[Mn(CN)_6]^{4-}$: d^5, low-spin Mn^{2+} complex is paramagnetic (one unpaired electron).

(b) $[Co(NH_3)_6]^{3+}$: d^6, low-spin Co^{3+} complex is diamagnetic.

(c) $[Fe(H_2O)_6]^{3+}$: d^5, low-spin Fe^{3+} complex is paramagnetic [one unpaired electron; same as part (a)].

(d) $[Cr(en)_3]^{2+}$: d^4, Cr^{2+} complex is paramagnetic (two unpaired electrons).

22.45 (a) Fe^{2+}, d^6, paramagnetic, four unpaired electrons
(b) Co^{2+}, d^7, paramagnetic, three unpaired electrons
(c) Mn^{2+}, d^5, paramagnetic, five unpaired electrons
(d) Zn^{2+}, d^{10}, diamagnetic, zero unpaired electrons

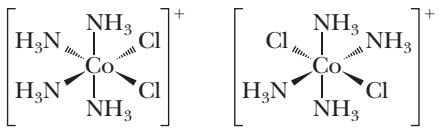
22.47 (a) 6
(b) Octahedral
(c) +2
(d) Four unpaired electrons (high spin)
(e) Paramagnetic

22.49 With four ligands, complexes of the d^8 Ni^{2+} ion can be either tetrahedral or square-planar. The CN^- ligand is at one end of the spectrochemical series and leads to a large ligand field splitting, whereas Cl^- is at the opposite end and often leads to complexes with small orbital splitting. With ligands such as CN^- the complex will be square-planar (and for a d^8 ion it will be diamagnetic). With a weak field ligand (Cl^-) the complex will be tetrahedral and, for the d^8 ion, two electrons will be unpaired, giving a paramagnetic complex.

22.51 The light absorbed is in the green region of the spectrum (page 1049). Therefore, the light transmitted—which is the color of the solution—is magenta.

22.53 Determine the magnetic properties of the complex. Square-planar Ni^{2+} (d^8) complexes are diamagnetic, whereas tetrahedral complexes are paramagnetic.

22.55 Fe^{2+} has a d^6 configuration. Low-spin octahedral complexes are diamagnetic, whereas high-spin octahedral complexes of this ion have four unpaired electrons and are paramagnetic.



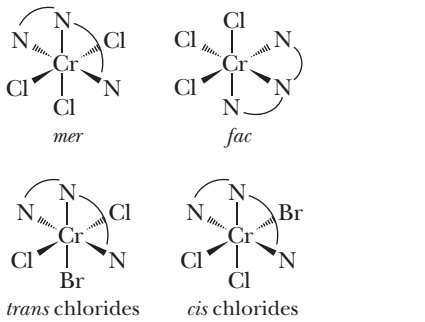
22.57 Square-planar complexes most often arise from d^8 transition metal ions. Therefore, it is likely that (b) $[Ni(CN)_4]^{2-}$ (Ni^{2+}) and (d) $[Pt(CN)_4]^{2-}$ (Pt^{2+}) are square planar. (See also Study Question 22.49.)

22.59 Two geometric isomers are possible.

22.61 Absorbing at 425 nm means the complex is absorbing light in the blue-violet end of the spectrum. Therefore, red and green light are transmitted, and the complex appears yellow.

22.63 (a) Mn^{2+}; (b) 6; (c) octahedral; (d) 5; (e) paramagnetic; (f) *cis* and *trans* isomers exist.

22.65 Name: tetraamminedichlorocobalt(III) chloride



cis *trans*

22.67 $[Co(en)_2(H_2O)Cl]^{2+}$

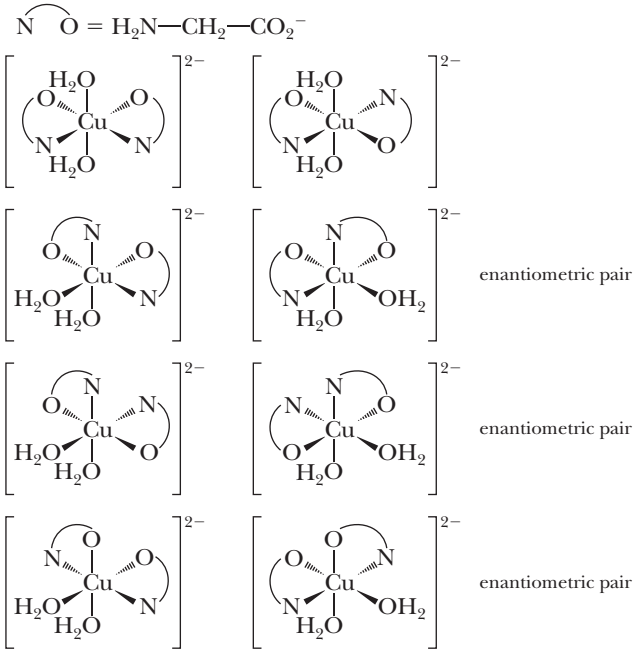
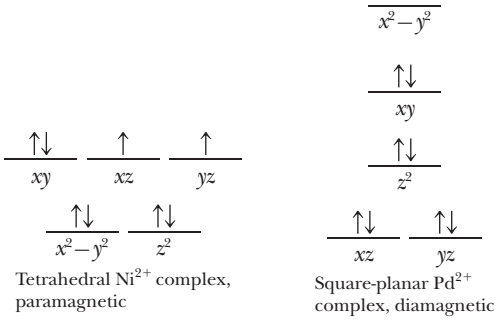
22.69

22.71

22.73 In $[Mn(H_2O)_6]^{2+}$ and $[Mn(CN)_6]^{4-}$, Mn has an oxidation number of +2 (Mn is a d^5 ion).



This shows that Δ_o for CN^- is greater than for H_2O.



22.75 (a) Ammonium tetrachlorocuprate(II)
(b) $[Cr(H_2O)_4Cl_2]Cl$
(c) $[Co(H_2O)(NH_2CH_2CH_2NH_2)_2(SCN)](NO_3)_2$

22.77 (a) The light absorbed is in the orange region of the spectrum (page 1049). Therefore, the light transmitted (the color of the solution) is blue or cyan.
(b) Using the cobalt(III) complexes in Table 22.3 as a guide, we might place CO_3^{2-} between F^- and the oxalate ion, $C_2O_4^{2-}$.
(c) Δ_o is small, so the complex should be high spin and paramagnetic.

22.79

22.81 (a) In complexes such as $M(PR_3)_2Cl_2$ the metal is Ni^{2+} or Pd^{2+}, both of which are d^8 metal ions. If an Ni^{2+} complex is paramagnetic it must be tetrahedral, whereas the Pd^{2+} must be square planar. (A d^8 metal complex cannot be diamagnetic if it has a tetrahedral structure.)

(b) A tetrahedral Ni^{2+} complex cannot have isomers, whereas a square-planar complex of the type $M(PR_3)_2Cl_2$ can have *cis* and *trans* isomers (see page 1038).

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

22.83 (a) Ce $[Xe]4f^15d^16s^2$
Ce^{3+} $[Xe]4f^1$
Ce^{4+} [Xe]

(b) Ce^{3+} is paramagnetic with 1 unpaired electron. Ce^{4+} is diamagnetic.

(c) A unit cell of CeO_2 consists of Ce^{4+} ions as a face-centered cube (4 Ce^{4+} ions) with O^{2-} ions in all of the tetrahedral holes (8 O^{2-} ions). The ratio of the two types of ions give an empirical formula of CeO_2.

22.85 A, dark violet isomer: $[Co(NH_3)_5Br]SO_4$

B, violet-red isomer: $[Co(NH_3)_5(SO_4)]Br$

$$[Co(NH_3)_5Br]SO_4(aq) + BaCl_2(aq) \rightarrow [Co(NH_3)_5Br]Cl_2(aq) + BaSO_4(s)$$

22.87 (a) There is 5.406×10^{-4} mol of $UO_2(NO_3)_2$, and this provides 5.406×10^{-4} mol of U^{n+} ions on reduction by Zn. The 5.406×10^{-4} mol U^{n+} requires 2.157×10^{-4} mol MnO_4^- to reach the equivalence point. This is a ratio of 5 mol of U^{n+} ions to 2 mol MnO_4^- ions. The 2 mol MnO_4^- ions require 10 mol of e^- (to go to Mn^{2+} ions), so 5 mol of U^{n+} ions provide 10 mol e^- (on going to 5 UO_2^{2+} ions, with a uranium oxidation number of +6). This means the U^{n+} ion must be U^{4+}.

(b) $Zn(s) \rightarrow Zn^{2+}(aq) + 2\ e^-$

$$UO_2^{2+}(aq) + 4\ H^+(aq) + 2\ e^- \rightarrow U^{4+}(aq) + 2\ H_2O(\ell)$$

$$UO_2^{2+}(aq) + 4\ H^+(aq) + Zn(s) \rightarrow U^{4+}(aq) + 2\ H_2O(\ell) + Zn^{2+}(aq)$$

(c) $$5[U^{4+}(aq) + 2\ H_2O(\ell) \rightarrow UO_2^{2+}(aq) + 4\ H^+(aq) + 2\ e^-]$$

$$2[MnO_4^-(aq) + 8\ H^+(aq) + 5\ e^- \rightarrow Mn^{2+}(aq) + 4\ H_2O(\ell)]$$

$$5\ U^{4+}(aq) + 2\ MnO_4^-(aq) + 2\ H_2O(\ell) \rightarrow 5\ UO_2^{2+}(aq) + 4\ H^+(aq) + 2\ Mn^{2+}(aq)$$

22.89 (a) Define length of the side of the cube as x, then the length of the diagonal across the cube is $x\sqrt{3}$. This is set equal to:
$2\ r_{Ti} + 2\ r_{Ni}$, i.e., $x\sqrt{3} = 2\ r_{Ti} + 2\ r_{Ni} = 540$ pm;
$x = 311.8$ pm $= 312$ pm ($a = b = c = 3.118 \times 10^{-8}$ cm $= 3.12 \times 10^{-8}$ cm)

(b) Calculated density:

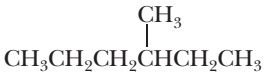
Mass of one unit cell is the mass of one Ti and one Ni atom = (47.87 g/mol)(1 mol/6.022 × 10^{23} atoms Ti) + (58.69 g/mol)(1 mol/6.022 × 10^{23} atoms Ti) = 1.770×10^{-22} g

Volume of the unit cell is $x^3 = (3.118 \times 10^{-8}\ cm)^3 = 3.030 \times 10^{-23}\ cm^3$

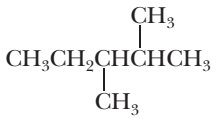
Calculated density = 1.770×10^{-22} g/$3.030 \times 10^{-23}\ cm^3 = 5.84\ g/cm^3$

The agreement is not very good, probably because atoms don't pack together as tightly as is assumed.

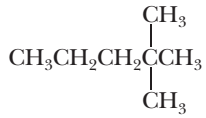
(c) As free atoms, both Ti and Ni are paramagnetic.



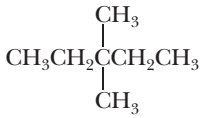
Chapter 23



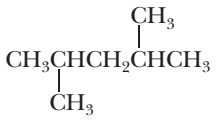
Check Your Understanding



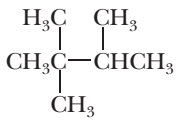
23.1 (a) Isomers of C_7H_{16}



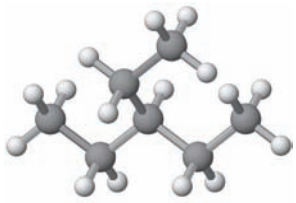
$CH_3CH_2CH_2CH_2CH_2CH_2CH_3$ heptane



2-methylhexane



3-methylhexane



2,3-dimethylpentane

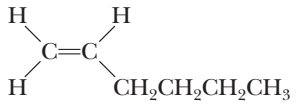
2,2-dimethylpentane

3,3-dimethylpentane

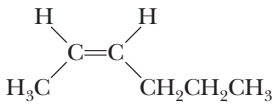
2,4-dimethylpentane

2,2,3-trimethylbutane

A model of 3-ethylpentane



(b) Two isomers, 3-methylhexane and 2,3-dimethylpentane, are chiral.



23.2 The names accompany the structures in the "Check Your Understanding" answer in Example 23.1.

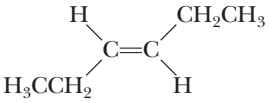
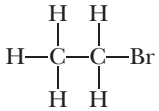
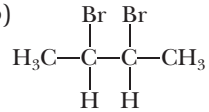
Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.



23.3 Isomers of C_6H_{12} in which the longest chain has six C atoms:



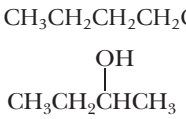


Names (in order, top to bottom): 1-hexene, *cis*-2-hexene, *trans*-2-hexene, *cis*-3-hexene, *trans*-3-hexene. None of these isomers is chiral.

23.4 (a)

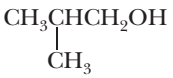
bromoethane

(b)

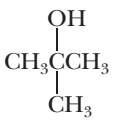


2,3-dibromobutane

23.5 1,4-diaminobenzene



23.6



1-butanol

2-butanol

2-methyl-1-propanol

2-methyl-2-propanol

23.7 (a) $CH_3CH_2CH_2OH$: 1-propanol, has an alcohol (—OH) group

CH_3CO_2H: ethanoic acid (acetic acid), has a carboxylic acid ($—CO_2H$) group

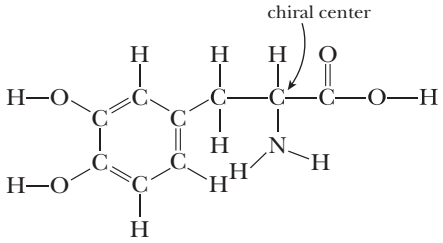
$CH_3CH_2NH_2$: ethylamine, has an amino ($—NH_2$) group

(b) 1-propyl ethanoate (propyl acetate)

(c) Oxidation of this primary alcohol first gives propanal, CH_3CH_2CHO. Further oxidation gives propanoic acid, $CH_3CH_2CO_2H$.

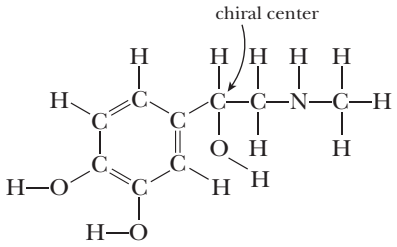
(d) *N*-ethylacetamide, $CH_3CONHCH_2CH_3$

(e) The amine is protonated by hydrochloric acid, forming ethylammonium chloride, $[CH_3CH_2NH_3]Cl$.



23.8 Kevlar is a condensation polymer, prepared by the reaction of terephthalic acid and 1,4-diaminobenzene.

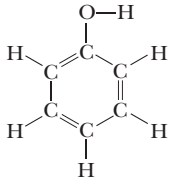
$$n\ H_2NC_6H_4NH_2 + n\ HO_2CC_6H_4CO_2H \rightarrow (—HNC_6H_4NHCOC_6H_4CO—)_n + 2n\ H_2O$$



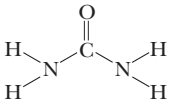
Applying Chemical Principles

23.1 An Awakening with L-DOPA

1. L-DOPA is chiral. Its chiral center is indicated in the following structural formula.



2. Dopamine is not chiral. Epinephrine is chiral. Its chiral center is indicated in the following structural formula.



3. 5.0 g L-DOPA (1 mol L-DOPA/197.2 g L-DOPA) = 0.025 mol L-DOPA

23.2 Green Adhesives

1. Structural formulas:

phenol

urea

formaldehyde

2. The electron-pair and molecular geometries are both trigonal-planar. The C—H σ bonds are each formed by the overlap of an sp^2 hybrid orbital on the C atom with the 1*s* orbital of the H atom. The σ bond between the C and O is formed by the overlap of an sp^2 hybrid orbital on the C with an sp^2 hybrid orbital on the O. The π bond between the C and O is formed by the overlap of a 2*p* orbital on C with a 2*p* orbital on O.

3. Similarity: Both nylon-6,6 and proteins are polyamides.

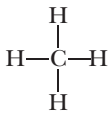
   Differences:

   1. In proteins there is one direction for the amide linkage: CONH. In nylon-6,6 two orientations are present: CONH and NHCO.
   2. In proteins there is only one C between the amide linkages. In nylon-6,6 there are four or six carbons between amide linkages.
   3. Proteins have numerous R groups that can be attached to the carbon in between the amide groups, whereas nylon-6,6 has only hydrogen atoms attached to the carbons in between the amide groups.
   4. Proteins are chiral, whereas nylon-6,6 is not.

23.3 Bisphenol A (BPA)

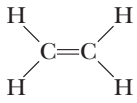
1. Reactants: 15 C, 18 H, 3 O, molar mass = 246;
   Products: 15 C, 16 H, 2 O, molar mass = 228.
   Atom economy = (228/246) × 100% = 92.7%

2. Both are condensation polymers.



3. (15 lb)(0.454 kg/1 lb)(13 μg/kg /day) = 89 μg/day.
   Yes, the infant ingests over 50 μg/day.

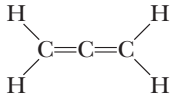
4. (156 lb)(0.454 kg/lb)(1.5 μg/kg) = 1.1×10^2 μg



5. Volume of base needed = (0.300 g BPA)
   (1 mol BPA/228 g BPA)(2 mol NaOH/1 mol BPA)
   (1.00 L/0.050 mol NaOH) = 0.053 L (or 53 mL)

Study Questions

23.1 (a)

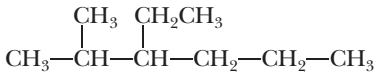


(b)

(c) H—C≡C—H

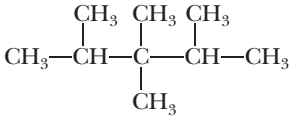
(d)

23.3 Energy = 299 kJ/mol of photons
This energy is not sufficient to break a C—C bond.



23.5 (b) Structural isomers

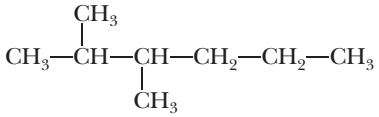
23.7 Two structural isomers (butane and 2-methylpropane) exist. There are no geometric or optical isomers.



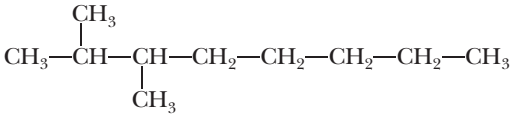
23.9 Heptane

23.11 (b) C_5H_{12} and (c) $C_{14}H_{30}$ are alkanes.

23.13 3-Ethyl-2-methylhexane

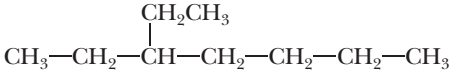


2,3,3,4-Tetramethylpentane

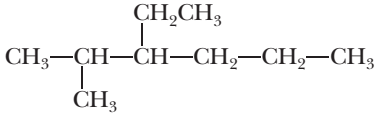


Other possibilities include 2,2,3,4-tetramethylpentane, 3-ethyl-2,2-dimethylpentane, 3-ethyl-2,3-dimethylpentane, and 3-ethyl-2,4-dimethylpentane.

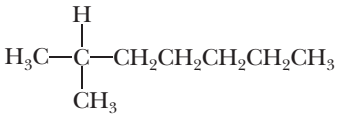
23.15 2,3-Dimethylbutane



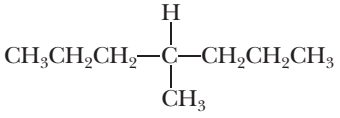
23.17 (a) 2,3-Dimethylhexane

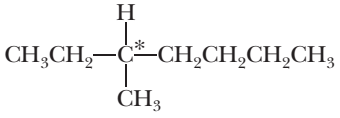


(b) 2,3-Dimethyloctane



(c) 3-Ethylheptane

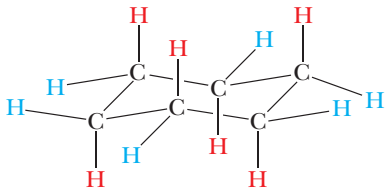




(d) 3-Ethyl-2-methylhexane

23.19

2-methylheptane



4-methylheptane

3-methylheptane. The C atom with an asterisk is chiral.

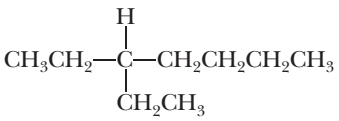
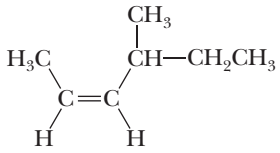
23.21 Chair form of cyclohexane:



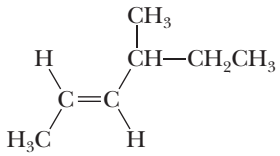
Axial hydrogens are shown in red; equatorial hydrogens are shown in blue.

23.23

4-ethylheptane. The compound is not chiral.



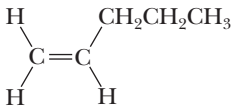
3-ethylheptane. Not chiral.



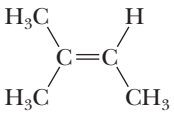
23.25 C_4H_{10}, butane: a low-molar-mass fuel gas at room temperature and pressure. Slightly soluble in water.

$C_{12}H_{26}$, dodecane: a colorless liquid at room temperature. Expected to be insoluble in water but quite soluble in nonpolar solvents.

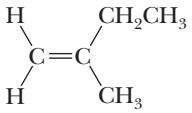
23.27



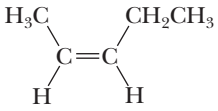
cis-4-methyl-2-hexene



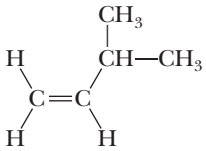
trans-4-methyl-2-hexene



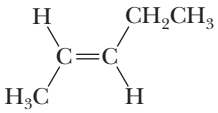
23.29 (a)



1-pentene

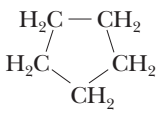


2-methyl-2-butene



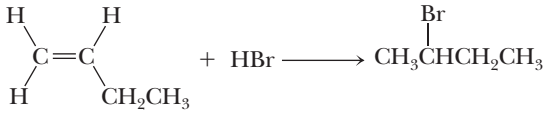
2-methyl-1-butene

cis-2-pentene

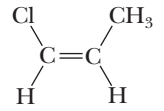


3-methyl-1-butene

trans-2-pentene

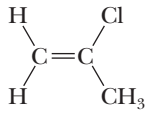


(b)

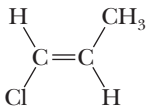


cyclopentane

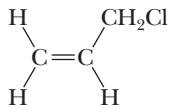
23.31 (a) 1,2-Dibromopropane, $CH_3CHBrCH_2Br$
(b) Pentane, $CH_3CH_2CH_2CH_2CH_3$



23.33 The three alkenes are 1-butene, *cis*-2-butene, and *trans*-2-butene. The reaction with 1-butene is shown below:

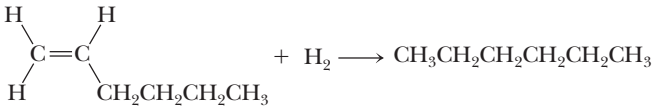


23.35 Four isomers are possible.

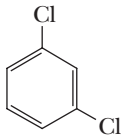


cis-1-chloropropene

2-chloropropene

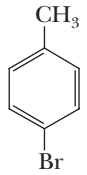


trans-1-chloropropene



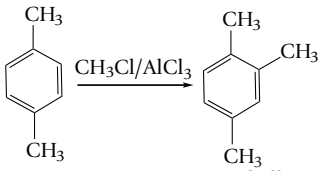
3-chloro-1-propene

23.37



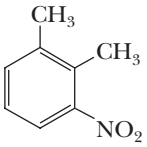
Hydrogenation is often carried out in the presence of a metal catalyst (Pt, Pd, Rh). Hydrogenation is used in the food industry to convert liquid oils to solids and to make them less susceptible to spoilage.

23.39 (a)



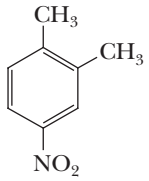
m-dichlorobenzene

(b)



p-bromotoluene

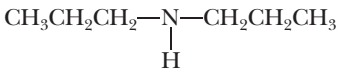
23.41



1,2,4-trimethylbenzene

23.43

1,2-dimethyl-3-nitrobenzene



1,2-dimethyl-4-nitrobenzene

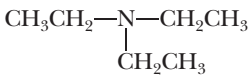
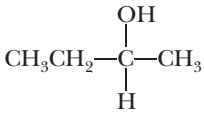
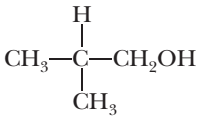
23.45 (a) 1-Propanol, primary
(b) 1-Butanol, primary
(c) 2-Methyl-2-propanol, tertiary
(d) 2-Methyl-2-butanol, tertiary



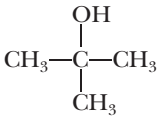
23.47 (a) Ethylamine, $CH_3CH_2NH_2$
(b) Dipropylamine, $(CH_3CH_2CH_2)_2NH$



(c) Butyldimethylamine

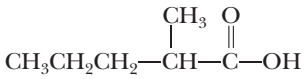


(d) Triethylamine

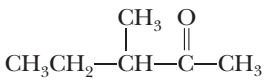


23.49 (a) 1-Butanol, $CH_3CH_2CH_2CH_2OH$
(b) 2-Butanol

(c) 2-Methyl-1-propanol

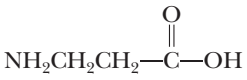


(d) 2-Methyl-2-propanol

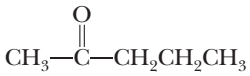


23.51 (a) $C_6H_5NH_2(\ell) + HCl(aq) \rightarrow (C_6H_5NH_3)Cl(aq)$
(b) $(CH_3)_3N(aq) + H_2SO_4(aq) \rightarrow [(CH_3)_3NH]HSO_4(aq)$

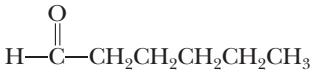
23.53 (a)



(b)



(c)

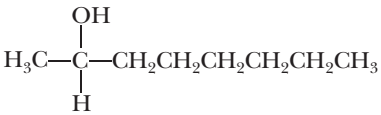


(d)

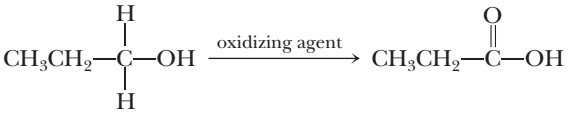
23.55 (a)

(b)

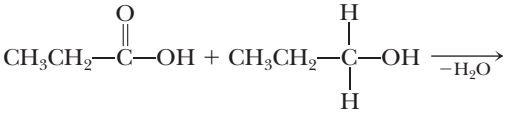
(c)



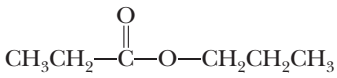
23.57 (a) Acid, 3-methylpentanoic acid
(b) Ester, methyl propanoate
(c) Ester, butyl acetate (or butyl ethanoate)
(d) Acid, *p*-bromobenzoic acid



23.59 (a) Pentanoic acid



(b) 2-Octanol



23.61 Step 1: Oxidize 1-propanol to propanoic acid.

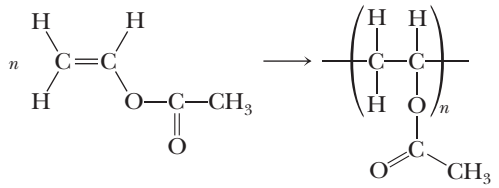
Step 2: Combine propanoic acid and 1-propanol.

23.63 Sodium acetate, $NaCH_3CO_2$, and 1-butanol, $CH_3CH_2CH_2CH_2OH$

23.65 (a) Trigonal-planar
(b) 120°
(c) The molecule is chiral. There are four different groups around the carbon atom marked 2.
(d) The acidic H atom is the H attached to the CO_2H (carboxyl) group.

23.67

This compound is an amide.



$CH_3CH_2CH_2CO_2H + CH_3NH_2 \rightarrow CH_3CH_2CH_2CONHCH_3 + H_2O$

23.69 (a) Alcohol (b) amide (c) acid (d) ester

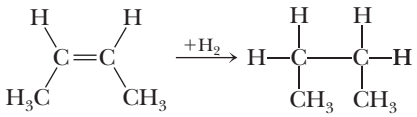
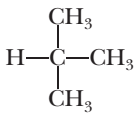
23.89

1,2,3-trimethylbenzene



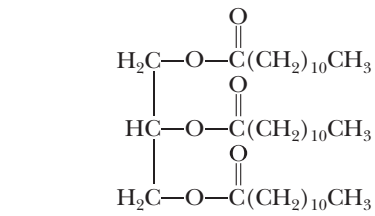
1,2,4-trimethylbenzene

1,3,5-trimethylbenzene

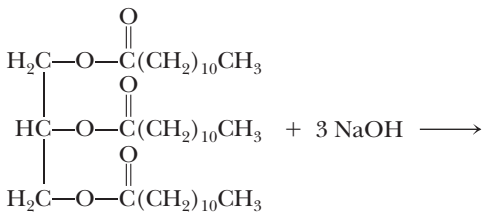


23.91 Replace the carboxylic acid group with an H atom.

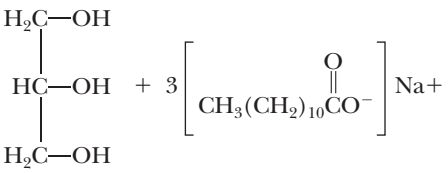
23.93 (a)



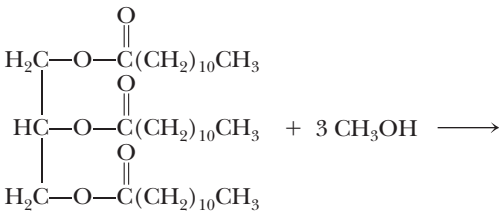
butane (not chiral)



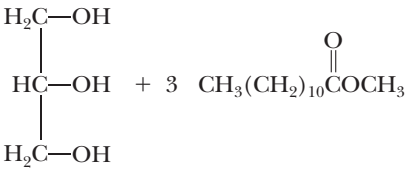
(b)

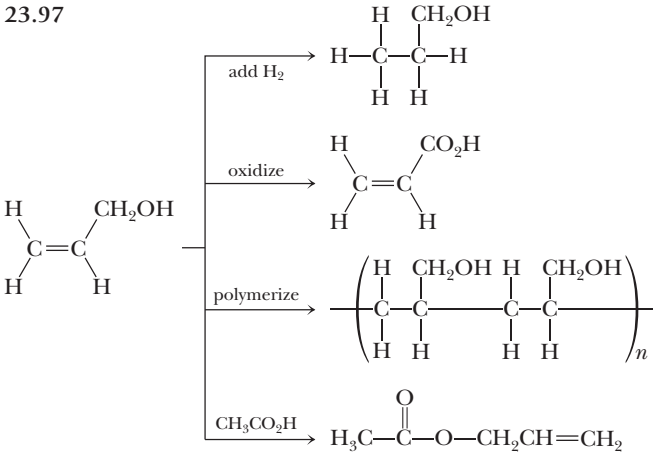


23.95

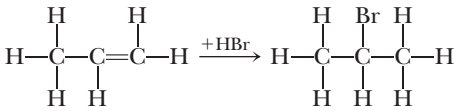


(a)

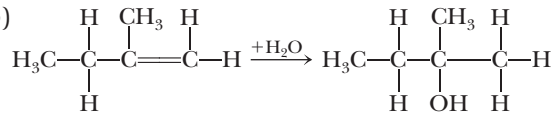




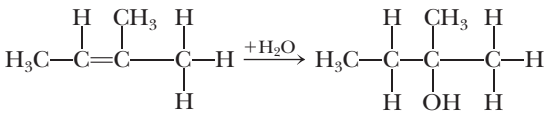
(b)



23.97



23.99 (a)

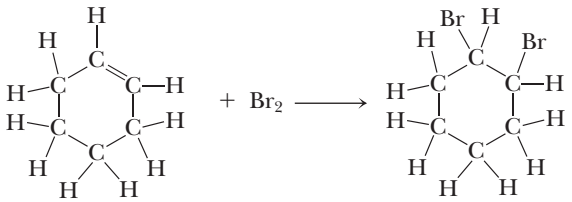


2-bromopropane

(b)

2-methyl-2-butanol

(c)



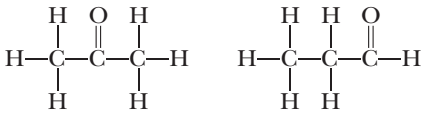
The product is the same for parts (b) and (c).

23.101 (a) The only structural difference between theobromine and caffeine occurs on the N in the six-member ring that is between the two C═O groups. In theobromine, there is an H atom attached to this N. In caffeine, there is a CH_3 group attached.

(b) 5.00 g sample (2.16 g theobromine/100 g sample) = 0.108 g theobromine

23.103 Compounds (b), acetaldehyde, and (c), ethanol, produce acetic acid when oxidized.

23.105 Cyclohexene, a cyclic alkene, will add Br_2 readily (to give $C_6H_{10}Br_2$).



Benzene, however, needs much more stringent conditions to react with bromine; then Br_2 will substitute for H atoms on benzene and not add to the ring.

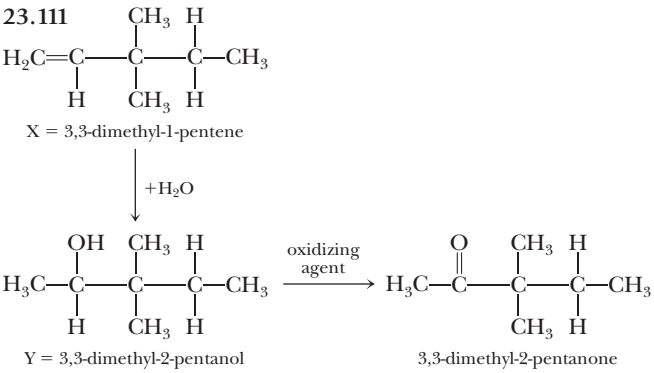
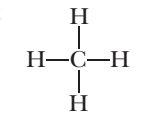
23.107 (a) The compound is either propanone, a ketone, or propanal, an aldehyde.



propanone (a ketone) | propanal (an aldehyde)

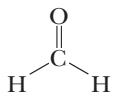
(b) The ketone will not undergo oxidation, but the aldehyde will be oxidized to the acid, $CH_3CH_2CO_2H$. Thus, the unknown is likely propanal.

(c) Propanoic acid

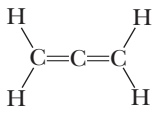


23.109 2-Propanol will react with an oxidizing agent such as $KMnO_4$ (to give the ketone), whereas methyl ethyl ether ($CH_3OC_2H_5$) will not react. In addition, the alcohol should be more soluble in water than the ether.

23.111



23.113 The ^{18}O label will be found in dimethyl terephthalate.



23.115

methane — four single bonds

formaldehyde — one double bond and two single bonds

allene — two double bonds

acetylene — one single bond and one triple bond

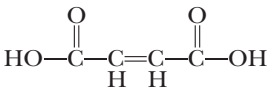
23.117 (a) Cross-linking makes the material very rigid and inflexible.

(b) The OH groups give the polymer a high affinity for water.

(c) Hydrogen bonding allows the chains to form coils and sheets with high tensile strength.

23.119 $C_2H_6(g) + 7/2\ O_2(g) \rightarrow 2\ CO_2(g) + 3\ H_2O(g)$

$C_2H_5OH(\ell) + 3\ O_2(g) \rightarrow 2\ CO_2(g) + 3\ H_2O(g)$



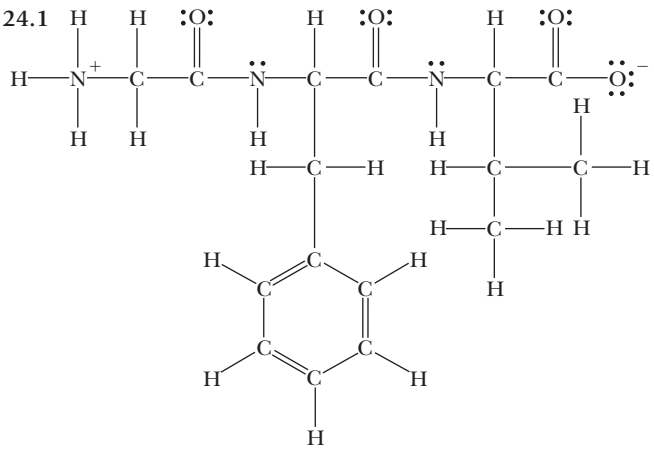
(a) Ethane enthalpy of combustion = −47.51 kJ/g
Ethanol enthalpy of combustion = −26.82 kJ/g

(b) The enthalpy change for the combustion of ethanol is less negative than for ethane, so partially oxidizing ethane to form ethanol decreases the amount of energy per gram available from the combustion of the substance.

23.121 (a) Empirical formula, CHO

(b) Molecular formula, $C_4H_4O_4$

(c)



(d) All four C atoms are sp^2 hybridized.

(e) 120°

Chapter 24

Check Your Understanding

24.1

24.2 5′-GTACGTATCG-3′

24.3 mRNA: 5′-AAA GCA CAA-3′
amino acid sequence: lysine-alanine-glutamine

Applying Chemical Principles

24.1 Antisense Therapy

1. 5′-GGUGCGAAGCAGACUGAGGC-3′
2. There are 19 phosphorus atoms present in the formula. This implies that there are 19 phosphorothioate linkages present, which implies that there are 20 nucleotides present in the molecule.
3. tetrahedral

24.2 Polymerase Chain Reaction

1. $2^{20} = 1{,}048{,}576$
2. Hydrogen bonds are weaker than covalent bonds. At 95 °C, the amount of thermal energy is not enough to break covalent bonds.

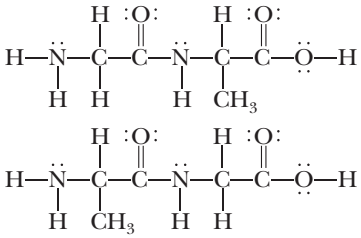
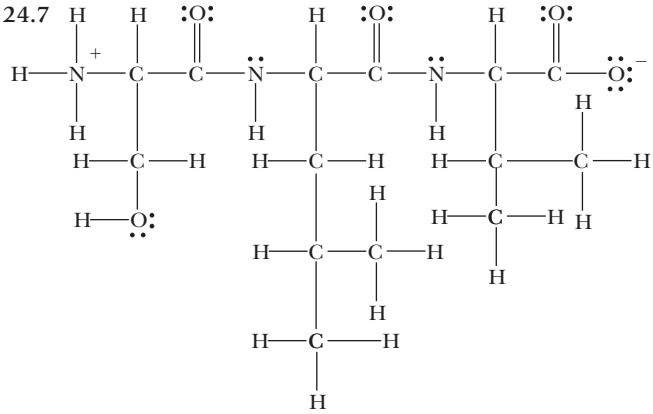
3. (a) Cytosine and guanine bind with three hydrogen bonds per base pair, whereas adenine and thymine (uracil) bind with only two. Sequences with a high number of cytosines and guanines will thus bind more strongly.
   (b) This sequence could fold over and base pair to itself instead of to the target strand.
   (c) Using a large excess of primers ensures that the target strands will bind to the primers instead of having the complementary target strands bind to each other.

Study Questions

24.1 (a)



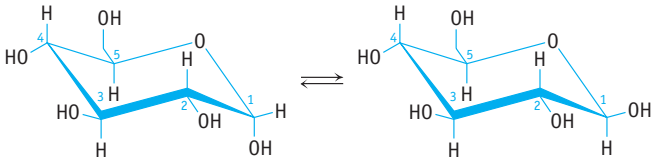
(b)



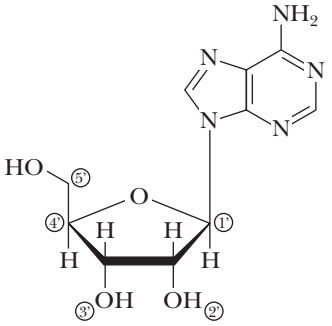
(c) The zwitterionic form is the predominant form at physiological pH.

24.3 Polar: serine, lysine, aspartic acid
Nonpolar: alanine, leucine, phenylalanine

24.5

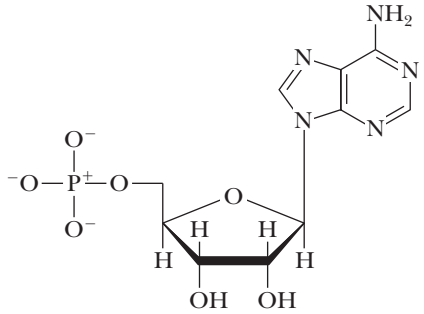


24.7

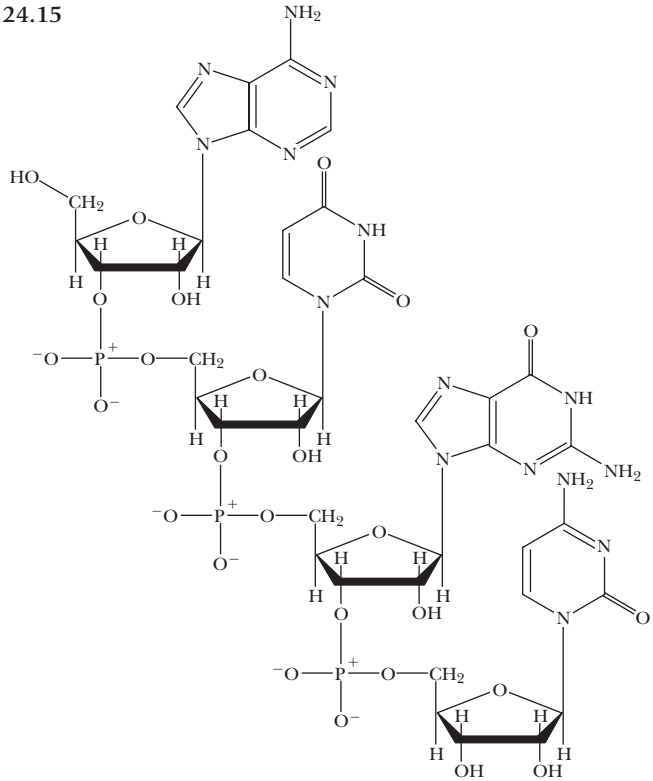


24.9 (a) Primary
(b) Quaternary
(c) Tertiary
(d) Secondary

24.11



α-D-glucose β-D-glucose



24.13 (a) The structure of ribose is given on page 1128.
(b) **Adenosine**

(c) **Adenosine-5′-monophosphate**

24.15

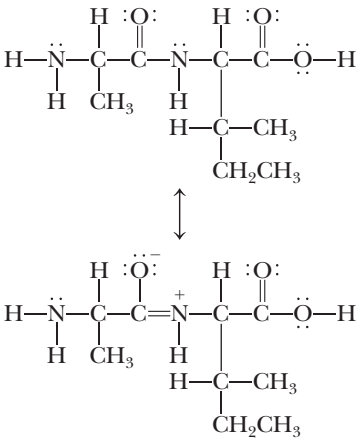
24.17 (a) 5′-GAATCGCGT-3′
(b) 5′-GAAUCGCGU-3′
(c) 5′-UUC-3′, 5′-CGA-3′, and 5′-ACG-3′
(d) glutamic acid, serine, and arginine

24.19

24.21 The 4-ring structure present in all steroids is given in Figure 24.20.

24.23 $C_6H_{12}O_6(s) + 6\ O_2(g) \rightarrow 6\ CO_2(g) + 6\ H_2O(\ell)$

$\Delta_r H° = \Sigma n\Delta_f H°(\text{products}) - \Sigma n\Delta_f H°(\text{reactants})$



$\Delta_r H° = (6\text{ mol } CO_2/\text{mol-rxn})[\Delta_f H°(CO_2)] +$
$(6\text{ mol } H_2O/\text{mol-rxn})[\Delta_f H°(H_2O)] -$
$(1\text{ mol } C_6H_{12}O_6/\text{mol-rxn})[\Delta_f H°(C_6H_{12}O_6)]$

$\Delta_r H° = (6\text{ mol } CO_2/\text{mol-rxn})(-393.5\text{ kJ/mol } CO_2) +$
$(6\text{ mol } H_2O/\text{mol-rxn})(-285.8\text{ kJ/mol } H_2O) -$
$(1\text{ mol } C_6H_{12}O_6/\text{mol-rxn})(-1273.3\text{ kJ/mol } C_6H_{12}O_6)$

$\Delta_r H° = -2{,}803\text{ kJ/mol-rxn}$

24.25 (a) NADH (c) O_2
(b) O_2 (d) NADH

24.27

24.29 (a) $6\ CO_2(g) + 6\ H_2O(\ell) \rightarrow C_6H_{12}O_6(s) + 6\ O_2(g)$

$\Delta_r H° = \Sigma n\Delta_f H°(\text{products}) - \Sigma n\Delta_f H°(\text{reactants})$

$\Delta_r H° = (1\text{ mol } C_6H_{12}O_6/\text{mol-rxn})[\Delta_f H°(C_6H_{12}O_6)]$
$- (6\text{ mol } H_2O/\text{mol-rxn})[\Delta_f H°(H_2O)] -$
$(6\text{ mol } CO_2/\text{mol-rxn})[\Delta_f H°(CO_2)]$

$\Delta_r H° = (1\text{ mol } C_6H_{12}O_6/\text{mol-rxn})$
$(-1273.3\text{ kJ/mol } C_6H_{12}O_6) -$
$(6\text{ mol } H_2O/\text{mol-rxn})(-285.8\text{ kJ/mol } H_2O) -$
$(6\text{ mol } CO_2/\text{mol-rxn})(-393.5\text{ kJ/mol } CO_2)$

$\Delta_r H° = +2{,}802.5\text{ kJ/mol-rxn}$
$= +2803\text{ kJ/mol-rxn}$

(b) $(2802.5\text{ kJ/mol})(1\text{ mol}/6.022 \times 10^{23}\text{ molecules})$
$(1000\text{ J}/1\text{ kJ}) = 4.654 \times 10^{-18}\text{ J/molecule}$

(c) $\lambda = 650\text{ nm}(1\text{ m}/10^9\text{ nm}) = 6.5 \times 10^{-7}\text{ m}$

$E = hc/\lambda = (6.626 \times 10^{-34}\text{ J} \cdot \text{s})$
$(3.00 \times 10^8\text{ m} \cdot \text{s}^{-1})/(6.5 \times 10^{-7}\text{ m}) =$
$3.1 \times 10^{-19}\text{ J}$

(d) The energy per photon is less than the amount required per molecule of glucose, therefore multiple photons must be absorbed.

24.31 There are four nucleotide bases, and each codon is three nucleotides long, so there are $4^3 = 64$ codons possible. Some amino acids have more than one codon.

24.33 oxidation: $C_6H_{12}O_6$
reduction: O_2

24.35 A graph of $y = 1/\text{Rate}$ and $x = 1/[S]$ yields a straight line with the equation $y = 1.5x + 9200$. The y-intercept corresponds to $1/\text{Rate}_{max}$, so $\text{Rate}_{max} = 1/9200 = 1.1 \times 10^{-4}\text{ mol/L} \cdot \text{min}$.

24.37 glycine

24.39 The sequences differ in the positions of attachments of the phosphate to deoxyribose on adjacent units. Consider the A-T attachments. In ATGC, the phosphate links the 3′ position on A to the 5′ position on T. In CGTA, the phosphate links the 5′ position on A to the 3′ position on T.

24.41 (a) In transcription, a strand of RNA complementary to the segment of DNA is constructed.
(b) In translation, an amino acid sequence is constructed based on the information in an mRNA sequence.

Chapter 25

Check Your Understanding

25.1 (a) Emission of six α particles leads to a decrease of 24 in the mass number and a decrease of 12 in the atomic number. Emission of four β particles increases the atomic number by 4 but doesn't affect the mass. The final product of this process has a mass number of $232 - 24 = 208$ and an atomic number of $90 - 12 + 4 = 82$, identifying it as $^{208}_{82}\text{Pb}$.

(b) Step 1: $^{232}_{90}\text{Th} \rightarrow {}^{228}_{88}\text{Ra} + {}^{4}_{2}\alpha$
Step 2: $^{228}_{88}\text{Ra} \rightarrow {}^{228}_{89}\text{Ac} + {}^{0}_{-1}\beta$
Step 3: $^{228}_{89}\text{Ac} \rightarrow {}^{228}_{90}\text{Th} + {}^{0}_{-1}\beta$

25.2 (a) $^{0}_{+1}\beta$ (b) $^{41}_{19}\text{K}$ (c) $^{0}_{-1}\beta$ (d) $^{22}_{10}\text{Ne}$

25.3 (a) $^{32}_{14}\text{Si} \rightarrow {}^{32}_{15}\text{P} + {}^{0}_{-1}\beta$
(b) $^{45}_{22}\text{Ti} \rightarrow {}^{45}_{21}\text{Sc} + {}^{0}_{+1}\beta$ or $^{45}_{22}\text{Ti} + {}^{0}_{-1}\text{e} \rightarrow {}^{45}_{21}\text{Sc}$
(c) $^{239}_{94}\text{Pu} \rightarrow {}^{4}_{2}\alpha + {}^{235}_{92}\text{U}$
(d) $^{42}_{19}\text{K} \rightarrow {}^{42}_{20}\text{Ca} + {}^{0}_{-1}\beta$

25.4 $\Delta m = 0.034345$ g/mol

$\Delta E = (3.4345 \times 10^{-5}$ kg/mol$)(2.998 \times 10^{8}$ m/s$)^2$
$= 3.0869 \times 10^{12}$ J/mol $(= 3.0869 \times 10^{9}$ kJ/mol$)$

$E_b = 5.145 \times 10^{8}$ kJ/mol nucleons

25.5 (a) 49.2 years is exactly four half-lives; quantity remaining = 1.5 mg$(1/2)^4 = 0.094$ mg
(b) Three half-lives, 36.9 years
(c) 1% is between six half-lives, 73.8 years (1/64 remains), and seven half-lives, 86.1 years (1/128 remains). [Using the integrated first-order rate equation with $[R]/[R]_0 = 0.010$ and $k = (\ln 2)/t_{1/2} = 0.05635$ y^{-1}, the amount of time is calculated to be 81.7 years.]

25.6 (a) $\ln([A]/[A_o]) = -kt$

$\ln([3.18 \times 10^3]/[3.35 \times 10^3]) = -k(2.00$ d$)$

$k = 0.02604$ d^{-1}

$t_{1/2} = 0.693/k = 0.693/(0.02604$ d$^{-1}) = 26.6$ d

(b) $k = 0.693/t_{1/2} = 0.693/200.$ y $= 3.465 \times 10^{-3}$ y^{-1}

$\ln([A]/[A_o]) = -kt$

$\ln([3.00 \times 10^3]/[6.50 \times 10^{12}]) = -(3.465 \times 10^{-3}$ y$^{-1})t$

$\ln(4.615 \times 10^{-10}) = -(3.465 \times 10^{-3}$ y$^{-1})t$

$t = 6.20 \times 10^3$ y

25.7 $\ln([A]/[A_o]) = -kt$

$\ln([9.32]/[13.4]) = -(1.21 \times 10^{-4}$ y$^{-1})t$

$t = 3.00 \times 10^3$ y

This compares quite well with the estimated date.

25.8 $^{98}_{42}\text{Mo} + {}^{1}_{0}\text{n} \rightarrow {}^{99}_{42}\text{Mo} + \gamma$

$^{99}_{42}\text{Mo} \rightarrow {}^{99}_{43}\text{Tc} + {}^{0}_{-1}\beta$

25.9 $4.17 \times 10^{-5}(0.0100$ g Pb$^{2+}) = 4.17 \times 10^{-7}$ g Pb^{2+}

Solubility $= [4.17 \times 10^{-7}$ g Pb^{2+} (1 mol Pb^{2+}/207.2 g Pb)(1 mol $PbCrO_4$/1 mol Pb^{2+})]/0.01000 L $= 2.01 \times 10^{-7}$ mol $PbCrO_4$/L

Applying Chemical Principles

25.1 A Primordial Nuclear Reactor

1. In a 100-g sample today, there are 0.720 g of ^{235}U and 99.274 g of ^{238}U.

For ^{235}U,
$k = \ln(2)/(7.038 \times 10^9$ y$) = 9.8486 \times 10^{-11}$ y^{-1}
$\ln(0.720) = -(9.8486 \times 10^{-11}$ y$^{-1})(2.0 \times 10^9$ y$) + \ln(x)$
$x = 0.877$ g

For ^{238}U,
$k = \ln(2)/(4.468 \times 10^{10}$ y$) = 1.5514 \times 10^{-11}$ y^{-1}
$\ln(99.274) = -(1.5514 \times 10^{-11}$ y$^{-1})(2.0 \times 10^9$ y$) + \ln(y)$
$y = 102.4$ g

Percent abundance of ^{235}U =
0.877 g/(0.877 g + 102.4 g) $\times$ 100% = 0.85%

2. The ratio of rates will be given by the ratio of the two rate constants.

k for ^{235}U/k for ^{238}U $= (9.8486 \times 10^{-11}$ yr$^{-1})/(1.5514 \times 10^{-11}$ yr$^{-1} = 6.348$ so ^{235}U decomposes 6.348 times faster than ^{238}U.

3. $^{235}_{92}\text{U} \rightarrow {}^{231}_{90}\text{Th} + {}^{4}_{2}\alpha$

4. $(0.00720)(235.0409) + (0.99274)(238.0508) = 238.01$

25.2 Technetium-99m and Medical Imaging

1. $^{99}_{42}\text{Mo} \rightarrow {}^{99}_{43}\text{Tc} + {}^{0}_{-1}\beta$

2. Oxidation number = 7

Tc^{7+} electron configuration = [Kr]

Diamagnetic

3. Amount $NaTcO_4 = (1.0\ \mu$g$)(1$ g$/10^6\ \mu$g$)(1$ mol$/184.9$ g$) = 5.41 \times 10^{-9}$ mol $= 5.4 \times 10^{-9}$ mol

Mass Tc $= (5.41 \times 10^{-9}$ mol $NaTcO_4)$
(1 mol Tc/mol $NaTcO_4)(97.9$ g Tc/mol$) =$
5.3×10^{-7} g Tc

4. 24 hours is 4 half-lives for ^{99m}Tc. Thus, mass remaining is 1/16th of 1.0 μg, or 0.063 μg.

5. Beta particle

6. The attractive forces binding an anion to the column are related to the anion charge. The anion MoO_4^{2-} has a higher charge than TcO_4^-.

25.3 The Age of Meteorites

1. $^{87}_{37}\text{Rb} \rightarrow {}^{87}_{38}\text{Sr} + {}^{0}_{-1}\beta$

2. (b) Beta emission

3. $k = \ln(2)/t_{1/2} = 0.693/(4.88 \times 10^{10}$ y$) = 1.420 \times 10^{-11}$ y$^{-1} = 1.42 \times 10^{-11}$ y^{-1}

4. $\ln([^{87}\text{Rb}]_t/[^{87}\text{Rb}]_0) = -(1.420 \times 10^{-11}$ y$^{-1})(4.5 \times 10^9$ y$)$

$[^{87}\text{Rb}]_t/[^{87}\text{Rb}]_0 = 0.94$

The fraction of ^{87}Rb that remains is 0.94, so the fraction that has decayed is 0.06.

5. A graph of $[^{87}\text{Sr}/^{86}\text{Sr}]$ versus $[^{87}\text{Rb}/^{86}\text{Sr}]$ was constructed using Microsoft Excel. The resulting equation of the line was $y = 0.0406x + 0.785$.

$e^{kt} - 1 = 0.0406$
$e^{kt} = 1.0406$
$kt = 0.039797$
$t = 0.039797/(1.420 \times 10^{-11}$ y$^{-1}) = 2.80 \times 10^9$ y

6. Begin with the integrated rate law for the first-order decomposition of ^{87}Rb.
$\ln([^{87}Rb]/[^{87}Rb]_0) = -kt$

This can be rearranged to give an equation for $[^{87}Rb]_0$,
$[^{87}Rb]_0 = [^{87}Rb]e^{kt}$

The $[^{87}Sr]$ equals its initial concentration plus the concentration created by the decomposition of ^{87}Rb:
$[^{87}Sr] = [^{87}Sr]_0 + ([^{87}Rb]_0 - [^{87}Rb])$

This can also be solved for $[^{87}Rb]_0$:
$[^{87}Rb]_0 = [^{87}Sr] + [^{87}Rb] - [^{87}Sr]_0$

Setting the two equations for $[^{87}Rb]_0$ equal to each other, we obtain
$[^{87}Sr] + [^{87}Rb] - [^{87}Sr]_0 = [^{87}Rb]e^{kt}$
$[^{87}Sr] = [^{87}Rb]e^{kt} - [^{87}Rb] + [^{87}Sr]_0$
$[^{87}Sr] = [^{87}Rb](e^{kt} - 1) + [^{87}Sr]_0$

Finally, dividing both sides of the equation by $[^{86}Sr]$ gives the desired equation:
$[^{87}Sr]/[^{86}Sr] = ([^{87}Rb]/[^{86}Sr])(e^{kt} - 1) + [^{87}Sr]_0/[^{86}Sr]$

Study Questions

25.1 (a) Increasing mass: $\gamma < \beta < \alpha$
(b) Increasing penetrating power: $\alpha < \beta < \gamma$

25.3 Binding energy per nucleon is determined by first calculating the mass defect for an isotope, converting the mass defect to binding energy (using $E = mc^2$), and then dividing the binding energy by the mass number of the nucleus.

25.5 An element of fairly high atomic number is bombarded with a beam of high-energy particles. Initially, neutrons were used; later, helium nuclei and then larger nuclei such as ^{11}B and ^{12}C were used; and, more recently, highly charged ions of elements such as calcium, chromium, cobalt, and zinc have been chosen. The bombarding particle fuses with the nucleus of the target atom, forming a new nucleus that lasts for a short time before decomposing.

Neutrons are effective when used as a bombarding particle because they have no charge. They are therefore not repelled by the positively charged nuclear particles.

25.7 While an organism lives, the percentage of carbon that is ^{14}C in the organism will equal the percentage in the atmosphere. When the organism dies, it no longer replenishes the ^{14}C. By measuring the activity of ^{14}C in the organism, comparing it to the ambient ^{14}C activity, and using first-order kinetics, it is possible to determine how long ago the organism stopped taking in ^{14}C (died). Limitations: (1) The method assumes that the amount of ^{14}C in the atmosphere has remained constant, whereas it has varied by as much as 10%. (2) ^{14}C dating cannot be used to date an object less than 100 or more than about 40,000 years old. (3) The accuracy of ^{14}C dating is about ± 100 years.

25.9 8 α and 6 β

25.11 The initiation step involves the addition of a neutron to ^{235}U and its subsequent fission. The fission produces neutrons that react with further ^{235}U atoms in the propagation step. The chain reaction is terminated when either there is no ^{235}U remaining or when the neutrons escape without reacting or when they are absorbed by a moderator.

25.13 A moderator is present in a nuclear reactor to control the rate of a fission reaction and are moved in and out of the reactor to slow or speed up the reaction.

25.15 (a) Curie: radioactive decomposition per second (1 curie = 3.7×10^{10} disintegrations per second)
(b) Rad: energy absorbed per mass of tissue (1 rad = 0.01 J per kilogram of tissue)

25.17 The isotope should concentrate in the tissue to be imaged. The radiation should cause minimal collateral damage (gamma radiation is preferred). To get successful imaging, there must be provision for detecting and processing the data obtained.

25.19 $^{14}_{7}N + {}^{2}_{1}H \rightarrow {}^{15}_{8}O + {}^{1}_{0}n$
$^{15}_{8}O \rightarrow {}^{15}_{7}N + {}^{0}_{+1}\beta$
$^{0}_{+1}\beta + {}^{0}_{-1}e \rightarrow 2\ \gamma$

25.21 (a) $^{56}_{28}Ni$; (b) $^{1}_{0}n$; (c) $^{32}_{15}P$; (d) $^{97}_{43}Tc$; (e) $^{0}_{-1}\beta$; (f) $^{0}_{1}e$ (positron)

25.23 (a) $^{0}_{-1}\beta$; (b) $^{87}_{37}Rb$; (c) $^{4}_{2}\alpha$; (d) $^{226}_{88}Ra$; (e) $^{0}_{-1}\beta$; (f) $^{24}_{11}Na$

25.25 $^{235}_{92}U \rightarrow {}^{231}_{90}Th + {}^{4}_{2}\alpha$
$^{231}_{90}Th \rightarrow {}^{231}_{91}Pa + {}^{0}_{-1}\beta$
$^{231}_{91}Pa \rightarrow {}^{227}_{89}Ac + {}^{4}_{2}\alpha$
$^{227}_{89}Ac \rightarrow {}^{227}_{90}Th + {}^{0}_{-1}\beta$
$^{227}_{90}Th \rightarrow {}^{223}_{88}Ra + {}^{4}_{2}\alpha$
$^{223}_{88}Ra \rightarrow {}^{219}_{86}Rn + {}^{4}_{2}\alpha$
$^{219}_{86}Rn \rightarrow {}^{215}_{84}Po + {}^{4}_{2}\alpha$
$^{215}_{84}Po \rightarrow {}^{211}_{82}Pb + {}^{4}_{2}\alpha$
$^{211}_{82}Pb \rightarrow {}^{211}_{83}Bi + {}^{0}_{-1}\beta$
$^{211}_{83}Bi \rightarrow {}^{211}_{84}Po + {}^{0}_{-1}\beta$
$^{211}_{84}Po \rightarrow {}^{207}_{82}Pb + {}^{4}_{2}\alpha$

25.27 (a) $^{198}_{79}Au \rightarrow {}^{198}_{80}Hg + {}^{0}_{-1}\beta$
(b) $^{222}_{86}Rn \rightarrow {}^{218}_{84}Po + {}^{4}_{2}\alpha$
(c) $^{137}_{55}Cs \rightarrow {}^{137}_{56}Ba + {}^{0}_{-1}\beta$
(d) $^{110}_{49}In \rightarrow {}^{110}_{48}Cd + {}^{0}_{1}e$

25.29 (a) $^{80}_{35}Br$ has a high neutron/proton ratio of 45/35. Beta decay will allow the ratio to decrease:
$^{80}_{35}Br \rightarrow {}^{80}_{36}Kr + {}^{0}_{-1}\beta$.
(b) Alpha decay is likely: $^{240}_{98}Cf \rightarrow {}^{236}_{96}Cm + {}^{4}_{2}\alpha$
(c) Cobalt-61 has a high n/p ratio, so beta decay is likely:
$^{61}_{27}Co \rightarrow {}^{61}_{28}Ni + {}^{0}_{-1}\beta$

(d) Carbon-11 has only five neutrons, so K-capture or positron emission may occur:

$^{11}_{6}C + {}^{0}_{-1}e \rightarrow {}^{11}_{5}B$

$^{11}_{6}C \rightarrow {}^{11}_{5}B + {}^{0}_{1}e$

25.31 Generally beta decay will occur when the *n/p* ratio is high, whereas positron emission will occur when the *n/p* ratio is low.

(a) Beta decay: $^{20}_{9}F \rightarrow {}^{20}_{10}Ne + {}^{0}_{-1}\beta$

$^{3}_{1}H \rightarrow {}^{3}_{2}He + {}^{0}_{-1}\beta$

(b) Positron emission

$^{22}_{11}Na \rightarrow {}^{22}_{10}Ne + {}^{0}_{1}\beta$

25.33 Binding energy per mole of nucleons for $^{11}B = 6.70 \times 10^{8}$ kJ

Binding energy per mole of nucleons for $^{10}B = 6.26 \times 10^{8}$ kJ

25.35 8.256×10^{8} kJ/mol nucleons. This value is consistent with the value shown in Figure 25.4.

25.37 7.700×10^{8} kJ/mol nucleons

25.39 0.781 micrograms

25.41 (a) $^{131}_{53}I \rightarrow {}^{131}_{54}Xe + {}^{0}_{-1}\beta$

(b) 0.075 micrograms

25.43 9.5×10^{-4} mg

25.45 (a) $^{222}_{86}Rn \rightarrow {}^{218}_{84}Po + {}^{4}_{2}\alpha$

(b) Time = 8.87 d

25.47 (a) 15.8 y; (b) 88%

25.49 $^{239}_{94}Pu + {}^{4}_{2}\alpha \rightarrow {}^{240}_{95}Am + {}^{1}_{1}H + 2\ {}^{1}_{0}n$

25.51 $^{48}_{20}Ca + {}^{242}_{94}Pu \rightarrow {}^{287}_{114}Fl + 3\ {}^{1}_{0}n$

25.53 (a) $^{115}_{48}Cd$; (b) $^{7}_{4}Be$; (c) $^{4}_{2}\alpha$; (d) $^{63}_{29}Cu$

25.55 $^{10}_{5}B + {}^{1}_{0}n \rightarrow {}^{7}_{3}Li + {}^{4}_{2}\alpha$

25.57 Time = 4.4×10^{10} y

25.59 If $t_{1/2} = 14.28$ d, then $k = 4.854 \times 10^{-2}$ d^{-1}. If the original disintegration rate is 3.2×10^{6} dpm, then (from the integrated first order rate equation), the rate after 365 d is 0.065 dpm. The plot will resemble Figure 25.5.

25.61 (a) $^{238}_{92}U + {}^{1}_{0}n \rightarrow {}^{239}_{92}U + \gamma$

(b) $^{239}_{92}U \rightarrow {}^{239}_{93}Np + {}^{0}_{-1}\beta$

(c) $^{239}_{93}Np \rightarrow {}^{239}_{94}Pu + {}^{0}_{-1}\beta$

(d) $^{239}_{94}Pu + {}^{1}_{0}n \rightarrow 2\ {}^{1}_{0}n$ + energy + other nuclei

25.63 (a) Calcium-48. Possible reaction is

$^{248}_{96}Cm + {}^{48}_{20}Ca \rightarrow {}^{296}_{116}Lv$

(b) Three neutrons

25.65 About 2700 years old

25.67 Plot ln (activity) versus time. The slope of the plot is $-k$, the rate constant for decay. Here, $k = 0.0050$ d^{-1}, so $t_{1/2} = 140$ d.

25.69 Time = 1.9×10^{9} y

25.71 Energy obtained from 1.000 lb (453.6 g) of $^{235}U = 4.05 \times 10^{10}$ kJ

Mass of coal required = 1.6×10^{3} ton (or about 3 million pounds of coal)

25.73 The percentage of tagged fish in the lake is (27/5250)100% = 0.51%. Therefore, 1000 tagged fish is 0.51% of the total or approximately 190,000 fish.

25.75 (a) The mass decreases by 4 units (with an $^{4}_{2}\alpha$ emission) or is unchanged (with a $^{0}_{-1}\beta$ emission), so the only masses possible are 4 units apart.

(b) ^{232}Th series, $m = 4n$; ^{235}U series $m = 4n + 3$

(c) ^{226}Ra and ^{210}Bi, $4n + 2$ series; ^{215}At, $4n + 3$ series; ^{228}Th, $4n$ series

(d) Each series is headed by a long-lived isotope (in the order of 10^{9} years, the age of the Earth). The $4n + 1$ series is missing because there is no long-lived isotope in this series. Over geologic time, all the members of this series have decayed completely.

25.77 (a) ^{231}Pa isotope belongs to the ^{235}U decay series (see Question 25.75b).

(b) $^{235}_{92}U \rightarrow {}^{231}_{90}Th + {}^{4}_{2}\alpha$

$^{231}_{90}Th \rightarrow {}^{231}_{91}Pa + {}^{0}_{-1}\beta$

(c) Pa-231 is present to the extent of 1 part per million. Therefore, 1 million grams of pitchblende need to be used to obtain 1 g of Pa-231.

(d) $^{231}_{91}Pa \rightarrow {}^{227}_{89}Ac + {}^{4}_{2}\alpha$

25.79 Pitchblende contains $^{238}_{92}U$ and $^{235}_{92}U$. Thus, both radium and polonium isotopes must belong to either the $4n + 2$ or $4n + 3$ decay series. Furthermore, the isotopes must have sufficiently long half-lives in order to survive the separation and isolation process. These criteria are satisfied by ^{226}Ra and ^{210}Po.

Index and Glossary

Italicized page numbers indicate pages containing illustrations, and those followed by "t" indicate tables. Glossary terms, printed in boldface, are defined here as well as in the text.

abbreviations, A-9

absolute temperature scale. *See* **Kelvin temperature scale**

absolute zero The lowest possible temperature, equivalent to −273.15 °C, used as the zero point of the Kelvin scale, 30, 456
  zero entropy at, 821–822

absorbance The negative logarithm of the transmittance, 205
  concentration and, *610*

absorption spectrum A plot of the intensity of light absorbed by a sample as a function of the wavelength of the light, 205, 1050
  excited states and, *285*
  of chlorophyll *a* and *b*, *1140*

absorptivity, molar, 205

abundance(s)
  of elements in Earth's crust, 67t
  of isotopes, 62, 64t

acceptor level, in semiconductor, 543

accuracy The agreement between the measured quantity and the accepted value, 35
  of acid–base indicators, 781

acetaldehyde, 1089t

acetaminophen, structure of, 1095

acetate ion
  buffer solution of, 764t
  reaction with phosphoric acid, 723

acetic acid, 1091t
  as weak acid, 130, 715, 717
  as weak electrolyte, 133
  buffer solution of, 764t
  glacial, 747
  hydrogen bonding in, *499*
  ionization of, 761
  orbital hybridization in, 423
  partial charges in, *740*
  production of, 1088, 1090
  quantitative analysis of, 183
  reaction with ammonia, 734
  reaction with sodium bicarbonate, 724
  reaction with sodium hydroxide, 145, 1091
  reaction with water, 142
  structure of, *142*, *1066*, 1087
  titration with sodium hydroxide, 774–777

acetic anhydride, 182

acetone, 1089t
  hydrogenation of, 394
  structure of, 423, 1087

acetylacetonate ion, as ligand (acac), 1031

N-acetyl-*p*-aminophenol, 1094

acetylene
  orbital hybridization in, 423
  structure of, 1066

N-acetylglucosamine (NAG), 1123

N-acetylmuramic acid (NAM), 1123

acetylsalicylic acid. *See* aspirin.

acid(s) A substance that, when dissolved in pure water, increases the concentration of hydrogen ions, 139–147. *See also* **Brønsted acid(s), Lewis acid(s)**.
  Arrhenius definition of, 140–141
  bases and, 708–749. *See also* **acid–base reaction(s)**.
  Brønsted–Lowry definition, 141–143, 709–710
  carboxylic. *See* **carboxylic acid(s).**
  common, names, 140t, 141
  Lewis definition of, 742–747
  pH of, 194–195
  reaction with bases, 144–146
  strengths of, 715, 717t
    direction of reaction and, 723
    in nonaqueous solvents, 746
    logarithmic (pK_a), 719
    molecular structure and, 737–742
    strong. *See* **strong acid.**
    weak. *See* **weak acid.**

acid–base adduct, 742, *743*

acid–base indicator(s), 780–782

acid–base reaction(s) An exchange reaction between an acid and a base producing a salt and water, 144–146, 156
  conjugate pairs in, 711–712
  direction of, acid–base strength and, 723
  equivalence point of, 199, 772
  pH after, 734
  titration using, 198–202, 772–773
  types of, 725, 725t

acid ionization constant (K_a) The equilibrium constant for the ionization of an acid in aqueous solution, 716, 717t
  relation to conjugate base ionization constant, 720
  values of, A-20

acid rain, 147, 920, 934, 943

acidic oxide(s) An oxide of a nonmetal that acts as an acid, 147

acidic solution A solution in which the concentration of hydronium ions is greater than the concentration of hydroxide ions, 713

acidosis, 801

acoustic energy The energy of compression and expansion of spaces between molecules, 17

Acrilan, 1098t

actinide(s) The series of elements between actinium and rutherfordium in the periodic table, 74, 1021
  electron configurations of, 321

activation energy (E_a) The minimum amount of energy that must be absorbed by a system to cause it to react, 632
  bond energies and, 638
  experimental determination, 636
  reduction by catalyst, 638

active site, in enzyme, 1123
active transport, through cell membrane, 1136–1137
activity (*A*) A measure of the rate of nuclear decay, the number of disintegrations observed in a sample per unit time, 1162
activity, thermodynamic, 675
actual yield The measured amount of product obtained from a chemical reaction, 180
acute mountain sickness, 476
addition polymer(s) A synthetic organic polymer formed by directly joining monomer units, 1096–1099
  production from ethylene derivatives, 1098t
addition reaction(s), of alkenes and alkynes, 1077
adduct, acid–base, 742
adenine, 395–396, *396*
  hydrogen bonding to thymine, 500, *500*, 1129
  in DNA and RNA, 1128, *1128–1131*
adenosine 5′-diphosphate (ADP), 843, 1138
adenosine 5′-triphosphate (ATP), 1138
  structure of, 843
adhesive force A force of attraction between molecules of two different substances, 515
adhesives
  chemistry of, 1104
  on gecko's toes, 505
adipoyl chloride, 1101
adrenaline, 1103, *1103*
adsorption, of gas molecules on solid surface, 474
aerosol, 592t
Agency for Toxic Substances and Disease Registry (ATSDR), 929
air
  argon in, 104
  components of, 465t
  density of, 462
  environmental concerns, 917–925
  fractional distillation of, 998
  noble gases in, 1005–1006
  pollution of, 942, 999
air bags, 477
alanine, structure of, *1119*
albite, dissolved by rain water, 209
alchemy, 973
alcohol(s) Any of a class of organic compounds characterized by the presence of a hydroxyl group bonded to a saturated carbon atom, 941, 1083–1087
  common, 1083t
  energy content of, 34
  miscibility in water, 1085
  naming of, 1083, A-17
  oxidation to carbonyl compounds, 1088
aldehyde(s) Any of a class of organic compounds characterized by the presence of a carbonyl group, in which the carbon atom is bonded to at least one hydrogen atom, 1088, 1089
  naming of, A-17
  reduction to primary alcohols, 1089
aldose, 1125
algae
  oxygen production by, 920
  phosphates and, 928
alkali metal(s) The metals in Group 1A of the periodic table, 67
  electron configuration of, 317
  ions, enthalpy of hydration, 493
  reaction with halogens, 970
  reaction with oxygen, 970
  reaction with water, 67, 970
alkaline battery, 873, *873*
alkaline earth metal(s) The elements in Group 2A of the periodic table, 67, 973–976
  biological uses of, 976
  electron configuration of, 317
alkaloid, 709
alkalosis, 800
alkane(s) Any of a class of hydrocarbons in which each carbon atom is bonded to four other atoms, 1069–1074
  derivatives of, 1082t
  general formula of, 1069t
  in petroleum, 938
  naming of, 1072, A-15
  properties of, 1073
  reaction with chlorine, 1073
  reaction with oxygen, 1073
  standard enthalpies of vaporization of, 508t
Alka-Seltzer®, *156*
alkene(s) Any of a class of hydrocarbons in which there is at least one carbon–carbon double bond, 907–910
  general formula of, 1069t
  hydrogenation of, 1078
  naming of, A-16
alkyl group A part of a molecular structure derived by removing a hydrogen atom from an alkane molecule, 1072
alkylation, of benzene, 1082
alkyne(s) Any of a class of hydrocarbons in which there is at least one carbon–carbon triple bond, 1076
  general formula of, 1069t
  naming of, A-16
allene, structure of, *1066*
allotrope(s) Different forms of the same element that exist in the same physical state under the same conditions of temperature and pressure, 71
  boron, 978
  carbon, 71, *71*, 844
  oxygen, 72, 998. *See also* ozone.
  phosphorus, 72
  sulfur, 72, 998
  tin, 555
alloy(s)
  aluminum, 978
  atom substitution in, 328
  iron, 1028
  magnesium in, 974
Alnico V, 1028
alpha-hydroxy acid(s), *735*
alpha particle(s) A helium nucleus ejected from certain radioactive substances, 1149
  bombardment with, 1166, 1169
  predicting emission of, 1157
alpha ray(s). *See* **alpha particle(s)**.
alternative energy sources, 937–942
altitude sickness, 476
alum
  crystallization of, 578
  in water purification, 927
aluminosilicates, 159, 986–987, *986–987*
  separation of, 979
aluminum
  abundance of, 71, 978
  chemistry of, 981
  electron configuration of, 321
  oxidation of, 177
  production of, 980
  reaction with bromine, 982
  reaction with copper ions, 861
  reaction with sodium hydroxide, 968
  reaction with water, 864
  reduction by sodium, 969
  similarity to beryllium, 978
aluminum bromide, dimerization of, 983
aluminum fluoride ion, 983
aluminum hydroxide, amphoterism of, 744, *744*
aluminum oxide, 979
  amphoterism of, 979
aluminum sulfate, coagulation of colloidal particles by, 594
amalgam, mercury, 883, 1038
americium, 1157
amethyst, 984
amide(s) Any of a class of organic compounds characterized by the presence of a carbonyl group, in which the carbon atom is bonded to an amino group, 1088, 1094
amide link, 1094, *1094*, 1101–1102, *1101–1102*, 1104, 1118, 1120–1121, *1120*
amine(s) A derivative of ammonia in which one or more of the hydrogen atoms are replaced by organic groups, 1086
  reaction with carboxylic acids, 1094
  solubility in water, 1086
α-amino acid(s) A compound containing an amino group and a carboxylic acid group, both attached to the same carbon atom, 1118
  chirality of, 1118

structure of, 1118
zwitterionic form, 1139
amino group A functional group related to ammonia, in which some or all of the hydrogen atoms are replaced by organic groups, 1094
ammine, naming ammonia as ligand, 1036
ammonia
aqueous, equilibrium constant expression for, 675
as Lewis base, 743, *743*, 745
as ligand, 1031, 1036
as refrigerant, 922
as weak base, 714, 715
bond angles in, 375, *376*
combustion of, balanced equation for, 127
decomposition of, 617
molecular polarity of, 385
orbital hybridization in, 417
oxidation of, 177, *178*
percent composition of, 93
pH of, 194
production of, as equilibrium process, 129
by Haber process, 695
entropy change for, 824
equilibrium constant for, 689
free energy change, 839
spontaneity of, 829
stoichiometry of, 464
reaction with acetic acid, 734
reaction with hydrochloric acid, 734
reaction with hydrogen chloride, 145, 468
reaction with hypochlorous acid, 949
reaction with sodium hypochlorite, 991
reaction with water, 141
relation to amines, 1086
titration with hydrochloric acid, 779
ammonium chloride
decomposition of, 829
in dry cell battery, 872
ammonium ion, 80, 83
in Lewis adduct, 742
ammonium nitrate
decomposition of, 992
dissolution of, 815
enthalpy of solution, 571
ammonium perchlorate, in rocket fuel, 1005
amorphous solid(s) A solid that lacks long-range regular structure and displays a melting range instead of a specific melting point, 546
amount, of pure substance, 87. *See also* **mole (mol)**.
amounts table, in solving stoichiometry problems, 175. *See also* ICE table.
ampere (A) The unit of electric current, 898, A-10
Ampère, André Marie, 1000
amphibole, 986
amphiprotic substance A substance that can behave as either a Brønsted acid or a Brønsted base, 143, 711
amphoteric substance A substance, such as a metal hydroxide, that can behave as either an acid or base, 744, 755t
aluminum oxide, 979
amplitude The height of a wave, as measured from the axis of propagation, *278*, 292
amylopectin starch, 1126, *1127*
amylose starch, 1126, *1127*
anaerobic fermentation, 1083
analysis, chemical. *See* **chemical analysis**.
spectrophotometric, 205
Anderson, Carl, 1154
anesthetic, xenon as, 1006
Ångstrom unit (Å), 31, A-12
angular momentum quantum number, 293
number of nodal surfaces and, 297
anhydrous compound The substance remaining after the water has been removed (usually by heating) from a hydrated compound, 85
aniline
as weak base, 719
reaction with sulfuric acid, 1087
structure of, 1080
anilinium hydrogen sulfate, 1087
anion(s) An ion with a negative electric charge, 77
acid–base properties of, 720
as Brønsted acids and bases, 710, 742
as Lewis bases, 742
naming, 83
noble gas electron configuration in, 324, 337
sizes of, 336
anode The electrode of an electrochemical cell at which oxidation occurs, 866
in corrosion, 899
in electrolysis cell, 893
sacrificial, 902
anthracite, 935, 935t
antibonding molecular orbital A molecular orbital in which the energy of the electrons is higher than that of the parent orbital electrons, 427
anticodon, 1131
antifreeze, 581
ethylene glycol in, 567
antilogarithms, A-3
antimatter, 1154
antimony
abundance of, 989
isotopic abundance of, 65
antineutrino, 1154
antisense therapy, 1140–1141
apatite(s), 975, 995
apophyllite, *987*
Appian Way, mortar in, 975
approximation
solving quadratic equations by, 684
successive, method of, 684, A-5
aqua, naming water as ligand, 1036
aqua regia, 994
aqua sphere. *See* water.
aqueous solution A solution in which the solvent is water, 131–135
balancing redox equations in, 861–864
electrolysis in, 894
equilibrium constant expression for, 675
aquifer, depletion of, 925
aragonite, solubility of, 947
arginine, structure of, *1119*
argon
abundance of, 1005
discovery of, 103
in atmosphere, 919
isotope ratios, 102
Arnold, James R., 1165
aromatic compound(s) Any of a class of hydrocarbons characterized by the presence of a benzene ring or related structure, 425, 1079–1082
general formula of, 1069t
in petroleum, 938
naming of, A-17
properties of, 1081–1082
Arrhenius, Svante, 139–140
Arrhenius equation A mathematical expression that relates reaction rate to activation energy, collision frequency, and molecular orientation, 635
arsenic
abundance of, 989
poisoning by, 103
water pollution by, 929
arsine, 994
asbestos, 973, 986
ascorbic acid, titration of, 203
asparagine, structure of, *1119*
aspartic acid, structure of, *1119*
Aspdin, Joseph, 977
aspirin
melting point of, *14*
molar mass of, 90
structure of, *29*, 1192
synthesis of, 182
astatine, abundance of, 1000
Athabasca sands, 937
atmosphere. *See also* air.
carbon-14 isotope in, 1164–1165
composition of, 465t, 917t
mass of, 918
pressure–temperature profile of, 918
standard, 452. *See also* **standard atmosphere (atm)**.

atom(s) The smallest particle of an element that retains the characteristic chemical properties of that element, 7, 9
Bohr model of, 284–289
composition of, 61
electron configurations of, 315–323. *See also* electron configuration(s).
mass of, 60
quantization of energy in, 284, 291
size of, 59, 328. *See also* atomic radius
structure of, 59, 69, 276–301
atom economy, 397
green chemistry and, 207
atomic bomb, 1174
atomic mass The experimentally determined mass of an atom of one isotope, 60–63
atomic mass unit (u) The unit of a scale of relative atomic masses of the elements; 1 u = 1/12 of the mass of a carbon atom with six protons and six neutrons, 60, A-13t
equivalent in grams, 60
atomic number (*Z*) The number of protons in the nucleus of an atom of an element, 60
chemical periodicity and, 70
even versus odd, and nuclear stability, 1156
in nuclear symbol, 1150
atomic orbital(s) The matter wave for an allowed energy state of an electron in an atom, 292
assignment of electrons to, 313–315
energies of, and electron assignments, 313–315
number of electrons in, 312t
order of energies in, 313, 322
orientations of, 297
overlapping of, in valence bond theory, 413
penetration of, 314
quantum numbers of, 292
shapes of, 294–297
atomic radius
bond length and, 390
bond length and, effective nuclear charge and, 329
in transition elements, 1025
periodicity, 328–330
determining, 451
atomic theory of matter A theory that describes the structure and behavior of substances in terms of ultimate chemical particles called atoms and molecules, 59
atomic weight The average mass of an atom in a natural sample of the element, 63
atropine, 746
Atwater system, for energy content of foods, 34
Aufbau principle, 313
austenite, unit cell of, 1062
autoionization of water Proton transfer between two water molecules to produce a hydronium ion and a hydroxide ion, 713
Autumn, Kellar, 505
average reaction rate, 611
Avogadro, Amedeo, 87, 458
Avogadro's hypothesis Equal volumes of gases under the same conditions of temperature and pressure have equal numbers of particles, 458
kinetic-molecular theory and, 471
Avogadro's number The number of particles in one mole of any substance ($6.022140857 \times 10^{23}$), 87, A-13t
axial position
in cyclohexane structure, 1074
in trigonal bipyramidal molecular geometry, 377
azo dye, 439
azomethane, decomposition of, 624, 626
azurite, 24, *783*, 787, *1022*

background radiation, 1173
bacteria
copper production by, 1028
destruction by copper, 1052–1053
in drinking water, 928
methane produced by, 925
bacteriocide, copper as, 339
baking powder, 997
baking soda, 148, 971
reaction with vinegar, 724
balance
laboratory, *3*
laboratory, precision of, *39*
balanced chemical equation A chemical equation showing the relative amounts of reactants and products, 123–128
enthalpy and, 245
ball-and-stick models, 76, 1067
balloon
helium, 966
hot-air, *461*
hydrogen, 966
models of electron pair geometries, *373*
weather, 457
Balmer, Johann, 284
Balmer equation, 284
Balmer series, 284, 288
in spectra of stars, 300
balsam, toluene in, 1079
band gap, 542
band of stability, nuclear, 1156
band theory
of metallic bonding, 541
of semiconductors, 542
bar A unit of pressure; 1 bar = 100 kPa, 452, A-7
barite, 784
barium
abundance of, 973
salts of, in fireworks, 300
barium chloride
as strong electrolyte, 132
reaction with sodium sulfate, 138, 183–184, 795
barium chloride dihydrate, 494
barium nitrate, as strong electrolyte, 132
barium sulfate
as x-ray contrast agent, 784, 976
precipitation of, 138, 794
solubility of, 785
barometer An apparatus used to measure atmospheric pressure, 451
mercury, 451–452, *451*
Bartlett, Neil, 1007
base(s) A substance that, when dissolved in pure water, increases the concentration of hydroxide ions, 140–148. *See also* **Brønsted base(s), Lewis base(s)**.
acids and, 708–749. *See also* **acid–base reaction(s)**.
amines as, 921
Arrhenius definition of, 140–141
Brønsted–Lowry definition, 141–143, 710
common, 140t
strong. *See* **strong base.**
weak. *See* **weak base.**
in DNA, 395
Lewis definition of, 742–747
nitrogenous, 956, *957*
pH of, 194–196
reaction with acids, 144–145
strengths of, 715, 717t
direction of reaction and, 723
base ionization constant (K_b) The equilibrium constant for the ionization of a base in aqueous solution, 716, 717t
relation to conjugate acid ionization constant, 720
base of logarithms, A-2
base pairing, hydrogen bonding and, 500
base units, SI, 30t
basic oxide(s) An oxide of a metal that acts as a base, 147
basic oxygen furnace, 1028
basic solution A solution in which the concentration of hydronium ions is less than the concentration of hydroxide ions, 713
battery A device consisting of two or more electrochemical cells, 871
energy per kilogram, 875
lithium-ion, 553, 874–875
types of, 871
bauxite, 979
Bayer process, 979
becquerel The SI unit of radioactivity, 1 decomposition per second, 1172
Becquerel, Henri, 68

Bednorz, Georg, 158
Beer-Lambert law The absorbance of a sample is proportional to the path length and the concentration, 205
belladonna, atropine in, 746
bends, 597
benzaldehyde, structure of, 1089
benzene
  boiling point elevation and freezing point depression constants for, 580t
  derivatives of, 1080, A-17
  liquid and solid volumes, *492*
  molecular orbital configuration of, *436*
  pi bonds in, 425, 1080
  reactions of, 1081
  resonance structures of, 366
  standard enthalpy of formation of, 257
  structure of, 1079
  vapor pressure of, 580
benzoic acid, 1090t
  buffer solution of, 767t
  pH in aqueous solution, 729
  structure of, 1080
benzonitrile, structure of, *1066*
benzyl acetate, 1093
benzyl butanoate, 1093t
beryllium
  abundance of, 959
  electron configuration of, 318
  similarity to aluminum, 978
beryllium dichloride, orbital hybridization in, 419
beta particle(s) An electron ejected at high speed from certain radioactive substances, 1150
  predicting emission of, 1157
beta rays. *See* **beta particle(s)**.
bicarbonate ion
  as acid, 146
  concentration in sea water, 945, *946*
  in biological buffer system, 801. *See also* hydrogen carbonate ion.
bidentate ligands, 1031
bilayer structure, of lipids, 1135
bimolecular process, 644
binary compound(s) A compound formed from two elements, 76
  bonding types in, 397
binding energy The energy required to separate a nucleus into individual protons and neutrons, 1158–1160
  per nucleon, 1159
biochemistry, 1116–1141
  thermodynamics and, 843
biodiesel, 941–942, *941–942*
biofuels, 941–942
biological effects of radiation, 1173
birefringence, 973, *974*
bismuth, abundance of, 989
bisphenol A, 1104–1105
bituminous coal, 935
black powder, 258
black smokers, metal sulfides from, 160
blackbody radiation, 280
blast furnace, 1027
bleach
  detection in food tampering, 208
  sodium hypochlorite in, 567, 1004
blimp, helium in, 477
blood
  buffers in, 763
  oxygen saturation of, 476
  pH of, 194, 800
boat form, 1074
body-centered cubic (bcc) unit cell, 529
Bohr, Christian, 1033
Bohr, Niels, 284
Bohr effect, in hemoglobin, 1033
Bohr radius, *298*, A-13t
boiling point The temperature at which the vapor pressure of a liquid is equal to the external pressure on the liquid, 513
  for common compounds, 508t, A-14t
  hydrogen bonding and, 497
  intermolecular forces and, 495
boiling point elevation, 579–581, 580t, 588, 590
boiling point elevation constant (K_{bp}), 580
Boltzmann, Ludwig, 469, 820–821, *820*
Boltzmann distribution curves. *See* Maxwell-Boltzmann distribution curves.
Boltzmann's constant, 820, A-13t
bomb calorimeter, 251
bombardier beetle, *615*
bond(s) An interaction between two or more atoms that holds them together by reducing the potential energy of their electrons, 351. *See also* bonding.
  amide link, 1094, 1101
  chemical, 352
  coordinate covalent, 369, 742, 1031
  covalent, 352
  formation of, 351–352
  glycosidic, 1125
  ionic, 352
  multiple, 357
    molecular geometry and, 378
  peptide, 1120
  polar, 379–381
  properties of, 389–394
  sigma, 414
  structural formulas showing, 75
  wedge representation of, 1067
bond angle The angle between two atoms bonded to a central atom, 373
  effect of lone pairs on, 375
  in strained hydrocarbons, 1073
bond dissociation energy. *See* bond energy.
bond dissociation enthalpy The enthalpy change for breaking a bond in a molecule, with the reactants and products in the gas phase at standard conditions, 391, 392t
  of halogen compounds, 1002t
bond energy
  acid strength and, 741
  activation energy and, 638
  compared to nuclear binding energy, 1158
  in network solids, 985
  of carbon–carbon bonds, 1068
  of noble gas compounds, 1006
bond length The distance between the nuclei of two bonded atoms, 390, 391t
  atomic radius and, 390
  bond order and, 390
  in benzene, 425
  resonance structures and, 365
bond order The number of bonding electron pairs shared by two atoms in a molecule, 389–390
  bond length and, 390
  fractional, 390, 429
  molecular orbitals and, 429
bond pair(s) Two electrons, shared by two atoms, that contribute to the bonding attraction between the atoms, 354
  angles between, 373
  in formal charge equation, 390
  molecular polarity and, 384–389, 400t
bond polarity
  electronegativity and, 379–381
  formal charge and, 381
bond strength. *See* bond energy.
bonding
  in carbon compounds, 1064–1105
  in coordination compounds, 1043–1048
  ligand field theory of, 1043–1048
  metallic, band theory of, 541
  molecular orbital theory of, 413, 427–436, 1043
  molecular structure and, 350–400
  multiple, 357, 421–425
  types of, 352
  valence bond theory of, 413–426
  van Arkel triangle diagram of, 397–398
bonding molecular orbital A molecular orbital in which the energy of the electrons is lower than that of the parent orbital electrons, 427
  filling in transition metals, 1025
boranes, 981
borate ion, structure of, *981*, 981
borax, 71, 369, 980, 981
boric acid, 369, 980
  in slime, *1097*
Born, Max, 291–292, 539
Born-Haber cycle, 539, 573

boron
abundance of, 980
atomic weight of, 63
chemistry of, 978, 981
coordinate covalent bonds to, 369
similarity to silicon, 978
boron carbide, *318*
in fireworks, 981
boron hydrides, 981, *981*
boron tetrafluoride ion, formal charges in, 382
boron trifluoride
molecular polarity of, 385
orbital hybridization in, 419
reaction with ammonia, 369
structure of, 382
borosilicate glass, 981
Bosch, Carl, 695
boundary surface, atomic orbital, 296
Boyle, Robert, 453, 459
Boyle's law, 453
kinetic-molecular theory and, 471
brain, PET scans of, *1176*
Brand, Hennig, 990
brass, bacteriocidal activity of, 339, 1052
breathing apparatus, closed-circuit, *970*
brine, electrolysis of, 970
British thermal unit (Btu), A-8t
bromine
abundance of, 1000
atomic weight of, 64
oxides of, 97
physical states of, *6*
production of, 1001
reaction with aluminum, 982
reaction with nitrogen monoxide, 643
bromobenzene, mass spectrum of, *100*
2-bromooctane, reaction with iodine, 645
bromphenol blue, *763*
Brønsted, Johannes N., 139
Brønsted acid(s) A proton donor, 709
Brønsted base(s) A proton acceptor, 709
Brønsted–Lowry acid(s) A proton donor, 141
Brønsted–Lowry base(s) A proton acceptor, 141
bronze, 72
bubble gum, rubber in, 1099
buckminsterfullerene ("buckyball"), 72, 844
buffer region, in titration of weak acid, 774
buffer solution(s) A solution that resists a change in pH when hydroxide or hydronium ions are added, 763–771
biological, 800
capacity of, 768
common, 764t
constant pH of, 770
equations for, 766
preparation of, 768–769
buret, *40*, *198*
1,3-butadiene
in styrene-butadiene copolymer, 1099
structure of, 1076
butane
conversion to isobutane, 678, 690
structural isomers of, 1070
butanone, 1089
1-butene, structure of, 1066, 1074
2-butene
cis and *trans* isomers of, 1067, 1074
iodine-catalyzed isomerization, 639
butter yellow dye, 439
butyl butanoate, 1093t
butyric acid, 1091, 1091t

cadaverine, 1087, *1087*
cadmium
in nickel-cadmium battery, 874
in nuclear reactor, 1171
cadmium sulfide, as pigment, 1022
caffeine
extraction with supercritical carbon dioxide, 514
structure of, *718*
calcite, ions in, *78*
calcium
abundance of, 973
chemistry of, 973–976
reaction with water, *974*
calcium carbonate
aquatic organisms and, 947
decomposition of, 255, 256, 258
temperature and spontaneity, 836
equilibrium with carbon dioxide in solution, 671
in iron production, 1027
in limestone, 128, 973
precipitation from hard water, 950
reaction with hydrochloric acid, 148, 196
solubility of, 782
uses of, 975
calcium fluoride, 1000, 1003
in fluorite, 973, 975
solubility of, 784
calcium hypochlorite, 1005
calcium orthosilicate, 986
calcium oxide, 147
uses of, 975
calcium phosphate, 997
calcium silicate, in blast furnace, 1028
calcium sulfate, in gypsum, 85, 973
calculation, significant figures in, 40
calculator
logarithms on, A-2
pH and, 194
scientific notation on, 41
calibration plot, for spectrophotometric analysis, 206
calomel electrode, 888
caloric fluid, 233
calorie (cal) The quantity of energy required to raise the temperature of 1.00 g of pure liquid water from 14.5 °C to 15.5 °C, 33, A-8t
calorimetry The experimental determination of the enthalpy changes of reactions, 247–251
camphor, boiling point elevation and freezing point depression constants for, 580t
candela (cd), A-10
capacity, of buffer solution, 768
capillary action, 514, *515*
carbohydrate(s) An aldehyde or ketone containing multiple hydroxyl groups; sugar(s), 1124–1127
biological oxidation of, 843
energy content of, 34
carbon
abundance of, 983
allotropes of, 71, *71*, 545, 844
as reducing agent, 154t
atomic mass unit relative to, 60
binding energy per nucleon, 1160
electron configuration of, 318
in compartments of global carbon cycle, *924*
Lewis structures involving, 362
nanotubes, 545, 554, *554*
organic compounds of, 1064–1106
phase diagram of, 844
radioactive isotopes of, 1184
removed from pig iron, 1028
trivalent, 696
carbon cycle, 924, *924*
carbon dioxide
acidification of sea water by, 945–947
as greenhouse gas, 944
as Lewis acid, 745
bond order in, 390
bonding in, 355
density of, 462
dissolved in Lake Nyos, 596
enthalpy of formation, 251
Henry's law constant, 574t
in atmosphere, 923–924, *924*
in biofuel production, 941
in oceans, 19
in photosynthesis, 920
Lewis electron dot structure of, 357
molecular geometry of, 378
molecular polarity of, 384
phase diagram of, 552
production of cement and, 977
reaction with water, 146
resonance structures, 382
sequestration of, 159
sublimation of, 237
supercritical, 513–514, 553
carbon monoxide
as ligand, 1036
bond order in, 390
calculating enthalpy of formation, 251
in water gas, 967
molecular orbital configuration of, 434

oxidation of, 177
reaction with hemoglobin, 1033
reaction with iron(III) oxide, 149
reaction with methanol, 1090
reaction with nitrogen dioxide, 619, 632, 648
carbon steel, 1028
carbon tetrachloride, Lewis structure of, 361
carbonate ion, 80
as polyprotic base, 735
bond order in, 391
molecular geometry, 378
resonance structures of, 366
carbonates, solubility in strong acids, 791
carbonation, pressure and, 574, 575
carbonic acid, 146
as polyprotic acid, 711t
in biological buffer system, 800
in ocean, 945
carbonyl, naming carbon monoxide as ligand, 1036
carbonyl group The functional group that characterizes aldehydes and ketones, consisting of a carbon atom doubly bonded to an oxygen atom, 1087–1095
carboxylate ion, resonance in, 740
carboxylic acid(s) Any of a class of organic compounds characterized by the presence of a carbonyl group, in which the carbon atom is bonded to another carbon atom and to a hydroxyl group, 1088, 1090
acid strengths of, 740
naming of, A-17
reaction with amine, 1094
β-carotene, 589, 1076
Carothers, Wallace, 1101
cast iron, 1027
catalase, *615*
catalyst(s) A substance that increases the rate of a reaction while not being consumed in the reaction, 615, 1078
effect on reaction rates, 638–641
homogeneous and heterogeneous, 639
in Haber-Bosch process, 695
in petroleum refining, 938
in rate equation, 617
zeolites as, 987
catalytic converter, 943
catalytic steam reformation, hydrogen production by, 979
cathode The electrode of an electrochemical cell at which reduction occurs, 866
in corrosion, 899
in electrolysis cell, 892
cathode rays, 68
cation(s) An ion with a positive electrical charge, 78
acid–base properties of, 720
as Brønsted acids and bases, 710
naming, 83
noble gas electron configuration in, 325, 337
sizes of, 335
cell(s)
electrochemical, 866–868
galvanic, 866
unit, 528
voltaic, 866–868
cell division, DNA replication and, 1130, *1130*
cell membrane, lipids in, 1135
cell potential, 877–884
cellulose, 1126, *1127*
Celsius temperature scale A scale defined by the freezing and boiling points of pure water, defined as 0 °C and 100 °C, 30
cement, green chemistry of, 977
centrifuge, isotope separation by, 1171
cerium(IV) oxide, 1054
cesium
abundance of, 968
melting point of, *71*
cesium chloride, crystal structure of, 534
CFC. *See* chlorofluorocarbons.
Chadwick, James, 69, 1166
chain reaction
free-radical, 651
nuclear, 1170
polymerase, 1141
chair form, 1074
chalcocite, 1028
chalcogens, 72
chalcopyrite, 1028
reaction with copper(II) chloride, 1028
characteristic The part of a logarithm to the left of the decimal point, A-3
charcoal, in gunpowder, 258
charge
balancing in chemical equation, 138
balancing in ionic compounds, 81
in Coulomb's law, 85
charge density, 498
charge distribution
in covalent compounds, 363
in molecules, 381
Charles, Jacques Alexandre César, 455, 459, 966
Charles's law, 456
kinetic-molecular theory and, 471
chelating ligand A ligand that forms more than one coordinate covalent bond with the central metal ion in a complex, 1031
chemical analysis The determination of the amounts or identities of the components of a mixture, 93, 183–188
chemical bonds. *See* **bond(s)**, bonding.
chemical change(s) A change that involves the transformation of one or more substances into one or more different substances,15–17. *See also* **reaction(s)**.
chemical compound(s). *See* **compound(s)**.
chemical energy The energy stored in chemical compounds, 17, 230
chemical equation(s) A written representation of a chemical reaction, showing the reactants and products, their physical states, and the direction in which the reaction proceeds, 15, 123–125
balancing, 125–128, 860–863
manipulating, equilibrium constant and, 687
chemical equilibrium, factors affecting, 690–696
chemical kinetics The study of the rates of chemical reactions under various conditions and of reaction mechanisms, 608–656
chemical property, 16
chemical reaction(s). *See* **reaction(s)**.
chemical vapor deposition (CVD), 844
chemistry, green. *See* green chemistry.
methods of, 3–5
organic, 1064–1106
Chernobyl, 1171
china clay, 986
chiral compound A molecule that is not superimposable on its mirror image, 1039, 1067. *See also* **enantiomers**.
α-amino acids as, 1118
center of chirality of, 1071
optical activity of, 1067
chlor-alkali industry, 970
chloramine, 949
chlorate ion, 83
formal charges in, 364
Lewis electron dot structure of, 358
chlorination, disinfection by, 949
chlorine
abundance of, 1000
as disinfectant, 949
coordinate covalent bonds to, 369
oxoacids of, 1004–1005
production by aqueous sodium chloride electrolysis, 896, 969, 1001
reaction with alkanes, 1073
reaction with methane, 651
reaction with nitrogen monoxide, 618
reaction with phosphorus, 123, *124*, 173
reaction with sodium, 2, 352
chlorine demand, 949
chlorine difluoride ion, molecular geometry of, 377
chlorine dioxide, 949
chlorite ion, 80t, 83, 1004t

  greenhouse gases and, 945
clinker, in cement production, 977
clock reaction, iodine, 614
close packing, in crystal lattice, 530
clown fish, 19
coagulation, of colloids, 593
coal
  as energy resource, 931
  capturing sulfur dioxide from, 934
  types of, 935t
coal tar, aromatic compounds from, 1079t
cobalt, colors of complexes of, 1050t
cobalt-60, use in cancer treatment, 1176
cobalt(II) chloride hexahydrate, 85, *494*
Cockcroft, J. D., 1166
codon A three-nucleotide sequence in mRNA that corresponds to a particular amino acid in protein synthesis, 1131
coefficient(s), stoichiometric, 125, 674, 687
coffee, decaffeination with supercritical carbon dioxide, 514
coffee-cup calorimeter, 247
cohesive force A force of attraction between molecules of a single substance, 515
coke
  in iron production, 1027
  in refining of silicon, 984
  production from coal, 935
colligative properties The properties of a solution that depend only on the number of solute particles per solvent molecule and not on the nature of the solute or solvent, 565, 577–591
  of solutions of ionic compounds, 589–591
collision theory A theory of reaction rates that assumes that molecules must collide in order to react, 631–637
colloid(s) A state of matter intermediate between a solution and a suspension, in which solute particles are large enough to scatter light but too small to settle out, 591–595
  types of, 593
color(s)
  of acid–base indicators, *780*, *782*
  of coordination compounds, 1048–1052
  of fireworks, 299–300
  of gemstones, 787, 1022
  of glass, 1022
  of transition metal compounds, 743, *743*, 1022
  pi bonding and, 439
  visible light, *278*, 1049
Colorado River, depletion of, 925
combined available chlorine, 949
combined gas law. *See* general gas law.
combustion analysis, determining empirical formula by, 185–188
combustion calorimeter, 250
combustion reaction The reaction of a compound with molecular oxygen to form products in which all elements are combined with oxygen, 126–128, *126*, 829
  of hydrocarbons, 934
  of organic compounds, 1083
  spontaneity of, 829
common ion effect The limiting of acid (or base) ionization caused by addition of its conjugate base (or conjugate acid), 761–763
  solubility and, 788–790
common logarithms, A-2
common names
  of binary compounds, 77
  of organic compounds, 1072, A-15
compact fluorescent bulb, europium in, *338*, 1054, *1054*
complementary strands, in DNA, 1129
completion, reaction going to, 677
complex(es), 743. *See also* **coordination complex(es)**; **coordination compound(s)**.
  solubility and, 789, 796–799
compound(s) Matter that is composed of two or more kinds of atoms chemically combined in definite proportions, 10
  binary, naming, 76
  coordination. *See* **coordination compound(s)**.
  covalent, 354
  determining formulas of, 93–99
  hydrated, 85, 494, 1030
  ionic, 77–86
  naming, 84
  molar mass of, 89
  molecular, 77
  odd-electron, 372
  organic, 1064–1106
  organic, stability of, 1069
  saturated, 1069
  specific heat capacity of, 232t
  standard molar enthalpy of formation of, 254
  volatile organic, 944
compressibility The change in volume with change in pressure, 453
concentration(s) The amount of solute dissolved in a given amount of solution, 188
  determination by cell potential, 887
  determination by spectrophotometric analysis, 206
  effect on equilibrium of changing, 690
  graph of, determining reaction rate from, 610
  in collision theory, 631–632
  in equilibrium constant expressions, 673
  known, preparation of, 191
  measurement by osmotic pressure, 585
  of ions in solution, 190
  partial pressures as, 675
  rate of change, 608–656
  reaction rate and, 616–621
  relation to absorbance, 205
  units of, 565
concrete, 977
condensation The state change from gas to liquid, 507
  intermolecular forces and, 495
condensation polymer(s) A synthetic organic polymer formed by combining monomer units in such a way that a small molecule, usually water, is eliminated, 1096, 1099–1102
  silicone, 988
condensation reaction(s) A reaction in which parts of the reactant molecules bond together and a small molecule, usually water, is eliminated, 1099
  of amino acids, 1118
  of disaccharides, 1125

condensed formula A variation of a molecular formula that shows groups of atoms, 75, 1067
condition(s), standard. *See* **standard state**.
conduction band, 542
conductivity
electrical, of solutions, 132
conductor(s), band theory of, 540
conjugate acid–base pair(s) A pair of compounds or ions that differ by the presence of one hydrogen ion, 712
in buffer solutions, 764
ionization constants of, 720
strengths of, 716
conservation law
energy, 18–19, 230
mass, 4
matter, 125
constant composition, law of, 11
constant(s)
acid and base ionization, 716, 717t, A-20, A-22
boiling point elevation, 580
Boltzmann, 820
equilibrium, 672–679
relation to rate equation, 649–651
Faraday, 885, 898
formation, 796, A-24
freezing point depression, 583
gas, 460, 585, 635
Henry's law, 574t
physical, A-13t
Planck's, 280
rate, 616, 617
Rydberg, 284
significant figures in, 39
solubility product, 783, A-23
van der Waals, 476t
water ionization, 712
continuous spectrum The spectrum of white light emitted by a heated object, consisting of light of all wavelengths, *278*, *280*, 284
conversion factor(s) A multiplier that relates the desired unit to the starting unit, 32, 43, A-9
energy units, A-8t
in mass/mole problems, 88
in pressure problems, 452–453
pressure units, A-7t
SI units, 30
coordinate covalent bond(s) Interatomic attraction resulting from the sharing of a lone pair of electrons from one atom with another atom, 369, 742, 1031
coordination complex(es) An ion in which a metal ion or atom is bonded to one or more molecules or anions to compose a structural unit, 743, 1031
equilibria of, 796–800
formation constants of, 796, A-24
coordination compound(s) A compound containing a coordination complex, 1031
bonding in, 1043–1048
colors of, 1048–1052
formulas of, 1033–1035
magnetic properties of, 1045
naming of, 1035–1037
spectrochemical series of, 1050–1052
structures of, 1037–1042
coordination geometry The arrangement in space of the central metal atom or ion in a coordination compound and the ligands attached to it, 1031
coordination isomers Two or more complexes in which a coordinated ligand and a noncoordinated counterion are exchanged, 1038
coordination number The number of ligands attached to the central metal atom or ion in a coordination compound, 1031
molecular geometry and, 1037
Copernicus, Nicolaus, 10
copolymer A polymer formed by combining two or more different monomers, 1099
copper
antimicrobial properties, 1052–1053
biochemistry of, 339
electrolytic refining, 1029
ores of, *1026*
oxidation by sea water, 902
production of, 1028
reaction with nitric acid, 993
reaction with silver ions, 150
copper(I) chloride
disproportionation of, 1028
in fireworks, 300
copper(II) carbonate, *783*
copper(II) chloride
dissociation of, 189
reaction with chalcopyrite, 1029
copper(II) ion
complexes of, 743, *743*
successive equilibria with ammonia, 796
copper(II) sulfate pentahydrate, 99
coral, calcium carbonate in, *140*
core electrons The electrons in an atom's completed set of shells, 317, 322, 353
molecular orbitals containing, 430
corn, ethanol production from, 259
corrosion The deterioration of metals by oxidation–reduction reactions, 899
of aluminum, 978
corundum, 982
cosmic radiation, 1174
coulomb (C) The quantity of charge that passes a point in an electric circuit when a current of 1 ampere flows for 1 second, 876–877, 898, A-7, A-11
Coulomb's law The force of attraction between the oppositely charged ions of an ionic compound is directly proportional to their charges and inversely proportional to the square of the distance between them, 85
Bohr equation and, 284
ion–dipole attractions and, 493
ion pair attraction energy and, 537
counterion(s) An ion in a coordination compound that is not part of the coordination complex, but is present for charge balance, 1034
in coordination isomers, 1038
covalent bond(s) An interatomic attraction resulting from the sharing of electrons between the atoms, 352, 397
polar and nonpolar, 379–383
valence bond theory of, 413–426
covalent compound(s) A compound formed by atoms that are covalently bonded to each other, 354
covalent radius, 329
covellite, 1028
cracking, in petroleum refining, 938
Crick, Francis, 396, 500, 1129
critical point The upper end of the curve of vapor pressure versus temperature, 513
critical pressure The pressure at the critical point, 513
critical temperature The temperature at the critical point; above this temperature the vapor cannot be liquefied at any pressure, 513
crocoite, *783*
Crookes, William, 68
cross-linked polyethylene (CLPE), 1097
cross-linking, in vulcanized rubber, 1099
cryolite, 975
in fireworks, 300
in Hall- Héroult process, 979, *980*, 1003
crystal lattice A solid, regular array of positive and negative ions, 85, 527–529
crystallization
colloids and, 592
heat of, 569
temperature change and, 578
cubic centimeter (cm^3), 33
cubic close-packed (ccp) unit cell, 533
cubic decimeter (dm^3), 33
cubic meter (m^3), 33
cubic unit cell A unit cell having eight identical points at the corners of a cube, 529
lead(II) sulfide, *790*
curie A unit of radioactivity, 1172
Curie, Marie and Pierre, 68, 72, 999, 1152
curium, 10, 66, 72
current, electric, unit of, 898
Cusumano, James, 5

cyanate ion, resonance structures, 382
cyanide ion, reaction with water, 143
cyanobacteria, *919*, 920, *921*
cyanuric acid, hydrogen bonding with melamine, 516
cycloalkanes, 1073
  general formula of, 1069t
  naming of, A-16
cyclobutane, structure of, 1073
cyclohexane, structure of, 1074
cyclohexene, structure of, 1076
cyclopentane, structure of, 1066
cyclopropane
  conversion to propene, 623
  structure of, 1073
cysteine
  molecular geometry of, 379
  structure of, *1119*
cytosine, 395
  hydrogen bonding to guanine, 500, 1129
  in DNA and RNA, 1128, *1128*
  structure of, 350

d orbital(s). *See also* **atomic orbital(s)**.
  hybrid orbitals and, 437
  in coordination compounds, 1043–1044
Dacron, 1100
Dalton, John, 60, 68, 465
Dalton's law of partial pressures The total pressure of a mixture of gases is the sum of the pressures of the components of the mixture, 465
data, graphing of, 44–45
dating
  isochron, 1180
  radiocarbon, 1164–1165
Davisson, C. J., 290
Davy, Humphry, 895, 902, 969
d-block elements, properties of, 1021
de Broglie, Louis Victor, 290
Debye, Peter, 384
debye unit, 384
decay constant, for radioactivity, 1163
decay series, radioactive, 1151–1153
deciliter (dL), 33
decimal point, in conversion between fixed and exponential notation, 38
decomposition, determining molecular formula by, 97
decomposition reaction(s) A reaction in which a compound is broken down into smaller constituents, 156
defined quantity, significant figures in, 39
definite proportions, law of, 11
delocalization, molecular orbital, 541
delta (δ), symbol for partial charge, 379
density The ratio of the mass of an object to its volume, 12
  balloons and, *461*
  of air, 462
  of gas, calculation from ideal gas law, 461
  of sulfuric acid in lead storage battery, 873
  of transition elements, 1025
  unit cell dimensions and, 536
  units of, 12
dental amalgam, 883
deoxyribonucleic acid, 1127
  amplification by polymerase chain reaction, 1141
  hydrogen bonding in, 500
  molecular geometry of, 395
  synthetic, 1130
deoxyribose, 1124, 1125, *1128*
2-deoxyribose, structure of, 350, 395
derived units, SI, A-11
desalination, by reverse osmosis, 585, 928
detergents, 594
  phosphates in, 928
deuterium, 62, 965
  binding energy of, 1158
  fusion of, 1172
  preparation of, 965
diagonal relationship, in periodic table, 978
diamagnetism The physical property of being repelled by a magnetic field, 325, 1046
diamond
  as insulator, 542
  interatomic distances in, *31*
  structure of, 71, *71*
  synthesis of, 545, 844
diatomic molecule(s)
  atomic radii in, 329
  heteronuclear, 434
  homonuclear, 430
  of elements, *72*
diberyllium cation, 430
diborane, 981
  hybridization in, 437
dibromine pentaoxide, 98
1,2-dichlorobenzene, 1080
dichlorodifluoromethane, 922
1,2-dichloroethylene
  isomers of, 424
  molecular polarity of, 388
dichlorotetrafluoroethane, 922
dichromate ion
  as oxidizing agent, 154t
  reaction with ethanol, 155
diene(s) A hydrocarbon containing two double bonds, 1076
  naming of, A-16
dietary Calorie, 33
diethyl ether, 1084
  vapor pressure curves for, *511*
diethyl ketone, 1089t
diffraction
  of electrons, 290
  of x-rays by crystals, 531
diffusion The gradual mixing of the molecules of two or more substances by random molecular motion, 471
  through cell membrane, 1136
dihelium, molecular orbital energy level diagram of, 429
dihydrogen phosphate ion
  amphiprotic nature of, 711
  buffer solution of, 764t
L-3,4-dihydroxyphenylalanine (L-DOPA), 1103
diiodocyclohexane, dissociation of, 682
dilithium, molecular orbital energy level diagram of, 430
dilution
  buffer pH and, 770
  isotope, 1176
  preparation of solutions by, 191
  serial, 193
dimensional analysis A general problem solving approach that uses the dimensions or units of each value to guide you through calculations, 32, 43
dimethyl ether, structure of, 75, 498, 1066
dimethyl phthalate (DMT), in recycling PET plastic, 1101
dimethyl sulfide, 999
1,3-dimethylbenzene, 1080
dimethylbutane, structural isomers of, 1071
dimethylglyoximate ion, *796*
dimethylglyoxime, as ligand (dmg), 1030, 1037
2,2-dimethylpropane, structure of, 1070
1,4-dinitrobenzene, 1080
dinitrogen
  bonding in, 355
  photoelectron spectrum of, 438
dinitrogen monoxide, 920, 992
  as greenhouse gas, 944
dinitrogen pentaoxide, 991
  decomposition of, 610
  rate equation, 616, 631
dinitrogen tetraoxide, 992
  decomposition of, 692
dinitrogen trioxide, 991
dioxovanadium(V) ion, reaction with zinc, 861
dioxygen. *See* oxygen.
dipolar bond. *See* **polar covalent bond**.
dipole(s), induced, 501
dipole moment (μ) The product of the magnitude of the partial charges in a molecule and the distance by which they are separated, 384, 385t
dipole–dipole attraction The electrostatic force between two neutral molecules that have permanent dipole moments, 495

dipole–induced dipole attraction The electrostatic force between two neutral molecules, one having a permanent dipole and the other having an induced dipole, 501
diprotic acid, 142
disaccharides, 1125–1126
disinfection, of water, 927
Disinfection Byproducts Rule (DBR), 949
disintegrations per second (dps), 1172
dispersion(s), colloidal, 591
dispersion forces Intermolecular attractions involving induced dipoles, 502
disproportionation reaction, 1004
dissociation, of electrolytes in solution, 132
distillation
  in petroleum refining, 938
  Raoult's law and, 595
diving, pressure and solubility in, 565
DNA. *See* deoxyribonucleic acid.
dolomite, 973
domain, ferromagnetic, 327
donor level, in semiconductor, 544
dopamine, 1103
dopant, in semiconductor, 543
double bond A bond formed by sharing two pairs of electrons, one pair in a sigma bond and the other in a pi bond, 355
  in alkenes, 1074
  melting point of triglycerides and, 1135
  rotation around, 638, 1067
  valence bond theory of, 421
double displacement reaction(s). *See* **exchange reaction(s)**.
double helix, in DNA structure, 1129
Downs cell, for producing sodium, 969, *969*
dry cell battery, 872
dry ice, 240, 553
d-to-*d* transition, 1050
dye(s)
  green chemistry of, 439
  pH indicating, 195
  rate of reaction with bleach, *610*, 612
dynamic equilibrium
  in solution process, 568
  molecular description of, 130
  vapor pressure and, 510
dynamite, *1084*

earth, alchemical meaning of, 973
effective nuclear charge (Z^*) The nuclear charge experienced by an electron in a multielectron atom, as modified by the other electrons, 314, 315t, 322
  atomic radius and, 329
effusion The movement of gas molecules through a membrane or other porous barrier by random molecular motion, 472
Ehrlich, Paul, 103
Eiffel Tower, 37
Einstein, Albert, 281, 1159
eka-silicon, 70
elastomer(s) A synthetic organic polymer with very high elasticity, 1099
electric current, unit of, 898
electric field, polar molecules aligned in, 384
electrical energy The energy due to the motion of electrons in a conductor, 17
electroactive substance, 894, 896
electrochemical cell(s) A device that produces an electric current as a result of an electron transfer reaction, 866–871
  commercial, 871–876
  corrosion and, 899
  nonstandard conditions for, 885–888
  notation for, 870
  potential of, 876–884
  work done by, 889
electrochemistry, 859
electrode(s) A device such as a metal plate or wire for conducting electrons into and out of solutions in electrochemical cells, 132, 866
  hydrogen, 869
  inert, 869
  pH, *194*, 195
  standard hydrogen, 878
  terminology for, 892
electrolysis The use of electrical energy to produce chemical change, 866, 892–897
  aluminum production by, 979, 980
  electrodes in, 893
  fluorine production by, 1000
  hydrogen produced by, 965, 966
  of aqueous solutions, 894
  of magnesium chloride, 974
  of sodium chloride, 464, 893, *971*
  of water, 9
  oxygen production by, 998
electrolyte(s) A substance that dissociates or ionizes in water to form an electrically conducting solution, 132–133
electromagnetic radiation Radiation that consists of wave-like electric and magnetic fields, including light, microwaves, radio signals, and x-rays, 277
  gamma rays as, 1150
electromotive force (emf), 876
electron(s) (e^-) A negatively charged subatomic particle found in the space about the nucleus, 59
  as beta particle, 1150
  as cathode rays, 68
  assignment to atomic orbitals, 313–315
  balancing in half-reaction method, 860
  bond pair, 354
  charge of, measurement of, 69, A-13t
  charge-to-mass ratio of, 68
  configuration. *See* electron configuration(s). core, 316, 353
  core, molecular orbitals containing, 430
  counting, 897–898
  delocalization of, 352. *See also* **molecular orbital theory**.
  diffraction of, 290
  in electrochemical cell, direction of flow, 878
  in photoelectric effect, 281
  in voltaic cell, direction of flow, 866
  lone pair, 354. *See also* **lone pair(s)**
  mass of, A-13t
  nuclear charge experienced by, 314
  octet of, 354
  quantization of potential energy, 284, 291
  sharing in Lewis acid–base reactions, 742
  shells and subshells, 293, 312t
  spin. *See* electron spin.
  transfer in oxidation–reduction reactions, 150
  valence, 317, 353. *See also* **bond pair(s)**, **lone pair(s)**.
    of main group elements, 961
    repulsions of, 373. *See also* **valence shell electron-pair repulsion (VSEPR) model**.
  wave properties of, 290
  wavelength of, 290
electron affinity The negative of the internal energy change occurring when an atom of the element in the gas phase gains an electron, 332
electron attachment enthalpy ($\Delta_{EA}H$) The enthalpy change occurring when an atom of the element in the gas phase gains an electron, 332
  acid strength and, 738
  values of, A-18
electron capture A nuclear process in which an inner-shell electron is captured, 1154
  predicting, 1157
electron cloud pictures, 295
electron configuration(s)
  in coordination compounds, 1045
  Lewis notation for, 353
  main group, 317–319
  noble gas notation for, 317
  of elements, 316t
  of heteronuclear diatomic molecules, 434
  of homonuclear diatomic molecules, 432
  of ions, 324–327
  of transition element ions, 325
  of transition elements, 321, 324, 1023, 1023t
  orbital box notation for, 311
  spdf notation for, 317

  isotopes of, 62–63
  line emission spectra of, 284
  main group, 66, *66*
    chemistry of, 958–1008
  molar mass of, 87, *88*
  monatomic ions of, charges on, 78–80
  monatomic ions of, sizes of, 335
  names of, 9, 11
  oxidation number of zero, 151
  p-block, 318
    molecular orbitals involving, 431
  periodic table of, 66–74
  s-block, 318
  sources of, *1026*
  specific heat capacity of, 232t
  standard enthalpy of formation of, 255
  standard enthalpy of vaporization of, 508t
  standard molar free energy of formation of, 833
  symbol for, 61
  synthesis of, 1168
  transition, *58*, 6673. *See also* transition elements.
  transuranium, 1166, 1167
elementary step A simple event in which some chemical transformation occurs; one of a sequence of events that form the reaction mechanism, 643
  rate equation for, 644
elephants, frontalin in, 1068
eluent, 516
emission spectrum, excited states and, *287*
  of elements, 283
empirical formula A chemical formula showing the simplest possible ratio of atoms in a compound, 94–97
  determination by combustion analysis, 185–188
  relation to molecular formula, 95
emulsifying agent, 594
emulsion A colloidal dispersion of one liquid in another, 592t, 594
enantiomers A stereoisomeric pair consisting of a chiral compound and its mirror image isomer, 1039, 1067
  of α-amino acids, 1118
end point. *See* **equivalence point**.
endocytosis, 1136
endothermic process A thermodynamic process in which heat flows into a system from its surroundings, 231, 816
  enthalpy change of, 243
  equilibrium constant of, 693
  in metabolism, 1138
energy The capacity to do work and transfer heat, 229–231
  activation. *See* **activation energy**.
  alternative sources of, 937–942
  binding, 1158–1160
  chemical, 230
  color of photons and, 282
  conversion of forms of, 18
  density, in batteries vs. gasoline, 875t
  direction of transfer, 230
  dispersal of, 817–820
  distribution in liquid, *508*
  effect on equilibrium, 576
  exchange, electron configuration and, 318, 324
  from combustion of hydrocarbons, 934
  global usage, 933
  in food, 34, 1137
  internal, 241
  ionization. *See* **ionization energy**.
  kinetic, distribution in gas, 468, 633
  of alpha and beta particles, 1150
  lattice, 537–540
  law of conservation of, 18, 230
  levels in hydrogen atom, 285, 287
  mass equivalence of, 1159
  nuclear, 1170
  quantization of, 284, 291, 818
  relation to frequency of radiation, 280
  sources for human activity, 229
  state changes and, 236–239
  supply and demand, 930–931
  thermal, 229
  units of, 33–34, A-7
energy level diagram, 252–253
  Born-Haber cycle, 539
  dissolution of ionic solid, 571
enthalpy (H) The sum of the internal energy of the system and the product of its pressure and volume, 242–243
  bond dissociation, 391–392
  effect on acid strength, 741
  entropy and, in spontaneous reaction, 828t
  in Gibbs free energy, 830
enthalpy change (ΔH) Energy transferred as heat at constant pressure, 243, 816
  as state function, 244
  calculations with, 251–257
  for chemical reactions, 245–247
  measurement of, 247
  sign conventions for, 243
enthalpy of formation
  standard molar, 254, A-25
enthalpy of fusion ($\Delta_{fus}H$) The energy required to convert one mole of a substance from a solid to a liquid at constant temperature, 549, 550t, A-14t
enthalpy of hydration, 493
enthalpy of solution ($\Delta_{soln}H$) The amount of heat involved in the process of solution formation, 570–574
  calculation of, 573
enthalpy of solvation, 493
enthalpy of sublimation ($\Delta_{sublimation}H$) The energy required to convert one mole of a substance from a solid to a vapor, 551
enthalpy of vaporization ($\Delta_{vap}H$) The quantity of heat required to convert 1 mol of a liquid to a gas at constant temperature, 507, 508t, A-14t
  intermolecular forces and, 495, 496t
  of nonpolar substances, 502t, 508t
  relation to vapor pressure, 512
entropy (S) A measure of the dispersal of energy in a system, 817
  effect on acid strength, 741
  in Gibbs free energy, 830
  molecular structure and, 822
  physical state and, 823
  second law of thermodynamics and, 825
  solution process and, 570, *571*
  standard molar, 822
  statistical basis of, 819
entropy change (ΔS)
  for universe, system, and surroundings, 825
  of reaction, 824
environment, chemistry of, 916–950. *See also* green chemistry.

enzyme(s) A biological catalyst, 641, 1122
catalysis by, 652
epichlorohydrin, structure of, 1105
epinephrine, 1103
epoxy resins, 1105
equation(s)
Arrhenius, 635
Balmer, 284
Beer-Lambert law, 205
Bohr, 284
boiling point elevation, 580
Boltzmann, 820
bond order, 389, 429
Boyle's law, 454
buffer solution pH, 766
Celsius-Kelvin scale conversion, 30
Charles's law, 456
chemical, 15, 123–125
Clausius–Clapeyron, 512
Coulomb's law, 85
Dalton's law, 465
de Broglie, 290
density, 461
dilution, 191
Einstein's, 1159
electronegativity, 398
enthalpy of formation, 255
entropy, 817
entropy change of reaction, 824
equilibrium constant expression, 674
equilibrium constant of electrochemical cell, 890
first law of thermodynamics, 241
formal charge, 363
free energy change at nonequilibrium conditions, 832
freezing point depression, 583
general gas law, 457
Gibbs free energy, 830
Graham's law, 472
half-life, 626
half-life, for radioactive decay, 1163
heat and temperature change, 232
Henderson-Hasselbalch, 767
Henry's law, 574
Hess's law, 255
ideal gas law, 460
integrated rate, 622–630
ion pair attraction energy, 537
ionization constants, for acids and bases, 716
ionization constants, for water, 712
K_a and K_b, 720
kinetic energy, 468–470
molality, 565
molarity, 188
mole fraction, 466, 566
Nernst, 885
net ionic, 137
of oxidation–reduction reactions, 861
of strong acid–strong base reactions, 144
nuclear reactions, 1150
osmotic pressure, 585
percent abundance of isotope, 62
pH, 194, 714
in titration of weak acid, 775
of buffer solution, 766
pK_a, 719
Planck's, 279
pressure–volume work, 242
quadratic, 684, A-4
Raoult's law, 577
rate, 610, 616. *See also* **rate equation(s).**
rms speed, 469
Schrödinger, 292
second law of thermodynamics, 825
solubility product, 783
speed of a wave, 278
standard free energy change of reaction, 832
standard molar free energy of formation, 833
standard potential, 879
straight line, 44
van der Waals, 475
equatorial position
in cyclohexane structure, 1074
in trigonal bipyramidal molecular geometry, 377
equilibrium A condition in which the forward and reverse reaction rates in a physical or chemical system are equal, 128–130
chemical, 670–696. *See also* chemical equilibrium.
dynamic, 130, 510
factors affecting, 690–696
in osmosis, 584
in reaction mechanism, 649–651
Le Chatelier's principle and, 576, 690–696
reversibility and, 818
solution process as, 568
successive, 796
thermal, 230
equilibrium constant (*K*) The constant in the equilibrium constant expression, 650, 672–689
calculating from initial concentrations and pH, 727
calculating from standard potential, 890
calculations with, 682–686
concentration vs. partial pressure, 675
determining, 680–681
for product-favored vs. reactant-favored reactions, 130, 677
for weak acid and base (K_a and K_b), 715–720
Gibbs free energy change and, 832
relation to reaction quotient, 677
relation to standard free energy of change of reaction, 838
simplifying assumption in, 685, 728, A-5
unitless, 675
equilibrium constant expression A mathematical expression that relates the concentrations of the reactants and products at equilibrium at a particular temperature to a numerical constant, 674
for gases, 676, 682
reverse reaction, 687
stoichiometric multipliers and, 687
equilibrium vapor pressure The pressure of the vapor of a substance at equilibrium in contact with its liquid or solid phase in a sealed container, 510
in phase diagram, 551
equivalence point The point in a titration at which one reactant has been exactly consumed by addition of the other reactant, 199
of acid–base reaction, 772, 774, 777, 780
error The difference between the measured quantity and the accepted value, 35
ester(s) Any of a class of organic compounds characterized by the presence of a carbonyl group, in which the carbon atom is bonded to another carbon atom and to an oxygen atom that is attached to another organic group, 941, 1088, 1093
hydrolysis of, 1092
naming of, A-17
esterification reaction A reaction between a carboxylic acid and an alcohol in which a molecule of water and an ester is formed, 1091
ethane
enthalpy of combustion, 247
Henry's law constant, 574t
structure of, 1066
1,2-ethanediol, 1084
ethanol, 1083
as biofuel, 941
as fuel, 259
as nonelectrolyte, 132
hydrogen bonding in, 498
iodine solubility in, 502
mass spectrum of, *100*
miscibility with water, 569
oxidation to acetic acid, 1088
reaction with dichromate ion, 155
standard molar enthalpy of formation of, 255
structure of, 75, 1066
vapor pressure curves for, *511*
ethene. *See* ethylene.
ether(s) Any of a class of organic compounds characterized by the presence of an oxygen atom singly bonded to two carbon atoms, 1084
ethyl acetate, 1092

ethylene, 1074
derivatives of, as monomers, 1098t
orbital hybridization in, 421
production of, 938
reaction with water, 1083
structure of, 1066
ethylene glycol, 1083
as antifreeze, 567, 583, 1085
as nonelectrolyte, 132
reaction with terephthalic acid, 1100
specific heat capacity of, 232t
1,2-ethylenediamine
as ligand (en), 1031
reaction with succinic acid, 1102
ethylenediaminetetraacetate ion ($EDTA^{4-}$), as ligand, 1032
ethyne. *See* acetylene.
eugenol, 581
europium, *74*
in phosphors, 338
uses of, 1054
evaporation. *See also* **vaporization**.
entropy change for, 824
intermolecular forces and, 495
exact number, significant figures in, 39
exchange energy, Hund's rule and, 318, 324
exchange reaction(s) A chemical reaction that proceeds by the interchange of reactant cation–anion partners, 135
excited state The state of an atom in which at least one electron is not in the lowest possible energy level, 285
nuclear, 1151
exclusion principle. *See* **Pauli exclusion principle**.
exothermic process A thermodynamic process in which heat flows from a system to its surroundings, 231, 816
enthalpy change of, 245
equilibrium constant of, 693
in metabolism, 1138
in nuclear fission, 1170
expansion molding, polystyrene, 1098
exponent, 37
exponential notation, 37, A-2
extensive properties Physical properties that depend on the amount of matter present, 14
extrinsic semiconductor, 543

f orbital(s). *See* **atomic orbital(s)**.
face-centered cubic (fcc) unit cell, 529, 533
facilitated diffusion, through cell membrane, 1136
factor-label method. *See* **dimensional analysis**.
Fahrenheit temperature scale A scale defined by the freezing and boiling points of pure water, defined as 32 °F and 212 °F, *31*
family, in periodic table. *See* **group(s)**.
Faraday, Michael, 895, 1079
Faraday constant (*F*) The proportionality constant that relates standard free energy of reaction to standard potential; the charge carried by one mole of electrons, 885, 905, A-13t
fat(s)
as lipids, 1134
energy content of, 34
reaction with methanol, 942
unsaturated, *1077*
fatty acid(s), 1134
feldspar, 987
fermentation, anaerobic, 1083
Fermi, Enrico, 1167
Fermi level The highest filled electron energy level in a metal at absolute zero temperature, 541
ferrite, unit cell of, 1043
ferromagnetism The physical property of certain solids in which the spins of unpaired electrons in a cluster of atoms are aligned in the same direction, 327
of lanthanides, 338
fertilizer
ammonia in, 695
nitrogen cycle and, 919
fiber, dietary, 1126
filling order, of electron subshells in atoms, 313
filtration, 9, 927
fire extinguisher, carbon dioxide, *462*
fireworks
boron carbide in, 981
colors of, 299–300
potassium perchlorate in, 1005
first law of thermodynamics The total energy of the universe is constant; the internal energy change for a system is equal to the sum of the energy transferred as heat and the energy transferred as work between the system and the surroundings, 240–244, 816, 889, 940
first-order reaction, 618
half-life of, 626–628
integrated rate equation, 622
nuclear, 1161, 1163
fission The highly exothermic process by which very heavy nuclei split to form lighter nuclei, 1169, 1178
fixed notation, 37
flash photolysis, 653–654
Fleming, Alexander, 1123
flerovium, 1168
flex-fuel cars, 941
flotation, for ore treatment, 1028
fluid, 6
supercritical, 514, 553
fluid-mosaic model, of cell membrane, 1136
fluorescence, 1000
fluorine
abundance of, 1000
bonding in, 354
chemistry of, 1002–1004
compounds of, hydrogen bonding in, 497
electron configuration of, 319
oxidation number of, 152
production of, 1000
reaction with nitrogen dioxide, 647
reaction with xenon, 1006
sigma bond in, 414
fluorite, *319*, 657, 787, 792, 973, 975
ions in, *78*
fluoroapatite, 975
fluorosulfonic acid, 747
fluorspar, *319*, 1000, 1003
flux
borax as, 980
cryolite as, 979
fluorspar as, 1000
foam, 592t
food
energy content of, 34, 1137
irradiation, 1177–1178
proteins in, 516
tampering, titration for detecting, 208
fool's gold. *See* iron pyrite.
force(s), A-6
intermolecular. *See* **intermolecular forces**.
formal charge The charge on an atom in a molecule or ion calculated by assuming equal sharing of the bonding electrons, 363
bond polarity and, 381–383
relation to acid strength, 739
formaldehyde, 1089t
Lewis electron dot structure of, 357
orbital hybridization in, 422
released by synthetic adhesives, 1104
structure of, 1087
formation
standard molar enthalpy change of, 254–255
standard molar free energy of, 833
formation constant An equilibrium constant for the formation of a complex ion, 796, A-24
formic acid, 1091t
as weak acid, 718
in water, equilibrium constant expression for, 687
Lewis structure of, 363t
pH in aqueous solution, 730
reaction with sodium hydroxide, 726
formula(s)
chemical, 11
condensed, 1067
empirical, 95, 185
general, of hydrocarbons, 1069t

molecular, 1067. *See also* **molecular formula.**
of ionic compounds, 81–82
structures and, 534–537
perspective, 1067
predicting, 963–965
structural, 1067, 1072. *See also* **structural formula.**
formula mass, 91
formula unit The simplest ratio of ions in an ionic compound, similar to the molecular formula of a molecular compound, 91
fossil fuels, 921–937
environmental impact of, 942–947
fracking. *See* hydraulic fracturing.
fractional abundance of isotopes, 65
fractional distillation, 595–596
fragment ion, in mass spectra, *100*
francium, abundance of, 968
Franklin, Rosalind, 396, 500
Fraunhofer, Joseph von, 300
free available chlorine, 949
free energy. *See* **Gibbs free energy**.
free energy change (ΔG), 830
equilibrium constant and, 832
standard molar, 830, 834
free energy of formation, 833
free radical(s) A chemical species containing an unpaired electron, 372, 696
chlorine, 1073
in reaction mechanism, 651
freezing point depression, 581–583
for ionic solutions, 590t
freezing point depression constant (K_{fp}), 583
frequency (ν) The number of complete waves passing a point in a given amount of time, 278
relation to energy of radiation, 276
frequency factor, in Arrhenius equation, 635
Frisch, Otto, 1170
frontalin, 1068
fructose, 1125–1126
fuel
biological sources of, 941–942
density of, 48
environmental impact of, 942–947
ethanol as, 259
fossil, 934–937
hydrogen as, 939
methanol as, 179
propane as, 939
fuel cell A voltaic cell in which reactants are continuously added, 875–876, 938–939
fugu, 709
Fukushima, 1171
Fuller, R. Buckminster, 72
functional group A structural fragment found in all members of a class of compounds, 1082
fusion The state change from solid to liquid, 236
enthalpy of, 549, 550t, A-14t
heat of, 236
nuclear, 1172

galena, 790
gallium
abundance of, 978
melting point of, *71*
gallium arsenide, 544, 994
Galvani, Luigi, 866
galvanic cell(s), 866
gamma ray(s) High-energy electromagnetic radiation, 278, 1150
from matter-antimatter annihilation, 1175
gangue A mixture of sand and clay in which a desired mineral is usually found, 1026
gas(es) The phase of matter in which a substance has no definite shape and a volume defined only by the size of its container, 6
compressibility of, 453–454
density, calculation from ideal gas law, 461
diffusion of, 471, 821
dissolution in liquids, 574–575
expansion as spontaneous process, 816
greenhouse, 514, 943
ideal, 460
in atmosphere, 917t
in equilibrium constant expression, 676, 682
kinetic-molecular theory of, 468–471
laws governing, 453–459, 471
mixtures of, partial pressures in, 465–467
natural, 931
noble. *See* noble gas(es)
nonideal, 474–476
pressure of, 451
properties of, 450–478
solubility in water, 502t
speeds of molecules in, 468
standard molar volume, 460
volume effects on equilibria of, 692
gas chromatography, 516
gas constant (R) The proportionality constant in the ideal gas law, 0.082057 L · atm/mol · K or 8.314510 J/mol · K, 460, A-13t
in Arrhenius equation, 635
in equilibrium constant expression, 676
in kinetic energy–temperature relation, 469
in Nernst equation, 885
in nonequilibrium free energy change, 832
in osmotic pressure equation, 585
gas-forming reaction(s), 147–149, 156
gasification, coal, 935
gasoline
energy per kilogram, 934t
production of, 938
Gay-Lussac, Joseph, 458
GC-MS. *See* gas chromatograph *and* mass spectrometers
gecko, wall-climbing ability of, 505
Geiger, Hans, 69
Geiger-Müller counter, *1162*
Geim, Andre, 554
gel A colloidal dispersion with a structure that prevents it from flowing, 593
gemstones
colors of, 1022
solubility of, 787
general gas law An equation that allows calculation of pressure, temperature, and volume when a given amount of gas undergoes a change in conditions, 457
genetic code, 1131
geometric isomers Isomers in which the atoms of the molecule are arranged in different geometric relationships, 878, 899
of alkenes, 1038
Gerlach, Walther, 297
germanium, 70
abundance of, 983
as semiconductor, 542
compounds of, 983
Germer, L. H., 290
Gibbs, J. Willard, 830
Gibbs free energy (G) A thermodynamic state function relating enthalpy, temperature, and entropy, 830–833
cell potential and, 889
work and, 833
gigaton, 918
Gimli Glider, 47
glacial acetic acid, 747
glass
colors of, 1022
etching by hydrogen fluoride, 1003
structure of, 546
glass electrode, 888
glassware
laboratory, *13*, 33, *189*
laboratory, significant figures and, *40*
global warming, 943–945
glucose
combustion of, stoichiometry of, 175
metabolism of, 1139
oxidation in respiration, 1137
structure and isomers of, 1125–1126
glue, chemistry of, 1104
glutamic acid, structure of, *1119*
glutamine, structure of, *1119*
glycerol, 941, 942, 1083–1084

glycine
adhesive based on, 1104
Lewis structure of, 363t
structure of, *1119*
glycogen, 1126, *1127*
glycolysis, 843
glycosidic bond, 1125
goethite, 792
goiter, 1001
gold
density of, 14
extraction from ore, 799
reaction with aqua regia, 994
Gomberg, Moses, 696
Goodyear, Charles, 1098
Goodyear blimp, 477
Graham, Thomas, 472, 592
Graham's law, 472
gram (g), 33
graph(s), analysis of, 44
graphene, 554
graphite, structure of, 71, *71*, *546*
graphite electrode, 869
oxidation of, 896
gravitational energy The energy due to the attraction between masses, 18
gray The SI unit of radiation dosage, 1172
green chemistry, 947–948
atom economy and, 207–208
of adhesives, 1104
of dyes and pigments, 439
polylactic acid, 1101
principles of, 5, 948
greenhouse gases, 943–944
ground state The state of an atom in which all electrons are in the lowest possible energy levels, 285, 315
nuclear, 1151
group(s) The vertical columns in the periodic table of the elements, 66
ion charge related to, 78–80
similarities within, 960t
Group 1A elements, 67. *See also* **alkali metal(s)**.
chemistry of, 968–973
Group 2A elements, 67. *See also* **alkaline earth metal(s)**.
chemistry of, 973–976
Group 3A elements, 71
chemistry of, 976–983
Group 4A elements, 71
chemistry of, 983–988
Group 5A elements, 72
chemistry of, 989–997
Group 6A elements, 72
chemistry of, 997–1000
Group 7A elements, 73. *See also* **halogens**.
chemistry of, 1000–1005
Group 8A elements, 73. *See also* **noble gas(es)**.
chemistry of, 1005–1008
guanine, 395
hydrogen bonding to cytosine, 500, 1129
in DNA and RNA, 1128, *1128*
guidelines
assigning oxidation numbers, 152
solubility of ionic compounds in water, *134*
Gummi Bear, *247*
guncotton, 258
gunpowder, 973
combustion of, 258
gypsum, 85, 973
ions in, *78*

Haber, Fritz, 539, 695
Haber-Bosch process, 695
Hahn, Otto, 1169
half-cell A compartment of an electrochemical cell in which a half-reaction occurs, 866
half-life ($t_{1/2}$) The time required for the concentration of one of the reactants to reach half of its initial value, 626
for radioactive decay, 1161
half-reaction method A systematic procedure for balancing oxidation–reduction reactions, 860
half-reactions The two chemical equations into which the equation for an oxidation–reduction reaction can be divided, one representing the oxidation process and the other the reduction process, 151, 860
sign of standard reduction potential for, 880
standard potentials for, 880
halide ions Ions of the elements of Group 7A, 83
halides, compounds with aluminum, 982
Hall, Charles Martin, 979
Hall-Héroult process, aluminum production by, 979
halogenation, of benzene, 1082
halogens The elements in Group 7A of the periodic table, 73
as oxidizing agents, 154t
chemistry of, 1000–1005
electron attachment enthalpies of, 334
electron configuration of, 319
oxidation number of, 152
ranked by oxidizing ability, 883
reaction with alkenes and alkynes, 1077
reaction with alkali metals, 970
halothane, 466
hard water, 950
detergents and, 595
heat
as form of energy, 230
as reactant or product, 692
entropy and, 817
from combustion of hydrocarbons, 934
sign conventions for, 232, 241t
temperature change and, 232
transfer, as spontaneous process, 816
calculations, 234
during phase change, 236
heat capacity, 231
heat of fusion The quantity of heat required to convert 1 g of a solid to a liquid at constant temperature, 236. *See also* **enthalpy of fusion**.
heat of solution. *See* **enthalpy of solution**.
heat of vaporization The quantity of heat required to convert 1 g of a liquid to a gas at constant temperature, 236. *See also* **enthalpy of vaporization**.
heat pack, supersaturated solution in, 569
heavy water, *62*, *965*
Heisenberg, Werner, 291, 292
Heisenberg's uncertainty principle It is impossible to determine both the position and the momentum of an electron in an atom simultaneously with great certainty, 292
Heliox, 597
helium
abundance of, 959
departure from ideal gas law, 475
discovery of, 73, 300, 959
electron configuration of, 317
Henry's law constant, 574t
in atmosphere, 919
in balloons, 966
in blimps, 477
nucleus as alpha particle, 1149
orbital box diagram, 312
hematite, 792, 1027
ions in, *78*
heme unit, 1033, 1121
hemoglobin, 339, 1033
carbonic anhydrase and, 653
iron in, 1022
structure of, 1121
Henderson-Hasselbalch equation, 767
Henry's law The concentration of a gas dissolved in a liquid at a given temperature is directly proportional to the partial pressure of the gas above the liquid, 574
heptane, separation from hexane, 596
Herculon, 1098t
Héroult, Paul, 969, 979
hertz The unit of frequency, or cycles per second; 1 Hz = 1 s^{-1}, 278
Hess's law If a reaction is the sum of two or more other reactions, the enthalpy change for the overall process is the sum of the enthalpy changes for the constituent reactions, 251–257
heterogeneous mixture A mixture in which the properties in one region or sample are different from those in another region or sample, 8

heteronuclear diatomic molecule(s) A molecule composed of two atoms of different elements, 434
hexachloroethane, in fireworks, 300
hexadentate ligands, 1032
hexagonal close-packed (hcp) unit cell, 533
hexamethylenediamine, 1101
hexane
  separation from heptane, 596
  structural isomers of, 1070
hexaphenylethane, 696
hexose, 1125
HFC. *See* hydrofluorocarbons.
high-density polyethylene (HDPE), 1096
high pressure liquid chromatograph (HPLC), *516*
high-spin configuration The electron configuration for a coordination complex with the maximum number of unpaired electrons, 1045
highest occupied molecular orbital (HOMO), 433t
Hindenburg, 966
Hippocrates, 1052
hippuric acid, formula of, 95
histidine, structure of, *1119*
hole(s)
  in crystal lattice, 534
  in metallic conduction, 541
  in semiconductors, 543
homogeneous catalyst A catalyst that is in the same phase as the reaction mixture, 639
homogeneous mixture A mixture in which the properties are the same throughout, regardless of the optical resolution used to examine it, 8
homonuclear diatomic molecule(s) A molecule composed of two identical atoms, 430
  electron configurations of, 432
hormones, 1134
Hund's rule The most stable arrangement of electrons in a subshell is that with the maximum number of unpaired electrons, all with the same spin direction, 318
  coordination complexes and, 1045
  molecular orbitals and, 427
hybrid, resonance, 366
hybrid orbital(s) An orbital formed by mixing two or more atomic orbitals, 416–422
  geometries of, *417*
  in benzene, 426
hydrated compound A compound in which molecules of water are associated with ions, 85
  formula unit of, 98
hydration
  enthalpy of, 493
  of ions, 572
hydraulic fracturing, 932
hydrazine, 77
  formula of, 94
  production by Raschig reaction, 648, 991
  reaction with water, 990
hydrides, 966
  boron, 981
  of Group 3A elements, 978
hydrocarbon(s) A compound that contains only carbon and hydrogen, 1069–1082
  catalytic steam reformation of, 967
  combustion analysis of, 185–188
  derivatives of, naming of, A-17
  immiscibility in water, 569
  Lewis structures of, 362
  naming of, 77, A-15
  strained, 1073
  types of, 1069t
hydrochloric acid, 1004. *See also* hydrogen chloride.
  reaction with ammonia, 734
  reaction with calcium carbonate, 148
  titration with sodium hydroxide, 772
hydrofluoric acid, production of, 975
hydrofluorocarbons (HFCs), 944
hydrogen
  as fuel, 876, 939
  as reducing agent, 154t
  binary compounds of, 76
  bonding in, 355
  bridging, 437
  chemistry of, 965–968
  compounds of, 497
    Lewis structures of, 360
    with nitrogen, 990
  electron configuration of, 317
  fusion of, 1172
  Henry's law constant, 574t
  in balloons, 966
  in fuel cell, 875–876, 939
  in oxoanions, 83
  ions formed by, 80
  isotopes of, 965
  line emission spectrum, *284*
    explanation of, 287–289
  molecular orbital energy level diagram, 428
  orbital box diagram, 312
  oxidation number of, 152
  potential energy during bond formation, 414
  preparation of, 967
  production by electrolysis, 940
  production by steam reforming, 940
  production by water–gas reaction, 940
  reaction with alkenes and alkynes, 1078
  reaction with iodine, 682
  reaction with iodine, mechanism of, 653
  reaction with nitrogen, 464
  reaction with oxygen, 15
  transportation of, 941
hydrogen bonding Attraction between a hydrogen atom that is bonded to a very electronegative atom, and another atom to produce an unusually strong dipole–dipole attraction, 497–501
  in biochemistry, 500
  in DNA, 395, 1129
  in polyamides, 1102
hydrogen carbonate ion, 146
hydrogen chloride
  as strong electrolyte, 132
  emitted by volcanoes, 209
  production of, 1004
  reaction with ammonia, 145, 468
  reaction with magnesium, 248
  reaction with 2-methylpropene, 1078
  reaction with sodium hydroxide, 144
hydrogen electrode, 869
  as pH meter, 888, *888*
  standard, 878
hydrogen fluoride
  electrostatic potential map of, 387
  production of, 1003
  reaction with silicon dioxide, 985, 1003
  sigma bond in, 414
hydrogen halides
  acid strengths of, 737–738
  standard enthalpies of formation of, 255t
  standard enthalpies of vaporization of, 508t
hydrogen iodide
  decomposition of, 653
  equilibrium with hydrogen and iodine, 816
hydrogen ion. *See* hydronium ion
hydrogen peroxide
  catalyzed decomposition of, 614, 615
  decomposition of, 624
hydrogen phosphate ion
  buffer solution of, 764t
  in respiration, 843
hydrogen phthalate ion, buffer solution of, 764t
hydrogen sulfide
  as polyprotic acid, 711t
  properties of, 999
  sulfur-oxidizing bacteria and, 999
hydrogenation An addition reaction in which the reagent is molecular hydrogen, 393, 1078
  of benzene, 1081
hydrolysis reaction A reaction with water, 1092
  of anions of insoluble salt, 791
  of ATP to ADP, 1138
  of ions in water, 721
  solubility and, 789
hydrometallurgy Recovery of metals from their ores by reactions in aqueous solution, 1027, 1028–1029
hydronium ion, $H_3O^+(aq)$, 141–142
  as Lewis adduct, 742
  concentration expressed as pH, 194
  molecular geometry of, 376

hydrophilic colloids, 594
hydrophobic colloids, 593
hydroxide ion, $OH^-(aq)$, 141
  as Lewis base, 744
  formal charges in, 364
hydroxides, solubility in strong acids, 791
hydroxyapatite, 989
  in teeth, *940*
2-hydroxyethylphosphonate ion, 476
4-(*p*-hydroxyphenyl)-2-butanone, 1107
hygroscopic compound A compound that absorbs water from the air, 299
hygroscopic salt, 971
hyperthyroidism, 1002
hypertonic solution, 587
hypervalent compound(s) A compound in which the central atom is surrounded by more than four valence electron pairs, 369, 371t
hyperventilation, respiratory alkalosis and, 800
hypochlorite ion, 83, 1005
  formal charges in, 364
  self-oxidation–reduction, 645
hypochlorous acid, 1004
  reaction with ammonia, 949
hypophosphoric acid, 996t
hypothesis A tentative explanation or prediction based on experimental observations, 3
hypothyroidism, 1002
hypotonic solution, 587
hypoxia, 476

ibuprofen, synthesis of, 207–208, 397
ice
  density of, 12
  hydrogen bonding in, 499
  melting of, 237
  structure of, 75, 499
ICE table, 673
  calculating K_a value from, 727
  completion of, 680, 682
  for common ion effect, 761
Icelandic spar, 973, *974*
Iceman, 1–3, 102
  radiochemical dating of, *1165*
ideal gas A simplification of real gases in which it is assumed that there are no forces between the molecules and that the molecules occupy no volume, 461
ideal gas law A law that relates pressure, volume, number of moles, and temperature for an ideal gas, 460–464
  departures from, 474
  osmotic pressure equation and, 585
  stoichiometry and, 465
ideal solution A solution that obeys Raoult's law, 577
ilmenite, 1000
imaging, medical, 1175–1176
immiscible liquids, 569
indicator(s) A substance used to signal the equivalence point of a titration by a change in some physical property such as color, 198
  acid–base, 780–782
indigo plant, 439
indium, abundance of, 978
induced dipole(s) Separation of charge in a normally nonpolar molecule, caused by the approach of a polar molecule, 501
induced dipole–induced dipole attraction The electrostatic force between two neutral molecules, both having induced dipoles, 502
inert gas(es). *See* **noble gas(es)**.
inertia, A-6
infant formula, adulteration of, 208
infrared goggles, 280
infrared (IR) radiation, 278
  in greenhouse effect, 943
initial rate The instantaneous reaction rate at the start of the reaction, 618
initiation step, in chain reaction, 651, 1170
inner transition elements. *See* **actinide(s)** and **lanthanide(s)**.
insoluble compound(s), 782
  solubility product constants of, 784t
instantaneous reaction rate, 618
integrated rate equation An equation relating the concentration of a reactant to its initial concentration and the elapsed time, 622–631
  for nuclear decay, 1163
integrity, in science, 4
intensive properties Physical properties that do not depend on the amount of matter present, 14
intercept, of straight-line graph, 44, 626
Intergovernmental Panel on Climate Change (IPCC), 924, 944
intermediate. *See* **reaction intermediate**.
intermolecular forces Interactions between molecules, between ions, or between molecules and ions, 490–517
  between amino acids in protein, 1121
  determining types of, 503
  energies of, 491, *503*
  in alcohols, 1085
  solubility and, 496, 571
internal energy The sum of the potential and kinetic energies of the particles in the system, 241
internal energy change
  as state function, 244
  measurement of, 249
  relation to enthalpy change, 243
International System of Units. *See* **SI**.
International Union of Pure and Applied Chemistry (IUPAC), 1072, A-15
interstitial hydrides, 966
intravenous solution(s), tonicity of, 587
intrinsic semiconductor, 543
iodide ion, reaction with iron(III) ion, 681
iodine
  abundance of, 1000
  as catalyst, 638
  clock reaction, 614
  dissociation of, 684
  production of, 1001
  reaction with hydrogen, 682
    mechanism of, 653
  reaction with sodium thiosulfate, 208
  solubility in liquids, 504
  solubility in polar and nonpolar solvents, 569
iodine-131
  radioactive half-life, 1161
  treatment of hyperthyroidism, 1002
iodine monochloride, decomposition of, 840
iodine tetrafluoride ion, molecular geometry of, 378
ion(s) An atom or group of atoms that has lost or gained one or more electrons so that it is no longer electrically neutral, 11, 78. *See also* **anion(s)**; **cation(s)**.
  acid–base properties of, 721t
  complex. *See* **coordination complex(es).**
  concentrations of, 190
  direction of flow in voltaic cells, 868
  electron configurations of, 324–327
  formation by metals and nonmetals, 78–80
  hydration of, 493, 572
  in aqueous solution, 131
  monatomic, 78–80
  noble gas electron configuration in, 337
  polyatomic, 80
  sizes of, 335–337
  spectator, 137
ion–dipole attraction The electrostatic force between an ion and a neutral molecule that has a permanent dipole moment, 493
  solubility in water and, 571
ion exchange, in water softener, 950
ionic bond(s) The attraction between a positive ion and a negative ion resulting from the complete (or nearly complete) transfer of one or more electrons from one atom to another, 352, 397
ionic compound(s) A compound formed by the combination of positive and negative ions, 77–86
  as electrolytes, 132
  balancing charges in, 81–83
  colligative properties of solutions of, 589–591
  crystal cleavage, 86
  formula mass of, 91
  formulas of, 81–84
  lattice energy of, 538t
  melting point of, 549, 550t

naming, 84
of main group elements, 961
properties of, 86
solubility in water, 134, 570, 571
temperature and, *577*
ionic radius
lattice energy and, 550
periodicity of, 334–335
ionic solid(s) A solid formed by the condensation of anions and cations, 534–537
ionization constant(s) The equilibrium constant for an ionization reaction, 712
acid and base, 716, A-20, A-22
water, 712
ionization energy The energy change required to remove an electron from an atom or ion in the gas phase, 330–331, 331t
in photoelectron spectroscopy, 333
periodicity of, 331
values of, A-18
iridium, density of, 1021
iron
biochemistry of, 339
combustion of, 258
corrosion of, 899
in meteorite, *329*
most stable isotope, 1159
production of, 1027–1028
reaction with copper ions, 868
reaction with oxygen, 126
iron(III) hydroxide, formation by precipitation, 136
iron(II) ion
complexes of, 743
in hemoglobin, 1033, 1120
oxidation by bacteria, 1029
oxidation–reduction titration of, 202
reaction with permanganate ion, 155, 863
iron(III) ion
coordination complex with oxalate ion, 1032
paramagnetism of, 326
reaction with iodide ion, 681
iron(III) nitrate, dilution of, 192
iron(III) oxide
formation by corrosion, 900
reaction with carbon monoxide, 149
reduction of, 1027
iron pyrite, 11, 787
irreversible process A process that involves nonequilibrium conditions, 818
isobutane, conversion to butane, 678, 690
isochron dating, 1180
isoelectronic ions Ions that have the same number of electrons but different numbers of protons, 336
isoelectronic species Molecules or ions that have the same number of valence electrons and similar Lewis structures, 361
isoflurane, 1003, 1007
isoleucine, structure of, *1119*
isomer(s) Two or more compounds with the same molecular formula but different arrangements of atoms, 424
cis-trans. *See cis-trans* isomers.
coordination, 1038
geometric, 1038, 1067, 1074
linkage, 1038
Markovnikov's rule and, 1078
mer-fac, 1039
number of, 1070
of organic compounds, 1066–1068
optical, 1039, 1067
structural. *See* **structural isomers**.
isomerization
cis-trans, 1038
in petroleum refining, 938
isoprene, in rubber, 1099
isopropyl alcohol, 1083
isotonic solution, 587
isotope(s) Atoms with the same atomic number but different mass numbers, because of a difference in the number of neutrons, 62–63
hydrogen, 965
in mass spectra, 99
metastable, 1175
oxygen, 921
percent abundance of, 62, 64t
radioactive, as tracers, 1176
radioactive decay of, 1151–1153
separation of, 1171
stable and unstable, 1156
synthesis of, 1166
isotope dilution, volume measurement by, 1176
isotope labeling, 1092
isotope ratio
dating meteorites by, 1179
geographic variations of, 102–103

jade
color of, *1050*
jasmine, oil of, 1093
JELL-O®, as colloid, 591–593
Joliot, Frédéric, 66
joule (J) The SI unit of energy, 33, A-7, A-11
Joule, James P., *33*, 233

K capture. *See* **electron capture**.
kaolinite clay, 986
Kekulé, August, 425, 1080
kelvin (K), 30, 455, A-10
in heat calculations, 235
Kelvin, Lord (William Thomson), 30, 455
Kelvin temperature scale A scale in which the unit is the same size as the Celsius degree but the zero point is the lowest possible temperature, 30. *See also* **absolute zero**.
kerosene, production of, 938
Ketelaar, J. A. A., 397
ketone(s) Any of a class of organic compounds characterized by the presence of a carbonyl group, in which the carbon atom is bonded to two other carbon atoms, 1088, 1089
naming of, A-17
reduction to secondary alcohols, 1089
ketose, 1125
Kevlar, structure of, 1102
kilocalorie (kcal), 33, A-8t
kilogram (kg) The SI base unit of mass, 33, A-10
kilojoule (kJ), 33
kilopascal (kPa), 452
kinetic energy The energy of a moving object, dependent on its mass and velocity, 6, 17
distribution in gas, 633
temperature and, 468–470
distribution in liquid, *508*
of alpha and beta particles, 1150–1151
total, 918
kinetic-molecular theory A theory of the behavior of matter at the molecular level, 6
gas laws and, 471
of gases, 468–471
physical states and, 491
kinetic stability, of organic compounds, 1068–1069
kinetics. *See* **chemical kinetics**.
Kohlrausch, Friedrich, 712
krypton, abundance of, 1006
Kynamro, 1140–1141

lactase, 1126
lactic acid, 1090t
acid ionization constant of, 727
optical isomers of, 1068
lactose, structure of, 1125
Lake Mead, 925, *926*
Lake Nyos, 596–597
lakes, freezing of, 500
lanthanide(s) The series of elements between lanthanum and hafnium in the periodic table, 74, 1021
electron configurations of, 321
properties of, 338
uses of, 1053–1054
lanthanide contraction The decrease in ionic radius that results from the filling of the 4*f* orbitals, 1025
lanthanum, in superconductors, 158
laser, synthetic ruby in, 982
lattice energy ($\Delta_{lattice}U$) The energy of formation of one mole of a solid crystalline ionic compound from ions in the gas phase, 537–540
ionic radius and, 549
relation to solubility, 571

    second, 817
    third, 821
  Raoult's, 577
  rate. *See* **rate equation(s)**.
Le Chatelier's principle A change in any of the factors determining an equilibrium will cause the system to adjust to reduce the effect of the change, 576, 690
  common ion effect and, 761
lead
  abundance of, 983
  density of, 12
  end of radioactive series, 1151
  isotope ratios, 102
  pollution by, 929
lead(II) chloride, solubility of, 789
lead(II) chromate, *783*
lead(II) iodide, dissolution of, *832*
lead(IV) oxide, in lead storage battery, 873
lead storage battery, 873–874
lead(II) sulfide
  formation by precipitation, 136
  roasting of, 999
  solubility of, 790
least-squares analysis, 45
lecithin, 594
Leclanché, Georges, 872
lemon juice, pH of, 195
length
  common units of, A-12
  measurement of, 31
leucine, structure of, *1119*
leveling effect, 715, 746–747
levo enantiomer, 1103
Lewis, Gilbert Newton, 353, 742
Lewis acid(s) A substance that can accept a pair of electrons to form a new bond, 742–747
  molecular, 745
Lewis base(s) A substance that can donate a pair of electrons to form a new bond, 742–747
  ligands as, 1031
  molecular, 745
Lewis electron dot symbol/structure(s) A notation for the electron configuration of an atom or molecule, 354–363
  predicting, 360–363
  procedure for constructing, 355
Li, Kaichang, 1104
Libby, Willard, 1164
life, chemistry of, 1116–1141
ligand(s) The molecules or anions bonded to the central metal atom in a coordination compound, 796, 1031
  as Lewis bases, 1031
  naming of, 1035
  spectrochemical series of, 1050–1052
ligand field splitting (Δ_0) The difference in potential energy between sets of *d* orbitals in a metal atom or ion surrounded by ligands, 1044
  spectrochemical series and, 1050
ligand field theory A theory of metal-ligand bonding in coordination compounds, 1043–1048
light. *See also* **electromagnetic radiation**.
  absorption and reemission by metals, 542
  absorption by pi bonds, 439
  plane-polarized, 1040, 1067
  scattering by colloids, 592
  speed of, 278, 1159, A-13t
  visible, 278, 1049
light-emitting diode (LED), 542, 933
lignite, 935
lime, 975
  in water softener, 950
  reaction with water, 147
  slaked, 976
limestone, 973
  dissolving in vinegar, *147*
  in iron production, 1027
  in stalactites and stalagmites, 128
limiting reactant The reactant present in limited supply that determines the amount of product formed, 177
line emission spectrum The spectrum of light emitted by excited atoms in the gas phase, consisting of discrete wavelengths, 283
linear electron-pair geometry, orbital hybridization and, 418–420, *419*
linear molecular geometry, 373–379, 1037
  in carbon compounds, 1066
linear regression analysis, 45
linkage isomers Two or more complexes in which a ligand is attached to the metal atom through different atoms, 1038
lipid(s) Any of a class of biological compounds that are poorly soluble in water but soluble in organic solvents, 1134–1137
liquefaction, coal, 935
liquid(s) The phase of matter in which a substance has no definite shape but a definite volume, 6
  miscible and immiscible, 569
  properties of, 506–517
liter (L) A unit of volume convenient for laboratory use; 1 L = 1000 cm^3, 33
lithium
  abundance of, 968
  bands of molecular orbitals in, *541*
  effective nuclear charge in, 314
  electron configuration of, 317
  reaction with water, 464
  transmutation to helium, 1166
  uses of, 553
lithium aluminum hydride, as reducing catalyst, 1089
lithium carbonate, 973
lithium-ion battery, 553, 874–875
lithium-ion polymer battery, 874–875
litmus, *194*, 195
Lockyer, Sir Joseph Norman, 300
logarithms, 194, A-2
London dispersion forces, 503
lone pair(s) Pairs of valence electrons that do not contribute to bonding in a covalent molecule, 354
  effect on electron-pair geometry, 375
  in formal charge equation, 363
  in Lewis base, 742
  in ligands, 1031
  valence bond theory and, 414
low-density polyethylene (LDPE), 1097
low-spin configuration The electron configuration for a coordination complex with the minimum number of unpaired electrons, 1045
lowest unoccupied molecular orbital (LUMO), 433t
Lowry, Thomas M., 139
Lucite, 1098t
lycopodium powder, *615*
Lyman series, 288
lysine, structure of, *1119*
lysozyme, 1123

Macintosh, Charles, 1098
macroscopic level Processes and properties on a scale large enough to be observed directly, 7
magic numbers, of protons and neutrons, 1168

magnesite, 973
magnesium
  abundance of, 973
  combustion of, 150, 151
  in chlorophyll, 976
  production of, 974
  reaction with hydrogen chloride, 248
  reaction with nitrogen, 989
  reduction of silicon by, 984
  salts of, in fireworks, 299
magnesium carbonate, in magnesite, 973
magnesium chloride
  electrolysis of, 974
  in table salt, 971
magnesium fluoride, solubility of, 786
magnesium hydroxide, precipitation of, 974
magnesium oxide, crystal structure of, 537
magnesium perchlorate, water absorption by, 185
magnetic quantum number, 293
magnetic resonance imaging (MRI), helium and, 73, 1005
magnetism. *See also* **diamagnetism**, **paramagnetism**.
  in high-spin and low-spin complexes, 1045
magnetite, 900
main group element(s), 66
  atomic radii, *329*
  chemistry of, 958–1008
  electron configurations, 317–320
  ionic compounds of, 961
  ionization energies, 331
  molecular compounds of, 962
malachite, *783*, *1026*
malic acid, *735*, 1090t
malleability, metallic, 540
manganese(II) carbonate, *783*
manganese(IV) dioxide, in dry cell battery, 872
manometer, U-tube, 452
mantissa The part of a logarithm to the right of the decimal point, A-3
Markovnikov, Vladimir, 1078
Markovnikov's rule, 1078
Marsden, Ernest, 69
mass A measure of the quantity of matter in a body, 33
  energy equivalence of, 1159
  in stoichiometry, 172–210
  units of, A-12
  weight and, A-6
mass balance, 138
mass defect, 63, 1158
mass number (*A*) The sum of the number of protons and neutrons in the nucleus of an atom of an element, 60–61
  in nuclear symbol, 1150
mass percent. *See* **percent composition**.
mass spectrometer, 63
  determining formula with, 99
matches, phosphorus sulfide in, 995
matter Anything that has mass and occupies space, 6, A-6
  classification of, 6–10
  dispersal of, 820–821
  law of conservation of, 4, 125, 230
  states of, 6, 491
matter-antimatter annihilation, 1175
matter wave, 290
mauveine, 439
Maxwell, James Clerk, 277, 469
Maxwell-Boltzmann distribution curves, 469, 633, 820
McMillan, Edwin, *1166*
mean square speed, of gas molecules, 469
measured quantity, significant figures in, 38
measurement(s), units of, 29–33, 452, A-10
mechanical energy The energy due to the motion of macroscopic objects, 17
mechanism, reaction. *See* **reaction mechanism**.
Meitner, Lise, 1170
melamine, pet food adulterated with, 516
melting point The temperature at which the crystal lattice of a solid collapses and solid is converted to liquid, 549, 550t, A-14t
  identifying compounds by, 14
  of ionic solids, 86
  of transition elements, 1025
membrane
  biological cell, 1135
  ion-permeable, 971
  proton exchange, 875
  semipermeable, 584
membrane cell, *971*
  chlorine production by, 1000–1001
Mendeleev, Dmitri Ivanovich, 70
meniscus, 514
Menten, Maud L., 642
mercury
  coal power and, 934
  from cinnabar, *2*
  in pressure measurement, 451
  line emission spectrum, *284*
  melting point of, 1021
  poisoning symptoms, 929
mercury electrode, 869
mercury(II) oxide, decomposition of, 124
mer-fac isomers, 1039
messenger RNA (mRNA), 1131
meta position, 1080
metabolic alkalosis and acidosis, 800–801
metabolism The entire set of chemical reactions that take place in the body, 1137–1140
metal(s) An element characterized by a tendency to give up electrons and by good thermal and electrical conductivity, 66
  as reducing agents, 154t
  biochemistry of, 339
  bonding in, band theory of, 540
  cations formed by, 78
    acid–base properties of, 720–721
  coordination compounds of, 1029
  electronegativity of, 380
  enthalpy of fusion of, 550t
  hydrated cations as Brønsted acids, 710, 743
  melting point of, 550t
  reaction with hydrogen chloride, 1004
  sulfides
    in black smokers, 159
    solubility product constants of, A-23
  transition. *See* transition elements.
  unit cell types of, 529, *530*
  water pollution by, 928
metal hydrides, reaction with water, 966
metallic bond(s), 397–398
metallic character, periodicity of, 961
metalloid(s) An element with properties of both metals and nonmetals, 66, 67
  electronegativity of, 380
metallurgy, 1026–1029
metaphosphoric acid, 996t
metastable isotope, 1175
metathesis reaction(s). *See* **exchange reaction(s)**.
meteorite, iron, *329*
meteorites, determining ages of, 1179–1180
meter (m) The SI base unit of length, 29, A-10
methane
  as fuel, 925
  as greenhouse gas, 925, 944
  bond angles in, *376*
  bond order in, 390
  combustion analysis of, 185
    standard free energy change, 835
  enthalpy of formation, 253
  Henry's law constant, 574t
  hybrid orbitals in, 415–418
  hydrogen produced from, 967
  in atmosphere, 925
  molar mass of, 90
  reaction with chlorine, 651
  standard free energy of formation of, 833
  structure of, *76*
methane hydrates, 925, 936
methanol, 1083
  as fuel, 179
  hydrogen bonding in, 506
  in fuel cell, 938
  Lewis structure of, 363t
  orbital hybridization in, 418
  reaction with carbon monoxide, 1090
  reaction with halide ions, 634
  spontaneity of formation reaction, 825
  synthesis of, 179

methicillin-resistant *Staphylococcus aureus* (MRSA), 1052
methionine, structure of, 1119
methoxyethyl group, 1140
methyl alcohol. *See* methanol.
methyl chloride, reaction with halide ions, 634
methyl ethyl ketone, 1089t
methyl mercaptan, 999
methyl methacrylate, synthesis of, 208
methyl salicylate, 588, 1092
N-methylacetamide, structure of, 1094
methylamine, 418
  as weak base, 719
  electrostatic potential map of, 387
  Lewis structure of, 363t
methylamines, 1086
2-methyl-1,3-butadiene. *See* isoprene.
2-methylbutane, structure of, 1070
3-methylbutyl acetate, 1093t
methylpentane, structural isomers of, 1071
2-methylpropane, structure of, 1070
2-methylpropene
  reaction with hydrogen chloride, 1078
  structure of, 1066, 1074
methylsiloxane, 988
metric system A decimal system for recording and reporting measurements, in which all units are expressed as powers of 10 times some basic unit, 29
metric ton, 918
mica, structure of, 986
Michaelis, Leonor, 642
microbial burden (MB), 1052
microstates, 818
microwave radiation, 277
Midgley, Thomas, 922
milligram (mg), 33
Millikan, Robert, 69
milliliter (mL) A unit of volume equivalent to one thousandth of a liter; 1 mL = 1 cm^3, 33
millimeter of mercury (mm Hg) A common unit of pressure, defined as the pressure that can support a 1-millimeter column of mercury; 760 mm Hg = 1 atm, 452, A-7t
mineral oil, density of, 46
minerals
  analysis of, 183
  clay, 986
  silicate, 985
  solubility of, 785
miscible liquids, 569
mixture(s) A combination of two or more substances that can be separated by physical techniques, 8–10
  analysis of, 183–188
  gaseous, partial pressures in, 465–467
  separation by chromatography, 515
mobile phase, in chromatography, 515
models, molecular, *11*, 75
moderator, nuclear, 1178
Mohr method, 209
Moissan, Henri, 1000
molal boiling point elevation constant (K_{bp}), 580
molality (m) The number of moles of solute per kilogram of solvent, 565
molar absorptivity, 205
molar enthalpy of vaporization ($\Delta_{vap}H°$), relation to molar enthalpy of condensation, 507
molar heat capacity The quantity of heat required to raise the temperature of 1.00 mol of a substance by 1.00 kelvin, 232
  values of, A-14t
molar mass (*M*) The mass in grams of one mole of particles of any substance, 87
  calculation from colligative properties, 588
  calculation from ideal gas law, 462
  determination by titration, 201
  effusion rate and, 473
  enthalpy of vaporization and, 507
  melting point and, 550
  molecular speed and, 469
  polarizability and, 502
molar volume, standard, 460
molarity (M) The number of moles of solute per liter of solution, 188, 565
mole (mol) The SI base unit for amount of substance, 87, A-10
  conversion to mass units, 88
  of reaction, 181, 245
mole fraction (*X*) The ratio of the number of moles of one substance to the total number of moles in a mixture of substances, 466, 566
  in Raoult's law, 577
molecular compound(s) A compound formed by the combination of atoms without significant ionic character, 77. *See also* **covalent compound(s)**.
  as Brønsted acids and bases, 709–711
  as Lewis acids, 745
  as nonelectrolytes, 132
  hydrogen in, 966
  of main group elements, 962
molecular formula A written formula that expresses the number of atoms of each type within one molecule of a compound, 75, 1067
  determining, 93–99
  relation to empirical formula, 95
molecular geometry The arrangement in space of the central atom and the atoms directly attached to it, 375
  coordination number and, 1037
  hybrid orbitals and, 416
  ligand field splitting and, 1044
  molecular polarity and, 384–389, 400t
  multiple bonds and, 378–379
molecular mass, average, 90
molecular models, *11*, 75–76
molecular orbital(s)
  bonding and antibonding, 427
  from atomic *p* orbitals, 431, 434
  highest occupied (HOMO), 433t
  lowest unoccupied (LUMO), 433t
  photoelectron spectroscopy and, 438
molecular orbital theory A model of bonding in which pure atomic orbitals combine to produce molecular orbitals that are delocalized over two or more atoms, 413, 427–436, 1043
  for metals and semiconductors, 540–544
  resonance and, 434–435
molecular polarity, 384–389, 400t
  intermolecular forces and, 492–494
  miscibility and, 569
  of lipids, 1134
  of surfactants, 594
molecular solid(s) A solid formed by the condensation of covalently bonded molecules, 544
  melting point of, 550t
  solubilities of, 570
molecular structure
  acid-base properties and, 737–742
  bonding and, 350–399
  entropy and, 823
  VSEPR model of, 373–379
molecular weight. *See* **molar mass**.
molecularity The number of particles colliding in an elementary step, 644
  reaction order and, 644
molecule(s) A neutral particle consisting of more than one atom in which the atoms are covalently bonded to each other, 11, 74
  calculating mass of, 93
  collisions of, reaction rate and, 631–635
  nonpolar, interactions of, 501–504
  polar, interactions of, 495
  polarity of, 384–389
  shapes of, 373–379
  speeds in gases, 468–470
  volume of, 475
molybdenite, 1025
molybdenum-99
  generation of technetium-99m from, 1179
monatomic ion(s) An ion consisting of one atom bearing an electric charge, 78–80
  naming, 83
  oxidation numbers in, 152
  sizes of, 335
monodentate ligands, 1031
monolayer, formation on solid surface, 474
monomer(s) The small units from which a polymer is constructed, 1095

monoprotic acid(s) A Brønsted acid that can donate one proton, 710
monosaccharides, 1125
mortar, lime in, 975–976
Moseley, Henry G. J., 70
Müller, Karl, 158
Mulliken, Robert S., 399, 413
Mullis, Kary, 1141
multiple bonds
  bond length of, 391t
  in resonance structures, 365
  Lewis electron dot structure of, 357
  molecular geometry and, 378
  valence bond theory of, 421–425
muscovite, 986
mussels, glue from, 1104
Mylar, 1100
myoglobin, 1033
  iron in, 1022

naming
  of alcohols, A-17
  of aldehydes and ketones, 1089t, 1090, A-17
  of alkanes, 1069t, 1072, A-15
  of alkenes, 1074, A-16
  of alkynes, 1077t, A-16
  of anions and cations, 83
  of aromatic compounds, A-17
  of benzene derivatives, A-17
  of binary nonmetal compounds, 77
  of carboxylic acids, 1090, 1091, A-17
  of common acids, 141
  of coordination compounds, 1035–1036
  of esters, 1092, A-17
  of ionic compounds, 84
  of substituted alkanes, 1077
nanometer, 29
nanotechnology, 29
nanotubes, carbon, 545
naphthalene
  melting point of, *14*
  structure of, 1079
narcosis, nitrogen, 597
National Ambient Air Quality Standards (NAAQS), 943
National Institute of Standards and Technology (NIST), 35, 245
natural gas, 936
  as energy resource, 931
  helium in, 1005
  hydrogen production from, 940
natural logarithms, A-2
neodymium
  in permanent magnets, 327
  magnetism of, 74
neon
  abundance of, 1006
  electron configuration of, 319
  line emission spectrum of, *284*
  mass spectrum of, *63*
nephrite, 545
neptunium, 1166, 1168
Nernst equation An equation that relates the potential of an electrochemical cell to the concentrations of the cell reactants and products, 885
net ionic equation(s) A chemical equation involving only those substances undergoing chemical changes in the course of the reaction, 137
  of oxidation–reduction reaction, 861
  of strong acid–strong base reactions, 144, 725
network solid(s) A solid composed of a network of covalently bonded atoms, 545–546
  bonding in, 454
  silicon dioxide, 985
  solubilities of, 570
neurotransmitter, 1103
neutral buoyancy, 477
neutral solution A solution in which the concentrations of hydronium ion and hydroxide ion are equal, 713
  pH of, 194
neutralization reaction(s) An acid–base reaction that produces a neutral solution of a salt and water, 144, 726
neutrino(s) A massless, chargeless particle emitted by some nuclear reactions, 1154
neutron(s) An electrically neutral subatomic particle found in the nucleus, 59
  bombardment with, 1168
  conversion to electron and proton, 1151
  demonstration of, 69
  discovery of, 1166
  in nuclear fission reaction, 1169
  in nuclear reactor, 1178
  nuclear stability and, 1157
neutron capture reactions, 1167
newton (N) The SI unit of force; $1\ N = 1\ kg \cdot m/s^2$, 452, A-7, A-11
nickel
  as catalyst in diamond synthesis, 844
  coordination complex with ammonia, 1031
  coordination complexes of, 1046
nickel(II) carbonate
  precipitation of, 792
  reaction with sulfuric acid, 148
nickel carbonyl, decomposition of, temperature and spontaneity, 837
nickel(II) chloride hexahydrate, 1029, *1030*
nickel(II) complexes, solubility of, *796*
nickel(II) ion, light absorption by, 203
nickel(II) sulfide, precipitation of, 792
nickel-cadmium (Ni-cad) battery, 874
nickel-metal hydride battery, 874
nicotinamide adenine dinucleotide (NADH), 1139
nicotine, structure of, 1087
night vision goggles, 280
nitrate ion
  Lewis structure of, 361
  molecular geometry of, 314
  resonance structures of, 366, 739
nitration, of benzene, 1082
nitric acid
  air pollution by, 942
  as oxidizing agent, 154t
  Lewis structure of, 361
  manufacture of, 177
  pH of, 195
  production by Ostwald process, 992
  reaction with aluminum, 981
  reaction with sodium hydroxide, 120
  strength of, 738
nitric oxide. *See* nitrogen monoxide.
nitride(s), 989
nitrite ion
  linkage isomers containing, 1038
  resonance structures of, 368
nitrito complex, 1038
nitro complex, 1038
nitrocellulose, 258
nitrogen
  abundance of, 989
  bond enthalpy of triple bond, 990
  bond order in, 390
  chemistry of, 990–993
  compounds of
    hydrogen bonding in, 497
    with hydrogen, 990
  electron configuration of, 319
  fixation of, 72
  Henry's law constant, 574t
  in testing food for protein content, 516
  Lewis structures involving, 360
  liquid, 455, 989
  liquid and gas volumes, *492*
  molecular orbital configuration of, 432
  oxidation numbers of, 990
  oxides and oxoacids of, 991
  reaction with hydrogen, 464
  reaction with oxygen, 685, 693
  solubility in blood, 597
  transmutation to oxygen, 1166
nitrogen cycle, 919
nitrogen dioxide, 920, 991
  air pollution by, 942
  dimerization of, 372, 679, 692, 992
  free radical, 372
  in formation of atmospheric ozone, 921
  reaction with carbon monoxide, 618, 632, 648
  reaction with fluorine, 647
  reaction with water, 147
nitrogen monoxide, 920, 990
  air pollution by, 942
  free radical, 372
  reaction with bromine, 643
  reaction with chlorine, 618
  reaction with oxygen, mechanism of, 649
  reaction with oxygen, standard entropy change of, 824
  reaction with ozone, 677

nitrogen narcosis, 597
nitrogen oxides, in atmosphere, 919–920
nitrogen trifluoride
  Lewis structure of, 361
  molecular polarity of, 387
nitrogenase, metals in, 1022
nitrogenous base(s), 1128, *1128*
nitroglycerin, *1084*
  decomposition of, 256
  in smokeless gunpowder, 258
nitronium ion, Lewis electron dot structure of, 358
nitrous acid, 992
  strength of, 738
nitrous oxide. *See* dinitrogen oxide.
nitrox, 597
Nobel, Alfred, *1084*
noble gas(es) The elements in Group 8A of the periodic table, 73
noble gas(es)
  compounds of, 1005–1007
  discovery of, 103
  electron configuration of, 79, 319, 337, 354, 961
    ionization energies and, 337–338
  in atmosphere, 919
noble gas notation An abbreviated form of *spdf* notation that replaces the completed electron shells with the symbol of the corresponding noble gas in brackets, 317
nodal surface A surface on which there is zero probability of finding an electron, 296–298
node(s) A point of zero amplitude of a wave, *278*
nonaqueous solvents, acid strength in, 746–747
nonbonding electrons. *See* **lone pair(s)**.
nonelectrolyte A substance that dissolves in water to form an electrically nonconducting solution, 132
nonideal gas, 480
nonmetal(s) An element characterized by a lack of metallic properties, 66, *66*, 67
  anions formed by, 79
  binary compounds of, 77
  electronegativity of, 380
nonpolar molecules, 385
  interactions of, 501–504
nonrenewable resources, 932
nonspontaneous reaction, 816. *See also* **reactant-favored reaction(s)**.
normal boiling point The boiling point of a liquid when the external pressure is 1 atm, 513
  for common compounds, 508t
northwest–southeast rule A product-favored reaction involves a reducing agent below and to the right of the oxidizing agent in the table of standard reduction potentials, 880
Novoselov, Kostya, 554
n-type semiconductor, 544
nuclear binding energy, 1158–1160
nuclear charge, effective, 314, 315t, 322
nuclear chemistry, 1148–1180
  applications of, 1175–1179
nuclear energy, 1171
nuclear fission, 1169
nuclear fusion, 1172
nuclear medicine, 1175
nuclear power generation, 933
nuclear reaction(s) A reaction involving one or more atomic nuclei, resulting in a change in the identities of the isotopes, 1150–1155
  artificial, 1166–1168
  predicting types of, 1157
  rates of, 1160–1165
nuclear reactor A container in which a controlled nuclear reaction occurs, 1170–1171
  natural, 1178
nucleic acid(s) A class of polymers, including RNA and DNA, that are the genetic material of cells, 1127–1134
nucleon A nuclear particle, either a neutron or a proton, 1159
nucleoside, 1128
nucleotide, 1128
nucleus The core of an atom, made up of protons and neutrons, 59
  size of, 69
  stability of, 1155–1160
nutrition label, energy content on, 34
nylon-6,6, 1101

ocean, acidification of, 945
octadecane, 516
octahedral electron-pair geometry, orbital hybridization and, 420
octahedral holes, 534
octahedral molecular geometry, 373, 374, 1037
  optical isomerism and, 881
octane
  combustion of, 126
  heat of combustion, 250
octet, of electrons, 354, 1065
octet rule When forming bonds, atoms of main group elements gain, lose, or share electrons to achieve a stable configuration having eight valence electrons, 354
  exceptions to, 355, 369–373, 696
odd-electron compounds, 372, 992
oil(s)
  as lipids, 1134
  reaction with methanol, 942
  soaps and, 594
oil sands, 937
Oklo, natural nuclear reactor at, 1178
Olah, George, *747*
oleic acid, 1090t
olivine, 986
omega-3-fatty acids, 1093
optical isomers Isomers that are nonsuperimposable mirror images of each other, 1039, 1040
orbital(s) The matter wave for an allowed energy state of an electron in an atom or molecule, 292
  atomic. *See* **atomic orbital(s)**.
  molecular. *See* **molecular orbital(s)**.
orbital box diagram A notation for the electron configuration of an atom in which each orbital is shown as a box and the number and spin direction of the electrons are shown by arrows, 311
orbital hybridization The combination of atomic orbitals to form a set of equivalent hybrid orbitals that minimize electron-pair repulsions, 415–418
  of nitrogen in amides, 1094
orbital overlap Partial occupation of the same region of space by orbitals from two atoms, 413
order, bond. *See* **bond order**.
  reaction. *See* **reaction order**.
ore(s) A sample of matter containing a desired mineral or element, usually with large quantities of impurities, 1026
  insoluble salts in, 792
organic compounds
  bonding in, 1064–1105
  Lewis structures of, 363
  naming of, 1069t, 1072, A-15
  stability of, 1068–1069
orientation of reactants, effect on reaction rate, 634, 635
Orlon, 1098t
orpiment, 103, 787
  ions in, *78*
ortho position, 1080
orthophosphoric acid, 996t
orthorhombic sulfur, 998
orthosilicates, 986
osmium, density of, 1021
osmosis The movement of solvent molecules through a semipermeable membrane from a region of lower solute concentration to a region of higher solute concentration, 584
  reverse, 585, 928
osmotic pressure (Π) The pressure exerted by osmosis in a solution system at equilibrium, 584
Ostwald, Friedrich Wilhelm, 87
Ostwald process, 992
Ötzi the Iceman, 1–2, 102–103, *1165*
outgassing, 474
overlap, orbital, 413
oxalate ion, as ligand (ox), 1031

oxalic acid, 1090t
as polyprotic acid, 711t
molar mass of, 92
structure of, *140*
titration of, 198, 777
oxidation The loss of electrons by an atom, ion, or molecule, 149
at anode of electrochemical cell, 866
half-reaction for, 860
of transition metals, 1023
oxidation number(s) A number assigned to each element in a compound in order to keep track of the electrons during a reaction, 151–153
formal charges and, 364
in redox reaction, 860
of Group 3A elements, 978
of Group 4A elements, 983
of Group 5A elements, 989
of transition elements, 1023, *1024*
oxidation reaction(s)
of alcohols, 1088
of organic compounds, 1069
oxidation–reduction reaction(s) A reaction involving the transfer of one or more electrons from one species to another, 149–155, 858–903
balancing equations for, 859–865
biological, 1139
in acidic and basic solutions, 861–863
recognizing, 153–155
titration using, 202
oxides, as acids and bases, 146
oxidizing agent(s) The substance that accepts electrons and is reduced in an oxidation–reduction reaction, 149–150, 859
relative strengths of, 882, 882–884
oxoacid(s)
acid strengths of, 738
Lewis structures of, 361
of chlorine, 1004
of nitrogen, 991–992
of phosphorus, 995–997
oxoanion(s) Polyatomic anions containing oxygen, 83
as Brønsted bases, 742
Lewis structures of, 361
oxy-acetylene torch, *1077*
oxygen
abundance of, 997
allotropes of, 72, 997
as oxidizing agent, 149, 154t
compounds of
hydrogen bonding in, 497
with nitrogen, 991
with phosphorus, 995
corrosion and, 899
deprivation and sickness, 476
discovery of, 124
dissolving in water, 501
electron configuration of, 319
from photosynthesis, 997
Henry's law constant, 574t
in atmosphere, 920–921
in fuel cell, 875–876, 939
in iron and steel production, 1027–1028
isotope ratios, 102
Lewis structures involving, 360
molecular orbital configuration of, 432
oxidation number of, 151
paramagnetism of, 427, 432
partial pressure and altitude, 918
reaction with alkali metals, 970
reaction with alkanes, 1073
reaction with hemoglobin, 1033
reaction with hydrogen, 16
reaction with nitrogen, 685, 693
reaction with nitrogen monoxide, mechanism of, 649
reaction with sulfur, 74
toxicity of, 597
oxygen-15, in PET imaging, 1002
oxyhemoglobin, 1033
ozone, 72, 998
as disinfectant, 928
decomposition of, mechanism, 644
depletion in stratosphere, 922
fractional bond order of, 390
in atmosphere, 921–923
molecular orbital configuration of, 434
reaction with nitrogen monoxide, 677
resonance structures of, 365
solar radiation absorbed by, 918

p orbital(s). *See* **atomic orbital(s)**.
packing, in crystal lattice, 533
paint
transition metal pigments in, 1022
white lead in, 929, 1007
pairing energy The additional potential energy due to the electrostatic repulsion between two electrons in the same orbital, 1045
palladium
coordination complexes of, 1046
in catalytic converter, 943
para position, 1080
paramagnetism The physical property of being attracted by a magnetic field, 325, *326*, 432, 1046
of transition metal ions, 1023
parent ion, in mass spectra, *100*
Parkinson's disease, 1103
partial charge(s) The charge on an atom in a molecule or ion calculated by assuming sharing of the bonding electrons proportional to the electronegativity of the atom, 379
partial pressure(s) The pressure exerted by one gas in a mixture of gases, 465
in equilibrium constant expression, 676, 729
particle accelerator, 1166
particulate level Representations of chemical phenomena in terms of atoms and molecules; also called submicroscopic level, 7
partition chromatography, 516
parts per million (ppm), 567
pascal (Pa) The SI unit of pressure; 1 Pa = 1 N/m^2, 452, A-7, A-11
passive diffusion, through cell membrane, 1136
path length, light absorption and, 205
Pauli, Wolfgang, 311
Pauli exclusion principle No two electrons in an atom can have the same set of four quantum numbers, 311–312
molecular orbitals and, 428
Pauling, Linus
and electronegativity, 380, 398
and theory of resonance, 366
and valence bond theory, 413
p-block elements, 318
molecular orbitals involving, 431
pentane, structural isomers of, 1070
pentanol, isomers of, 1084–1085
pentenes, isomers of, 1075–1076
pentose, 1125
peptide bond, 1118
peptide linkage, 1094
percent abundance The percentage of the atoms of a natural sample of the pure element represented by a particular isotope, 62
percent composition The percentage of the mass of a compound represented by each of its constituent elements, 93
percent error The difference between the measured quantity and the accepted value, expressed as a percentage of the accepted value, 35
percent yield The actual yield of a chemical reaction as a percentage of its theoretical yield, 180–182
perchlorate ion, 83
perchlorates, 1005
perchloric acid, 1004
periodic table of the elements, 10, 66–74, 960–965
electron configurations and, *315*
historical development of, 70
ion charges and, 78–80
metallic character in, 961
periodicity
of atomic orbital energies, 322
of atomic radii, 328
of chemical properties, 70, 337–339
of electron affinity, 334
of electron attachment enthalpy, 333
of electronegativity, 380, *380*
of enthalpy of fusion, *549*
of ionic radius, 335
of ionization energy, 331
periods The horizontal rows in the periodic table of the elements, 66
Perkin, William, 439
permanganate ion
as oxidizing agent, 154t
reaction with iron(II) ion, 155, 202

perovskite, crystal structure of, 535
peroxides, 970
  oxidation number of oxygen in, 152
peroxyacyl nitrates (PANs), 920
perspective formula, 1067
pertechnetate ion, 1179
pet food, adulteration of, 516
petroleum, 937
  chemistry of, 938
pH The negative of the base-10 logarithm of the hydrogen ion concentration; a measure of acidity, 194–196, 712–714
  calculating
    after acid–base reaction, 734
    from equilibrium constant, 682–686
    polyprotic acids and bases, 735
    salts, 732–733
    weak acids, 728, 732–733
  calculating equilibrium constant from, 727
  change in, during acid–base titration, 772
  common ion effect and, 761–763
  in buffer solutions, 763–771
  of blood, 800
  of ocean, 945
  standard in biochemical reactions, 843
  zwitterions and, 1118
pH indicator(s), 780–782
pH meter, *194*, 195, *762*, 888
phase
  of atomic orbitals, 431
phase change
  as spontaneous process, 816
  heat transfer in, 236
  tin disease, 555
phase diagram A graph showing which phases of a substance exist at various temperatures and pressures, 551–553
phenanthroline, as ligand (phen), 1031
phenol, structure of, 1080
phenolphthalein, structure of, *781*
phenyl group, stable free radical and, 696
phenylalanine, structure of, *1119*
Philosopher's Stone, 990
phosgene
  molecular polarity of, 385
  reaction with bisphenol A, 1105
phosphate ion
  buffer solution of, 764t
  in biological buffer system, 800
  resonance structures of, 370
phosphate rock, 995, 999
phosphates
  solubility in strong acids, 791
  water pollution by, 928
phosphine, 77, 994
  rate of decomposition of, 613
phosphodiester group, in nucleic acids, 1128
phosphoenolpyruvate (PEP), 843
phospholipids, 1135
phosphoric acid
  as polyprotic acid, 711t, 719
  reaction with acetate ion, 723
  uses of, 996
phosphorothioate group, 1140
phosphorous acid, 996t
phosphorus
  abundance of, 989
  allotropes of, 72, 989
  chemistry of, 994–997
  coordinate covalent bonds to, 369
  discovery of, 990
  hydrides of, 994
  oxides of, 994–995
  reaction with chlorine, 123, *124*, 173
  reaction with oxygen, 125
  removed from pig iron, 1028
  sulfides of, 994–995
phosphorus-32
  as radioactive tracer, 1176
  production of, 1167
phosphorus oxoacids, 995
phosphorus pentachloride, decomposition of, 683
photocell, *281*
photochemical smog, 920
photoelectric effect The ejection of electrons from a metal bombarded with light of at least a minimum frequency, 281
photoelectron spectroscopy
  ionization energy determined by, 333
  molecular orbital energy determined by, 438
photolysis, flash, 653
photon(s) A "particle" of electromagnetic radiation having zero mass and an energy given by Planck's law, 282
photosynthesis, 920, 941, 1139
phthalic acid, buffer solution of, 764t
physical change A change that involves only physical properties, 15–16
physical properties Properties of a substance that can be observed and measured without changing the composition of the substance, 12–15
  temperature dependence of, 13
pi (π) bond(s) The second (and third, if present) bond in a multiple bond; results from sideways overlap of *p* atomic orbitals, 421
  in benzene, 435
  in ozone, 435
  molecular orbital view of, 431
picometer, 31
pig iron, 1027
pigments
  green chemistry of, 439
  transition metals in, 1022
pitchblende, 68, 1152
pK_a The negative of the base-10 logarithm of the acid ionization constant, 719
  at midpoint of acid–base titration, 774
  pH of buffer solution and, 766
planar node. *See* **atomic orbital(s)** and **nodal plane**.
Planck, Max, 280
Planck's constant (*h*) The proportionality constant that relates the frequency of radiation to its energy, 280, 284, A-13t
Planck's equation, 279–281
plasma A gas-like phase of matter that consists of charged particles, 1172
plaster of Paris, 85
plastic(s). *See also* **polymer(s)**.
  types of, 1096
plastic sulfur, 998
platinum
  coordination complexes of, 1046
  in catalytic converter, 943
  in cisplatin, 1053
  in oxidation of ammonia, *178*
platinum electrode, 869
platinum group metals, 1025
platinum hexafluoride, as oxidizing agent, 1007
Plexiglas, 1098t
plotting. *See* graph(s).
plutonium, 1168, 1171
plutonium-239, fission of, 1171
plywood, adhesives in, 1104
pOH The negative of the base-10 logarithm of the hydroxide ion concentration; a measure of basicity, 714
poisoning
  arsenic, 103
  carbon monoxide, 1033
  hydrogen sulfide, 999
  mercury, 929
  methanol, 1083
polar covalent bond A covalent bond in which there is unequal sharing of the bonding electron pair, 379
polarity
  bond, 379–381
  molecular, 384–389, 400t
    intermolecular forces and, 492–494
    miscibility and, 569, 1085
    solubility of carboxylic acids and, 1091
  of α-amino acids, 1118, *1119*
polarizability The extent to which the electron cloud of an atom or molecule can be distorted by an external electric charge, 502
polarized light, rotation by optical isomers, 1040, *1040*, 1067, 1125
polonium, 68, 72
  abundance of, 997
  from decay of uranium, 1152
polyacrylonitrile, 1098t

polyamide(s) A condensation polymer formed by elimination of water between two types of monomers, one with two carboxylic acid groups and the other with two amine groups, 1101
polyatomic ion(s) An ion consisting of more than one atom, 80
names and formulas of, 80t
oxidation numbers in, 152
polycarbonate, synthesis of, 1105
polydentate ligands, 1031
polydimethylsiloxane, 988
polyester(s) A condensation polymer formed by elimination of water between two types of monomers, one with two carboxylic acid groups and the other with two alcohol groups, 1100
polyethylene, 1095, 1098t
types of, 1096
polyethylene terephthalate (PET), 1100
recycling, 1101
polyisoprene, all-*cis,* 1099
polylactic acid (PLA), 1100–1101
polymer(s) A large molecule composed of many smaller repeating units, usually arranged in a chain, 1095–1102
addition, 1096–1099
classification of, 1095–1096
condensation, 1096, 1099–1102
osmotic pressure of, 585, 586
silicone, 988
polymerase chain reaction (PCR), 1141
polymethyl methacrylate, 1098t
polypeptide, 1118
polypropylene, 928, 1098t
polyprotic acid(s) A Brønsted acid that can donate more than one proton, 710
acid–base properties of, 721
ionization constants of, 719
pH of, 735
titration of, 777
polyprotic base(s) A Brønsted base that can accept more than one proton, 711
pH of, 735
polysaccharide(s) A polymer in which the monomers are sugar molecules, 1123, 1126, *1127*
polystyrene, 1096, 1098t, 1098
polytetrafluoroethylene, 1098t
polyvinyl acetate (PVA), 1097, 1098t
polyvinyl alcohol, 1097
polyvinyl chloride (PVC), 1096, 1096t
polyvinylidene fluoride, 928
popcorn, percent yield of, *182*
porphyrin, 1033
Portland cement, 977, 986
positron(s) A nuclear particle having the same mass as an electron but a positive charge, 1154
emitters of, 1175
predicting emission of, 1157
positron emission tomography (PET), 1175
potassium
absorption by plants, 969
abundance of, 968
preparation of, 969
salts of, in fireworks, 299
potassium aluminum sulfate, as coagulant, 927
potassium chlorate
decomposition of, 998
in matches, 995
potassium dichromate, 191
oxidation of alcohol by, *1088*
potassium dihydrogen phosphate, crystallization of, *578*
potassium fluoride
dissolution of, 571
electrolysis of, 1000
potassium ions, pumping in cells, 1138
potassium nitrate, 972–973
in gunpowder, 258
potassium perchlorate, 1005
potassium permanganate, 189
absorption spectrum of, *206*
dissolution of, 821
in redox titration, 202
oxidation of alcohol by, 1088
reaction with iron(II) ion, 863
potassium superoxide, 970
molecular orbital configuration of, 433
potential, of electrochemical cell, 876–884
potential energy The energy that results from an object's position, 18
bond formation and, 413
of electron in hydrogen atom, 284
potential ladder, *879*
pounds per square inch (psi), as pressure unit, 452, A-7t
power The amount of energy delivered per unit time, A-7
powers, on calculator, 41, A-4
precipitate A water-insoluble solid product of a reaction, usually of water-soluble reactants, 135
gelatinous, 593
precipitation reaction(s) An exchange reaction that produces an insoluble salt, or precipitate, from soluble reactants, 135–139, 156, 782–792
solubility product constant and, 792–794
precision The agreement of repeated measurements of a quantity with one another, 34
prefixes
for ligands, 1036
for organic substituent groups, 1072
for SI units, 29, 30t, A-11
pressure The force exerted on an object divided by the area over which the force is exerted, 451
atmospheric, altitude and, 476, A-7
constant, calorimetry at, 247
critical, 513
effect on solubility, 574
gas, volume and, 453
of atmosphere, 919
partial. *See* **partial pressure**.
relation to boiling point, 513
standard, 460
units of, 452, A-7
vapor. *See* **vapor pressure**.
pressure–volume work, 241
Priestley, Joseph, 124
primary alcohols, 1088
primary amines, 1086
primary battery, 871
primary colors, 1049
primary standard A pure, solid acid or base that can be accurately weighed for preparation of a titrating reagent, 200
primary structure, of protein, 1121
primer, in polymerase chain reaction, 1141
primitive cubic (pc) unit cell, 529
principal quantum number, 285, 293
probability
diffusion and, 820–821
in quantum mechanics, 292
probability density The probability of finding an atomic electron within a given region of space, related to the square of the electron's wavefunction, 292, 295
problem solving strategies, 45–47
Problem Solving Tip
balanced equations and equilibrium constants, 688
balancing equations in basic solution, 865
balancing oxidation–reduction equations, 864
buffer solutions, 770
calculating ΔT, 235
choosing the central atom in a dot structure, 359
concepts of equilibrium, 672
concepts of thermodynamics, 816
determining a rate equation, 621
determining strong and weak acids, 716
drawing structural formulas, 1072
electrochemical conventions for voltaic cells and electrolysis cells, 892
entropy-favored processes, 823
finding empirical and molecular formulas, 95
formulas for ions and ionic compounds, 84
ligand field theory, 1048
multiple bond formation, 425
naming aldehydes, ketones, and carboxylic acids, 1090

Problem Solving Tip—*continued*
pH during acid–base reaction, 780
pH of equal molar amounts of acid and base, 733
preparing a solution by dilution, 192
reactions with a limiting reactant, 181
recognizing gas-forming reactions, 148
relating rate equations and reaction mechanisms, 652
stoichiometry calculations, 175
stoichiometry calculations involving solutions, 196
using a calculator, 41
using Hess's law, 253
using the quadratic formula, 686
writing net ionic equations, 138
product(s) A substance formed in a chemical reaction, 15, 123
effect of adding or removing, 690–691
heat as, 693
in equilibrium constant expression, 674
rate of concentration change, 612
product-favored reaction(s) A reaction in which reactants are completely or largely converted to products at equilibrium, 130, 257–258
equilibrium constant for, 677
predicting, 833
proline, structure of, *1119*
promethium, 1168
propagation step, in chain reaction, 651, 1170
propane
as fuel, 939
combustion of, balanced equation for, 126
enthalpy of combustion, 246
percent composition of, 93
structure of, 1066
1,2,3-propanetriol, 1084
propanoic acid, as weak acid, 718
propanol, isomers of, 1083
2-propanol, structure of, 394
propene, 623, 1074
hydrogenation of, 393
reaction with bromine, 1078
propionic acid, 1091t
proportionality constant, 454, 469
proportionality symbol, 616
propyl alcohol, 1083
propyl propanoate, 1095
propylene, 1074
protein(s) A polymer formed by condensation of amino acids, sometimes conjugated with other groups, 1117–1124
as emulsifying agent, 594
drawing structures of, 1120
energy content of, 34
molar masses of, 1120
structural levels of, 1121
synthesis, DNA and, 1131–1133
testing food for, 516
protium, 62, 965
proton(s) A positively charged subatomic particle found in the nucleus, 59
bombardment with, 1166
donation by Brønsted acid, 142, 710
nuclear stability and, 1156
proton exchange membrane (PEM), 875
Prussian blue, 1022
pseudo-first-order reaction, 618
p-type semiconductor, 543
pufferfish, 709
pure substance A form of matter that cannot be separated into two different species by any physical technique, and that has a unique set of properties, 7–8
purification
of mixtures, 9
of water, 927
putrescine, 1087
pyrite, iron, 11
pyrometallurgy Recovery of metals from their ores by high-temperature processes, 1026
pyrophosphoric acid, 996t
pyroxenes, structure of, 986

quadratic equations, A-4
quadratic formula, use in concentration problems, 683–686
qualitative information Nonnumerical experimental observations, such as descriptive or comparative data, 3, 29
quantitative analysis, 183
quantitative information Numerical experimental data, such as measurements of changes in mass or volume, 3, 29
quantity, of pure substance, 87
quantization
of electron spin, 297
of electron's potential energy, 284, 291
Planck's assumption of, 279–281
quantum mechanics A general theoretical approach to atomic behavior that describes the electron in an atom as a matter wave, 291–294
quantum number(s) A set of numbers that define the properties of an atomic orbital, 292–293
allowed values of, 293, 294t
angular momentum, 293
magnetic, 293
Pauli exclusion principle and, 311–312
principal, 285, 293
spin, 297–299
quartz, 984
structure of, *546*
synthesis of, 985
quaternary structure, of protein, 1122

rad A unit of radiation dosage, 1172
radial distribution plot, atomic orbital, *295*, 295
radiation
background, 1173
cancer treatment with, 1176
cosmic, 1174
electromagnetic, 277
health effects of, 1172–1174
treatment of food with, 1177
units of, 1172–1173
radiation absorbed dose (rad), 1172
radioactive decay series A series of nuclear reactions by which a radioactive isotope decays to form a stable isotope, 1151–1153
radioactivity
discovery of, 68
natural, 1149–1150
radiocarbon dating, 1164
radioisotopes, uses in medical procedures, 1175t
radium, 67
abundance of, 973
from decay of uranium, 1152
radius
atomic, 328
covalent, 329
ionic, 335, 550
radon
abundance of, 1006
from decay of uranium, 1152
radioactive half-life of, 629
radon-222, radioactive half-life, 1163
radura, on packages of irradiated food, *1177*
Ramsay, Sir William, 103, 695
Raoult's law The vapor pressure of the solvent is proportional to the mole fraction of the solvent in a solution, 577
rare earth elements. *See* **lanthanide(s)**.
rare gas(es). *See* **noble gas(es)**.
Raschig reaction, 648, 991
rate. *See* **reaction rate(s)**.
rate constant (*k*) The proportionality constant in the rate equation, 616
Arrhenius equation for, 635
calculating, 618
for radioactivity, 1163
half-life and, 627
units of, 618
rate-determining step The slowest elementary step of a reaction mechanism, 647
rate equation(s) The mathematical relationship between reactant concentrations and reaction rate, 616
determining, 618
first-order, nuclear, 1163
for elementary step, 643
graphical determination of, 626

integrated, 622–630
for nuclear decay, 1163
reaction mechanisms and, 646–652
stoichiometry and, 631
rate law. *See* **rate equation(s)**.
Rayleigh, Lord (John William Strutt), 103
reactant(s) A starting substance in a chemical reaction, 15, 123
concentration of, reaction rate and, 616–621
effect of adding or removing, 690–691
heat as, 693
in equilibrium constant expression, 674
rate of concentration change, 612
reactant-favored reaction(s) A reaction in which only a small amount of reactants is converted to products at equilibrium, 130, 257–258
equilibrium constant for, 677
predicting, 830
reaction(s) A process in which substances are changed into other substances by rearrangement, combination, or separation of atoms, 15. *See also* under element, compound, or chemical group of interest.
(n, γ), 1167
acid–base, 144–146. *See also* **acid–base reaction(s)**.
addition, 1077
autoionization, 712
chain, 651, 1141, 1170
condensation, 1099, 1118, 1125
coupling of, 843
decomposition, 156
direction of, reaction quotient and, 678
disproportionation, 1004
electron transfer, 858–903. *See also* **oxidation–reduction reaction(s)**.
enthalpy change for, 245–247, 255
enzyme-catalyzed cleavage, 1124
esterification, 927
exchange, 135, 156
free energy change for, 831
gas-forming, 147–148, 156
gas laws and, 464
hydrogenation, 393
hydrolysis, 1092
in aqueous solution, 132
stoichiometry of, 196–203
types of, 155–158
moles of, 181, 245, 613
neutralization, 144, 726
neutron capture, 1167
nuclear, 1150–1155
artificial, 1166–1168
rates of, 1160–1165
order of. *See* **reaction order.**
oxidation of alcohols, 1088
oxidation of organic compounds, 1069
oxidation–reduction, 149–155. *See also* **oxidation–reduction reaction(s)**.
precipitation, 135–139, 156, 782–792
solubility product constant and, 792–795
product-favored vs. reactant-favored, 130, 257–258, 677
predicting, 833
proton transfer. *See* **acid–base reaction(s)**.
Raschig, 991
rate of. *See* **reaction rate(s)**.
reduction of aldehydes and ketones, 1089
reduction of carboxylic acids, 1091
reverse, equilibrium constant expression for, 687
reversibility of, 128, 671
spontaneity of, predicting, 825–829
standard enthalpy of, 245
standard reduction potentials of, 880, 881t
substitution, 645, 1081
sum of, equilibrium constant expression for, 688
synthesis, 156
thermite, 173
transesterification, 1100
water–gas, 940, 967
reaction coordinate diagram, 632, 634
reaction intermediate A species that is produced in one step of a reaction mechanism and completely consumed in a later step, 639
identification of, 654
in rate equation, 649
reaction mechanism(s) The sequence of events at the molecular level that control the speed and outcome of a reaction, 609, 642–652
effect of catalyst on, 638
free-radical chain reaction in, 651
initial equilibrium step in, 649–651
rate-determining step of, 647
rate equation and, 646–652
verification of, 654
reaction order The exponent of a concentration term in the reaction's rate equation, 617
determining, 626
molecularity and, 644
reaction quotient (*Q*) The product of concentrations of products divided by the product of concentrations of reactants, each raised to the power of its stoichiometric coefficient in the chemical equation, 677. *See also* **equilibrium constant**.
calculating free energy change from, 833
Gibbs free energy change and, 832–833
relation to cell potential, 885
solubility product constant and, 792
reaction rate(s) The change in concentration of a reagent per unit time, 608–654
Arrhenius equation and, 635
average versus instantaneous, 611
catalysts and, 638–641
collision theory of, 631–641
conditions affecting, 614–615
effect of concentration, 631
effect of molecular orientation, 634, 635
effect of temperature, 633
expression for. *See* **rate equation(s)**.
initial, 618
radioactive disintegration, 1160–1165
stoichiometry and, 613
receptor proteins, 1136
rechargeable battery, 871, 873
recycling, 933
redox reaction(s). *See* **oxidation–reduction reaction(s)**.
reducing agent(s) The substance that donates electrons and is oxidized in an oxidation–reduction reaction, 149–150, 859
relative strengths of, 882, 882–883
reduction The gain of electrons by an atom, ion, or molecule, 149
at cathode of electrochemical cell, 866, 892
half-reaction for, 860
reduction potential(s), standard, 880, 881t, A-32
reduction reaction(s)
of aldehydes and ketones, 1089
of carboxylic acids, 1091
reformation, in petroleum refining, 938
relative atomic mass The ratio of the average mass per atom of an element to 1/12 of the mass of an atom of ^{12}C, 60. *See also* **atomic weight**.
rem A unit of radiation dosage to biological tissue, 1173
renewable resources, 932, 941
replication, of DNA, 1129
resin, in ion exchanger, 950
resonance, molecular orbital theory and, 434–435
resonance stabilization, 1081
resonance structure(s) The possible structures of a molecule for which more than one Lewis structure can be written, differing by the number of bond pairs between a given pair of atoms, 365–368
amides, 1094
benzene, 366, 425, 1080
carbonate ion, 366
effect on acid strength, 739
nitrate ion, 366
ozone, 365
resources, energy, 931
respiration, 1138, 1139
production of ATP by, 843
respiratory alkalosis and acidosis, 800
reverse osmosis The application of pressure greater than the osmotic pressure of impure solvent to force solvent through a semipermeable membrane to the region of lower solute concentration, 585, 928

reversibility
equilibrium and, 671
of chemical reactions, 128
reversible process A process for which it is possible to return to the starting conditions along the same path without altering the surroundings, 818
rhodochrosite, *783*, 787
rhubarb, oxalic acid in, 1090t
ribonucleic acid, 1127
hydrogen bonding in, 500
ribose, 1124, 1125, *1128*
ribosome, 1131
ring structure
in benzene, 425–426
in glucose, 1125
Ritz-Paschen series, 289
rms speed. *See* **root-mean-square speed**.
RNA. *See* ribonucleic acid.
Roberts, Nicolas-Louis, *459*
rock salt crystal structure, 535
rocket, fireworks, *300*
roentgen A unit of radiation dosage, 1172
Wilhelm, 1172
roentgen equivalent man (rem), 1173
Roman numerals, in names of cations, 83
root-mean-square (rms) speed The square root of the average of the squares of the speeds of the molecules in a sample, 469
roots, on calculator, 41, A-4
rose, reaction with acid and base, *140*
rose petals, pigment as indicator, *780*
Rosenberg, Barnett, 1053
rotation
around bonds in alkanes, 1070
around peptide bonds in proteins, 1118–1119
around sigma and pi bonds, 424, 1067
of polarized light, 1040, *1040*, 1067, 1125
rounding off, 41
ROY G BIV, 1049
rubber
isoprene in, 1099
natural and synthetic, 1098–1099
styrene-butadiene, 1099
vulcanized, 1099
rubidium
abundance of, 968
isotope ratio of, 1179
ruby
ion charges in, 81
synthetic, 982
rust, 899. *See also* iron(III) oxide.
reaction with oxalic acid, 1032
Rutherford, Ernest, 59, 69, 1149, 1166
Rydberg, Johannes, 284
Rydberg constant, 284, A-13t
s orbital(s). *See* **atomic orbital(s)**.
saccharin, structure of, 1079
Sacks, Oliver, 1103
sacrificial anode, 903
safety match, 995
salad dressing, as emulsion, 594
salicylic acid, 182, 1092
salt(s) An ionic compound whose cation comes from a base and whose anion comes from an acid, 141
acid–base properties of, 720
calculating pH of aqueous solution, 732
concentration in sea water, 209, 926
electrolysis of, 893
hydrated, bonding in, 497
insoluble, precipitation of, 792–795
solubility of, 782–791
solubility product constants of, 784t
salt bridge A device for maintaining the balance of ion charges in the compartments of an electrochemical cell, 867
saltpeter, 968. *See also* sodium nitrate.
in gunpowder, 258
salvarsan, in syphilis treatment, 103
samarium, in permanent magnets, 338
sapphire, 343, 982
sarin, 746
saturated compound(s) A hydrocarbon containing only single bonds, 1069. *See also* **alkanes**.
saturated fatty acids, 1134–1135
saturated solution(s) A stable solution in which the maximum amount of solute has been dissolved, 568, 783
reaction quotient in, 792
saturation state (Ω), 947
s-block elements, 318
scanning electron microscopy (SEM), 32
Scheele, Carl Wilhelm, 124, 1000–1001
Schrödinger, Erwin, 291
science
goals of, 4
methods of, 1–4
scientific notation, A-2
operations in, 38
Scott, Robert, 555
screening, of nuclear charge, 314
scrubber, in coal-fired power plant, 934
sea level, rising, 927
sea urchin, 19
sea water
density of, 43
desalination by reverse osmosis, 585, 928
gold in, 926
halogens in, 1000
ion concentrations in, 926t
magnesium in, 974
pH of, 194, 945, 947
salt concentration in, 209, 926
sodium and potassium ions in, 969
Seaborg, Glenn T., *1166*
seaweed, iodine in, 1001
second, definition of, A-10
second law of thermodynamics The total entropy of the universe is continually increasing, 817
secondary alcohols, 1088
secondary amines, 1086
secondary battery, 871
secondary colors, 1049
secondary structure, of protein, 1121
second-order reaction, 617
half-life of, 628
integrated rate equation, 625
seesaw molecular geometry, 376, *377*
selenium
abundance of, 997
uses of, 998
semiconductor(s) Substances that can conduct small quantities of electric current, 542–544
band theory of, 542
semimetals. *See* **metalloid(s)**.
semipermeable membrane A thin sheet of material through which only certain types of molecules can pass, 584
serial dilution, 193
serine, structure of, *1119*
setae, on gecko's toes, 505
shell, electron, 293
SI Abbreviation for Système International d'Unités, a uniform system of measurement units in which a single base unit is used for each measured physical quantity, 29, A-10
sickle cell anemia, 1122
sievert The SI unit of radiation dosage to biological tissue, 1173
sigma (σ) bond(s) A bond formed by the overlap of orbitals head to head, and with bonding electron density concentrated along the axis of the bond, 414
in molecular orbital theory, 427
sign conventions
for electron affinity, 332
for energy calculations, 241t
for voltaic cells, 866, *867*
significant figure(s) The digits in a measured quantity that are known exactly, plus one digit that is inexact to the extent of ±1, 38–40
in molar masses, 88
logarithms and, A-3
silica, 984
silica gel, 985
silicates
minerals containing, 985
structure of, 545
silicon
abundance of, 984
as semiconductor, 543

bond energy compared to carbon, 1068
chemistry of, 983–988
compounds of, 72
electron configuration of, 319
purification of, 984
similarity to boron, 976
silicon carbide, crystal structure of, 557
silicon dioxide, 985
reaction with hydrogen fluoride, 1003
silicon tetrachloride, 984
molecular geometry of, 374
silicone polymers, 988
Silly Putty, 988
silt, formation of, *593*
silver acetate, solubility of, 788
silver bromide
solubility of, 783
solubility of, in aqueous thiosulfate ion, 799
silver chloride
free energy change of dissolution, 838
K_{sp} of, 891
solubility of, 786, 793
in aqueous ammonia, 688, 798
silver chromate
formation by precipitation, 136
solubility of, 209, 787, 789
silver nitrate, reaction with potassium chloride, 135, 137
silver oxide battery, 872
simple cubic (sc) unit cell, 529
single bond A bond formed by sharing one pair of electrons; a sigma bond, 414
slag, in blast furnace, 1028
slaked lime, 147, 976
in water purification, 927
slime, *1097*
slope, of straight line graph, 45, 611, 626
Smalley, Richard, 930
smog, 943
photochemical, 920
soap A salt produced by the hydrolysis of a fat or oil by a strong base, 594
hard water and, 950
soapstone, 973
soda ash. *See* sodium carbonate.
Soddy, Frederick, 1150
sodium
abundance of, 968
preparation of, 969
reaction with chlorine, 2, 352
reaction with water, *4*
salts of, in fireworks, 299
sodium acetate
calculating pH of aqueous solution, 732
in heat pack, 569
sodium azide, in air bags, 477
sodium bicarbonate, 971. *See also* sodium hydrogen carbonate.
reaction with acetic acid, 723
sodium borohydride, 981
as reducing agent, 1089
sodium bromide, bromine production from, 1001
sodium carbonate, 190, 971
calculating pH of aqueous solution, 736
primary standard for acid–base titration, 199
sodium chloride
as strong electrolyte, 132
composition of, 2, 11
crystal lattice of, 85, 534
electrolysis of, 464, 893, 969, *971*
enthalpy of solution, 570
entropy of solution process, 826
lattice enthalpy calculation for, 538
melting ice and, 589
oxidation by dichromate ion, 1001
reaction with sulfuric acid, 1004
standard molar enthalpy of formation of, 255
structure of, *528*
sodium cyanide, extraction of gold with, 799–800
sodium halides, aqueous, products of electrolysis of, 896
sodium hydrogen carbonate
reaction with citric acid, 156
reaction with tartaric acid, 148
sodium hydroxide
enthalpy of solution, 570
production of, 970–971, 1000
reaction with acetic acid, 144
reaction with aluminum, 968
reaction with formic acid, 726
reaction with hydrogen chloride, 144
reaction with nitric acid, 144
titration of acetic acid with, 774–777
titration with hydrochloric acid, 772
sodium hypochlorite, 208
as disinfectant, 928
in bleach, 567
reaction with ammonia, 991
sodium iodide, aqueous, electrolysis of, 894
sodium ions
in ion exchanger, 950
pumping in cells, 1138
sodium laurylbenzenesulfonate, structure of, 595
sodium monofluorophosphate, in toothpaste, 976
sodium monohydrogen phosphate, 996
sodium nitrate, 971
sodium perchlorate, 1005
sodium peroxide, 970
sodium phosphate, 996
sodium silicate, 985
sodium stearate, as soap, 594
sodium sulfate
quantitative analysis of, 183–184
reaction with barium chloride, 138
sodium thiosulfate, reaction with iodine, 208
sol A colloidal dispersion of a solid substance in a fluid medium, 592
solid(s) The phase of matter in which a substance has both definite shape and definite volume, 6
amorphous, 546
chemistry of, 526–563
concentration of, in equilibrium constant expression, 674
dissolution in liquids, 570
ionic, 534–536
molecular, 544
network, 545
types of, 545t
solubility The concentration of solute in equilibrium with undissolved solute in a saturated solution, 568
common ion effect and, 788–789
estimating from solubility product constant, 786–788
factors affecting, 574–578
intermolecular forces and, 496, 571
of complex ions, 796–799
of gases in water, 502t
of ionic compounds in water, 133
of salts, 782–792
temperature and, 576–577
undissociated salt and, 789
solubility product constant (K_{sp}) An equilibrium constant relating the concentrations of the ionization products of a dissolved substance, 783
calcium carbonate, 946
calculating free energy change from, 839
reaction quotient and, 792–793
standard potential and, 891
values of, A-23
solute The substance dissolved in a solvent to form a solution, 131
solution(s) A homogeneous mixture in a single phase, 7–9, 131, 564–597
acidic and basic, redox reactions in, 861–865
aqueous, balancing redox equations, 861–865
pH and pOH of, 194–196, 714
reactions in, 130
boiling process in, 579–580
buffer. *See* **buffer solution(s)**.
concentrations in, 188–193
enthalpy of, 570–574
ideal, 577
osmosis in, 584
process of forming, 568–574
Raoult's law, 577
saturated, 568
supersaturated, 569
solvation
effect on acid strength, 741
enthalpy of, 493
Solvay process, 971
solvent The medium in which a solute is dissolved to form a solution, 131, 565
soy protein, adhesive made from, 1104
space-filling models, 76, 1067
spatulae, on gecko's toes, 505

***spdf* notation** A notation for the electron configuration of an atom in which the number of electrons assigned to a subshell is shown as a superscript after the subshell's symbol, 293, 317

specific heat capacity (*C*) The quantity of heat required to raise the temperature of 1.00 g of a substance by 1.00 kelvin, 231–237
  hydrogen bonding and, 500
  values of, A-13t

spectator ion(s) An ion that is present in a solution in which a reaction takes place, but that is not involved in the net process, 137

spectrochemical series An ordering of ligands by the magnitudes of the splitting energies they cause, 1050–1054

spectrometer, mass, 62–63

spectrophotometer, *205*

spectrophotometry An analytical method based on the absorption and transmission of specific wavelengths of light, 203–207

spectroscopy, photoelectron, 333

spectrum
  absorption, 204, 1050
  electromagnetic, *278*, 1049
    continuous, *278*, *280*, 283–284
    line, 283
    of heated body, 279
  solar, *300*

speed(s)
  of gas molecules, 468
  of wave, 277

spin, electron, 297

sponge, skeletal structure of, 31, *32*

spontaneous reaction, 815. *See also* **product-favored reaction(s)**.
  effect of temperature on, 829
  Gibbs free energy change and, 830
  relation to enthalpy and entropy, 828t

square planar molecular geometry, 378, *378*, 1037
  optical isomerism and, 1041

square pyramidal molecular geometry, *377*, 378

stability, nuclear, band of, 1156
  of organic compounds, 1068
  standard enthalpy of formation and, 254

stabilization, resonance, 1081

stainless steel, 1028

stalactites and stalagmites, 128

standard atmosphere (atm) A unit of pressure; 1 atm = 760 mm Hg, 452, A-7

standard conditions In an electrochemical cell, all reactants and products are pure liquids or solids, or 1.0 M aqueous solutions, or gases at a pressure of 1 bar, 877. *See also* **standard state**.

standard deviation A measure of precision, calculated as the square root of the sum of the squares of the deviations for each measurement from the average, divided by one less than the number of measurements, 36

standard entropy change of reaction ($\Delta_r S°$) The sum of the standard molar entropies of the products, each multiplied by its stoichiometric coefficient, minus the sum of the standard molar entropies of the reactants, each multiplied by its stoichiometric coefficient, 824

standard free energy change of reaction ($\Delta_r G°$) The free energy change for a reaction in which all reactants and products are in their standard states, 831
  cell potential and, 889
  relation to equilibrium constant, 838

standard hydrogen electrode (SHE), 878
  zero voltage assigned to, 879

standard molar enthalpy of formation ($\Delta_f H°$) The enthalpy change of a reaction for the formation of one mole of a compound directly from its elements, all in their standard states, 254, 816
  enthalpy of solution calculated from, 573
  values of, A-25

standard molar enthalpy of fusion ($\Delta_{fus} H°$) The quantity of heat required to convert 1 mol of a solid to a liquid at 1 bar and constant temperature, 246

standard molar enthalpy of vaporization ($\Delta_{vap} H°$) The quantity of heat required to convert 1 mol of a liquid to a gas at 1 bar and constant temperature, 246, 502t, 509

standard molar entropy ($S°$) The entropy of a substance in its most stable form at a pressure of 1 bar, 821
  values of, A-25

standard molar free energy of formation ($\Delta_f G°$) The free energy change for the formation of one mole of a compound from its elements, all in their standard states, 833
  values of, A-25

standard molar volume The volume occupied by 1 mol of gas at standard temperature and pressure; 22.414 L, 460

standard potential ($E°$cell) The potential of an electrochemical cell measured under standard conditions, 878
  calculation of, 879
  equilibrium constant calculated from, 890

standard reaction enthalpy ($\Delta_r H°$) The enthalpy change of a reaction that occurs with all reactants and products in their standard states, 245
  product-favored vs. reactant-favored reactions and, 257–258

standard reduction potential(s), 880, 881t
  of halogens, 1001t
  of transition metals, 1023
  values of, A-32

standard state The most stable form of an element or compound in the physical state in which it exists at 1 bar and the specified temperature, 245, 816
  in biochemical reactions, 843

standard temperature and pressure (STP) A temperature of 0 °C and a pressure of exactly 1 atm, 460

standardization The accurate determination of the concentration of an acid, base, or other reagent for use in a titration, 200

standing wave A single-frequency wave having fixed points of zero amplitude, 291

Staphylococcus aureus, 1052

starch, 1126, *1127*

starch-iodide paper, 208

state(s), 6
  changes of, 236
  ground and excited, 285, 1151
  physical, entropy and, 824
    in chemical equations, 123–124
    of matter, 6, 491
    reaction enthalpy and, 245
  standard. *See* **standard state**.

state function A quantity whose value is determined only by the state of the system, 244, 816

stationary phase, in chromatography, 515

steam reforming, 940

stearic acid, 1090t

steel
  production of, 1028

stereoisomers Two or more compounds with the same molecular formula and the same atom-to-atom bonding, but with different arrangements of the atoms in space, 1067

sterilization
  by irradiation, 1177

Stern, Otto, 297

steroids, 1135

stibnite, 787

stoichiometric coefficients The multiplying numbers assigned to the species in a chemical equation in order to balance the equation, 125
  electrochemical cell potential and, 880
  exponents in rate equation vs., 617

fractional, 245
in calculating enthalpy of formation, 255
in equilibrium constant expression, 674, 687
stoichiometric factor(s) A conversion factor relating moles of one species in a reaction to moles of another species in the same reaction, 174, 464
in solution stoichiometry, 196
stoichiometry The study of the quantitative relations between amounts of reactants and products, 125
ICE table and, 674
ideal gas law and, 464
mass relationships in, 172–176
of reactions in aqueous solution, 196–203
rate equation of elementary step and, 643
rate equations and, 644
reaction rates and, 611
unit cell and, 528
storage battery, 873
STP. *See* **standard temperature and pressure**.
strained hydrocarbons, 1073
Strassman, Fritz, 1169
strategies, problem-solving, 45–47
stratosphere, 644, 918
strike anywhere match, 995
strong acid(s) An acid that ionizes completely in aqueous solution, 141, 715
reaction with strong base, 725
reaction with weak base, 726
titration of, 772
strong base(s) A base that ionizes completely in aqueous solution, 141, 715
strong electrolyte A substance that dissolves in water to form a good conductor of electricity, 132
strontium
abundance of, 973
isotope ratio of, 102, 1180
salts of, in fireworks, 299–300
strontium-90, radioactive half-life, 1161
structural formula A variation of a molecular formula that expresses how the atoms in a compound are connected, 75, 1067, 1072
structural isomers Two or more compounds with the same molecular formula but with different atoms bonded to each other, 1037, 1066
of alcohols, 1083
of alkanes, 1070
of alkenes, 1074
structure, molecular, 351
Strutt, John William (Lord Rayleigh), 103
styrene, structure of, 1080
styrene-butadiene rubber (SBR), 1099
Styrofoam, 1098t
Styron, 1098t
subatomic particles A collective term for protons, neutrons, and electrons, 59
properties of, 61t
sublimation The direct conversion of a solid to a gas, 240, 551
submicroscopic level Representations of chemical phenomena in terms of atoms and molecules; also called particulate level, 7
entropy at, 818
subscript, in chemical formula, 11
subshells
electron, 293
labels for, 293
number of electrons in, 312t
order of energies of, 313
substance(s), pure A form of matter that cannot be separated into two different species by any physical technique, and that has a unique set of properties, 7
substance(s), pure, amount of, 87
substituent group(s) A group of atoms attached to an organic molecule, replacing a hydrogen atom, 1072
common, A-16t
substitution reaction(s)
bimolecular, mechanism of, 645
of aromatic compounds, 1081
substrate, in enzyme-catalyzed reaction, 641, 1123
successive approximations, method of, 684, 731
successive equilibria, 796
succinic acid, reaction with 1,2-ethylenediamine, 1102
sucrose
as nonelectrolyte, 132
enthalpy of combustion, 246
half-life of decomposition, 629
structure of, 1125
sugar, dietary Calories in, *247*
sugar cane, biofuel from, 941
sulfate ion, resonance structures of, 370
sulfide(s)
in black smokers, 160
roasting of, 999
solubility of, 791
sulfonate group, in detergents, 595
sulfur
abundance of, 997
allotropes of, 72, 998
combustion of, 674
compounds with phosphorus, 994
electron configuration of, 320
in coal, 934, 999
in gunpowder, 258
in iron pyrite, 11
in vulcanized rubber, 1099
mining of, *145*
natural deposits of, 997
reaction with oxygen, 74, 126
removed from pig iron, 1028
sulfur dioxide
as Lewis acid, 743
as refrigerant, 922
production of, 999
reaction with oxygen, 564
reaction with water, 145
sulfur hexafluoride, 369
molecular orbitals in, 437
sulfur oxides, air pollution by, 999
sulfur tetrafluoride, molecular polarity of, 388
sulfur trioxide, 999
sulfuric acid
as polyprotic acid, 710
in lead storage battery, 873
production of, 999
properties and uses of, 145
reaction with calcium fluoride, 1003
reaction with calcium phosphate, 999
reaction with nickel(II) carbonate, 148
reaction with sodium chloride, 1004
reaction with water, 142
Sullivan, John H., 653
Sun, chemistry of, 300
sun protection factor (SPF), 299
sunscreens, 299
superacid(s), 746
superconductor(s) A material that has no resistance to the flow of electric current, 158
supercritical fluid A substance at or above the critical temperature and pressure, 514, 553
superoxide ion, molecular orbital configuration of, 433
superoxides, 970
oxidation number of oxygen in, 152
superphosphate fertilizer, 999
supersaturated solution(s) A solution that temporarily contains more than the saturation amount of solute, 569
reaction quotient in, 792
surface area
of colloid, 593
reaction rate and, 615
surface density plot, atomic orbital, *295*, 296
surface science, 474
surface tension The energy required to disrupt the surface of a liquid, 514
detergents and, 595
surfactant(s) A substance that changes the properties of a surface, typically in a colloidal dispersion, 594–595
surroundings Everything outside the system in a thermodynamic process, 230, 816
entropy change for, 825
suspension A distribution of solid particles within a solvent, which gradually separate and settle to the bottom of the container, 591
sustainability, 5–6

transfer RNA (tRNA), 1131
transition
between electron energy states, 287
d-to-*d*, 1050
transition elements Some elements that lie in rows 4 to 7 of the periodic table, comprising scandium through zinc, yttrium through cadmium, and lanthanum through mercury, 66, *58*, 73
transition elements
atomic radii, 330
cations formed by, 79
chemistry of, 1020–1054
electron configurations of, 321, 324, 1023, 1023t
electron configurations of ions, 325
inner. *See* **actinide(s)** and **lanthanide(s)**.
naming in ionic compounds, 83
oxidation numbers of, 1023, *1024*
paramagnetism of ions, 325
production of, 1026–1029
properties of, 1021–1026
transition state The arrangement of reacting molecules and atoms at the point of maximum potential energy, 632
translation, of RNA, 1132
transmittance (*T*) The ratio of the amount of light transmitted by the sample to the amount of incident light, 204
transmutation The conversion of atoms of one element to another element by a nuclear reaction, 1166. *See also* **nuclear reaction(s)**.
transport proteins, 1136
transuranium elements, 1168, 1167
trendline, 44
triatomic molecules, of elements, *72*
trichlorobenzene, isomers of, 1081
1,1,1-trifluorobromochloroethane (halothane), 467
triglycerides, 1134
trigonal bipyramidal electron-pair geometry, orbital hybridization and, 420
trigonal bipyramidal molecular geometry, 373, 374
axial and equatorial positions in, 377
trigonal planar electron-pair geometry
in benzene, 426
orbital hybridization and, *419*
trigonal planar molecular geometry, 373, 374
in carbon compounds, 1066
in DNA structure, 396
trigonal pyramidal molecular geometry, 375
Trimix, 597
triphenylmethyl radical, 696
triple bond, valence bond theory of, 423
triple point The temperature and pressure at which the solid, liquid, and vapor phases of a substance are in equilibrium, 551
tritium, 62, 965
fusion of, 1172
trona, 971, *972*
troposphere, 918
tryptophan, structure of, *1119*
T-shaped molecular geometry, 377, *378*
tube wells, 930
tungsten
melting point of, 549t, 1021
ore, 1025
turquoise, 787
Tyndall effect, 592
Tyrian purple dye, 439
tyrosine, structure of, *1119*

U.S. Food and Drug Administration (FDA), 208
ulexite, *980*
ultraviolet catastrophe, 280
ultraviolet (UV) radiation, 278
absorption by ozone, 921
in photoelectron spectroscopy, 333, 438
skin damage and, 299
uncertainty principle, 292
unimolecular process, 644
unit(s)
canceling in conversion calculation, 43
of measurement, 29–33, 452
SI, 29
unit cell(s) The smallest repeating unit in a crystal lattice that has the characteristic symmetry of the solid, 528
counting atoms in, 530
shapes of, *529*
universe
entropy change for, 826
total energy of, 18
unpaired electrons, in transition metal ions, 1023
unsaturated compound(s) A hydrocarbon containing double or triple carbon–carbon bonds, 1077
unsaturated fatty acids, 1135
unsaturated solution(s), reaction quotient in, 793
uracil, in RNA, 1128, *1129*
uranium
isotopes of, 1178
isotopic enrichment, 1171
isotopic separation, 1004
radioactive series from, 1151
uranium-235, fission of, 1169
uranium-238, radioactive half-life, 1161
uranium hexafluoride, 1004, 1025, 1171
urine, phosphorus distilled from, 990
vacuum chamber, 474
valence band, 542
valence bond theory A model of bonding in which a bond arises from the overlap of atomic orbitals on two atoms to give a bonding orbital with electrons localized between the atoms, 413–426
valence electron(s) The outermost and most reactive electrons of an atom, 317, 322, 353
Lewis symbols and, 353
of main group elements, 961
valence shell electron-pair repulsion (VSEPR) model A model for predicting the shapes of molecules, in which structural electron pairs are arranged around each atom to maximize the angles between them, 373
valeric acid, 1091t
valine, structure of, *1119*
van Arkel, Anton Eduard, 397
van Arkel–Ketelaar diagram, *353*, 397
van der Waals, Johannes, 475
van der Waals equation A mathematical expression that describes the behavior of nonideal gases, 475
van der Waals force(s), 491, 505
van't Hoff, Jacobus Henricus, 590
van't Hoff factor The ratio of the experimentally measured freezing point depression of a solution to the value calculated from the apparent molality, 590
vancomycin-resistant *Enterococcus* (VRE), 1052
vapor pressure The pressure of the vapor of a substance in contact with its liquid or solid phase in a sealed container, 510–512
Raoult's law and, 577
relation to enthalpy of vaporization, 512
of water, A-19
vaporization The state change from liquid to gas, 236, 507
enthalpy of, 508t
enthalpy of, intermolecular forces and, 495
heat of, 236
Vectra, 1098t
Villard, Paul, 1150
vinegar, 1088
pH of, 194
reaction with baking soda, 724
viscosity The resistance of a liquid to flow, 515
visible light, 278, 1049
vitamin B_{12}, cobalt in, 1022
vitamin C. *See* ascorbic acid.
volatile organic compounds (VOCs), 944
volatility The tendency of the molecules of a substance to escape from the liquid phase into the gas phase, 510

PHYSICAL AND CHEMICAL CONSTANTS

Avogadro's number	$N_A = 6.022140857 \times 10^{23}$/mol	π	$\pi = 3.1415926536$
Electronic charge	$e = 1.60217662 \times 10^{-19}$ C	Planck's constant	$h = 6.62607 \times 10^{-34}$ J · s
Faraday's constant	$F = 96{,}485.3$ C/mol electrons	Speed of light (in a vacuum)	$c = 2.99792458 \times 10^{8}$ m/s
Gas constant	$R = 8.31446$ J/K · mol $= 0.082057$ L · atm/K · mol		

USEFUL CONVERSION FACTORS AND RELATIONSHIPS

Length

SI unit: Meter (m)

1 kilometer = 1000 meters
= 0.62137 mile
1 meter = 100 centimeters
1 centimeter = 10 millimeters
1 nanometer = 1.00×10^{-9} meter
1 picometer = 1.00×10^{-12} meter
1 inch = 2.54 centimeter (exactly)
1 Ångstrom = 1.00×10^{-10} meter

Volume

SI unit: Cubic meter (m^3)

1 liter (L) = 1.00×10^{-3} m^3
= 1000 cm^3
= 1.056710 quarts
1 gallon = 4.00 quarts

Pressure

SI unit: Pascal (Pa)

1 pascal = 1 N/m^2
= 1 kg/m · s^2
1 atmosphere = 101.325 kilopascals
= 760 mm Hg = 760 torr
= 14.70 lb/in^2
= 1.01325 bar
1 bar = 10^5 Pa (exactly)

Mass

SI unit: Kilogram (kg)

1 kilogram = 1000 grams
1 gram = 1000 milligrams
1 pound = 453.59237 grams = 16 ounces
1 ton = 2000 pounds

Energy

SI unit: Joule (J)

1 joule = 1 kg · m^2/s^2
= 0.23901 calorie
= 1 C × 1 V
1 calorie = 4.184 joules

Temperature

SI unit: kelvin (K)

0 K = −273.15 °C
K = °C + 273.15°C
? °C = (5 °C/9 °F)(°F − 32 °F)
? °F = (9 °F/5 °C)(°C) + 32 °F

†The atomic weights of many elements can vary depending on the origin and treatment of the sample. This is particularly true for Li; commercially available lithium-containing materials have Li atomic weights in the range of 6.939 and 6.996. The uncertainties in atomic weight values are given in parentheses following the last significant figure to which they are attributed.

*Elements with no stable nuclide; the value given in parentheses is the atomic mass number of the isotope of longest known half-life. However, three such elements (Th, Pa, and U) have a characteristic terrestrial isotopic composition, and the atomic weight is tabulated for these.
